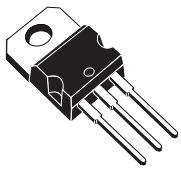
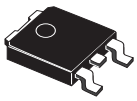
LM217M, LM317M

Medium current 1.2 to 37 V adjustable voltage regulator

Datasheet - production data



TO-220



DPAK

Description

The LM217M and LM317M are monolithic integrated circuits in TO-220 and DPAK packages used as positive adjustable voltage regulators. They are designed to supply until 500 mA of load current with an output voltage adjustable over a 1.2 to 37 V range. The nominal output voltage is selected by one resistive divider only, making the device exceptionally easy to configure and avoiding the use of several fixed regulators.

Features

- Output voltage range: 1.2 to 37 V
- Output current in excess of 500 mA
- Line regulation typ. 0.01%
- Load regulation typ. 0.1%
- Thermal overload protection
- Short-circuit protection
- Output transition safe area compensation
- Floating operation for high voltage applications

6 Application information

The LM217M and LM317M provide an internal reference voltage (1.25 V) between the output and adjustment terminals. These devices set a constant current flow across an external resistor divider (see *Figure 6*), giving the following output voltage:

Equation 1

$V_O = V_{REF} (1 + R_2 / R_1) + I_{ADJ} R_2$

These devices minimize the term I_{ADJ} (100 µA max.) and keep it constant with line and load changes. Usually, the error terms: $I_{ADJ} \times R_2$ can be neglected. To obtain the previous requirement, the regulator quiescent current is returned to the output terminal, imposing a minimum load current condition. If the load is insufficient, the output voltage rises.

Since the LM217M and LM317M devices are floating regulators and only “see” the input-to-output differential voltage, high voltage supplies can be regulated as long as the maximum input-to-output differential is not exceeded. Furthermore, programmable regulators are easily obtained and, by connecting a fixed resistor between the adjustment and output, the devices can be used as precision current regulators. In order to optimize the load regulation, R_1, the current set resistor (see *Figure 6*) should be as closer as possible to the regulator, while R_2, the ground terminal should be near the ground of the load to provide remote ground sensing.

6.1 External capacitors

Usually, capacitors are not necessary unless the devices are far from the input filter capacitors; in this case an input bypass is needed.

To reduce the sensitivity to input line impedance, a 0.1 µF disc or 1 µF tantalum input bypass capacitor (C_I) is recommended.

The adjustment terminal may be bypassed to ground to improve ripple rejection. This capacitor (C_{ADJ}) avoids the amplification of ripple as the output voltage rises. A 10 µF capacitor should improve ripple rejection about 80 dB at 120 Hz in a 10 V application.

Although the devices are stable without any output capacitors, some external capacitance values can cause excessive ringing. A 1 µF solid tantalum or 25 µF aluminum electrolytic output capacitor swamps this effect and assures stability.

6.2 Protection diodes

When external capacitors are used with any IC regulator, sometimes some protection diodes have to be added to prevent the capacitors from discharging through low current points into the regulator.

Figure 8 shows the devices with the recommended protection diodes for output voltages in excess of 25 V or high capacitance values (C_3 > 25 µF, C_2 > 10 µF). Diode D1 prevents C_3 from discharging through the IC during an input short-circuit. The combination of diodes D1 and D2 prevents C_2 from discharging through the regulator during an input or output short-circuit.

6.3 Start-up block

Reboot of the device is not guaranteed when the junction temperature is over 85 °C.
