Single PoE/PoE+/LTPoE++ PSE Controller

FEATURES

- **Compliant with IEEE 802.3at Type 1 and 2**
- **Low Power Dissipation**
  - **0.25Ω Sense Resistance Per Channel**
- **Very High Reliability 4-Point PD Detection**
  - **2-Point Forced Voltage**
  - **2-Point Forced Current**
- **High Capacitance Legacy Device Detection**
- 1MHz I²C Compatible Serial Control Interface
- Midspan Backoff Timer
- Supports 2-Pair and 4-Pair Output Power
- Available in Multiple Power Grades
  - LTC4274A-1: LTPoE++™ 38.7W
  - LTC4274A-2: LTPoE++ 52.7W
  - LTC4274A-3: LTPoE++ 70W
  - LTC4274A-4: LTPoE++ 90W
  - LTC4274C: PoE 13W
- Available in 38-Lead 5mm × 7mm QFN Package

APPLICATIONS

- LTPoE++ PSE Switches/Routers
- LTPoE++ PSE Midspans
- IEEE 802.3at Type 1 PSE Switches/Routers
- IEEE 802.3at Type 1 PSE Midspans

DESCRIPTION

The LTC®4274A is a single Power Sourcing Equipment (PSE) controller capable of delivering up to 90W of LTPoE++ power to a compatible LTPoE++ Powered Device (PD). A proprietary detection/classification scheme allows mutual identification between a LTPoE++ PSE and LTPoE++ PD while remaining compatible and interoperable with existing Type 1 (13W) and Type 2 (25.5W) PDs. The LTC4274A feature set is a superset of the popular LTC4274. These PSE controllers feature low-R_{ON} external MOSFETs and 0.25Ω sense resistors which are especially important at the LTPoE++ current levels to maintain the lowest possible heat dissipation.

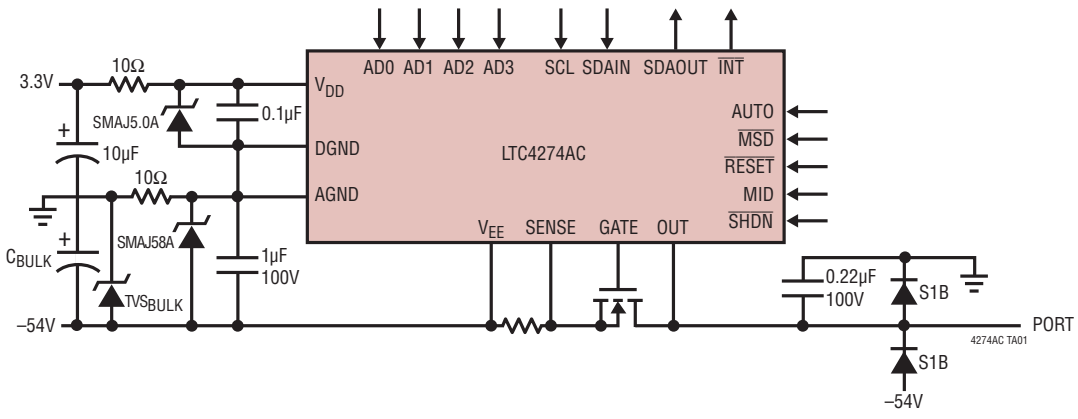
The LTC4274C targets fully automatic PSE systems powering Type 1 (up to 13W) PDs.

Advanced power management features include: a 14-bit current monitoring ADC, DAC-programmable current limit, and versatile quick port shutdown. PD Discovery uses a proprietary dual-mode 4-point detection mechanism ensuring excellent immunity from false PD detection. The LTC4274A/LTC4274C includes an I²C serial interface operable up to 1MHz.

The LTC4274A/LTC4274C is available in multiple power grades, allowing delivered PD power of 13W, 25.5W, 38.7W, 52.7W, 70W and 90W. These controllers are available in a 38-lead 5mm × 7mm QFN package.

TYPICAL APPLICATION

Complete Single-Port Ethernet High Power Source



ABSOLUTE MAXIMUM RATINGS

Supply Voltages (Note 1)

AGND – V_{EE} ..... –0.3V to 80V

DGND – V_{EE} ..... –0.3V to 80V

V_{DD} – DGND ..... –0.3V to 5.5V

Digital Pins

SCL, SDAIN, SDAOUT, $\overline{INT}$, $\overline{SHDN}$, $\overline{MSD}$, AD, $\overline{RESET}$, AUTO, MID..... DGND –0.3V to V_{DD} + 0.3V

Analog Pins

GATE, SENSE, OUT ..... V_{EE} –0.3V to V_{EE} + 80V

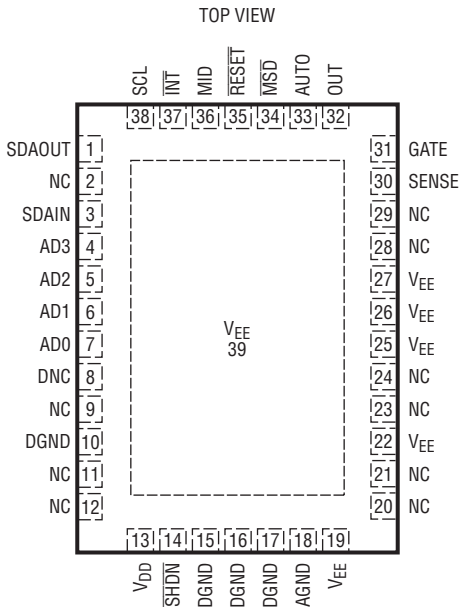
Operating Temperature Range .....–40°C to 85°C

Junction Temperature (Note 2) ..... 125°C

Storage Temperature Range .....–65°C to 150°C

Lead Temperature (Soldering, 10 sec).....300°C

PIN CONFIGURATION



UHF PACKAGE
38-LEAD (5mm × 7mm) PLASTIC QFN
EXPOSED PAD IS V_{EE} (PIN 39) MUST BE SOLDERED TO PCB
T_{JMAX} = 125°C, θ_{JA} = 34°C/W

ORDER INFORMATION

LEAD FREE FINISH	TAPE AND REEL	PART MARKING	PACKAGE DESCRIPTION	MAX PWR	TEMPERATURE RANGE
LTC4274CIUHF#PBF	LTC4274CIUHF#TRPBF	4274C	38-Lead (5mm × 7mm) Plastic QFN	13W	–40°C to 85°C
LTC4274AIUHF-1#PBF	LTC4274AIUHF-1#TRPBF	4274A1	38-Lead (5mm × 7mm) Plastic QFN	38.7W	–40°C to 85°C
LTC4274AIUHF-2#PBF	LTC4274AIUHF-2#TRPBF	4274A2	38-Lead (5mm × 7mm) Plastic QFN	52.7W	–40°C to 85°C

	ARA to $\overline{INT}$ Pin High Time	(Notes 7, 9)	●			1.5	µs
	SCL Fall to ACK Low	(Notes 7, 9)	●			120	ns

Note 1: Stresses beyond those listed under Absolute Maximum Ratings may cause permanent damage to the device. Exposure to any Absolute Maximum Rating condition for extended periods may affect device reliability and lifetime.

Note 2: This IC includes overtemperature protection that is intended to protect the device during momentary overload conditions. Junction temperature will exceed 140°C when overtemperature protection is active. Continuous operation above the specified maximum operating junction temperature may impair device reliability.

Note 3: All currents into device pins are positive; all currents out of device pins are negative.

Note 4: The LTC4274A/LTC4274C operates with a negative supply voltage (with respect to ground). To avoid confusion, voltages in this data sheet are referred to in terms of absolute magnitude.

Note 5: t_{DIS} is the same as t_{MPDO} defined by IEEE 802.3at.

Note 6: The LTC4274A/LTC4274C digital interface operates with respect to DGND. All logic levels are measured with respect to DGND.

Note 7: Guaranteed by design, not subject to test.

Note 8: The IEEE 802.3af specification allows a PD to present its Maintain Power Signature (MPS) on an intermittent basis without being disconnected. In order to stay powered, the PD must present the MPS for t_{MPS} within any t_{MPDO} time window.

Note 9: Values measured at $V_{ILD(MAX)}$ and $V_{IHD(MIN)}$.

Note 10: If fault condition occurs during an I²C transaction, the $\overline{INT}$ pin will not be pulled down until a stop condition is present on the I²C bus.

Note 11: Load Characteristic of the LTC4274A/LTC4274C during Mark: 7V < (AGND – V_{OUT}) < 10V or I_{OUT} < 50µA

Note 12: See the LTC4274A/LTC4274C Software Programming documentation for information on serial bus usage and device configuration and status registers.

PIN FUNCTIONS

$\overline{\text{RESET}}$: Chip Reset, Active Low. When the $\overline{\text{RESET}}$ pin is low, the LTC4274A/LTC4274C is held inactive with the port off and all internal registers reset to their power-up states. When $\overline{\text{RESET}}$ is pulled high, the LTC4274A/LTC4274C begins normal operation. $\overline{\text{RESET}}$ can be connected to an external capacitor or RC network to provide a power turn-on delay. Internal filtering of the $\overline{\text{RESET}}$ pin prevents glitches less than 1µs wide from resetting the LTC4274A/LTC4274C. Internally pulled up to V_{DD}.

MID: Midspan Mode Input. When high, the LTC4274A/LTC4274C acts as a midspan device. Internally pulled down to DGND.

$\overline{\text{INT}}$: Interrupt Output, Open Drain. $\overline{\text{INT}}$ will pull low when any one of several events occur in the LTC4274A/LTC4274C. It will return to a high impedance state when bits 6 or 7 are set in the Reset PB register (1Ah). The $\overline{\text{INT}}$ signal can be used to generate an interrupt to the host processor, eliminating the need for continuous software polling. Individual $\overline{\text{INT}}$ events can be disabled using the Int Mask register (01h). See the LTC4274A/LTC4274C Software Programming documentation for more information. The $\overline{\text{INT}}$ pin is only updated between I^2C transactions.

SCL: Serial Clock Input. High impedance clock input for the I^2C serial interface bus. SCL must be tied high if not used.

SDAOUT: Serial Data Output, Open Drain Data Output for the I^2C Serial Interface Bus. The LTC4274A/LTC4274C uses two pins to implement the bidirectional SDA function to simplify optoisolation of the I^2C bus. To implement a standard bidirectional SDA pin, tie SDAOUT and SDAIN together. SDAOUT should be grounded or left floating if not used. See the Applications Information section for more information.

SDAIN: Serial Data Input. High impedance data input for the I^2C serial interface bus. The LTC4274A/LTC4274C uses two pins to implement the bidirectional SDA function to simplify optoisolation of the I^2C bus. To implement a standard bidirectional SDA pin, tie SDAOUT and SDAIN together. SDAIN must be tied high if not used. See the Applications Information section for more information.

AD3: Address Bit 3. Tie the address pins high or low to set the I^2C serial address to which the LTC4274A/LTC4274C responds. This address will be $010A_3A_2A_1A_0b$. Internally pulled up to V_{DD}.

AD2: Address Bit 2. See AD3.

AD1: Address Bit 1. See AD3.

AD0: Address Bit 0. See AD3.

NC, DNC: All pins identified with "NC" or "DNC" must be left unconnected.

DGND: Digital Ground. DGND is the return for the V_{DD} supply.

V_{DD}: Logic Power Supply. Connect to a 3.3V power supply relative to DGND. V_{DD} must be bypassed to DGND near the LTC4274A/LTC4274C with at least a 0.1µF capacitor.

$\overline{\text{SHDN}}$: Shutdown, Active Low. When pulled low, $\overline{\text{SHDN}}$ shuts down the port, regardless of the state of the internal registers. Pulling $\overline{\text{SHDN}}$ low is equivalent to setting the Reset Port bit in the Reset Pushbutton register (1Ah). Internal filtering of the $\overline{\text{SHDN}}$ pin prevents glitches less than 1µs wide from resetting the port. Internally pulled up to V_{DD}.

AGND: Analog Ground. AGND is the return for the V_{EE} supply.

SENSE: Current Sense Input. SENSE monitors the external MOSFET current via a 0.5Ω or 0.25Ω sense resistor between SENSE and V_{EE}. Whenever the voltage across the sense resistor exceeds the overcurrent detection threshold V_{CUT}, the current limit fault timer counts up. If the voltage across the sense resistor reaches the current limit threshold V_{LIM}, the GATE pin voltage is lowered to maintain constant current in the external MOSFET. See the Applications Information section for further details.

PIN FUNCTIONS

GATE: Gate Drive. GATE should be connected to the gate of the external MOSFET for the port. When the MOSFET is turned on, the gate voltage is driven to 12V (typ) above V_{EE}. During a current limit condition, the voltage at GATE will be reduced to maintain constant current through the external MOSFET. If the fault timer expires, GATE is pulled down, turning the MOSFET off and recording a t_{CUT} or t_{START} event.

OUT: Output Voltage Monitor. OUT should be connected to the output port. A current limit foldback circuit limits the power dissipation in the external MOSFET by reducing the current limit threshold when the drain-to-source voltage exceeds 10V. The Power Good bit is set when the voltage from OUT to V_{EE} drops below 2.4V (typ). A 500k resistor is connected internally from OUT to AGND when the port is idle.

V_{EE}: Main Supply Input. Connect to a –45V to –57V supply, relative to AGND.

AUTO: AUTO Pin Mode Input. AUTO pin mode allows the LTC4274A/LTC4274C to detect and power up a PD even if there is no host controller present on the I^2C bus. The voltage of the AUTO pin determines the state of the internal registers when the LTC4274A/LTC4274C is reset or comes out of V_{DD} UVLO (see the LTC4274A/LTC4274C Software Programming documentation). The states of these register bits can subsequently be changed via the I^2C interface. The real-time state of the AUTO pin is read at bit 0 in the Pin Status register (11h). Internally pulled down to DGND. Must be tied locally to either V_{DD} or DGND.

$\overline{MSD}$: Maskable Shutdown Input. Active low. When pulled low, all ports that have their corresponding mask bit set in the Misc Config register (17h) will be reset, equivalent to pulling the $\overline{SHDN}$ pin low. Internal filtering of the $\overline{MSD}$ pin prevents glitches less than 1µs wide from resetting ports. Internally pulled up to V_{DD}.

OPERATION

Overview

Power over Ethernet, or PoE, is a standard protocol for sending DC power over copper Ethernet data wiring. The IEEE group that administers the 802.3 Ethernet data standards added PoE powering capability in 2003. This original PoE spec, known as 802.3af, allowed for 48V DC power at up to 13W. This initial spec was widely popular, but 13W was not adequate for some requirements. In 2009, the IEEE released a new standard, known as 802.3at or PoE+, increasing the voltage and current requirements to provide 25W of power.

The IEEE standard also defines PoE terminology. A device that provides power to the network is known as a PSE, or power sourcing equipment, while a device that draws power from the network is known as a PD, or powered device. PSEs come in two types: Endpoints (typically network switches or routers), which provide data and power; and Midspans, which provide power but pass through data. Midspans are typically used to add PoE capability to existing non-PoE networks. PDs are typically IP phones, wireless access points, security cameras, and similar devices.

PoE++ Evolution

Even during the process of creating the IEEE PoE+ 25.5W specification, it became clear that there was a significant and increasing need for more than 25.5W of delivered power. The LTC4274A family responds to this market by allowing a reliable means of providing up to 90W of delivered power to a LTPoE++ PD. The LTPoE++ specification provides reliable detection and classification extensions to the existing IEEE PoE technique that are backward compatible and interoperable with existing Type 1 and Type 2 PDs. Unlike other proprietary PoE++ solutions, Linear's LTPoE++ solution provides mutual identification between the PSE and PD. This ensures that the LTPoE++ PD knows it may use the requested power at start-up because it has detected a LTPoE++ PSE. LTPoE++ PSEs can differentiate between a LTPoE++ PD and all other types of IEEE compliant PDs allowing LTPoE++ PSEs to remain compliant and interoperable with existing equipment.

OPERATION

LTC4274 Product Family

The LTC4274 is a third-generation single PSE controller that implements four PSE ports in either an end-point or midspan design. Virtually all necessary circuitry is included to implement an IEEE 802.3at compliant PSE design, requiring only an external power MOSFET and sense resistor; these minimize power loss compared to alternative designs with an on-board MOSFET.

The LTC4274 comes in three grades which support different PD power levels.

The A-grade LTC4274 extends PoE power delivery capabilities to LTPoE++ levels. LTPoE++ is a Linear Technology proprietary specification allowing for the delivery of up to 90W to LTPoE++ compliant PDs. The LTPoE++ architecture extends the IEEE physical power negotiation to include 38.7W, 52.7W, 70W and 90W power levels. The A-grade LTC4274 also incorporates all B- and C-grade features.

The B-grade LTC4274 is a fully IEEE-compliant Type 2 PSE supporting autonomous detection, classification and powering of Type 1 and Type 2 PDs. The B-grade LTC4274 also incorporates all C-grade features. The B-grade LTC4274 is marketed and numbered without the B suffix for legacy reasons; the absence of power grade suffix infers a B-grade part.

The C-grade LTC4274 is a fully autonomous 802.3at Type 1 PSE solution. Intended for use only in AUTO pin mode, the C-grade chipset autonomously supports detection, classification and powering of Type 1 PDs. As a Type 1 PSE, 2-event classification is prohibited and Class 4 PDs are automatically treated as Class 0 PDs.

PoE Basics

Common Ethernet data connections consist of two or four twisted pairs of copper wire (commonly known as CAT-5 cable), transformer-coupled at each end to avoid ground loops. PoE systems take advantage of this coupling arrangement by applying voltage between the center-taps of the data transformers to transmit power from the PSE to the PD without affecting data transmission. Figure 10 shows a high-level PoE system schematic.

To avoid damaging legacy data equipment that does not expect to see DC voltage, the PoE spec defines a protocol that determines when the PSE may apply and remove power. Valid PDs are required to have a specific 25k common-mode resistance at their input. When such a PD is connected to the cable, the PSE detects this signature resistance and turns on the power. When the PD is later disconnected, the PSE senses the open circuit and turns power off. The PSE also turns off power in the event of a current fault or short-circuit.

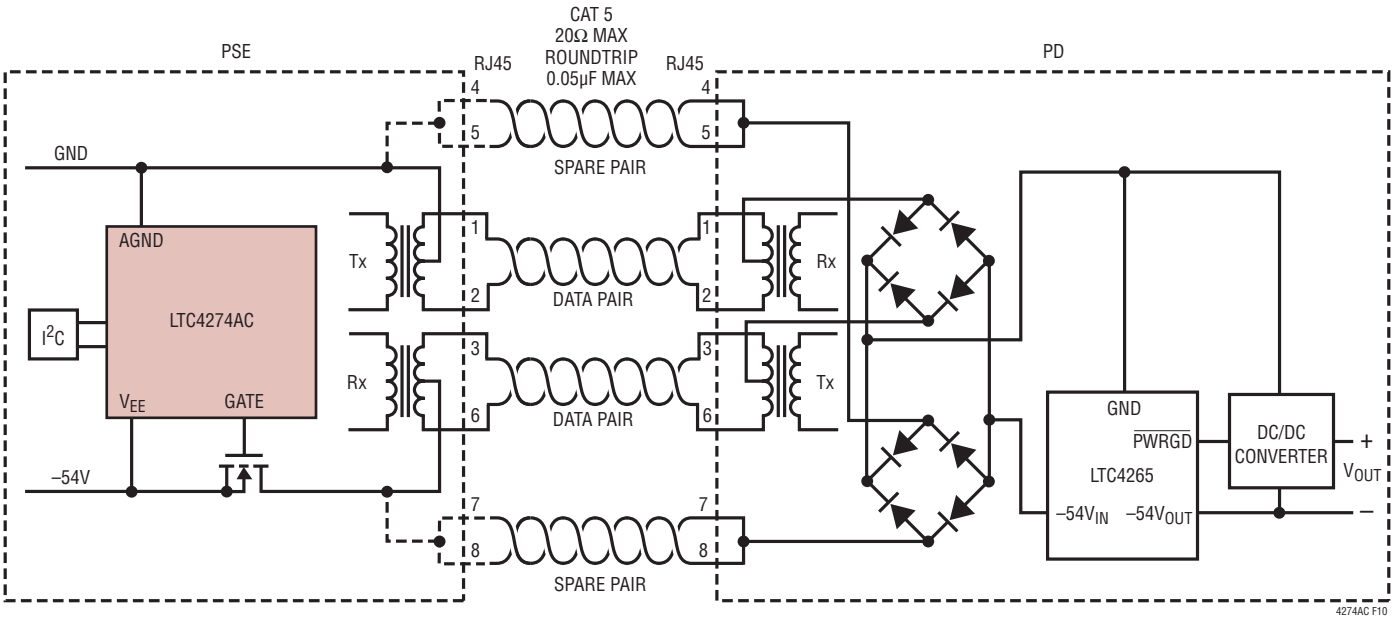

Figure 10. Power Over Ethernet System Diagram

OPERATION

When a PD is detected, the PSE optionally looks for a classification signature that tells the PSE the maximum power the PD will draw. The PSE can use this information to allocate power among several ports, police the current consumption of the PD, or to reject a PD that will draw more power that the PSE has available. For a 802.3af PSE, the classification step is optional; if a PSE chooses not to classify a PD, it must assume that the PD is a 13W (full 802.3af power) device.

New in 802.3at

The newer 802.3at standard supersedes 802.3af and brings several new features:

- A PD may draw as much as 25.5W. Such PDs (and the PSEs that support them) are known as Type 2. Older 13W 802.3af equipment is classified as Type 1. Type 1 PDs will work with all PSEs; Type 2 PDs may require Type 2 PSEs to work properly. The LTC4274A/LTC4274C is designed to work in both Type 1 and Type 2 PSE designs, and also supports non-standard configurations at higher power levels.
- The Classification protocol is expanded to allow Type 2 PSEs to detect Type 2 PDs, and to allow Type 2 PDs to determine if they are connected to a Type 2 PSE. Two versions of the new Classification protocol are available: an expanded version of the 802.3af Class Pulse protocol, and an alternate method integrated with the existing LLDP protocol (using the Ethernet data path). The LTC4274A/LTC4274C fully supports the new Class Pulse protocol and is also compatible with the LLDP protocol (which is implemented in the data communications layer, not in the PoE circuitry).
- Fault protection current levels and timing are adjusted to reduce peak power in the MOSFET during a fault; this allows the new 25.5W power levels to be reached using the same MOSFETs as older 13W designs.

Extended Power LTPoE++

The LTC4274A adds the capability to autonomously deliver up to 90W of power to the PD. LTPoE++ PDs may forego 802.3 LLDP support and rely solely on the LTPoE++ Physical Classification to negotiate power with LTPoE++ PSEs; this greatly simplifies high-power PD implementations.

LTPoE++ classification may be optionally enabled for the LTC4274A by setting both the High Power Enable and LTPoE++ Enable bits.

The higher levels of LTPoE++ delivery impose additional layout and component selection constraints. The LTC4274A is offered in four power levels (-1, -2, -3, and -4) which allows the AUTO pin mode LTC4274A to autonomously power up to supported power levels. If the AUTO pin is high, internal circuitry determines the maximum deliverable power. PDs requesting more than the available power limits are not powered.

Table 1. LTPoE++ Auto Pin Mode Maximum Delivered Power Capabilities

PART	PAIRS	PD POWER
LTC4274A-1	4	38.7W
LTC4274A-2	4	52.7W
LTC4274A-3	4	70W
LTC4274A-4	4	90W

APPLICATIONS INFORMATION

Operating Modes

The LTC4274A/LTC4274C can operate in one of four modes: manual, semi-auto, AUTO pin, or shutdown.

Table 2. Operating Modes

MODE	AUTO PIN	OPMD	DETECT/ CLASS	POWER-UP	AUTOMATIC I_{CUT}/I_{LIM} ASSIGNMENT
AUTO Pin	1	11b	Enabled at Reset	Automatically	Yes
Reserved	0	11b	N/A	N/A	N/A
Semi-auto	0	10b	Host Enabled	Upon Request	No
Manual	0	01b	Once Upon Request	Upon Request	No
Shutdown	0	00b	Disabled	Disabled	No

- In manual mode, the port waits for instructions from the host system before taking any action. It runs a single detection or classification cycle when commanded to by the host, and reports the result in its Port Status register. The host system can command the port to turn on or off the power at any time. This mode should only be used for diagnostic and test purposes.
- In semi-auto mode, the port repeatedly attempts to detect and classify any PD attached to it. It reports the status of these attempts back to the host, and waits for a command from the host before turning on power to the port. The host must enable detection (and optionally classification) for the port before detection will start.
- AUTO pin mode operates the same as semi-auto mode except that it will automatically turn on the power to the port if detection is successful. In AUTO pin mode, I_{CUT} and I_{LIM} values are set automatically by the LTC4274A/LTC4274C. This operational mode is only valid if the AUTO pin is high at reset or power-up and remains high during operation.
- In shutdown mode, the port is disabled and will not detect or power a PD.

Regardless of which mode it is in, the LTC4274A/LTC4274C will remove power automatically from a port which generates a current limit fault. It will also automatically remove power from any port that generates a disconnect event if disconnect detection is enabled. The host controller may also command the port to remove power at any time.

Reset and the AUTO/MID Pins

The initial LTC4274A/LTC4274C configuration depends on the state of the AUTO and MID pins during reset. Reset occurs at power-up, or whenever the $\overline{\text{RESET}}$ pin is pulled low or the global Reset All bit is set. Changing the state of AUTO or MID after power-up will not properly change the port behavior of the LTC4274A/LTC4274C until a reset occurs.

Although typically used with a host controller, the LTC4274A/LTC4274C can also be used in a standalone mode with no connection to the serial interface. If there is no host present, the AUTO pin must be tied high so that, at reset, the port will be configured to operate automatically. The port will detect and classify repeatedly until a PD is discovered, set I_{CUT} and I_{LIM} according to the classification results, apply power after successful detection, and remove power when a PD is disconnected.

Table 3 shows the I_{CUT} and I_{LIM} values that will be automatically set in standalone (AUTO pin) mode, based on the discovered class.

Table 3. I_{CUT} and I_{LIM} Values in AUTO Pin Mode

CLASS	I_{CUT}	I_{LIM}
Class 1	112mA	425mA
Class 2	206mA	425mA
Class 3 or Class 0	375mA	425mA
Class 4	638mA	850mA

The automatic setting of the I_{CUT} and I_{LIM} values only occurs if the LTC4274A/LTC4274C is reset with the AUTO pin high.

If the standalone application is a midspan, the MID pin must be tied high to enable correct midspan detection timing.

DETECTION

Detection Overview

To avoid damaging network devices that were not designed to tolerate DC voltage, a PSE must determine whether the connected device is a real PD before applying power. The IEEE specification requires that a valid PD have a

APPLICATIONS INFORMATION

common-mode resistance of 25k ±5% at any port voltage below 10V. The PSE must accept resistances that fall between 19k and 26.5k, and it must reject resistances above 33k or below 15k (shaded regions in Figure 11). The PSE may choose to accept or reject resistances in the undefined areas between the must-accept and must-reject ranges. In particular, the PSE must reject standard computer network ports, many of which have 150Ω common-mode termination resistors that will be damaged if power is applied to them (the black region at the left of Figure 11).

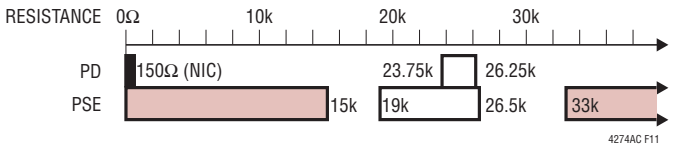

Figure 11. IEEE 802.3af Signature Resistance Ranges

4-Point Detection

The LTC4274A/LTC4274C uses a 4-point detection method to discover PDs. False-positive detections are minimized by checking for signature resistance with both forced-current and forced-voltage measurements. Initially, two test currents are forced onto the port (via the OUT pin) and the resulting voltages are measured. The detection circuitry subtracts the two V-I points to determine the resistive slope while removing offset caused by series diodes or leakage at the port (see Figure 12). If the forced-current detection yields a valid signature resistance, two test voltages are then forced onto the port and the resulting currents are measured and subtracted. Both methods must report valid resistances for the port to report a valid detection. PD signature resistances between 17k and 29k (typically) are detected as valid and reported as Detect Good in the corresponding Port Status register. Values outside this range, including open and short-circuits, are also reported. If the port measures less than 1V at the first forced-current test, the detection cycle will abort and Short Circuit will be reported. Table 4 shows the possible detection results.

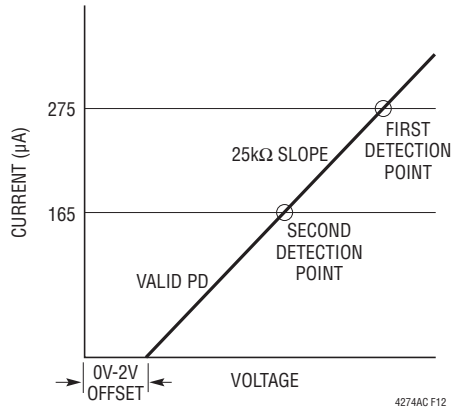

Figure 12. PD Detection

Table 4. Detection Status

MEASURED PD SIGNATURE	DETECTION RESULT
Incomplete or Not Yet Tested	Detect Status Unknown
<2.4k	Short Circuit
Capacitance > 2.7µF	C_{PD} Too High
2.4k < R_{PD} < 17k	R_{SIG} Too Low
17k < R_{PD} < 29k	Detect Good
>29k	R_{SIG} Too High
>50k	Open Circuit
Voltage > 10V	Port Voltage Outside Detect Range

More On Operating Modes

The port's operating mode determines when the LTC4274A/LTC4274C runs a detection cycle. In manual mode, the port will idle until the host orders a detect cycle. It will then run detection, report the results, and return to idle to wait for another command.

In semi-auto mode, the LTC4274A/LTC4274C autonomously polls a port for PDs, but it will not apply power until commanded to do so by the host. The Port Status register is updated at the end of each detection cycle. If a valid signature resistance is detected and classification is enabled, the port will classify the PD and report that result as well. The port will then wait for at least 100ms (or 2 seconds if midspan mode is enabled), and will repeat the detection cycle to ensure that the data in the Port Status register is up-to-date.

If the port is in semi-auto mode and high power operation is enabled, the port will not turn on in response to a power-on command unless the current detect result is Detect Good. Any other detect result will generate a t_{START} fault if a power-on command is received. If the port is not

APPLICATIONS INFORMATION

in high power mode, it will ignore the detection result and apply power when commanded, maintaining backwards compatibility with the LTC4259A.

Behavior in AUTO pin mode is similar to semi-auto; however, after Detect Good is reported and the port is classified (if classification is enabled), it is automatically powered on without further intervention. In standalone (AUTO pin) mode, the I_{CUT} and I_{LIM} thresholds are automatically set; see the Reset and the AUTO/MID Pin section for more information.

The signature detection circuitry is disabled when the port is initially powered up with the AUTO pin low, in shutdown mode, or when the corresponding Detect Enable bit is cleared.

Detection of Legacy PDs

Proprietary PDs that predate the original IEEE 802.3af standard are commonly referred to today as legacy devices. One type of legacy PD uses a large common-mode capacitance (>10µF) as the detection signature. Note that PDs in this range of capacitance are defined as invalid, so a PSE that detects legacy PDs is technically noncompliant with the IEEE spec.

The LTC4274A/LTC4274C can be configured to detect this type of legacy PD. Legacy detection is disabled by default, but can be manually enabled. When enabled, the port will report Detect Good when it sees either a valid IEEE PD or a high-capacitance legacy PD. With legacy mode disabled, only valid IEEE PDs will be recognized.

CLASSIFICATION

802.3af Classification

A PD can optionally present a classification signature to the PSE to indicate the maximum power it will draw while operating. The IEEE specification defines this signature as a constant current draw when the PSE port voltage is in the V_{CLASS} range (between 15.5V and 20.5V), with the current level indicating one of 5 possible PD classes. Figure 13 shows a typical PD load line, starting with the slope of the 25kΩ signature resistor below 10V, then transitioning to

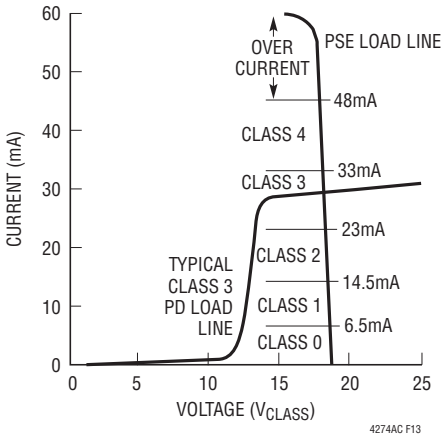

Figure 13. PD Classification

the classification signature current (in this case, Class 3) in the V_{CLASS} range. Table 5 shows the possible classification values.

Table 5. Classification Values

CLASS	RESULT
Class 0	No Class Signature Present; Treat Like Class 3
Class 1	3W
Class 2	7W
Class 3	13W
Class 4	25.5W (Type 2)

If classification is enabled, the port will classify the PD immediately after a successful detection cycle in semi-auto or AUTO pin modes, or when commanded to in manual mode. It measures the PD classification signature by applying 18V for 12ms (both values typical) to the port via the OUT pin and measuring the resulting current; it then reports the discovered class in the Port Status register. If the LTC4274A/LTC4274C is in AUTO pin mode, it will additionally use the classification result to set the I_{CUT} and I_{LIM} thresholds. See the Reset and the AUTO/MID Pin section for more information.

The classification circuitry is disabled when the port is initially powered up with the AUTO pin low, in shutdown mode, or when the corresponding Class Enable bit is cleared.

APPLICATIONS INFORMATION

802.3at 2-Event Classification

The 802.3at specification defines two methods of classifying a Type 2 PD. The LTC4274A supports 802.3at 2-event classification. The LTC4274C does not support 2-event classification.

One method adds extra fields to the Ethernet LLDP data protocol; although the LTC4274A/LTC4274C is compatible with this classification method, it cannot perform classification directly since it doesn't have access to the data path. LLDP classification requires the PSE to power the PD as a standard 802.3af (Type 1) device. It then waits for the host to perform LLDP communication with the PD and update the PSE port data. The LTC4274A/LTC4274C supports changing the I_{LIM} and I_{CUT} levels on the fly, allowing the host to complete LLDP classification.

The second 802.3at classification method, known as 2-event classification or ping-pong, is supported by the LTC4274A. A Type 2 PD that is requesting more than 13W will indicate Class 4 during normal 802.3af classification. If the LTC4274A sees Class 4, it forces the port to a specified lower voltage (called the mark voltage, typically 9V), pauses briefly, and then re-runs classification to verify the Class 4 reading (Figure 1). It also sets a bit in the High Power Status register to indicate that it ran the second classification cycle. The second cycle alerts the PD that it is connected to a Type 2 PSE which can supply Type 2 power levels.

2-event ping-pong classification is enabled by setting a bit in the port's High Power Mode register. Note that a ping-pong enabled port only runs the second classification cycle when it detects a Class 4 device; if the first cycle returns Class 0 to 3, the port assumes it is connected to a Type 1 PD and does not run the second classification cycle.

Invalid Type 2 Class Combinations

The 802.3at specification defines a Type 2 PD class signature as two consecutive Class 4 results; a Class 4 followed by a Class 0-3 is not a valid signature. In AUTO pin mode, the LTC4274A will power a detected PD regardless of the classification results, with one exception: if the PD presents an invalid Type 2 signature (Class 4 followed by Class 0 to 3), the LTC4274A will not provide power and will restart the detection process. To aid in diagnosis, the Port Status register will always report the results of the last class pulse, so, for example, an invalid Class 4–Class 2 combination would report a second class pulse was run in the High Power Status register (which implies that the first cycle found Class 4), and Class 2 in the Port Status register.

POWER CONTROL

External MOSFET, Sense Resistor Summary

The primary function of the LTC4274A/LTC4274C is to control the delivery of power to the PSE port. It does this by controlling the gate drive voltage of an external power MOSFET while monitoring the current via an external sense resistor and the output voltage at the OUT pin. This circuitry serves to couple the raw V_{EE} input supply to the port in a controlled manner that satisfies the PD's power needs while minimizing power dissipation in the MOSFET and disturbances on the V_{EE} backplane.

The LTC4274A/LTC4274C is designed to use 0.25Ω sense resistors to minimize power dissipation. It also supports 0.5Ω sense resistors, which are the default when LTC4258/LTC4259A compatibility is desired.

Inrush Control

Once the command has been given to turn on a port, the LTC4274A/LTC4274C ramps up the GATE pin of the port's external MOSFET in a controlled manner. Under normal power-up circumstances, the MOSFET gate will rise until the port current reaches the inrush current limit level (typically 450mA), at which point the GATE pin will be servoed to maintain the specified I_{INRUSH} current. During this inrush period, a timer (t_{START}) runs. When output charging is complete, the port current will fall and the GATE pin will be allowed to continue rising to fully enhance the MOSFET and minimize its on-resistance. The final V_{GS} is nominally 12V. The inrush period is maintained until the t_{START} timer expires. At this time if the inrush current limit level is still exceeded the port will be turned back off and a t_{START} fault reported.

APPLICATIONS INFORMATION

Current Limit

The LTC4274A/LTC4274C port includes two current limiting thresholds (I_{CUT} and I_{LIM}), each with a corresponding timer (t_{CUT} and t_{LIM}). Setting the I_{CUT} and I_{LIM} thresholds depends on several factors: the class of the PD, the voltage of the main supply (V_{EE}), the type of PSE (Type 1 or Type 2), the sense resistor (0.5Ω or 0.25Ω), the SOA of the MOSFET, and whether or not the system is required to implement class enforcement.

Per the IEEE specification, the LTC4274A/LTC4274C will allow the port current to exceed I_{CUT} for a limited period of time before removing power from the port, whereas it will actively control the MOSFET gate drive to keep the port current below I_{LIM}. The port does not take any action to limit the current when only the I_{CUT} threshold is exceeded, but does start the t_{CUT} timer. If the current drops below the I_{CUT} current threshold before its timer expires, the t_{CUT} timer counts back down, but at 1/16 the rate that it counts up. If the t_{CUT} timer reaches 60ms (typical) the port is turned off and the port t_{CUT} fault is set. This allows the current limit circuitry to tolerate intermittent overload signals with duty cycles below about 6%; longer duty cycle overloads will turn the port off.

The I_{LIM} current limiting circuit is always enabled and actively limiting port current. The t_{LIM} timer is enabled only when the programmable t_{LIM} field is non-zero. This allows t_{LIM} to be set to a shorter value than t_{CUT} to provide more aggressive MOSFET protection and turn off a port before MOSFET damage can occur. The t_{LIM} timer starts when the I_{LIM} threshold is exceeded. When the t_{LIM} timer reaches 1.7ms (typ) times the programmable t_{LIM} field the port is turned off and the port t_{LIM} fault is set. When the t_{LIM} field is zero, t_{LIM} behaviors are tracked by the t_{CUT} timer, which counts up during both I_{LIM} and I_{CUT} events.

I_{CUT} is typically set to a lower value than I_{LIM} to allow the port to tolerate minor faults without current limiting.

Per the IEEE specification, the LTC4274A/LTC4274C will automatically set I_{LIM} to 425mA (shown in bold in Table 6) during inrush at port turn-on, and then switch to the programmed I_{LIM} setting once inrush has completed. To maintain IEEE compliance, I_{LIM} should be kept at 425mA for all Type 1 PDs, and 850mA if a Type 2 PD is detected. I_{LIM} is automatically reset to 425mA when a port turns off.

Table 6. Example Current Limit Settings

	INTERNAL REGISTER SETTING (hex)	
I_{LIM} (mA)	R_{SENSE} = 0.5Ω	R_{SENSE} = 0.25Ω
53	88	
106	08	88
159	89	
213	80	08

1700		40
1913		4A
2125		50
2338		5A
2550		60
2975		52

I_{LIM} Foldback

The LTC4274A/LTC4274C features a two-stage foldback circuit that reduces the port current if the port voltage falls below the normal operating voltage. This keeps MOSFET power dissipation at safe levels for typical 802.3af MOSFETs, even at extended 802.3at power levels. Current limit and foldback behavior are programmable. Table 6 gives examples of recommended I_{LIM} register settings.

APPLICATIONS INFORMATION

The LTC4274A/LTC4274C will support current levels well beyond the maximum values in the 802.3at specification. The shaded areas in Table 6 indicate settings that may require a larger external MOSFET, additional heat sinking, or enabling t_{LIM}.

MOSFET Fault Detection

The LTC4274A/LTC4274C PSE port is designed to tolerate significant levels of abuse, but in extreme cases it is possible for the external MOSFET to be damaged. A failed MOSFET may short source to drain, which will make the port appear to be on when it should be off; this condition may also cause the sense resistor to fuse open, turning off the port but causing the LTC4274A/LTC4274C SENSE pin to rise to an abnormally high voltage. A failed MOSFET may also short from gate to drain, causing the LTC4274A/LTC4274C GATE pin to rise to an abnormally high voltage. The LTC4274A/LTC4274C OUT, SENSE and GATE pins are designed to tolerate up to 80V faults without damage.

If the LTC4274A/LTC4274C sees any of these conditions for more than 180µs, it disables all port functionality, reduces the gate drive pull-down current for the port and reports a FET Bad fault. This is typically a permanent fault, but the host can attempt to recover by resetting the port, or by resetting the entire chip if a port reset fails to clear the fault. If the MOSFET is in fact bad, the fault will quickly return, and the port will disable itself again.

An open or missing MOSFET will not trigger a FET Bad fault, but will cause a t_{START} fault if the LTC4274A/LTC4274C attempts to turn on the port.

Voltage and Current Readback

The LTC4274A/LTC4274C measures the output voltage and current at the port with an internal A/D converter. Port data is only valid when the port power is on. The converter has two modes:

- Slow mode: 14 samples per second, 14.5 bits resolution
- Fast mode: 440 samples per second, 9.5 bits resolution

In fast mode, the least significant 5 bits of the lower byte are zeroes so that bit scaling is the same in both modes.

Disconnect

The LTC4274A/LTC4274C monitors the port to make sure that the PD continues to draw the minimum specified current. A disconnect timer counts up whenever port current is below 7.5mA (typ), indicating that the PD has been disconnected. If the t_{DIS} timer expires, the port will be turned off and the disconnect bit in the fault event register will be set. If the current returns before the t_{DIS} timer runs out, the timer resets and will start counting from the beginning if the undercurrent condition returns. As long as the PD exceeds the minimum current level more often than t_{DIS}, it will stay powered.

Although not recommended, the DC disconnect feature can be disabled by clearing the DC Disconnect Enable bit. Note that this defeats the protection mechanisms built into the IEEE spec, since a powered port will stay powered after the PD is removed. If the still-powered port is subsequently connected to a non-PoE data device, the device may be damaged.

The LTC4274A/LTC4274C does not include AC disconnect circuitry, but includes an AC Disconnect Enable bit to maintain compatibility with the LTC4259A. If the AC Disconnect Enable bit is set, DC disconnect will be used.

Shutdown Pin

The LTC4274A/LTC4274C includes a hardware $\overline{SHDN}$ pin. When the $\overline{SHDN}$ pin is pulled to DGND, the port will be shut off immediately. The port remains shut down until re-enabled via I^2C or a device reset in AUTO pin mode.

Masked Shutdown

The LTC4274A/LTC4274C provides a low latency port shedding feature to quickly reduce the system load when required. By allowing a pre-determined set of ports to be turned off, the current on an overloaded main power supply can be reduced rapidly while keeping high priority devices powered. Each port can be configured to high or low priority; all low-priority ports will shut down within 6.5µs after the $\overline{MSD}$ pin is pulled low. If a port is turned off via $\overline{MSD}$, the corresponding Detection and Classification Enable bits are cleared, so the port will remain off until the host explicitly re-enables detection.

APPLICATIONS INFORMATION

SERIAL DIGITAL INTERFACE

Overview

The LTC4274A/LTC4274C communicates with the host using a standard SMBus/I^{2}C 2-wire interface. The LTC4274A/LTC4274C is a slave-only device, and communicates with the host master using the standard SMBus protocols. Interrupts are signaled to the host via the $\overline{INT}$ pin. The timing diagrams (Figures 5 through 9) show typical communication waveforms and their timing relationships. More information about the SMBus data protocols can be found at www.smbus.org.

The LTC4274A/LTC4274C requires both the V_{DD} and V_{EE} supply rails to be present for the serial interface to function.

Bus Addressing

The LTC4274A/LTC4274C's primary serial bus address is 010xxxxb, with the lower four bits set by the AD3-AD0 pins; this allows up to 16 LTC4274A/LTC4274Cs on a single bus. All LTC4274A/LTC4274Cs also respond to the address 0110000b, allowing the host to write the same command (typically configuration commands) to multiple LTC4274A/LTC4274Cs in a single transaction. If the LTC4274A/LTC4274C is asserting the $\overline{INT}$ pin, it will also respond to the alert response address (0001100b) per the SMBus spec.

Interrupts and SMBALERT

Most LTC4274A/LTC4274C port events can be configured to trigger an interrupt, asserting the $\overline{INT}$ pin and alerting the host to the event. This removes the need for the host to poll the LTC4274A/LTC4274C, minimizing serial bus traffic and conserving host CPU cycles. Multiple LTC4274A/LTC4274Cs can share a common $\overline{INT}$ line, with the host using the SMBALERT protocol (ARA) to determine which LTC4274A/LTC4274C caused an interrupt.

Register Description

For information on serial bus usage and device configuration and status, refer to the LTC4274A/LTC4274C Software Programming documentation.

EXTERNAL COMPONENT SELECTION

Power Supplies and Bypassing

The LTC4274A/LTC4274C requires two supply voltages to operate. V_{DD} requires 3.3V (nominally) relative to DGND. V_{EE} requires a negative voltage of between –45V and –57V for Type 1 PSEs, –51V to –57V for Type 2 PSEs or –54.75V to –57V for LTPoE++ PSEs, relative to AGND. The relationship between the two grounds is not fixed; AGND can be referenced to any level from V_{DD} to DGND, although it should typically be tied to either V_{DD} or DGND.

V_{DD} provides power for most of the internal LTC4274A/LTC4274C circuitry, and draws a maximum of 3mA. A ceramic decoupling cap of at least 0.1µF should be placed from V_{DD} to DGND, as close as practical to each LTC4274A/LTC4274C chip.

Figure 14 shows a three component low dropout regulator for a negative supply to DGND generated from the negative V_{EE} supply. V_{DD} is tied to AGND and DGND is negative referenced to AGND. This regulator drives a single LTC4274A/LTC4274C device. In Figure 15, DGND is tied to AGND in this boost converter circuit for a positive V_{DD} supply of 3.3V above AGND. This circuit can drive multiple LTC4274A/LTC4274C devices and opto couplers.

V_{EE} is the main supply that provides power to the PD. Because it supplies a relatively large amount of power and is subject to significant current transients, it requires more design care than a simple logic supply. For minimum IR loss and best system efficiency, set V_{EE} near maximum amplitude (57V), leaving enough margin to account for transient over- or undershoot, temperature drift, and the line regulation specs of the particular power supply used.

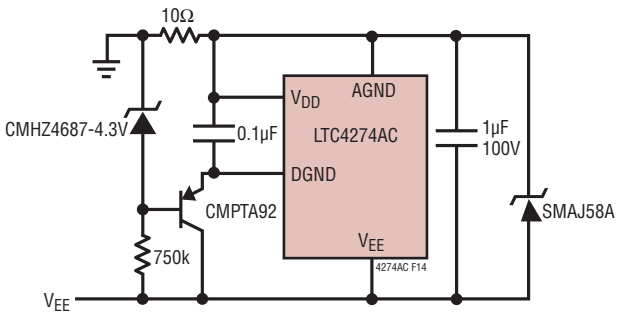

Figure 14. Negative LDO to DGND

APPLICATIONS INFORMATION

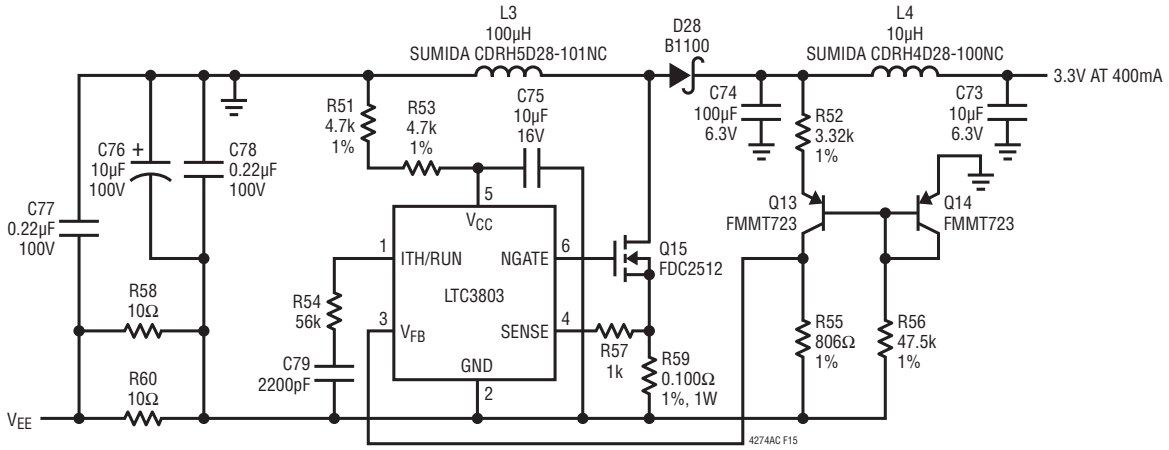

Figure 15. Positive V_{DD} Boost Converter

Bypass capacitance between AGND and V_{EE} is very important for reliable operation. If a short-circuit occurs at the output port it can take as long as 1µs for the LTC4274A/LTC4274C to begin regulating the current. During this time the current is limited only by the small impedances in the circuit and a high current spike typically occurs, causing a voltage transient on the V_{EE} supply and possibly causing the LTC4274A/LTC4274C to reset due to a UVLO fault. A 1µF, 100V X7R capacitor placed near the V_{EE} pin is recommended to minimize spurious resets.

Isolating the Serial Bus

The LTC4274A/LTC4274C includes a split SDA pin (SDAIN and SDAOUT) to ease opto-isolation of the bidirectional SDA line.

IEEE 802.3 Ethernet specifications require that network segments (including PoE circuitry) be electrically isolated from the chassis ground of each network interface device. However, network segments are not required to be isolated from each other, provided that the segments are connected to devices residing within a single building on a single power distribution system.

For simple devices such as small PoE switches, the isolation requirement can be met by using an isolated main power supply for the entire device. This strategy can be used if the device has no electrically conducting ports other than twisted-pair Ethernet. In this case, the SDAIN and SDAOUT pins can be tied together and will act as a standard I^2C/SMBus SDA pin.

If the device is part of a larger system, contains additional external non-Ethernet ports, or must be referenced to protective ground for some other reason, the Power over Ethernet subsystem (including all LTC4274A/LTC4274Cs) must be electrically isolated from the rest of the system. Figure 16 shows a typical isolated serial interface. The SDAOUT pin of the LTC4274A/LTC4274C is designed to drive the inputs of an opto-coupler directly. Standard I^2C/SMBus devices typically cannot drive opto-couplers, so U1 is used to buffer the signals from the host controller side.

External MOSFET

Careful selection of the power MOSFET is critical to system reliability. LTC recommends either Fairchild IRFM120A, FDT3612, FDMC3612 or Philips PHT6NQ10T for their proven reliability in Type 1 and Type 2 PSE applications. Non-standard applications that provide more current than the 850mA IEEE maximum may require heat sinking and other MOSFET design considerations. Contact LTC Applications before using a MOSFET other than one of these recommended parts.

Sense Resistor

The LTC4274A/LTC4274C is designed to use either 0.5Ω or 0.25Ω current sense resistors. For new designs 0.25Ω is recommended to reduce power dissipation; the 0.5Ω option is intended for existing systems where the LTC4274A/LTC4274C is used as a drop-in replacement for the LTC4258 or LTC4259A. The lower sense resistor values reduce heat dissipation. Four commonly available 1Ω resistors (0402 or larger package size) can be used in parallel

APPLICATIONS INFORMATION

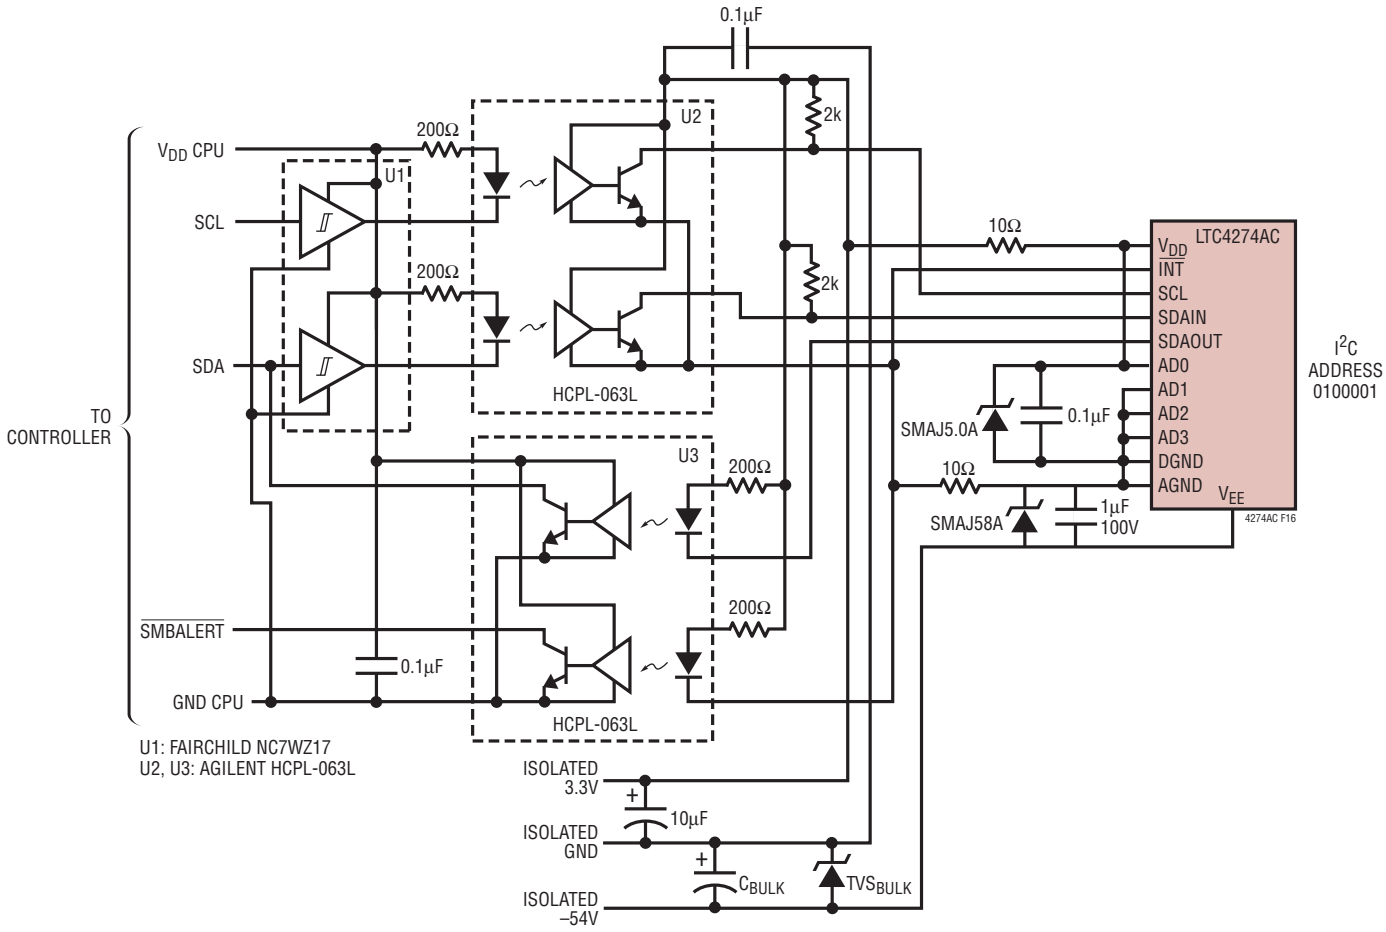

Figure 16. Opto-Isolating the I²C Bus

APPLICATIONS INFORMATION

in place of a single 0.25Ω resistor. In order to meet the I_{CUT} and I_{LIM} accuracy required by the IEEE specification, the sense resistors should have ±1% tolerance or better, and no more than ±200ppm/°C temperature coefficient.

Port Output Cap

The port requires a 0.22µF cap across its output to keep the LTC4274A/LTC4274C stable while in current limit during startup or overload. Common ceramic capacitors often have significant voltage coefficients; this means the capacitance is reduced as the applied voltage increases. To minimize this problem, X7R ceramic capacitors rated for at least 100V are recommended.

Surge Protection

Ethernet ports can be subject to significant cable surge events. To keep PoE voltages below a safe level and protect the application against damage, protection components, as shown in Figure 17, are required at the main supply, at the LTC4274A/LTC4274C pins, and at each port.

Bulk transient voltage suppression (TVS_{BULK}) and bulk capacitance (C_{BULK}) are required across the main PoE supply and should be sized to accommodate system level surge requirements. A large capacitance of 10µF or greater (C3) is required across the +3.3V supply if V_{DD} is above AGND.

Each LTC4274A/LTC4274C requires a 10Ω, 0805 resistor (R1) in series from supply AGND to the LTC4274A/LTC4274C AGND pin. Across the LTC4274A/LTC4274C AGND pin and V_{EE} pin are an SMAJ58A, 58V TVS (D1) and a 1µF, 100V bypass capacitor (C1). These components must be placed close to the LTC4274A/LTC4274C pins.

If the V_{DD} supply is above AGND, each LTC4274A/LTC4274C requires a 10Ω, 0805 resistor (R2) in series from the +3.3V supply positive rail to the LTC4274A/LTC4274C V_{DD} pin. Across the LTC4274A/LTC4274C V_{DD} pin and DGND pin are an SMAJ5.0A, 5.0V TVS (D2) and a 0.1µF capacitor (C2). These components must be placed close to the LTC4274A/LTC4274C pins. DGND is tied directly to the protected AGND pin. Pull-ups at the logic pins should be to the protected side of the 10Ω resistors at the V_{DD} pin. Pull-downs at the logic pins should be to the protected side of the 10Ω resistors at the tied AGND and DGND pins.

Finally, each port requires a pair of S1B clamp diodes, one from OUTn to supply AGND (D3) and one from OUTn to supply V_{EE} (D4). The diodes at the ports steer harmful surges into the supply rails where they are absorbed by the surge suppressors and the V_{EE} bypass capacitance. The layout of these paths must be low impedance.

Further considerations include LTC4274A/LTC4274C applications with off-board connections, such as a daughter card to a mother board or headers to an external supply or host control board. Additional protection may be required at the LTC4274A/LTC4274C pins to these off-board connections.

LAYOUT GUIDELINES

Strict adherence to board layout, parts placement and routing guidelines is critical for optimal current reading accuracy, IEEE compliance, system robustness, and thermal dissipation.

Power delivery above 25.5W imposes additional component and layout restraints. Specifically MOSFET, sense resistor and transformer selection is crucial to safe and reliable system operation.

Contact LTC Applications to obtain a full set of layout guidelines, example layouts and BOMs.

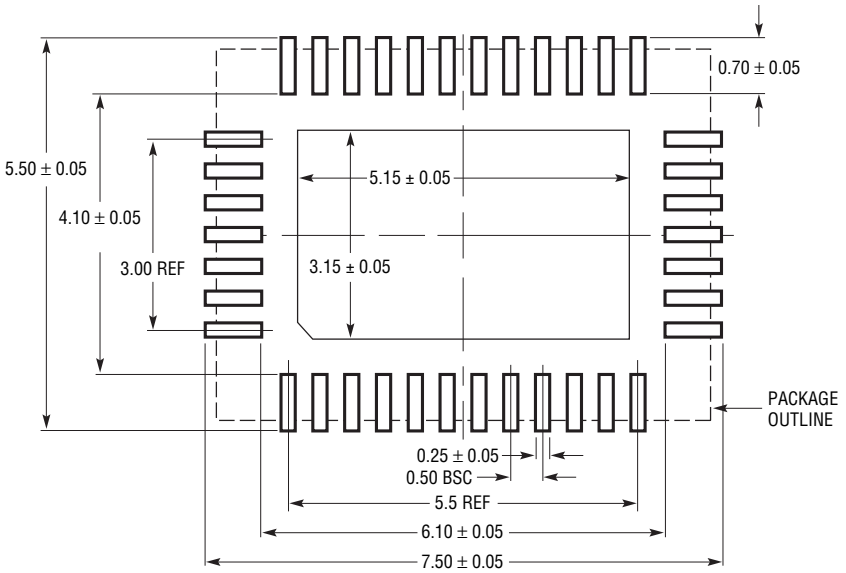
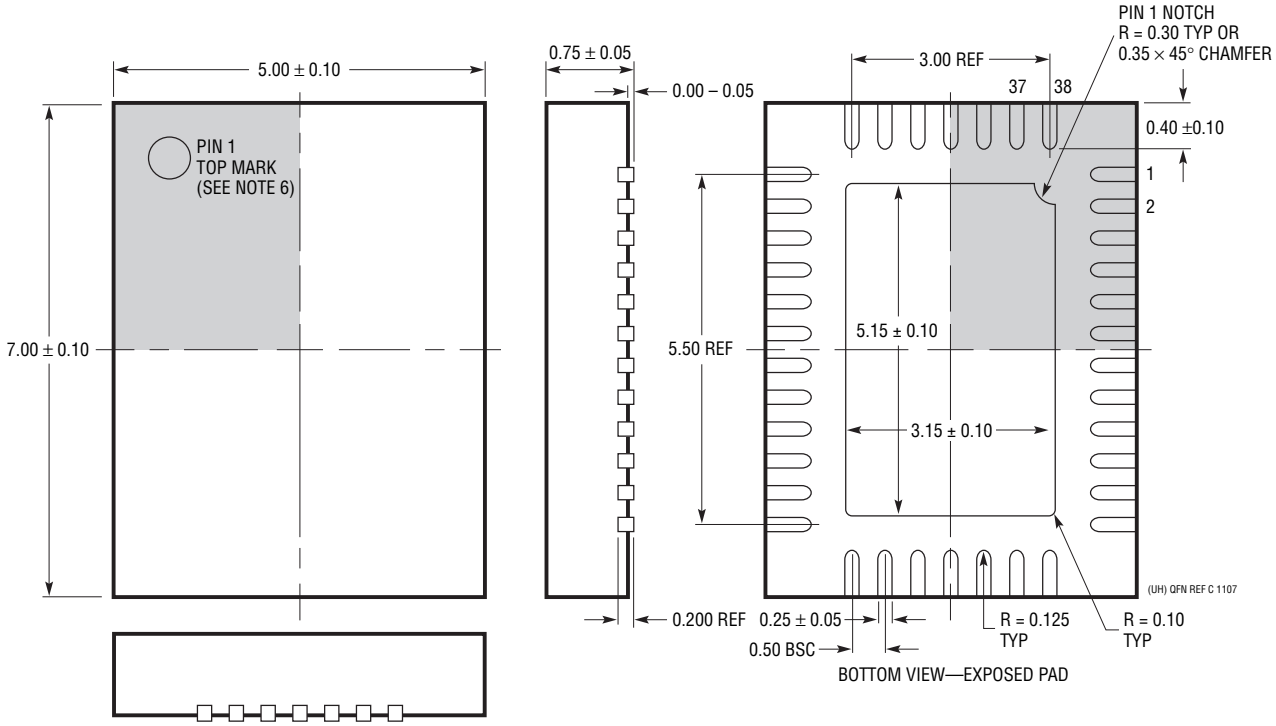
PACKAGE DESCRIPTION

Please refer to http://www.linear.com/designtools/packaging/ for the most recent package drawings.

UHF Package
38-Lead Plastic QFN (5mm × 7mm)
(Reference LTC DWG # 05-08-1701 Rev C)



RECOMMENDED SOLDER PAD LAYOUT
APPLY SOLDER MASK TO AREAS THAT ARE NOT SOLDERED



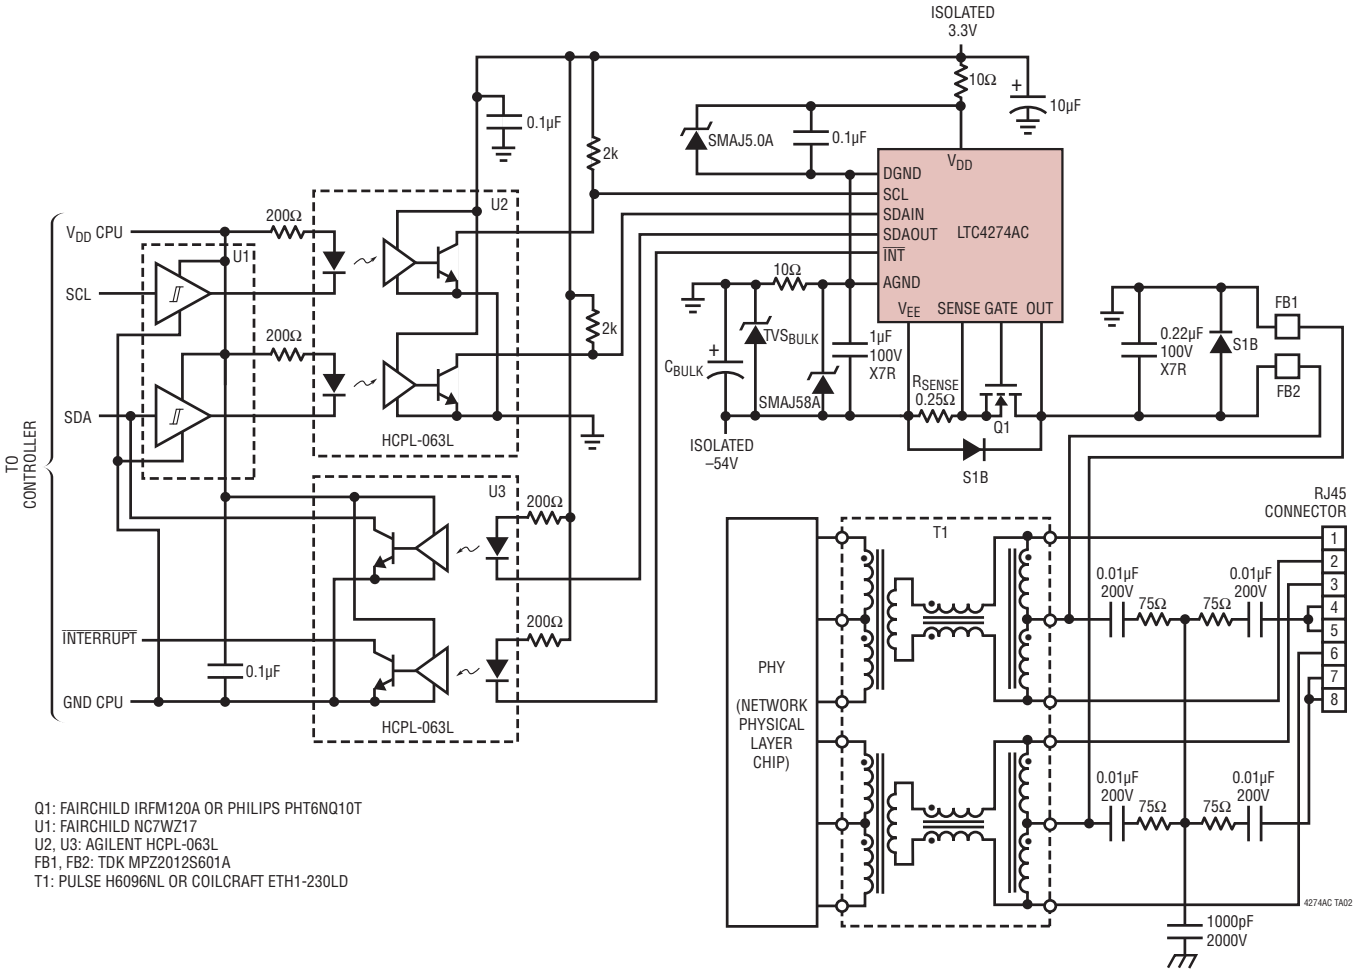
NOTE:
1. DRAWING CONFORMS TO JEDEC PACKAGE OUTLINE M0-220 VARIATION WHKD
2. DRAWING NOT TO SCALE
3. ALL DIMENSIONS ARE IN MILLIMETERS
4. DIMENSIONS OF EXPOSED PAD ON BOTTOM OF PACKAGE DO NOT INCLUDE MOLD FLASH. MOLD FLASH, IF PRESENT, SHALL NOT EXCEED 0.20mm ON ANY SIDE
5. EXPOSED PAD SHALL BE SOLDER PLATED
6. SHADED AREA IS ONLY A REFERENCE FOR PIN 1 LOCATION ON THE TOP AND BOTTOM OF PACKAGE

REVISION HISTORY

REV	DATE	DESCRIPTION	PAGE NUMBER
A	9/11	Changed GATE typ voltage to 12V.	3, 15, 21
		Revised V_{ILD} text under Digital Interface.	4
		Table 4 reference and caption changed to Table 5.	20
		Revised power supply voltage figures under Power Supplies and Bypassing.	24
		Text CUT/LIM changed to I_{CUT}/I_{LIM} in the Related Parts section.	30
		Specified SMAJ58A for Zener diode.	30
B	1/12	Changed LTPoE++ power levels from 35W, 45W to 38.7W, 52.7W respectively.	1, 2, 16, 17
		Revised Max value for V_{ILD} I^2C Input Low Voltage.	4
		Clarified AUTO Pin mode relationship to Reset pin.	18
C	8/12	Table 1: Changed twisted pair requirement from 2-pair to 4-pair for 38.7W and 52.7W	17
D	7/15	Updated surge protection recommendations	1, 24, 26, 27, 30
		Simplified Power over Ethernet system diagram	16
		Added component value (Figure 15)	25

TYPICAL APPLICATION

One Complete 100base-t Isolated Powered Ethernet IEEE 802.3at Port



Q1: FAIRCHILD IRFM120A OR PHILIPS PHT6NQ10T
U1: FAIRCHILD NC7WZ17
U2, U3: AGILENT HCPL-063L
FB1, FB2: TDK MPZ2012S601A
T1: PULSE H6096NL OR COILCRAFT ETH1-230LD
