

## FEATURES

- 1.5V to 36V Supply Input Range
- Adjustable Wake-Up Period: 250ms to 39 Days
- Adjustable Maximum Awake Time
- 0.8 $\mu$ A Quiescent Current
- 0.3 $\mu$ A Shutdown Current
- Pushbutton Input with Debouncing
- Low Leakage EN Output Allows DC/DC Converter Control (LTC2956-1)
- High Voltage  $\overline{\text{EN}}$  Output Drives External P-Channel MOSFET (LTC2956-2)
- $\pm 25\text{kV}$  ESD HBM on  $\overline{\text{PB}}$  Input
- 12-Lead 3mm  $\times$  3mm QFN and MSOP Packages

## APPLICATIONS

- Heartbeat Timers
- Periodic Wake-Up Control
- Portable and Battery-Powered Equipment
- Intervalometers
- Data Acquisition

## DESCRIPTION

The **LTC<sup>®</sup>2956** is a micropower, wide input voltage range, configurable wake-up timer with pushbutton control. It periodically wakes up and turns on a connected system to perform tasks like monitoring temperature or capturing images. After completing the task, the LTC2956 turns the system off to conserve power.

The wake-up timer period can be adjusted from 250ms to 39 days using configuration resistors. The system awake time can be controlled by the input pulse at the  $\overline{\text{SLEEP}}$  pin or adjusted by the capacitor at the  $\text{ONMAX}$  pin. The LTC2956 operates over a wide supply input range from 1.5V to 36V. The low 800nA quiescent current suits battery powered applications.

The pushbutton input allows the user to shutdown, turn on or reset the wake-up timer. With the timer in shutdown, the quiescent current drops to 300nA. The LTC2956 also provides three status outputs to indicate mode transitions and pushbutton events. Two versions are available for applications requiring either positive or negative enable polarities.

## PIN FUNCTIONS

**EN:** Enable Output (LTC2956-1). EN is an active high output to control the turn-on/off of a load. Connect this pin to the RUN or SHUTDOWN pin of a voltage regulator. The LTC2956-1 pulls EN high through an internal 900k resistor and Schottky diode to a 3.3V regulated supply when the pushbutton is pressed or when the wake-up period is reached. EN pulls low during the Sleep state. This pin may be left open if unused.

**$\overline{\text{EN}}$ :** Inverted Enable Output (LTC2956-2).  $\overline{\text{EN}}$  is an active low output to control the turn-on/off of the system power. It may drive a voltage regulator's active low enable input, or it may drive the gate of a P-channel MOSFET directly. In the Sleep state, the LTC2956-2 pulls this pin to  $V_{\text{IN}}$  through an internal 900k resistor. The LTC2956-2 pulls  $\overline{\text{EN}}$  to GND when the pushbutton is pressed or when the wake-up timer period is reached. This pin may be left open if unused.

**Exposed Pad (QFN only):** Exposed Pad. Leave open or connect to device ground.

**GND:** Device Ground.

**LONG:** Long Power Down Time Selection Input. Connect a resistor from the LONG pin to GND. Together with the 100k resistor between the RANGE and LONG pin, this adjusts the  $t_{\text{LONG}}$  power down time ( $t_{\text{LONG}}$  can be adjusted from 128ms to 16.4s). If SLEEP is pulled high or PB is pulled low longer than  $t_{\text{LONG}}$ , the part goes into SHUTDOWN mode. See Applications Information for details.

**OFFALERT:** Off Alert Open Drain Output. The LTC2956 pulls this pin low for 1 second ( $t_{\text{OFF}}$ ) whenever the part goes from RUN mode to SHUTDOWN mode. This pin can be connected to the interrupt input of the system (with a pull-up resistor to the system supply) to alert the system before shutdown. It can also be used to drive an external LED to give a visual indication. This pin may be left open if unused.

**ONALERT:** On Alert Open Drain Output. The LTC2956 pulls this pin low whenever the part goes from SHUTDOWN

mode to RUN mode. The pin stays low while the EN pin is high and it can be used as an input to the system to request for initial boot up routine. This pin may be left open if unused.

**ONMAX:** Maximum Awake Timer Capacitor Input. Connect a capacitor from this pin to GND adjust the maximum allowed awake time ( $t_{\text{ONMAX}}$ ) at 13.3ms/nF. If this pin is left floating, the minimum awake time is limited to 8ms. Tie this pin to GND if unused.

**PB:** Pushbutton Input. This is an active low input with a 900k $\Omega$  pull-up to an internal 3.3V regulated supply. Connect one terminal of the pushbutton switch to this pin and connect the other terminal of a pushbutton switch to GND. The pin may be left open if unused.

**PBOUT:** Debounced Pushbutton Open Drain Output. This pin follows the debounced PB input. This pin may be left open if unused.

**PERIOD:** Wake-Up Timer Adjust Input. Connect a resistor from the PERIOD pin to GND to adjust the wake-up timer period. See the Application Section for resistor selection information.

**RANGE:** Wake-Up Timer Range Selection Input. Connect a resistor from the RANGE pin to GND and a 100k resistor between the RANGE and LONG pin to choose the wake-up timer period range setting. See Application Section for information about the resistor selection.

**SLEEP:** SLEEP Input. The SLEEP input is active during RUN mode. In the Awake state, a falling edge at the SLEEP input will pull EN low ( $\overline{\text{EN}}$  high) and put the system into the Sleep state. If the SLEEP input goes high during the Sleep state, the LTC2956 re-enters the Awake state and pulls EN high ( $\overline{\text{EN}}$  low) to turn on the system. Holding SLEEP high for more than  $t_{\text{LONG}}$  will force the system into the SHUTDOWN mode. If unused, tie SLEEP to GND, and use the ONMAX pin to control the awake time.

**$V_{\text{IN}}$ :** Power Supply Input (1.5V to 36V).

**BLOCK DIAGRAM**

# OPERATION

Figure 1. Functional State Diagram

2956 F01

## OPERATION

### OVERVIEW

The LTC2956 is a micropower, highly configurable wake-up timer with pushbutton control. It controls power to a connected system to allow that system to perform a periodic task. After completing the task, the LTC2956 turns the system off to conserve power. Figure 1 shows a simplified state diagram of the LTC2956. The LTC2956 has two modes of operation: RUN mode and SHUTDOWN mode.

In RUN mode, the LTC2956 cycles between the Awake state and the Sleep state with a period of  $t_{PERIOD}$ . During the Awake state the EN pin is pulled high to turn the system on, and the  $t_{ONMAX}$  timer runs. The LTC2956 exits the Awake state when a falling edge is detected on the  $\overline{SLEEP}$  pin or if the  $t_{ONMAX}$  timer expires. The LTC2956 ignores any  $\overline{SLEEP}$  pin transitions for  $t_{AWAKE\_MIN}$  (typically 8ms) after entering the Awake state to ensure that the minimum on time is met.

In the Sleep state, the EN output stays low, and the connected system turns off. The LTC2956 returns to the Awake state if the  $t_{PERIOD}$  time is reached, if the pushbutton (connected to the  $\overline{PB}$  pin) is pressed, or if a logic high is detected on the  $\overline{SLEEP}$  pin. The minimum duration for the Sleep state is  $t_{SLEEP\_MIN}$  (typically 128ms), and any input or  $t_{PERIOD}$  transitions during this time are ignored in order to allow the system supply to sufficiently discharge.

SHUTDOWN mode is a very low power mode with the timer disabled, entered through a long press of the pushbutton or a long high pulse at the  $\overline{SLEEP}$  input. This is useful for products that are shipped with their batteries installed. A short press on the pushbutton brings the LTC2956 back into RUN mode. The LTC2956 can be configured to start in either RUN or SHUTDOWN mode at power-up via the LONG pin (see the Applications Information section).

SHUTDOWN mode consists of the Shutting Off state and the Off state. The Shutting Off state occurs first during the transition from RUN mode to SHUTDOWN mode, and allows time for the system to perform any shutdown tasks before the EN pin goes low in the Off state. This state is indicated by the  $\overline{OFFALERT}$  pin pulling low and lasts for

$t_{OFF}$  (typically 1s). Once the  $t_{OFF}$  timer completes, the LTC2956 transitions to the Off state, the EN pin is pulled low and all timers are disabled, and the quiescent current drops to about 0.3 $\mu$ A.

When the LTC2956 returns to the RUN mode from the SHUTDOWN mode, it first enters the From Off state to allow the connected system to run initialization tasks. This is indicated by the  $\overline{ONALERT}$  pin pulling low. The EN pin is pulled high to turn the connected system on.

The LTC2956 turns the connected system on and off via the EN pin. The LTC2956-1's active high EN pin can be connected to the system supply RUN pin while the LTC2956-2's active low  $\overline{EN}$  pin can directly control the system supply through a P-channel MOSFET.

The wake-up timer period can be adjusted from 250ms to 39 days via resistors at the PERIOD and RANGE pins. The timing of the long pushbutton press and  $\overline{SLEEP}$  pulse can be adjusted via resistors connected to the LONG pin. To minimize the quiescent current, the RANGE, LONG, and PERIOD pins are biased only when the LTC2956 performs a configuration cycle.

Timer configuration is performed once every 66 seconds while the part is operating in RUN mode, and it is also performed following power-up and whenever the LTC2956 exits the SHUTDOWN mode. During configuration, the LTC2956 biases and reads the voltages at the RANGE and LONG pins that are defined by external configuration resistors. See Configuration section for more details.

### Operations with $\overline{SLEEP}$ Tied Low (Passive System)

The LTC2956 is designed to control the power of both active and passive systems. With a passive system where the  $\overline{SLEEP}$  pin is not managed by a microcontroller, the  $\overline{SLEEP}$  pin can be tied low and a capacitor connected to the ONMAX pin determines the awake time. The minimum  $t_{ONMAX}$  must be longer than the maximum expected time the system takes to complete its routine tasks.

## OPERATION

Figure 2 shows the timing waveform of a passive system application using a LTC2956-1. When the  $t_{\text{PERIOD}}$  time is reached, the LTC2956 enters the Awake state and pulls the EN output high to turn on the system. The  $t_{\text{PERIOD}}$  timer restarts and the  $t_{\text{ONMAX}}$  timer starts running. Once the  $t_{\text{ONMAX}}$  timer expires, the LTC2956 re-enters the Sleep state and pulls the EN output low. The  $t_{\text{PERIOD}}$  timer continues to run until the next period is reached.

Note that the  $t_{\text{PERIOD}}$  timer is a digital counter inside the LTC2956, but it is illustrated as a simple ramp in all the figures in this data sheet. The  $t_{\text{ONMAX}}$  timer counts using both the analog ramp on the ONMAX pin as well as an internal digital counter. It is also represented as a simple ramp in all the figures in this data sheet.

The LTC2956 ignores the  $t_{\text{ONMAX}}$  timer during the first 8ms ( $t_{\text{AWAKE\_MIN}}$ ) after the EN output is pulled high which limits the minimum  $t_{\text{AWAKE}}$  time to  $t_{\text{AWAKE\_MIN}}$  (8ms typical).

### Operations with $\overline{\text{SLEEP}}$ Toggling (Active System)

With an active system, i.e. microprocessor based, the system can toggle the  $\overline{\text{SLEEP}}$  pin to terminate the Awake state immediately after it has completed a routine/periodic task. The LTC2956 will pull the EN output low to turn off

the system and enter the Sleep state. This keeps the awake time to a minimum and helps minimize the drain on the system battery.

Figure 3 shows the timing waveform for an active system application. When the  $t_{\text{PERIOD}}$  time is reached, the LTC2956-1 enters the Awake state and pulls the EN output high to turn on the system. The  $t_{\text{PERIOD}}$  timer resets, and the  $t_{\text{ONMAX}}$  timer start running. When the system has completed its periodic task, the LTC2956 is commanded to re-enter the Sleep state by pulling the  $\overline{\text{SLEEP}}$  pin low.

The LTC2956 ignores both the  $\overline{\text{SLEEP}}$  pin and  $t_{\text{ONMAX}}$  timer during the  $t_{\text{AWAKE\_MIN}}$  interval (8ms typical) just after EN goes high in order to guarantee that the system has stabilized. If the system completes its task before  $t_{\text{AWAKE\_MIN}}$  is reached, it can toggle  $\overline{\text{SLEEP}}$  continuously until the LTC2956 responds by pulling EN low (Figure 4). If the system only toggles the  $\overline{\text{SLEEP}}$  pin during  $t_{\text{AWAKE\_MIN}}$ , the LTC2956 will not respond to the  $\overline{\text{SLEEP}}$  pin's falling edge(s) and remains in the Awake state until the  $t_{\text{ONMAX}}$  timer expires.

If  $\overline{\text{SLEEP}}$  is held low during the entire Awake state period, the  $t_{\text{ONMAX}}$  timer will timeout (Figure 2) forcing the

Figure 2. Operation with  $\overline{\text{SLEEP}}$  Tied Low (Passive System)

**OPERATION**

**Figure 3. Operation with  $\overline{\text{SLEEP}}$  Toggling (Active System)**

**Figure 4. Toggling  $\overline{\text{SLEEP}}$  Continuously to Enter Sleep State**

LTC2956-1 back into the Sleep state. This  $t_{ONMAX}$  watchdog timer feature is particularly useful in applications where an active system’s software/firmware might encounter a stuck state or infinite loop thus preventing the system from excessively discharging the battery.

**Power Up**

The LTC2956 can be configured to power up automatically in either RUN or SHUTDOWN mode. This is done through

the resistive divider setting at LONG pin. If the voltage on the LONG pin is configured to be greater than  $V_{CC}/2$  (see Table 2), the LTC2956 enters the RUN mode (see Figure 5). If the voltage on the LONG pin is configured to be less than  $V_{CC}/2$ , the LTC2956 enters the SHUTDOWN mode. In SHUTDOWN mode, a press of the push button is needed to transition the wake-up timer to the Awake state and start the  $t_{PERIOD}$  timer (Figure 6).  $t_{CONFIGURATION}$  is the system configuration time. It can last between 0.1s to 1s.

# OPERATION

Figure 5. Wake-Up Timer Goes into RUN Mode After Power-Up ( $V_{LONG} > V_{CC}/2$ )

Figure 6. Using the  $\overline{PB}$  to Start the Wake-Up Timer

## OPERATION

The  $\overline{\text{ONALERT}}$  open drain output is pulled low on the first Awake state after exiting SHUTDOWN mode or when first powered up with  $V_{\text{LONG}} > V_{\text{CC}}/2$  selected. This output can be used to notify an active system to perform a power-up initialization routine.

### Shutting Off with a Long $\overline{\text{PB}}$ Press

The LTC2956 can be put into the low power SHUTDOWN mode by holding the push button  $\overline{\text{PB}}$  input low for a duration longer than  $t_{\text{LONG}}$ . The  $t_{\text{LONG}}$  can be adjusted with the resistive divider at the LONG pin. Figure 7 shows the timing during a long press. After the  $t_{\text{LONG}}$  timeout, the part enters the Shutting Off state, and the  $\overline{\text{OFFALERT}}$  pin is pulled low. This state persists for  $t_{\text{OFF}}$  (typically 1s) thus

allowing an active system to perform power down tasks before the enable output is pulled low.

If the push button input is held low for a duration shorter than  $t_{\text{LONG}}$ , the LTC2956 pulls EN high but does not enter the Shutting off state. Once  $\overline{\text{PB}}$  is released, the LTC2956 pulls the EN output low if the  $\overline{\text{SLEEP}}$  pin has pulsed once or if  $t_{\text{ONMAX}}$  has timed out. This short press can be used to override the timer for early wake-up or it can be used with the  $\overline{\text{PBOUT}}$  output to drive the software menu.

Pressing the pushbutton will always restart the  $t_{\text{PERIOD}}$  timer. This is useful for manual synchronization of the wake-up time with an external event. When the external event occurs, a short press will turn on the system and the next turn on will be  $t_{\text{PERIOD}}$  later.

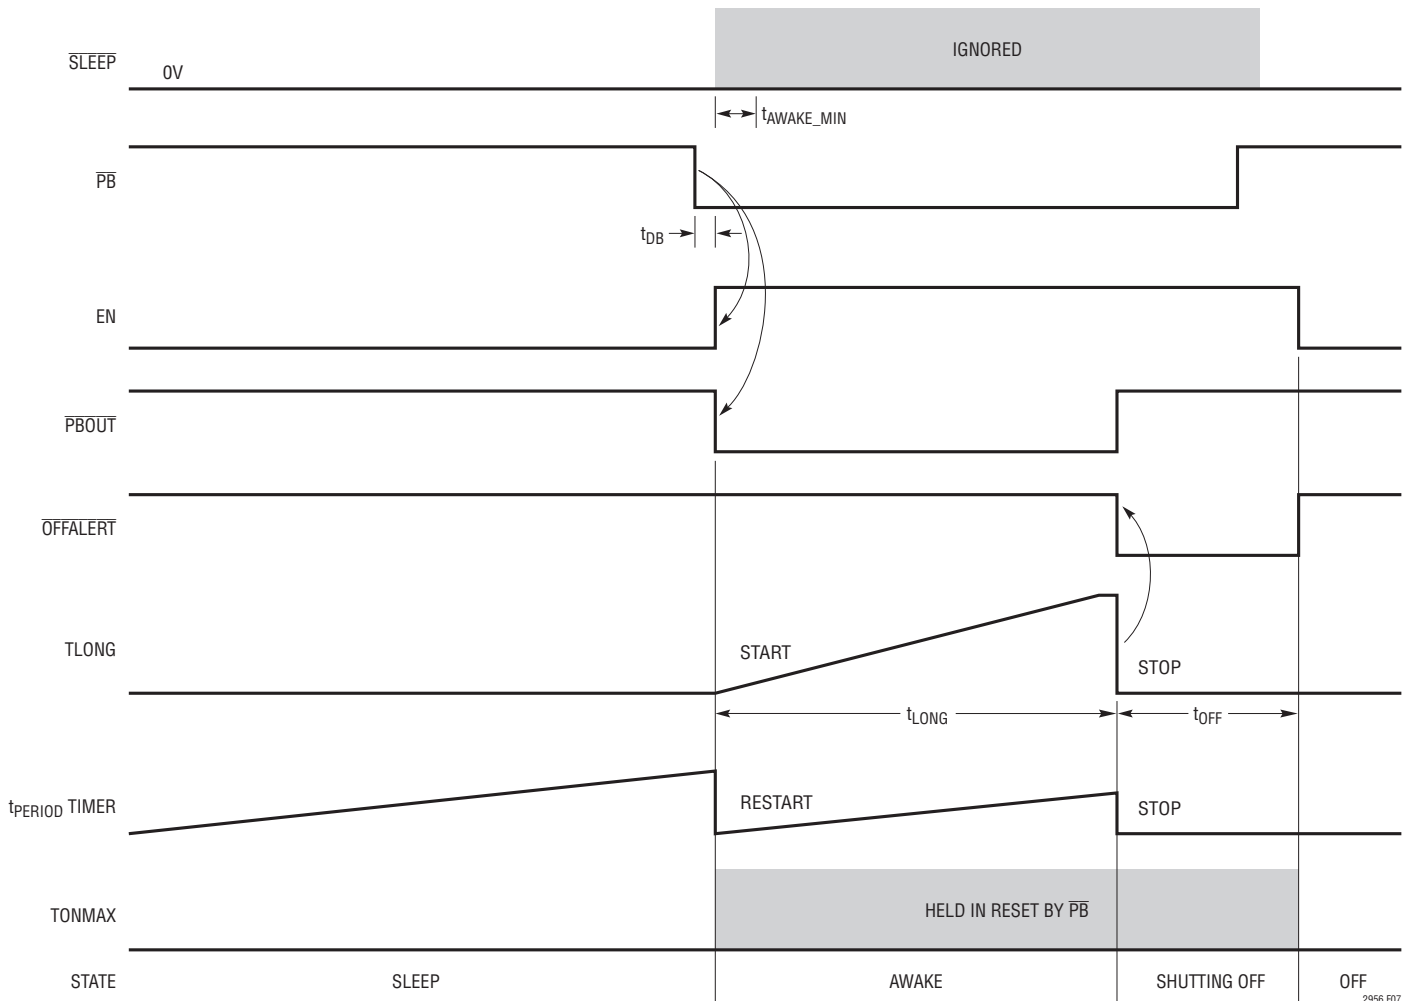

Figure 7. Holding  $\overline{\text{PB}}$  Low to Enter SHUTDOWN Mode

2956 F07

## OPERATION

Figure 8. Holding  $\overline{SLEEP}$  High to Enter SHUTDOWN Mode

### Shutting Off with a Long $\overline{SLEEP}$ Pulse

In an active system, the LTC2956 can also be placed into the low power SHUTDOWN mode by holding  $\overline{SLEEP}$  high for a duration greater than  $t_{LONG}$  (Figure 8). The  $\overline{OFFALERT}$  pin is pulled low when  $t_{LONG}$  times out and remains low during the Shutting Off state. Unlike a long push button press event, however, the  $t_{ONMAX}$  timer remains enabled while  $\overline{SLEEP}$  is pulled high. If  $t_{ONMAX}$  is adjusted to be less than  $t_{LONG}$ , a long  $\overline{SLEEP}$  pulse can never trigger a shutdown.

If the  $\overline{SLEEP}$  pulse width is shorter than  $t_{LONG}$ , the LTC2956 pulls the EN output high but does not enter the Shutting Off state. Once  $\overline{SLEEP}$  goes low (or if  $t_{ONMAX}$  times out first), the EN output goes low and the device enters the Sleep state.

### Pulling $\overline{SLEEP}$ High During the Sleep State

During the Sleep state, the system can prompt the LTC2956 to enter the Awake state by pulling  $\overline{SLEEP}$  pin high even if the  $t_{PERIOD}$  time is not up. This is illustrated in Figure 9.

The LTC2956 automatically restarts the  $t_{PERIOD}$  timer when it enters the Awake state in response to the logic high on the  $\overline{SLEEP}$  input.

Upon entering the Sleep state, the LTC2956 ignores all inputs for  $t_{SLEEP\_MIN}$ . This allows time for the system's power supply to fully discharge before it is allowed to turn on again. If the system pulls  $\overline{SLEEP}$  high during  $t_{SLEEP\_MIN}$ , the LTC2956 will wait until  $t_{SLEEP\_MIN}$  expires before re-entering the Awake state.

### Prolonging Awake Time

The LTC2956 restarts the  $t_{PERIOD}$  timer on every rising edge of EN. This allows the Awake time,  $t_{AWAKE}$  to vary from cycle to cycle while the turn-on period stay constant. However, if  $t_{AWAKE}$  extends toward or beyond  $t_{PERIOD}$ , the next Awake state may be delayed due to the minimum Sleep duration,  $t_{SLEEP\_MIN}$  (128ms typically). This  $t_{SLEEP\_MIN}$  ensures that the system supply has sufficient time to discharge. Refer to Figure 10, the second Awake time is longer, resulting in a longer  $t_{PERIOD}$  due to  $t_{SLEEP\_MIN}$ .

**OPERATION**

**Figure 9. Pulling the  $\overline{\text{SLEEP}}$  Input High to Enter Awake State**

**Figure 10. Prolonged Awake State**

**Push Button Debounce and  $\overline{\text{PBOUT}}$**

The  $\overline{\text{PB}}$  input is debounced by an internal timer. This debounced signal is available at the  $\overline{\text{PBOUT}}$  open drain output, and it can be used to interrupt the system for software purposes such as choosing an option from a menu. The initial  $\overline{\text{PBOUT}}$  pulse in Awake state typically has a width of at least t<sub>PBOUT\_FIRST</sub> (128ms typical) which allows the

system sufficient time to respond just after powering up (see Figure 11). Subsequent  $\overline{\text{PBOUT}}$  pulses have a width of at least t<sub>PD\_DB</sub> (32ms typical). Note that if the system's microcontroller toggles  $\overline{\text{SLEEP}}$  during t<sub>PBOUT\_FIRST</sub>, the LTC2956 will enter the Sleep state and release  $\overline{\text{PBOUT}}$  high without waiting for t<sub>PBOUT\_FIRST</sub> to complete.

## OPERATION

## APPLICATIONS INFORMATION

### Configuration

Configuring the LTC2956 wake-up timer is a 3-step process. The wake-up timer period is determined by the resistor to ground at the PERIOD pin and the resistive divider at the RANGE pin. Then the minimum time required for a long push button press that forces the wake-up timer into the SHUTDOWN mode is determined by another resistive divider at the LONG pin. Finally, the maximum awake time ( $t_{\text{ONMAX}}$ ) is set with a capacitor to GND at the ONMAX pin. The LTC2956 biases and samples the voltages or current at these pins once every 66s while in RUN mode. The part also samples these pins following power-up and when in from Off state.

*Step 1: Set  $t_{\text{PERIOD}}$  with resistors at the PERIOD and RANGE pins*

The required resistance value at the PERIOD pin to set the wake-up timer period can be determined as follows:

$$R_{\text{PERIOD}} = 400 \cdot t_{\text{PERIOD}} / \text{NRANGE} \text{ [k}\Omega\text{/s]}$$

NRANGE is the internal clock divider and can be adjusted through the resistive divider at the RANGE pin as shown in Table 1. It is advisable to select an NRANGE value that yields the largest allowable  $R_{\text{PERIOD}}$  value. The LTC2956's oscillator can run with values of  $R_{\text{PERIOD}}$  ranging from 32.4k $\Omega$  to 324k $\Omega$ .

For example, if a  $t_{\text{PERIOD}}$  of 3s is desired,  $R_{\text{PERIOD}} = 75\text{k}$  and  $\text{NRANGE} = 16$  could be used, but  $R_{\text{PERIOD}} = 300\text{k}$  and  $\text{NRANGE} = 4$  is a better choice.

## APPLICATIONS INFORMATION

**Table 1. RANGE Programming**

RECOMMENDED $t_{PERIOD}$	NRANGE	$R_{RANGE}^*$ [k $\Omega$ ]
0.25s to 0.8s	1	9.76
0.4s to 3.2s	4	17.4
1.6s to 12.8s	16	26.1
6.4s to 51.2s	64	35.7
25.6s to 3.4min	256	47.5
102s to 14min	1,024	61.9
6.8min to 55min	4,096	78.7
27min to 3.6hr	16,384	100
1.82hr to 15hr	65,536	127
7.28hr to 58hr	262,144	162
29hr to 233hr	1,048,576	210
233hr to 932hr	4,194,304	280

\* $R_{COM} = 100k\Omega$

*Step 2: Set required pushbutton time for shutdown with the resistive divider at the LONG pin*

The resistive divider at the LONG pin sets the  $t_{LONG}$  value and Power Up mode as shown in Table 2:

**Table 2.  $t_{LONG}$  Programming**

$t_{LONG}$	POWER UP MODE	$R_{LONG}^*$ [k $\Omega$ ]
0.128s	SHUTDOWN	9.76
0.256s	SHUTDOWN	17.4
0.512s	SHUTDOWN	26.1
1.024s	SHUTDOWN	35.7
2.048s	SHUTDOWN	47.5
4.096s	SHUTDOWN	61.9
8.192s	SHUTDOWN	78.7
16.384s	SHUTDOWN	100
0.128s	RUN	127
0.256s	RUN	162
0.512s	RUN	210
1.024s	RUN	280
2.048s	RUN	383
4.096s	RUN	576
8.192s	RUN	1020
16.384s	RUN	Open

\* $R_{COM} = 100k\Omega$

*Step 3: Set maximum Awake time using capacitor at ONMAX pin*

The value of  $C_{ONMAX}$  can be determined by the equation:

$$C_{ONMAX} = t_{ONMAX} \cdot 75 \text{ [nF/s]}$$

For example, a  $t_{ONMAX}$  of 133ms requires a 10nF capacitor.

### High Voltage PowerPath™ Switching

The high voltage  $\overline{EN}$  open drain output of the LTC2956-2 is designed to switch on/off an external power P-channel MOSFET. This allows a user to connect/disconnect a power supply (or battery) to its load by toggling the  $\overline{PB}$  pin. Figure 12 shows the LTC2956-2 switching a 24V battery application. R6 slows down the turning on of M1 so as to limit the inrush current when needed to charge up the capacitor at  $V_{OUT}$ . R5 is optional – it helps to speed up the turning off of M1 and also to keep M1 off when the input voltage rise time is fast.

\*R5 IS OPTIONAL

**Figure 12. Switching 24V Battery Stack with External P-Channel MOSFET**

### $\overline{PB}$ Pin in a Noisy Environment

The rugged  $\overline{PB}$  pin is designed to operate in noisy environments. Transients below ground and above  $V_{IN}$  will not damage the  $\overline{PB}$  pin. Additionally, the  $\overline{PB}$  pin can withstand ESD HBM strikes of up to  $\pm 25kV$ . However, if the pushbutton switch is located physically far from the

## APPLICATIONS INFORMATION

LTC2956  $\overline{\text{PB}}$  pin, the parasitic capacitance and parasitic series inductance of the connecting cable or PCB trace can cause erratic behavior. The parasitic capacitance can couple external noise onto the  $\overline{\text{PB}}$  input; placing a  $0.1\mu\text{F}$  capacitor at the pin lessens the impact of this coupling. The parasitic series inductance may cause unpredictable ringing at the  $\overline{\text{PB}}$  pin; placing a  $5.1\text{k}$  resistor from the  $\overline{\text{PB}}$  pin to the pushbutton switch reduces this ringing. Figure 13 shows an example of this RC network at the  $\overline{\text{PB}}$  pin.

### External Pull-Up Resistor on $\overline{\text{PB}}$ Pin

An internal  $900\text{k}$  pull-up resistor on the  $\overline{\text{PB}}$  pin makes an external pull-up resistor unnecessary. Leakage current on the  $\overline{\text{PB}}$  board trace, however, will affect the open circuit voltage on the  $\overline{\text{PB}}$  pin. If the leakage is too large ( $>2\mu\text{A}$ ), the  $\overline{\text{PB}}$  voltage may fall close to the threshold window. To mitigate the effect of board leakage, a  $10\text{k}$  pull-up resistor to  $V_{\text{IN}}$  can be used (see Figure 14).

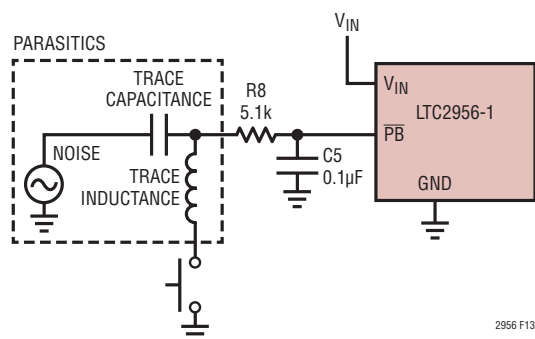

Figure 13. Noisy  $\overline{\text{PB}}$  Trace

Figure 14. External Pull-Up Resistor on  $\overline{\text{PB}}$  Pin for Board Leakage Greater than  $2\mu\text{A}$

### Enhancing $V_{\text{IN}}$ Ruggedness and Reverse Battery Protection

Placing a  $1\text{k}$  resistor and a  $10\text{nF}$  capacitor at the  $V_{\text{IN}}$  pin can be used to enhance ruggedness in some applications (see Figure 15). The peak operating current of the LTC2956 is less than  $10\mu\text{A}$ , creating an insignificant  $10\text{mV}$  drop across the  $1\text{k}$  resistor. The  $10\text{nF}$  bypass capacitor in combination with the  $1\text{k}$  series resistor can protect against high voltage input transients that momentarily exceed the  $40\text{V}$  absolute maximum voltage rating of the  $V_{\text{IN}}$  pin. These can occur during hot-plugging into a battery or AC adapter. This R-C filter can also protect against transients that may appear on the PCB ground during large ESD strikes at the  $\overline{\text{PB}}$  pin.

A  $1\text{k}$  resistor in series with the  $V_{\text{IN}}$  pin also allows the LTC2956 to withstand reverse-input voltages up to  $-40\text{V}$ . The LTC2956's  $V_{\text{IN}}$  pin is internally clamped to one diode voltage below ground and can tolerate up to  $50\text{mA}$  of reverse current. In applications where a battery could be inserted backwards, this resistor will limit the reverse current to a safe level thus allowing internal clamping to protect the pin.

Figures 16a and 16b shows some additional simple reverse battery protection circuits that use a single MOSFET. Figure 16a illustrates a high-side PMOS in the power path while Figure 16b shows a low-side NMOS in the ground path. In each circuit, the MOSFET body diode is orientated in the direction of normal current flow. When the battery is installed incorrectly, the NMOS/PMOS gate is low/high, thus preventing the circuit from turning on. When the battery is properly installed, the NMOS/PMOS FET gate voltage is taken high/low, and its channel shorts out the diode.

Figure 15. Enhancing  $V_{\text{IN}}$  Ruggedness

Interface with Switching Regulators

The LTC2956-1 EN pin can be connected directly to most switching regulator SHUTDOWN inputs. The EN pin high level output voltage ( $V_{EN}(V_{OH})$ ) is typically 3.3V when  $V_{IN} > 3.5V$ , and  $V_{EN}(V_{OH}) = V_{IN} - 0.1V$  if  $V_{IN} < 3.0V$ . With a minimum  $V_{IN}$  of 1.5V,  $V_{EN}(V_{OH})$  is still higher than most SHUTDOWN thresholds. Figure 17 shows one such application. The LTC3528 regulator is a boost converter with a SHUTDOWN high threshold of 0.88V (maximum).

If a higher  $V_{EN}(V_{OH})$  is required, an external pull-up resistor can be connected from the EN pin to any higher voltage ( $< 36V$ ). The EN pin is designed to be able to sink at least 1mA of current during turn-off, so this external pull-up resistor value must be selected to source less than 1mA with EN at 0V. The LTC2956-1 EN pin can also be connected to switching regulators with a RUN/SS pin. RUN/SS typically has a dual function of a SHUTDOWN threshold and soft-start. Switching regulators optimized for

Figure 17. 2-Cell with 3.3V Output

## APPLICATIONS INFORMATION

micro-power applications may require an external pull-up resistor and capacitor to create a soft-start ramp. The EN pin's integrated 900k pull-up resistance and an external capacitor can be used for this purpose. Figure 18 shows the LTC2956-1 EN pin connected to an LT8610 step-down regulator's EN/UV pin.

### Layout Considerations

Figure 19 shows example PCB layouts for the QFN and MS packages with external components. Position the bypass capacitor close to the LTC2956 on the same side of the PCB, and keep the traces short in order to give the best protection against  $\overline{PB}$  pin ESD transients.
