Note 1: Stresses beyond those listed under Absolute Maximum Ratings may cause permanent damage to the device. Exposure to any Absolute Maximum Rating condition for extended periods may affect device reliability and lifetime.

Note 2: All voltages with respect to GND unless otherwise noted. Positive currents are into pins; negative currents are out of pins unless otherwise noted.

Note 3: This IC includes overtemperature protection that is intended to protect the device during momentary overload conditions. Junction temperature can exceed 150°C when overtemperature protection is active. Continuous operation above the specified maximum operating junction temperature may impair device reliability.

Note 4: Detection signature resistance specifications do not include resistance added by the external diode bridge which can add as much as 1.1k Ω to the port resistance.

Note 5: I_{GPU} available in PoE powered operation. That is, available after $V(VPORT) > V_{HSON}$ and $V(AUX) < V_{AUXT}$, over the range where $V(VPORT)$ is between V_{HSOFF} and 60V.

Note 6: Guaranteed by design, not subject to test.

Note 7: Specified as the percentage of the period which T2P is low impedance with respect to V_{CC} .

PIN FUNCTIONS

GND (Pins 1, 19, Exposed Pad Pin 29): Device Ground. Exposed Pad must be electrically and thermally connected to pins 1, 19 and PCB GND.

AUX (Pin 2): Auxiliary Sense. Assert AUX via a resistive divider from the auxiliary power input to set the voltage at which the auxiliary supply takes over. Asserting AUX pulls down HSGATE, disconnects the detection signature resistor and disables classification signature. The AUX pin sinks I_{AUXH} when below its threshold voltage, of V_{AUXT} , to provide hysteresis. Connect to GND if not used.

RCLASS++ (Pin 3): Class Select Input. Connect a resistor between RCLASS++ to GND per Table 1.

RCLASS (Pin 4): Class Select Input. Connect a resistor between RCLASS and GND per Table 1.

T2P (Pin 5): PSE Type Indicator. Open drain with respect to V_{CC} . See the Applications Information section for pin behavior.

V_{CC} (Pins 6, 7, 8, 9, 21): Switching Regulator Controller Supply Voltage. Connect a local ceramic capacitor from V_{CC} pin 21 to GND pin 19 as close as possible to LT4295 as shown in Table 2.

ROSC (Pin 10): Programmable Frequency Adjustment. Resistor to GND programs operating frequency. Leave open for default frequency of 214kHz.

SFST (Pin 11): Soft-Start. Capacitor to GND sets soft-start timing.

FFSDLY (Pin 12): Forward/Flyback Select and Primary Gate Delay Adjustment. Resistor to GND adjusts gate drive delay for a flyback topology. Resistor to V_{CC} adjusts gate drive delay for a forward topology.

ITHB (Pin 13): Current Threshold Control. The voltage on this pin corresponds to the peak current of the external primary FET. Note that the voltage gain from ITHB to the input of the current sense comparator (V_{SENSE}) is negative.

FB31 (Pin 14): Feedback Input. In flyback mode, connect external resistive divider from the third winding feedback. Reference voltage is 3.17V. Connect to GND in forward mode.

RLDCMP (Pin 15): Load Compensation Adjustment. Optional resistor to GND controls output voltage set point as a function of peak switching current. Leave RLDCMP open if load compensation is not needed.

ISEN⁻ (Pin 16): Current Sense, Negative Input. Route as a dedicated trace to the return side of the current sense resistor.

ISEN⁺ (Pin 17): Current Sense, Positive Input. Route as a dedicated trace to the sense side of the current sense resistor.

SG (Pin 18): Secondary (Synchronous) Gate Drive Output.

PG (Pin 20): Primary Gate Drive Output.

DNC (Pin 22): Do Not Connect. Leave pin open.

SWVCC (Pin 23): Switch Driver for V_{CC} 's Buck Regulator. This pin drives the base of a PNP in a buck regulator to generate V_{CC} .

V_{IN} (Pin 24): Buck Regulator Supply Voltage. Usually separated from HSSRC by a pi filter.

HSSRC (Pin 25): External Hot Swap MOSFET Source. Connect to source of the external MOSFET.

HSGATE (Pin 26): External Hot Swap MOSFET Gate Control Output. Capacitance to GND determines inrush time.

NC (Pin 27): No Connection. Not internally connected.

VPORT (Pin 28): PD Interface Supply Voltage and External Hot Swap MOSFET Drain Connection.

BLOCK DIAGRAM

APPLICATIONS INFORMATION

OVERVIEW

Power over Ethernet (PoE) continues to gain popularity as products take advantage of the combination of DC power and high speed data available from a single RJ45 connector. The LT4295 is IEEE 802.3bt (Draft 2.0)-compliant and allows up to 71 watt operation while maintaining backwards compatibility with existing PSE systems. The LT4295 combines a PoE PD interface controller and a switching regulator controller capable of either flyback or forward isolated power supply operation.

SIGNIFICANT DIFFERENCES FROM PREVIOUS PRODUCTS

The LT4295 has several significant differences from previous Linear Technology products. These differences are briefly summarized below.

IEEE 802.3bt vs LTPoE++ Available PD Power

The LT4295 supports IEEE 802.3bt PD power levels up to 71 Watts. A PD requiring more than 71 Watts is beyond the allowable power levels of IEEE 802.3bt.

The LT4275 and LT4276 are available to support PD power levels up to 90W under the LTPoE++ standard. See the Related Parts section for a list of LTPoE++ PSEs and PDs.

ITHB Is Inverted from the Usual ITH pin

The ITHB pin voltage has an inverse relationship to the current sense comparator threshold, V_{SENSE} . Furthermore, the ITHB pin offset voltage, $V_{ITHB(OS)}$, is 3.17V. See Figure 1.

Figure 1. V_{SENSE} vs. V_{ITHB}

Duty-Cycle Based Soft-Start

The LT4295 uses a duty cycle ramp soft-start that injects charge into ITHB. This allows startup without appreciable overshoot using inexpensive external components.

The Feedback Pin FB31 is 3.17V Rather Than 1.25V

The error amp feedback voltage V_{FB} is 3.17V.

Flyback/Forward Mode Is Pin Selectable

The LT4295 operates in flyback mode if FFSDLY is pulled down by a resistor to GND. It operates in forward mode if FFSDLY is pulled up by a resistor to V_{CC} . The value of this resistor determines the $t_{PGDELAY}$ and t_{PGSG} .

T2P Pin Response

The T2P pin outputs high impedance to V_{CC} , low impedance to V_{CC} , 50% duty cycle, or 25% duty cycle, responsive to the number of classification/mark event and responsive to

Table 1. Single-Signature Classification Codes, Power Levels and Resistor Selection

CLASS	PD POWER AVAILABLE	PD TYPE	NOMINAL CLASS CURRENT	RESISTOR (1%)	
				R_{CLS}	R_{CLS++}
0	13W	Type 1	2.5mA	1.00k Ω	Open
1	3.84W	Type 1 or 3	10.5mA	150 Ω	Open
2	6.49W	Type 1 or 3	18.5mA	80.6 Ω	Open
3	13W	Type 1 or 3	28mA	52.3 Ω	Open
4	25.5W	Type 2 or 3	40mA	35.7 Ω	Open
5	40W	Type 3	40mA/2.5mA	1.00k Ω	37.4 Ω
6	51W	Type 3	40mA/10.5mA	150 Ω	47.5 Ω
7	62W	Type 4	40mA/18.5mA	80.6 Ω	64.9 Ω
8	71W	Type 4	40mA/28mA	52.3 Ω	118 Ω

APPLICATIONS INFORMATION

PoE or auxiliary power operation. See T2P Output section in the Application Information.

V_{CC} Is Powered by Internally Driven Buck Regulator

The LT4295 includes a buck regulator controller that must be used to generate the V_{CC} supply voltage.

PoE MODES OF OPERATION

The LT4295 has several modes of operation, depending on the input voltage sequence applied to the V_{PORT} pin.

Detection Signature

During detection, the PSE looks for a 25kΩ detection signature resistor which identifies the device as a PD. The LT4295 detection signature resistor is smaller than 25k to compensate for the additional series resistance introduced by the IEEE required diode bridge or the LT4321-based ideal diode bridge.

IEEE 802.3bt Single-Signature vs Dual-Signature PDs

IEEE 802.3bt defines two PD topologies: single-signature and dual-signature. The LT4295 primarily targets single-signature PD topologies, eliminating the need for a second PD controller. All PD descriptions and IEEE 802.3 standard references in this data sheet are limited in scope to single-signature PDs.

The LT4295 may be deployed in dual-signature PD applications. For more information, contact Linear Technology Applications.

Classification Signature and Mark

The classification/mark process varies depending on the PSE type. A PSE, after a successful detection, may apply a classification probe voltage of 15.5V to 20.5V and measure the PD classification signature current. Once the PSE applies a classification probe voltage, the PSE returns the PD voltage into the mark voltage range before applying another classification probe voltage, or powering up the PD.

An example of 1-Event classification is shown in Figure 2. In 2-Event classification, a PSE probes for power classification twice as shown in Figure 3. An IEEE 802.3bt PSE may apply as many as 5 events before powering up the PD.

Figure 2. 1-Event Classification Signaling Waveform

Figure 3. 2-Event Classification/Mark Signaling Waveform

IEEE 802.3bt Physical Classification and Demotion

IEEE 802.3bt defines physical classification to allow a PD to communicate its power classification to the connected PSE and to allow the PSE to inform the PD of the PSE's available power. Demotion is provided if the PD requested power level is not available at the PSE. If demoted, the PD must operate in a lower power state.

IEEE 802.3bt provides nine PD classes and four PD types, as shown in Table 1. The LT4295 class is configured by setting the R_{CLS} and R_{CLS++} resistor values.

IEEE 802.3bt PSEs present a single classification event (see Figure 2) to Class 0 thru 3 PDs. A Class 0 thru 3 PD presents its class signature to the PSE and is then

APPLICATIONS INFORMATION

powered on if sufficient power is available. Power limited IEEE 802.3bt PSEs may issue a single event to Class 4 and higher PDs in order to demote those PDs to 13W.

IEEE 802.3bt PSEs present up to three classification events depending on type to Class 4 PDs (see Figure 4). Class 4 PDs present a class signature 4 on all events. This third event differentiates a Class 4 PD from a higher class PD. Power limited IEEE 802.3bt PSEs may issue three events to Class 5 and higher PDs in order to demote those PDs to 25.5W.

Figure 4. 3-Event Classification/Mark Signaling Waveform

IEEE 802.3bt PSEs present four classification events (see Figure 5) to Class 5 and 6 PDs. Class 5 and 6 PDs present a class signature 4 on the first two events. Class 5 and 6 PDs present a class signature 0 or 1, respectively, on the remaining events. Power limited IEEE 802.3bt PSEs may issue four events to Class 7 and higher PDs in order to demote those PDs to 51W.

IEEE 802.3bt PSEs present five classification events (see Figure 6) to Class 7 and 8 PDs. Class 7 and 8 PDs present a class signature 4 on the first two events. Class 7 and 8 PDs present a class signature 2 or 3 respectively, on the remaining events.

The PD must monitor the number of classification/mark events, which is communicated through the LT4295 T2P pin.

Figure 5. 4-Event Classification/Mark Signaling Waveform

Figure 6. 5-Event Classification/Mark Signaling Waveform

Classification Resistors (R_{CLS} and R_{CLS++})

The R_{CLS} and R_{CLS++} resistors set the classification currents corresponding to the PD power classification. Select the value of R_{CLS} and R_{CLS++} from Table 1 and connect the 1% resistor between the RCLASS, RCLASS++ pin and GND.

Detection Signature Corrupt During Mark Event

During the mark event, the LT4295 presents $<11\text{ k}\Omega$ to the port as required by the IEEE 802.3 specification.

Inrush and Powered On

After the PSE detects and optionally classifies the PD, the PSE then powers on the PD. When the PD port voltage rises above the V_{HSON} threshold, it begins to source I_{GPU} out of the HSGATE pin. This current flows into an external

APPLICATIONS INFORMATION

capacitor C_{GATE} in Figure 7 and causes a voltage to ramp up the gate of the external MOSFET. The external MOSFET acts as a source follower and ramps the voltage up on the output bulk capacitor, C_{PORT} , thereby determining the inrush current, I_{INRUSH} . To meet IEEE requirements, design I_{INRUSH} to be $\sim 100\text{mA}$.

Figure 7. Programming I_{INRUSH}

The LT4295 internal charge pump enables an N-channel MOSFET solution, replacing a larger and more costly P-channel FET. The low $R_{DS(ON)}$ MOSFET also maximizes power delivery and efficiency, reduces power and heat dissipation, and eases thermal design.

DELAY START

After the HSGATE charges up to approximately 7V above HSSRC, fully enhancing the external hot swap MOSFET, the switching regulator controller operates after a delay of t_{START} .

EXTERNAL V_{CC} SUPPLY

The external V_{CC} supply must be configured as a buck regulator shown in Figure 8. To optimize the buck regulator, use the external component values in Table 4 corresponding to the V_{IN} operating range. This buck regulator runs in discontinuous mode with the inductor peak current considerably higher than average load current on V_{CC} . Thus, the saturation current rating of the inductor must exceed the values shown in Table 2. Place the capacitor, C , as close as possible to V_{CC} pin 21 and GND pin 19. For

optimal performance, place these components as close as possible to the LT4295.

Figure 8. V_{CC} Buck Regulator

Table 2 . Buck Regulator Component Selection

V_{IN}	C	L	I_{SAT}	R_e	D
9V-57V PoE	22 μ F 10 μ F	22 μ H 100 μ H	$\geq 1.2\text{A}$ $\geq 300\text{mA}$	1 Ω 20 Ω	Schottky Ultrafast Diode

AUXILIARY SUPPLY OVERRIDE

If the AUX pin is held above V_{AUXT} , the LT4295 enters auxiliary power operation. In this mode the detection signature resistor is disconnected, classification is disabled, and HSGATE is pulled down.

The AUX pin allows for setting the auxiliary supply turn on (V_{AUXON}) and turn off (V_{AUXOFF}) voltage thresholds. The auxiliary supply hysteresis voltage, V_{AUXHYS} , is set by sinking current, I_{AUXH} , only when the AUX pin voltage is less than V_{AUXT} . Use the following equations to set V_{AUXON} and V_{AUXOFF} via $R1$ and $R2$ in Figure 9. A capacitor up to 1000pF may be placed between the AUX pin and GND to improve noise immunity.

V_{AUXON} must be lower than V_{HSOFF} .

$$R1 = \frac{V_{AUXON} - V_{AUXOFF}}{I_{AUXH}} = \frac{V_{AUXHYS}}{I_{AUXH}}$$

$$R2 = \frac{R1}{\left(\frac{V_{AUXOFF}}{V_{AUXT}} - 1\right)}$$

$$R1 \geq \frac{V_{AUX(MAX)} - V_{AUXT}}{1.4\text{mA}}$$

Figure 9. AUX Threshold and Hysteresis Calculation

APPLICATIONS INFORMATION

T2P OUTPUT

The LT4295 communicates the available power to the PD application via the T2P pin. The T2P pin state is determined by the number of classification/mark events, the PD classification signature, and whether the PD is in PoE or auxiliary power operation. The LT4295 uses a 4-state encoding on the T2P pin.

During PoE operation after completing inrush, the T2P pin presents a high impedance (Hi-Z) to V_{CC} to indicate 1-Event classifications. The T2P pin presents a low impedance (Low-Z) to V_{CC} to indicate 2-Event or 3-Event classification. The T2P pin presents an alternating low/high impedance to V_{CC} at 50% duty cycle to indicate 4-Event classification. The T2P pin presents an alternating 25% low/75% high impedance to V_{CC} duty cycle to indicate 5-Event classification. The T2P pin toggles at a rate of f_{T2P} . This feature is summarized in Table 3.

During auxiliary power operation, when configured for Class 4 or lower (i.e. RCLASS++ pin is floating), the T2P presents low impedance to V_{CC} . When configured Class 5 or higher (i.e. with a resistor on the RCLASS++ pin to GND), the T2P presents a 25% duty cycle. This feature is summarized in Table 4.

Table 3. T2P Response vs Number of Class/Mark Events During PoE Operation

NUMBER OF CLASSIFICATION/MARK EVENTS	T2P WRT V_{CC}	PD POWER
1	Hi-Z	13W
2 or 3	Low-Z	25.5W
4	50% Hi-Z/50% Low-Z	Minimum(PD Class, 51W)
5	25% Low-Z, 75% Hi-Z	Minimum(PD Class, 71W)

Table 4. T2P Response During Auxiliary Power Operation

PD CLASSIFICATION SIGNATURE	T2P WRT V_{CC}
0-4	Low-Z
5-8	25% Low-Z, 75% Hi-Z

SWITCHING REGULATOR CONTROLLER OPERATION

The switching regulator controller portion of the LT4295 is a current mode controller capable of implementing either a flyback or a forward power supply. When used in flyback mode, no opto-isolator is required for feedback

because the output voltage is sensed via the transformer's third winding.

Flyback Mode

The LT4295 is programmed into flyback mode by placing a resistor R_{FFSDLY} from the FFSDLY pin to GND. This resistor must be in the range of 5.23k Ω to 52.3k Ω . If using a potentiometer to adjust R_{FFSDLY} , ensure the adjustment of the potentiometer does not exceed 52.3k Ω . The value of R_{FFSDLY} determines $t_{PGDELAY}$ according to the following equations:

$$t_{PGDELAY} \approx 2.69ns / k\Omega \cdot R_{FFSDLY} + 30ns$$

$$t_{PGSG} \approx 20ns$$

The SG pin must be connected to the secondary side MOSFET through a gate drive transformer as shown in Figure 11. Add a Schottky diode from PG to GND as shown in Figure 11 to prevent PG from going negative.

Figure 10. PG and SG Timing Relationship in Flyback Mode

Figure 11. Example PG and SG Connections in Flyback Mode

APPLICATIONS INFORMATION

Forward Mode

The LT4295 is programmed into forward mode by placing a resistor R_{FFSDLY} from the FFSDLY pin to V_{CC} . The R_{FFSDLY} resistor must be in the range of 10.5k Ω to 52.3k Ω . If using a potentiometer to adjust R_{FFSDLY} ensure the adjustment of the potentiometer does not exceed 52.3k Ω .

The value of R_{FFSDLY} determines $t_{PGDELAY}$ and t_{PGSG} according to the following equations:

$$t_{PGDELAY} \approx 7.16\text{ns/k}\Omega \cdot R_{FFSDLY} + 17\text{ns}$$

$$t_{PGSG} \approx 5.60\text{ns/k}\Omega \cdot R_{FFSDLY} + 7.9\text{ns}$$

The PG and SG relationships in forward mode are shown in Figure 12.

In forward mode, the SG pin has the correct polarity to drive the active clamp P-channel MOSFET through a simple level shifter as shown in Figure 13. Add a Schottky diode from the PG to GND as shown in Figure 13 to prevent PG from going negative.

Figure 12. PG and SG Timing Relationship in Forward Mode

Figure 13. Example PG and SG Connections in Forward Mode

FEEDBACK AMPLIFIER

In the flyback mode, the feedback amplifier senses the output voltage through the transformer's third winding as shown in Figure 14. The amplifier is enabled only during the fixed interval, t_{FB} , as shown in Figure 15. This eliminates the opto-isolator in isolated designs, thus greatly improving the dynamic response and stability over lifetime. Since t_{FB} is a fixed interval, the time-averaged transconductance, gm, varies as a function of the user-selected switching frequency.

Figure 14. Feedback and Load Compensation Connection

Figure 15. Feedback Amplifier Timing Diagram

APPLICATIONS INFORMATION

FEEDBACK AMPLIFIER OUTPUT, ITHB

As shown in the Block Diagram, V_{SENSE} is the input of the Current Sense Comparator. V_{SENSE} is derived from the output of a linear amplifier whose input is the voltage on the ITHB pin, V_{ITHB} .

This linear amplifier inverts its input, V_{ITHB} , with a gain, $\Delta V_{SENSE}/\Delta V_{ITHB}$, and with an offset voltage of $V_{ITHB(OS)}$ to yield its output, V_{SENSE} . This relationship is shown graphically in Figure 1. Note the slope $\Delta V_{SENSE}/\Delta V_{ITHB}$ is a negative number and is provided in the electrical characteristics table.

$$V_{ITHB} = V_{ITHB(OS)} + V_{SENSE} \cdot \left(\frac{\Delta V_{SENSE}}{\Delta V_{ITHB}} \right)^{-1}$$

The block diagram shows V_{SENSE} is compared against the voltage across the current sense resistor, $V(I_{SEN}^+) - V(I_{SEN}^-)$ modified by the internal slope compensation voltage discussed subsequently.

LOAD COMPENSATION

As can be seen in Figure 15, the voltage on the FB31 pin droops slightly during the flyback period. This is mostly caused by resistances of components of the secondary side such as: the secondary winding, $R_{DS(ON)}$ of the synchronous MOSFET, ESR of the output capacitor, etc. These resistances cause a feedback error that is proportional to the current in the secondary loop at the time of feedback sample window. To compensate for this error, the LT4295 places a voltage proportional to the peak current in the primary winding on the RLDCMP pin.

Determining Feedback and Load Compensation Resistors

Because the resistances of components on the secondary side are generally not well known, an empirical method must be used to determine the feedback and load compensation resistor values.

INITIALLY SET $R_{FB2} = 2k\Omega$

$$R_{FB1} \approx R_{FB2} \frac{V_{OUT}}{V_{FB}} \frac{N_{THIRD}}{N_{SECONDARY}} - R_{FB2}$$

Connect the resistor R_{LDCMP} between the RLDCMP pin and GND. R_{LDCMP} must be at least $10k\Omega$. Adjust R_{LDCMP} for minimum change of V_{OUT} over the full input and output load range. A potentiometer in series with $10k\Omega$ may be initially used for R_{LDCMP} and adjusted. The potentiometer+ $10k\Omega$ may then be removed, measured, and replaced with the equivalent fixed resistor. The resulting V_{OUT} differs from the desired V_{OUT} due to offset injected by load compensation. The change to R_{FB2} to correct this is predicted by:

$$\Delta R_{FB2} = \frac{\Delta V_{OUT}}{V_{FB}} \frac{N_{THIRD}}{N_{SECONDARY}} \frac{R_{FB2}^2}{R_{FB1}}$$

Where: ΔV_{OUT} is the desired change to V_{OUT}
 ΔR_{FB2} is the required change to R_{FB2}

$N_{THIRD}/N_{SECONDARY}$ is the transformer third winding to secondary winding

OPTO-ISOLATOR FEEDBACK

For forward mode operation, the flyback voltage cannot be sensed across the transformer. Thus, opto-isolator feedback must be used. When using opto-isolator feedback, connect the FB31 pin to GND and leave the RLDCMP pin open. In this condition, the feedback amplifier sinks an average current of I_{SINK} into the ITHB pin. An example for feedback connections is shown in Figure 16. Note that since I_{SINK} is time-averaged over the switching period, the sink current varies as a function of the user-selected switching frequency.

Figure 16. Opto-isolator Feedback Connections in the Forward Mode

SOFT-START

In PoE applications, a proper soft-start design is required to prevent the PD from drawing more current than the PSE can provide.

APPLICATIONS INFORMATION

The soft-start time, t_{SFST} , is approximately the time in which the power supply output voltage, V_{OUT} , is charging its output capacitance, C_{OUT} . This results in an inrush current at the port of the PD, I_{port_inrush} (not to be confused with I_{INRUSH} discussed earlier in Applications Information section). Care must be taken in selecting t_{SFST} to prevent the PD from drawing more current than the PSE can provide.

In the absence of an output load current, the I_{port_inrush} , is approximated by the following equation:

$$I_{port_inrush} \approx \frac{C_{OUT} \cdot V_{OUT}^2}{\eta \cdot t_{SFST} \cdot V_{IN}}$$

where η is the power supply efficiency,

V_{IN} is the input voltage of the PD

I_{port_inrush} plus the port current due to the load current must be below the current the PSE can provide. Note that the PSE current capability depends on the PSE operating standard.

The LT4295 contains a soft-start function that controls t_{SFST} by connecting an external capacitor, C_{SFST} , between the SFST pin and GND. The SFST pin is pulled up with I_{SFST} when the LT4295 begins switching. The voltage ramp on the SFST pin is proportional to the duty cycle ramp for PG.

For flyback mode, the soft-start time is:

$$t_{SFST} = \frac{600\mu A}{nF} \left(\frac{C_{SFST}}{I_{SFST}} \right) (t_{PGon} + t_{PGDELAY} - t_{MIN})$$

where t_{PGon} is the time when PG is high as shown in Figure 8 once the power supply is in steady-state.

In forward mode, each of the back page applications schematics provides a chart with t_{SFST} vs. C_{SFST} . Select the application and choose a value of C_{SFST} that corresponds to the desired soft-start time.

CURRENT SENSE COMPARATOR

The LT4295 uses a differential current sense comparator to reduce the effects of stray resistance and inductance on the measurement of the primary current. $ISEN^+$ and $ISEN^-$ must be Kelvin connected to the sense resistor pads.

Like most switching regulator controllers, the current sense comparator begins sensing the current t_{MIN} after PG turns on. Then, the comparator turns PG off after the voltage across $ISEN^+$ and $ISEN^-$ exceeds the current sense comparator threshold, V_{SENSE} . Note that the voltage across $ISEN^+$ and $ISEN^-$ is modified by LT4295's internal slope compensation.

SLOPE COMPENSATION

The LT4295 incorporates current slope compensation. Slope compensation is required to ensure current loop stability when the duty cycle is greater than or near 50%. The slope compensation of the LT4295 does not reduce the maximum peak current at higher duty cycles.

CONTROL LOOP COMPENSATION

In flyback mode, loop frequency compensation is performed by connecting a resistor/capacitor network from the output of the feedback amplifier (ITHB pin) to GND as shown in Figure 14. In forward mode, loop compensation is performed by varying R_X and C_X in Figure 16.

ADJUSTABLE SWITCHING FREQUENCY

The LT4295 has a default switching frequency, f_{OSC} , of 214 kHz when the ROOSC pin is left open. If a higher switching frequency, f_{SW} , is desired (up to 300kHz), a resistor no smaller than 45.3k Ω may be added between the ROOSC pin to GND. The resistor can be calculated below:

$$R_{OSC} = \frac{3900k\Omega \cdot kHz}{(f_{SW} - f_{OSC})} (k\Omega)$$

SHORT CIRCUIT RESPONSE

If the power supply output voltage is shorted, overloaded, or if the soft-start capacitor is too small, an overcurrent fault event occurs when the voltage across the sense pins exceeds V_{FAULT} (after the blanking period of t_{MIN}). This begins the internal fault timer t_{FAULT} . For the duration of t_{FAULT} , the LT4295 turns off PG and SG and pulls the SFST pin to GND. After t_{FAULT} expires, the LT4295 initiates soft-start.

APPLICATIONS INFORMATION

The fault and soft-start sequence repeats as long as the short circuit or overload conditions persist. This condition is recognized by the PG waveform shown in Figure 17 repeating at an interval of t_{FAULT} .

Figure 17. PG Waveforms with Output Shorted

OVERTEMPERATURE PROTECTION

The IEEE 802.3 specification requires a PD to withstand any applied voltage from 0V to 57V indefinitely. During classification, however, the power dissipation in the LT4295 may be as high as 1.5W. The LT4295 can easily tolerate this power for the maximum IEEE classification timing but overheats if this condition persists abnormally.

The LT4295 includes an overtemperature protection feature which is intended to protect the device during momentary overload conditions. If the junction temperature exceeds the overtemperature threshold, the LT4295 pulls down HSGATE pin, disables classification, and disables the switching regulator operation.

MAXIMUM DUTY CYCLE

The maximum duty cycle of the PG pin is modified by the chosen t_{PGDELAY} and f_{SW} . It is calculated below:

$$\begin{aligned} \text{MAX POWER SUPPLY DUTY CYCLE} \\ = D_{\text{MAX}} - t_{\text{PGDELAY}} \cdot f_{\text{SW}} \end{aligned}$$

For an appropriate margin during transient operation, the forward or flyback power supply should be designed so that its maximum steady-state duty cycle should be about 10% lower than the LT4295 Maximum Power Supply Duty Cycle calculated above.

EXTERNAL INTERFACE AND COMPONENT SELECTION

PoE Input Diode Bridge

PDs are required to polarity-correct its input voltage. When diode bridges are used, the diode forward voltage drops affect the voltage at the VPORT pin. The LT4295 is designed to tolerate these voltage drops. The voltage

parameters shown in the Electrical Characteristics are specified at the LT4295 package pins.

For high efficiency applications, the LT4295 supports an LT4321-based PoE ideal diode bridge that reduces the forward voltage drop from 0.7V to nearly 20mV per diode in normal operation, while maintaining IEEE 802.3 compliance.

Auxiliary Input Diode Bridge

Some PDs are required to receive AC or DC power from an auxiliary power source. A diode bridge is typically required to handle the voltage rectification and polarity correction.

In high efficiency applications, or in low auxiliary input voltage applications, the voltage drop across the rectifier cannot be tolerated. The LT4295 can be configured with an LT4320-based ideal diode bridge to recover the diode voltage drop and ease thermal design.

For applications with auxiliary input voltages below 10V, the LT4295 must be configured with an LT4320-based ideal diode bridge to recover the voltage drop and guarantee the minimum VPORT voltage is within the VPORT AUX range as specified in the Electrical Characteristics table.

Input Capacitor

A 0.1 μF capacitor is needed from VPORT to GND to meet the input impedance requirement in IEEE 802.3 and to properly bypass the LT4295. This capacitor must be placed as close as possible to the VPORT and GND pins.

Transient Voltage Suppressor

The LT4295 specifies an absolute maximum voltage of 100V and is designed to tolerate brief overvoltage events due to Ethernet cable surges.

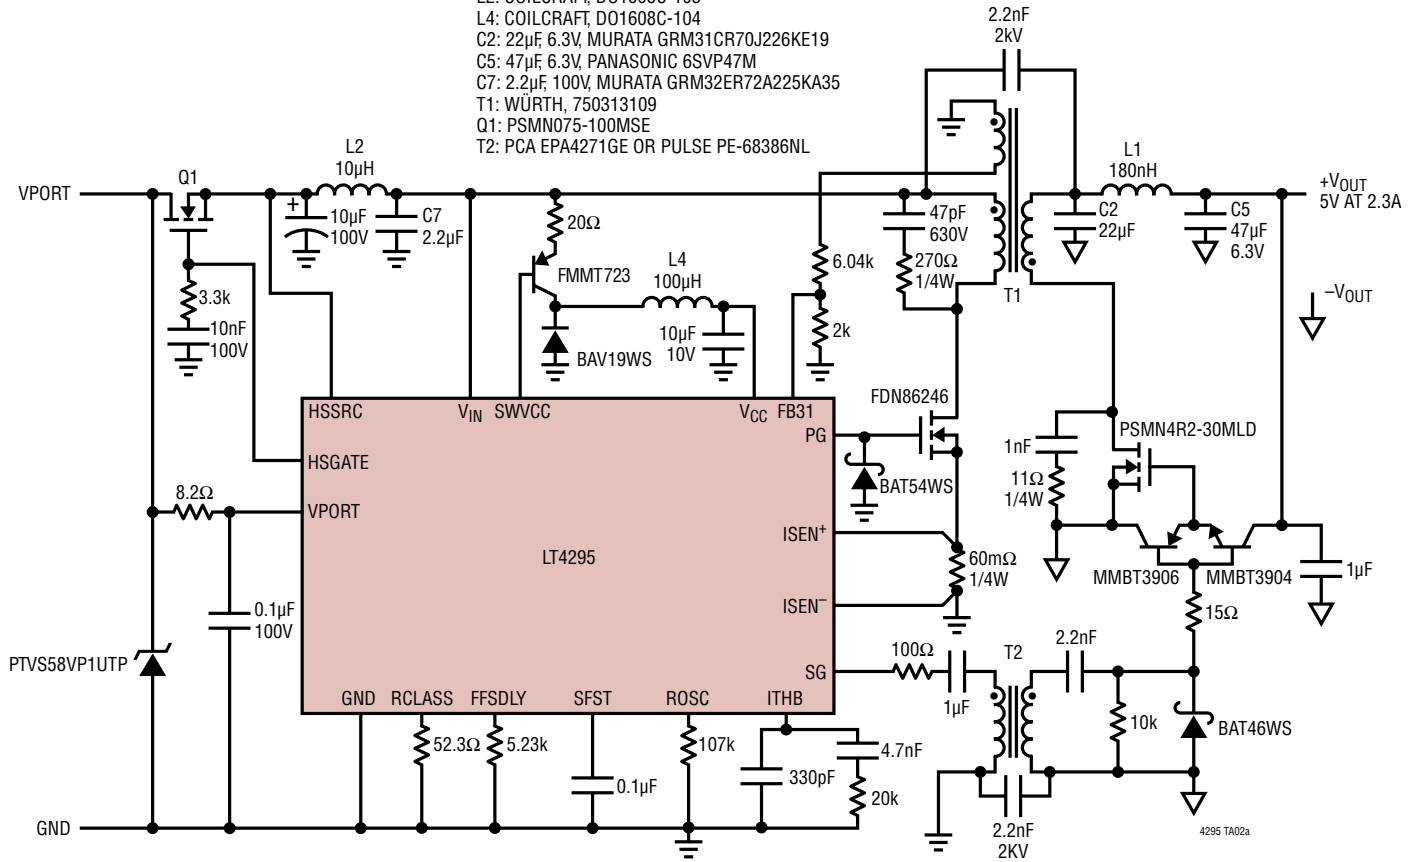

To protect the LT4295 from an overvoltage event, install a unidirectional transient voltage suppressor (TVS) such as an SMAJ58A between the VPORT and GND pins. This TVS must be placed as close as possible to the VPORT and GND pins of the LT4295. For PD applications that require an auxiliary power input, install a TVS between V_{IN} and GND as close as possible to the LT4295.

For extremely high cable discharge and surge protection contact Linear Technology Applications.
