## Ultra-Low-Power, Single-Supply Op Amp + Comparator + Reference

## Features

- Op Amp + Comparator + Reference in an 8-Pin $\mu$ MAX Package (MAX951/MAX952)
- $7 \mu \mathrm{~A}$ Typical Supply Current (Op Amp + Comparator + Reference)
- Comparator and Op Amp Input Range Includes Ground
- Outputs Swing Rail to Rail
- 2.4 V to 7 V Supply Voltage Range
- Unity-Gain Stable and 125 kHz Decompensated $A_{V} \geq 10 \mathrm{~V} / \mathrm{V}$ Op Amp Options
- Internal $1.2 \mathrm{~V} \pm 2 \%$ Bandgap Reference
- Internal Comparator Hysteresis
- Op Amp Capable of Driving up to 1000 pF Load

## Selector Guide

## Absolute Maximum Ratings

8-Pin SO (derate $5.88 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ above $+70^{\circ} \mathrm{C}$ )............... 471 mW
8-Pin $\mu$ MAX (derate $4.10 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ above $+70^{\circ} \mathrm{C}$ )........ 330 mW
8-Pin CERDIP (derate $8.00 \mathrm{~mW} / /^{\circ} \mathrm{C}$ above $+70^{\circ} \mathrm{C}$ )...... 640 mW
Operating Temperature Ranges
MAX95_E_A......................................... $-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$
MAX95_MJA........................................... $-55^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$
Maximum Junction Temperatures
MAX95_E_A................................................................................................................................................... $+305^{\circ} 0^{\circ} \mathrm{C}$

Stresses beyond those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

## Electrical Characteristics

## Functional Diagrams

Figure 1. MAX951-MAX954 Functional Diagrams

## Detailed Description

The MAX951-MAX954 are combinations of a micropower op amp, comparator, and reference in an 8-pin package, as shown in Figure 1. In the MAX951/MAX952, the comparator's negative input is connected to a $1.20 \mathrm{~V} \pm 2 \%$ bandgap reference. All four devices are optimized to operate from a single supply. Supply current is less than $10 \mu \mathrm{~A}$ ( $7 \mu \mathrm{~A}$ typical) for the MAX951/MAX952 and less than $8 \mu \mathrm{~A}$ ( $5 \mu \mathrm{~A}$ typical) for the MAX953/MAX954.

## Op Amp

The op amps in the MAX951/MAX953 are internally compensated to be unity-gain stable, while the op amps in the MAX952/MAX954 feature 125kHz typical gain bandwidth, $66 \mathrm{~V} / \mathrm{ms}$ slew rate, and stability for gains of $10 \mathrm{~V} / \mathrm{V}$ or greater. All these op amps feature high-impedance differential
inputs and a common-mode input voltage range that extends from the negative supply rail to within 1.6 V of the positive rail. They have a CMOS output stage that swings rail to rail and is driven by a proprietary high gain stage, which enables them to operate with an ultra-low supply current while maintaining linearity under loaded conditions. Careful design results in good DC characteristics over their entire operating temperature range, minimizing input referred errors.

## Comparator

The comparator in the MAX951-MAX954 has a highimpedance differential input stage with a common-mode input voltage range that extends from the negative supply rail to within 1.6 V of the positive rail. Their CMOS output stage swings rail-to-rail and can continuously source as much as 40 mA . The comparators eliminate power-supply

Figure 2. External Hysteresis
glitches that commonly occur when changing logic states, minimizing parasitic feedback and making them easier to use. In addition, they include internal hysteresis ( $\pm 3 \mathrm{mV}$ ) to ensure clean output switching, even with slow-moving input signals. The inputs can be taken above and below the supply rails up to 300 mV without damage. Input voltages beyond this range can forward bias the ESDprotection diodes and should be avoided.
The MAX951-MAX954 comparator outputs swing rail-torail (from $V_{D D}$ to $V_{S S}$ ). TTL compatibility is assured by using a $5 \mathrm{~V} \pm 10 \%$ supply.
The MAX951-MAX954 comparators continuously output source currents as high as 40 mA and sink currents of over 5 mA , while keeping quiescent currents in the microampere range. The output can source 100 mA (at $\mathrm{V}_{\mathrm{DD}}=$ 5 V ) for short pulses, as long as the package's maximum power dissipation is not exceeded. The output stage does not generate crowbar switching currents during transitions; this minimizes feedback through the supplies and helps ensure stability without bypassing.

## Reference

The internal reference in the MAX951/MAX952 has an output of 1.20 V with respect to $\mathrm{V}_{\mathrm{SS}}$. Its accuracy is $\pm 2 \%$ in the $-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$ temperature range. It is comprised of a trimmed bandgap reference fed by a proportional-to-absolute-temperature (PTAT) current source and buffered by a micropower unity-gain amplifier. The REF output is typically capable of sourcing and sinking $20 \mu \mathrm{~A}$. Do not bypass the reference output. The reference is stable for capacitive loads less than 100pF.

## Applications Information

The micropower MAX951-MAX954 are designed to extend battery life in portable instruments and add functionality in power-limited industrial controls. Following are some practical considerations for circuit design and layout.

## Comparator Hysteresis

Hysteresis increases the comparator's noise immunity by increasing the upper threshold and decreasing the lower threshold. The comparator in these devices contain a $\pm 3 \mathrm{mV}$ wide internal hysteresis band to ensure clean output switching, even with slow-moving signals.
When necessary, hysteresis can be increased by using external resistors to add positive feedback, as shown in Figure 2. This circuit increases hysteresis at the expense of more supply current and a slower response. The design procedure is as follows:

1) Set R2. The leakage current in COMPIN+ is less than 5 nA (up to $+85^{\circ} \mathrm{C}$ ), so current through R2 can be as little as 500nA and still maintain good accuracy. If R2 $=2.4 \mathrm{M} \Omega$, the current through R 2 at the upper trip point is $V_{R E F} / R 2$ or 500 nA .
2) Choose the width of the hysteresis band. In this example choose $\mathrm{V}_{\mathrm{EHYST}}=50 \mathrm{mV}$

$$
\mathrm{R} 1=\mathrm{R} 2 \frac{\left[\mathrm{~V}_{\mathrm{EHYST}}-2 \mathrm{~V}_{\mathrm{IHYST}}\right]}{\left(\mathrm{V}_{\mathrm{DD}}+2 \mathrm{~V}_{\mathrm{IHYST}}\right)}
$$

where the internal hysteresis is $\mathrm{V}_{\mathrm{IHYST}}=3 \mathrm{mV}$.
3) Determine R1. If the supply voltage is 5 V , then $\mathrm{R} 1=$ $24 \mathrm{k} \Omega$.
4) Check the hysteresis trip points. The upper trip point is

$$
\mathrm{V}_{\mathrm{IN}(\mathrm{H})}=\frac{(\mathrm{R} 1+\mathrm{R} 2)}{\mathrm{R} 2}\left(\mathrm{~V}_{\mathrm{REF}}+\mathrm{V}_{\mathrm{IHYST}}\right)
$$

or 1.22 V in our example. The lower trip point is 50 mV less, or 1.17 V in our example.
If a resistor divider is used for R1, the calculations should be modified using a Thevenin equivalent model.
5) Determine $R_{A}$ :

## Ultra-Low-Power, Single-Supply Op Amp + Comparator + Reference

Figure 3. Compensation for Feedback-Node Capacitance

$$
R_{A} \approx R 2 \frac{V_{S H Y S T}}{V_{D D}} \text {, for } V_{S H Y S T} \gg V_{I H Y S T}
$$

In the example, $\mathrm{R}_{\mathrm{A}}$ is again $24 \mathrm{k} \Omega$.
6) Select the upper trip point $\mathrm{V}_{\mathrm{S}(\mathrm{H})}$. Our example is set at 4.75 V .
7) Calculate $R_{B}$.

$$
R_{B}=\frac{\left(V_{R E F}+V_{I H Y S T}\right)(R 2)\left(R_{A}\right)}{(R 2)\left(V_{S(H)}\right)-\left(V_{R E F}+V_{I H S Y T}\right)\left(R_{A}+R 2\right)}
$$

where $R_{B}$ is $8.19 \mathrm{k} \Omega$, or approximately $8.2 \mathrm{k} \Omega$.

## Input Noise Considerations

Because low power requirements often demand highimpedance circuits, effects from radiated noise are more significant. Thus, traces between the op amp or comparator inputs and any resistor networks attached should be kept as short as possible.

## Crosstalk

## Reference

Internal crosstalk to the reference from the comparator is package dependent. Typical values $\left(V_{D D}=5 \mathrm{~V}\right)$ are 45 mV for the plastic DIP package and 32 mV for the SO package. Applications using the reference for the op amp or external circuitry can eliminate this crosstalk by using a simple RC lowpass filter, as shown in Figure 5.

## Op Amp

Internal crosstalk to the op amp from the comparator is package dependent, but not input-referred. Typical values $\left(\mathrm{V}_{\mathrm{DD}}=5 \mathrm{~V}\right)$ are 4 mV for the plastic DIP package and $280 \mu \mathrm{~V}$ for the SO package.

Figure 4. Low-Frequency Radio Receiver Application

## Op Amp Stability and Board Layout Considerations

Unlike other industry-standard micropower CMOS op amps, the op amps in the MAX951-MAX954 maintain stability in their minimum gain configuration while driving heavy capacitive loads, as demonstrated in the MAX951/ MAX953 Op Amp Percent Overshoot vs. Capacitive Load graph in the Typical Operating Characteristics.
Although this family is primarily designed for low-frequency applications, good layout is extremely important. Lowpower, high-impedance circuits may increase the effects of board leakage and stray capacitance. For example, the combination of a $10 \mathrm{M} \Omega$ resistance (from leakage between traces on a contaminated, poorly designed PC board) and a 1 pF stray capacitance provides a pole at approximately 16 kHz , which is near the amplifier's bandwidth. Board routing and layout should minimize leakage and stray capacitance. In some cases, stray capacitance may be unavoidable and it may be necessary to add a 2 pF to 10 pF capacitor across the feedback resistor to compensate; select the smallest capacitor value that ensures stability.

## Input Overdrive

With 100 mV overdrive, comparator propagation delay is typically $6 \mu \mathrm{~s}$. The Typical Operating Characteristics show propagation delay for various overdrive levels.
Supply current can increase when the op amp in the MAX951-MAX954 is overdriven to the negative supply rail. For example, when connecting the op amp as a comparator and applying a -100 mV input overdrive, supply current rises by around $15 \mu \mathrm{~A}$ and $32 \mu \mathrm{~A}$ for supply voltages of 2.8 V and 7 V , respectively.

Figure 5. Infrared Receiver Application

## Power-Supply Bypassing

Power-supply bypass capacitors are not required if the supply impedance is low. For single-supply applications, it is good general practice to bypass $\mathrm{V}_{\mathrm{DD}}$ with a $0.1 \mu \mathrm{~F}$ capacitor to ground. Do not bypass the reference output.

## Applications Circuits

## Low-Frequency Radio Receiver for Alarms and Detectors

The circuit in Figure 4 is useful as a front end for low-frequency RF alarms. The unshielded inductor (M7334-ND from Digikey) is used with capacitors $\mathrm{C} 1_{\mathrm{A}}, \mathrm{C} 1_{\mathrm{B}}$, and $\mathrm{C} 1_{\mathrm{C}}$ in a resonant circuit to provide frequency selectivity. The op amp from a MAX952 amplifies the signal received. The comparator improves noise immunity, provides a signal strength threshold, and translates the received signal into a pulse train. Carrier frequencies are limited to around 10 kHz .10 kHz is used in the example in Figure 4.
The layout and routing of components for the amplifier should be tight to minimize 60 Hz interference and crosstalk from the comparator. Metal shielding is recommended to prevent RFI from the comparator or digital circuitry from exciting the receiving antenna. The transmitting antenna can be long parallel wires spaced about 7.2 cm apart, with equal but opposite currents. Radio waves from this antenna will be detectable when the receiver is brought within close proximity, but cancel out at greater distances.

## Infrared Receiver Front End for Remote Controls and Data Links

The circuit in Figure 5 uses the MAX952 as a pin photodiode preamplifier and discriminator for an infrared receiver. The op amp is configured as a Delyiannis-Friend

Figure 6. Sensor Preamp and Alarm Trigger Application
bandpass filter to reduce disturbances from noise and eliminate low-frequency interference from sunlight, fluorescent lights, etc. This circuit is applicable for TV remote controls and low-frequency data links up to 20 kbps . Carrier frequencies are limited to around 10 kHz .10 kHz is used in the example circuit.
Component layout and routing for the amplifier should be tight to reduce stray capacitance, 60 Hz interference, and RFI from the comparator. Crosstalk from comparator edges will distort the amplifier signal. In order to minimize the effect, a lowpass RC filter is added to the connection from the reference to the noninverting input of the op amp.

## Sensor Preamp and Alarm Trigger for Smoke Detectors

The high-impedance CMOS inputs of the MAX951MAX954 op amps are ideal for buffering high-impedance sensors, such as smoke detector ionization chambers, piezoelectric transducers, gas detectors, and pH sensors. Input bias currents are typically less than 3pA at room temperature. A $5 \mu \mathrm{~A}$ typical quiescent current for the MAX953 will minimize battery drain without resorting to complex sleep schemes, allowing continuous monitoring and immediate detection.
lonization-type smoke detectors use a radioactive source, such as Americium, to ionize smoke particles. A positive voltage on a plate attached to the source repels the positive smoke ions and accelerates them toward an outer electrode connected to ground. Some ions collect on an intermediate plate. With careful design, the voltage on this plate will stabilize at a little less than one-half the supply voltage under normal conditions, but rise higher when smoke increases the ion current. This voltage is buffered

## Ultra-Low-Power, Single-Supply Op Amp + Comparator + Reference

by the high-input-impedance op amp of a MAX951 (Figure 6 ). The comparator and resistor voltage divider set an alarm threshold to indicate a fire.
Design and fabrication of the connection from the intermediate plate of the ionization chamber to the noninverting input of the op amp is critical, since the impedance of this node must be well above $50 \mathrm{M} \Omega$. This connection must be as short and direct as possible to prevent charge leakage and 60 Hz interference. Where possible, the grounded outer electrode or chassis of the ionization chamber should shield this connection to reduce 60 Hz interference. Pay special attention to board cleaning, to prevent leakage due to ionic compounds such as chlorides, flux, and other contaminants from the manufacturing process. Where applicable, a coating of high-purity wax may be used to insulate this connection and prevent leakage due to surface moisture or an accumulation of dirt.

## Ordering Information
