## features

- 50.0dBm OIP3 at 240MHz into a $100 \Omega$ Diff Load
- $\mathrm{NF}=3.0 \mathrm{~dB}$ at 240 MHz
- 20MHz to 2000MHz Bandwidth
- 15.2dB Gain
- A-Grade $\mathbf{1 0 0 \%}$ OIP3 Tested at 240MHz
- $1.0 \mathrm{nV} / \sqrt{\mathrm{Hz}}$ Total Input Noise
- S11 <-15dB Up to 1.2 GHz
- S22 <-15dB Up to $1.2 G H z$
- $>2.75 \mathrm{~V}_{\text {p-p }}$ Linear Output Swing
- P1dB = 24.0dBm
- Insensitive to $V_{\text {CC }}$ Variation
- 100 Differential Gain-Block Operation
- Input/Output Internally Matched to $100 \Omega$ Diff
- Single 5V Supply
- DC Power = 800mW
- Unconditionally Stable
- $4 \mathrm{~mm} \times 4 \mathrm{~mm}$, 24-Lead QFN Package

## APPLICATIONS

- Differential ADC Driver
- Differential IF Amplifier
- OFDM Signal Chain Amplifier
- $50 \Omega$ Balanced IF Amplifier
- $75 \Omega$ CATV Amplifier
- 700MHz to 800MHz LTE Amplifier

## High Linearity Differential RF/IF Amplifier/ADC Driver DESCRIPTIOn

The LTC ${ }^{\circledR} 6430-15$ is a differential gain block amplifier designed to drive high resolution, high speed ADCs with excellent linearity beyond 1000MHz and with Iow associated output noise. The LTC6430-15 operates from a single 5 V power supply and consumes only 800 mW .
In its differential configuration, the LTC6430-15 can directly drive the differential inputs of an ADC. Using 1:2 baluns, the device makes an excellent $50 \Omega$ wideband balanced amplifier. While using 1:1.33 baluns, the device makes a high fidelity 50 MHz to $1000 \mathrm{MHz} 75 \Omega$ CATV amplifier.
The LTC6430-15 is designed for ease of use, requiring a minimum of support components. The device is internally matched to $100 \Omega$ differential source/load impedance. Onchip bias and temperature compensation ensure consistent performance over environmental changes.
The LTC6430-15 uses a high performance SiGe BiCMOS process for excellent repeatability compared with similar GaAs amplifiers. All A-grade LTC6430-15 devices are tested and guaranteed for OIP3 at 240MHz. The LTC6430-15 is housed in a $4 \mathrm{~mm} \times 4 \mathrm{~mm}, 24$-lead, QFN package with an exposed pad for thermal management and low inductance. For a single-ended $50 \Omega$ IF gain block with similar performance, see the related LTC6431-15.

TYPICAL APPLICATION
Differential 16-Bit ADC Driver

## ORDER INFORMATION

The LTC6430－15 is available in two grades．The A－grade guarantees a minimum OIP3 at 240MHz while the B－grade does not．

| LEAD FREE FINISH | TAPE AND REEL | PART MARKING | PACKAGE DESCRIPTION | TEMPERATURE RANGE |
| :--- | :--- | :--- | :--- | :--- |
| LTC6430AIUF－15\＃PBF | LTC6430AIUF－15\＃TRPBF | 43015 | $24-L e a d ~(4 \mathrm{~mm} \times 4 \mathrm{~mm})$ Plastic QFN | $-40^{\circ} \mathrm{C}$ to $85^{\circ} \mathrm{C}$ |

Note 1: Stresses beyond those listed under Absolute Maximum Ratings may cause permanent damage to the device. Exposure to any Absolute Maximum Rating condition for extended periods may affect device reliability and lifetime.
Note 2: Guaranteed by design and characterization. This parameter is not tested.

Note 3: The LTC6430-15 is guaranteed functional over the case operating temperature range of $-40^{\circ} \mathrm{C}$ to $85^{\circ} \mathrm{C}$.
Note 4: Small signal parameters S and noise are de-embedded to the package pins, while large signal parameters are measured directly from the test circuit.
 unless otherwise noted (Note 3). Measurements are performed using Test Circuit A, measuring from $50 \Omega$ SMA to $50 \Omega$ SMA without de-embedding (Note 4).

Differential Input Match (S11 ${ }_{\text {DD }}$ ) vs Frequency Over Temperature

Differential Output Match (S22dD) vs Frequency Over Temperature

Differential Stability Factor K vs Frequency Over Temperature

Differential Gain (S21 ${ }_{\text {DD }}$ ) vs Frequency Over Temperature

Common Mode Gain (S21cc) vs Frequency Over Temperature

Noise Figure vs Frequency Over Temperature

Differential Reverse Isolation (S12dD) vs Frequency Over Temperature

CM-DM Gain (S21dc) vs Frequency Over Temperature

 unless otherwise noted (Note 3). Measurements are performed using Test Circuit A, measuring from $50 \Omega$ SMA to $50 \Omega$ SMA without de-embedding (Note 4).

 unless otherwise noted (Note 3). Measurements are performed using Test Circuit A, measuring from $50 \Omega$ SMA to 50 de-embedding (Note 4).

Total Current ( $\mathrm{I}_{\text {TOT }}$ ) vs Case Temperature

## PIn fUnCTIONS

GND (Pins 8, 14, 17, 23, Exposed Pad Pin 25): Ground. For best RF performance, all ground pins should be connected to the printed circuit board ground plane. The exposed pad (Pin 25) should have multiple via holes to an underlying ground plane for low inductance and good thermal dissipation.
+IN (Pin 24): Positive Signal Input Pin. This pin has an internally generated 2V DC bias. A DC-blocking capacitor is required. See the Applications Information section for specific recommendations.
-IN (Pin 7): Negative Signal Input Pin. This pin has an internally generated 2V DC bias. A DC-blocking capacitor is required. See the Applications Information section for specific recommendations.
$\mathbf{V}_{\text {cc }}$ (Pins 9, 22): Positive Power Supply. Either or both $V_{C C}$ pins should be connected to the 5 V supply. Bypass the $V_{C C}$ pin with 1000 pF and $0.1 \mu \mathrm{~F}$ capacitors. The 1000 pF capacitor should be physically close to a $V_{c c}$ pin.
+OUT (Pin 18): Positive Amplifier Output Pin. Atransformer with a center tap tied to $\mathrm{V}_{\text {cc }}$ or a choke inductor tied to 5 V supply is required to provide DC current and RF isolation. For best performance select a choke with low loss and high self resonant frequency (SRF). See the Applications Information section for more information.
-OUT (Pin 13): Negative Amplifier Output Pin. A transformer with a center tap tied to $\mathrm{V}_{\mathrm{CC}}$ or a choke inductor is required to provide DC current and RF isolation. For best performance select a choke with low loss and high SRF.
DNC (Pins 1 to 6, 10 to 12, 15, 19 to 21): Do Not Connect. Do not connect these pins, allow them to float. Failure to float these pins may impair the performance of the LTC6430-15.

T_DIODE (Pin 16): Optional. Adiode which can be forward biased to ground with up to 1 mA of current. The measured voltage will be an indicator of the chip temperature.

## TEST CIßCUIT A Differential Application Test Circuit A (Balanced Amp)

Figure 1. Test Circuit A

## OPGRATION

The LTC6430-15 is a highly linear, fixed-gain amplifier for differential signals. It can be considered a pair of $50 \Omega$ single-ended devices operating 180 degrees apart. Its core signal path consists of a single amplifier stage minimizing stability issues. The input is a Darlington pair for high input impedance and high current gain. Additional circuit enhancements increase the output impedance commensurate with the input impedance and minimize the effects of internal Miller capacitance.

The LTC6430-15 uses a classic RF gain block topology, with enhancements to achieve excellent linearity. Shunt and series feedback elements are added to lower the input/ output impedance and match them simultaneously to the source and load. An internal bias controller optimizes the bias point for peak linearity over environmental changes. This circuit architecture provides low noise, good RF power handling capability and wide bandwidth; characteristics that are desirable for IF signal-chain applications.

## APPLICATIONS INFORMATION

The LTC6430-15 is a highly linear fixed-gain amplifier which is designed for ease of use. Both the input and output are internally matched to $100 \Omega$ differential source and load impedance from 20MHz to 1700MHz. Biasing and temperature compensation are also handled internally to deliver optimized performance. The designer need only supply input/output blocking capacitors, RF chokes and decoupling capacitors for the 5V supply. However, because the device is capable of such wideband operation, a single application circuit will probably not result in optimized performance across the full frequency band.

Differential circuits minimize the common mode noise and 2 nd harmonic distortion issues that plague many designs. Additionally, the LTC6430's differential topology matches well with the differential inputs of an ADC. However, evaluation of these differential circuits is difficult, as high resolution, high frequency, differential test equipment is lacking.
Our test circuit is designed for evaluation with standard single ended $50 \Omega$ test equipment. Therefore, 1:2 balun transformers have been added to the input and output to transform the LTC6430-15's $100 \Omega$ differential source/load impedance to $50 \Omega$ single-ended impedance compatible with most test equipment.

Other than the balun, the evaluation circuit requires a minimum of external components. Input and output DCblocking capacitors are required as this device is internally biased for optimal operation. A frequency appropriate choke and de-coupling capacitors provide DC bias to the RF $\pm$ OUT nodes. Only a single 5 V supply is necessary to either of the $V_{C C}$ pins on the device. Both $V_{C C}$ pins are connected inside the package. Two $\mathrm{V}_{C C}$ pins are provided for the convenience of supply routing on the PCB. An optional parallel $60 \mathrm{pF}, 350 \Omega$ input network has been added to ensure low frequency stability.
The particular element values shown in Test Circuit A are chosen for wide bandwidth operation. Depending on the desired frequency, performance may be improved by custom selection of these supporting components.

## Choosing the Right RF Choke

Not all choke inductors are created equal. It is always important to select an inductor with low R Loss as resistance will drop the available voltage to the device. Also look for an inductor with high self resonant frequency (SRF) as this will limit the upper frequency where the choke is useful. Above the SRF, the parasitic capacitance dominates and the choke's impedance will drop. For these reasons, wirewound inductors are preferred, while multilayer ceramic chip inductors should be avoided for an RF choke if possible. Since the LTC6430-15 is capable of such wideband operation, a single choke value will not result in optimized performance across its full frequency band. Table 1 lists common frequency bands and suggested corresponding inductor values.
Table 1. Target Frequency and Suggested Inductor Value

| FREQUENCY <br> BAND (MHz) | INDUCTOR VALUE ( nH ) | $\begin{aligned} & \text { SRF } \\ & \text { (MHz) } \end{aligned}$ | MODEL NUMBER | MANUFACTURER |

| 500 t 1000 | 100nH | 1150 | 0603LS |  |
| 1000 to 2000 | 51 nH | 1400 | 0603LS |  |

## DC-Blocking Capacitor

The role of a DC-blocking capacitor is straightforward: block the path of DC current and allow a low series impedance path for the AC signal. Lower frequencies require a higher value of DC-blocking capacitance. Generally, 1000pF to $10,000 \mathrm{pF}$ will suffice for operation down to 20 MHz . The LTC6430-15 linearity is insensitive to the choice of blocking capacitor.

## RF Bypass Capacitor

RF bypass capacitors act to shunt the AC signals to ground with a low impedance path. They prevent the AC signal from getting into the DC bias supply. It is best to place the bypass capacitor as close as possible to the DC supply pins of the amplifier. Any extra distance translates into additional series inductance which lowers the effectiveness of the bypass capacitor network. The suggested bypass capacitor network consists of two capacitors: a low value 1000 pF capacitor to shunt high frequencies

## APPLICATIONS INFORMATION

and a larger $0.1 \mu \mathrm{~F}$ capacitor to handle lower frequencies. Use ceramic capacitors of appropriate physical size for each capacitance value (e.g., 0402 for the $1000 \mathrm{pF}, 0805$ for the $0.1 \mu \mathrm{~F}$ ) to minimize the equivalent series resistance (ESR) of the capacitor.

## Low Frequency Stability

Most RF gain blocks suffer from low frequency instability. To avoid stability issues, the LTC6430-15, contains an internal feedback network that lowers the gain and matches the input and output impedance of the intrinsic amplifier. This feedback network contains a series capacitor, whose value is limited by physical size. So, at some low frequencies, this feedback capacitor looks like an open circuit; the feedback fails, gain increases and gross impedance mismatches occur which can create instability. This situation is easily resolved with a parallel capacitor and a resistor network on the input. This is shown in Figure 1. This network provides resistive loss at low frequencies and is bypassed by the capacitor at the desired band of operation. However, if the LTC6430-15 is preceded by a low frequency termination, such as a choke or balun transformer, the input stability network is not required. A choke at the output can also terminate low frequencies out-of-band and stabilize the device.

## Exposed Pad and Ground Plane Considerations

As with any RF device, minimizing the ground inductance is critical. Care should be taken with PC board layouts using exposed pad packages, as the exposed pad provides the lowest inductive path to ground. The maximum allowable number of minimum diameter via holes should be placed underneath the exposed pad and connected to as many ground plane layers as possible. This will provide good RF ground and low thermal impedance. Maximizing thecopper ground plane at the signal and microstrip ground will also improve the heat spreading and lower inductance. It is a good idea to cover the via holes with solder mask on the
backside of the PCB to prevent the solder from wicking away from the critical PCB to exposed pad interface. One to two ounces of copper plating is suggested to improve heat spreading from the device.

## Frequency Limitations

The LTC6430-15 is a wide bandwidth amplifier but it is not intended for operation down to DC. The lower frequency cutoff is limited by on-chip matching elements. The cutoff may be arbitrarily pushed lower with off chip elements; however, the translation between the low fixed DC common mode input voltage and the higher open collector DC common mode output bias point make DC-coupled operation impractical.

## Test Circuit A

Test Circuit A, shown in Figure 1, is designed to allow for the evaluation of the LTC6430-15 with standard singleended $50 \Omega$ test equipment. This allows the designer to verify the performance when the device is operated differentially. This evaluation circuit requires a minimum of external components. Since the LTC6430-15 operates over a very wide band, the evaluation test circuit is optimized for wideband operation. Obviously, for narrowband operation, the circuit can be further optimized.

Input and output DC-blocking capacitors are required, as this device is internally DC biased for optimal performance. A frequency appropriate choke and decoupling capacitors are required to provide DC bias to the RF output nodes (+OUT and -OUT). A 5V supply should also be applied to one of the $\mathrm{V}_{\mathrm{Cc}}$ pins on the device.

Components for a suggested parallel $60 \mathrm{pF}, 350 \Omega$ stability network have been added to ensure low frequency stability. The 60pF capacitance can be increased to improve low frequency (<150 MHz) performance, however the designer needs to be sure that the impedance presented at low frequency will not create an instability.

## APPLICATIONS InFORMATION

## Balanced Amplifier Circuit, $50 \Omega$ Input and $50 \Omega$ Output

This balanced amplifier circuit is a replica of the Test Circuit A. It is useful for single-ended $50 \Omega$ amplifier requirements and is surprisingly wideband. Using this balanced arrangement and the frequency appropriate baluns, one can achieve the intermodulation and harmonic performance listed in the AC Electrical Characteristics specifications of this data sheet. Besides its impressive intermodulation performance, the LTC6430-15 has impressive 2nd harmonic suppression as well. This makes it particularly well suited for multioctave applications where the 2nd harmonic cannot be filtered.

This balanced circuit example uses two Mini-Circuits 1:2 baluns. The baluns were chosen for their bandwidth and frequency options that utilize the same package footprint (see Table 2). A pair of these baluns, back-to-back has less than 1.5 dB of loss, so the penalty for this level of performance is minimal. Any suitable $1: 2$ balun may be used to create a balanced amplifier with the LTC6430-15.
The optional stability network is only required when the balun's bandwidth reaches below 20MHz. It is included in
the circuit as a comprehensive protection for any passive element placed at the LTC6430-15 input. Its performance degradation at low frequencies can be mitigated by increasing the 60pF capacitor's value.

Demo Boards 1774A-A and 1774A-B implement this balanced amplifier circuit. It is shown in Figure 18 and Figure 19.

Please note that a number of DNC pins are connected on the evaluation board. These connections are not necessary for normal circuit operation.
The evaluation board also includes an optional back to back pair of baluns so that their losses may be measured. This allows the designer to de-embed the balun losses and more accurately predict the LTC6430-15 performance in a differential circuit.

# APPLICATIONS INFORMATION 

Driving the LTC2158, 14-Bit, 310Msps ADC with 1.25 GHz of Bandwidth

Boasting high linearity, low associated noise and wide bandwidth, the LTC6430-15 is well suited to drive high speed, high resolution ADCs with over a GHz of input bandwidth. To demonstrate its performance, the LTC643015 was used to drive an LTC2158 14-bit, 310Msps ADC with 1.25 GHz of input bandwidth in an undersampling application. Typically, a filter is used between the ADC driver amplifier and ADC input to minimize the noise contribution from the amplifier. However, with the typical SNR of higher sample rate ADCs, the LTC6430-15 can drive them without any intervening filter, and with very little penalty in SNR. This system approach has the added benefit of allowing over two octaves of usable frequency range. The LTC6430-15 driving the LTC2158, as shown in the circuit in Figure 3, with band limiting provided only by the 1.25 GHz input BW of the ADC, still produces 64.4 dB SNR, and offers IM performance that varies little from 300 MHz to 1 GHz . At the lower end of this frequency range, the IM contribution of the ADC and amplifier are comparable, and the third-order IM products may be additive, or may see cancelation. At 1 GHz input, the ADC is dominant in terms of IM and noise contribution, limited
by internal clock jitter and high input signal amplitude. Table 3 shows noise and linearity performance. Example outputs at 380 MHz and 1000 MHz are shown in Figure 5, Figure 6, Figure 7, Figure 8 and Figure 9.

As a final display of the utility of this LTC6430-15/LTC2158 combination with real world signals, Figure 9 shows a wideband code division multiple access (WCDMA) signal was introduced to the LTC6430-15/LTC2158 combination at 830 MHz . The output indicates an ACPR near 60dB calculated from the adjacent power on the upper side where the filter stop band suppresses the contribution from the generator. Please note that the adjacent channels on the lower side are not suppressed as they are within the passband of the filter.

The LTC6430-15 can directly drive the high speed ADC inputs and settles quickly. Mostfeedback amplifiers require protection from the sampling disturbances, the mixing products that result from direct sampling. This is in part due to the fact that unless the ADC input driving circuitry offers settling in less than one-half clock cycle, the ADC may not exhibit the expected linearity. If the ADC samples the recovery process of an amplifier it will be seen as distortion. If an amplifier exhibits envelope detection in

## APPLICATIONS INFORMATION

Figure 3. Wideband ADC Driver, LTC6430-15 Directly Driving the LTC2158 ADC

Figure 4. Wideband ADC Driver, LTC6430-15 Directly Driving the LTC2158 ADC—Alternative Using Mini Circuits 2:1 Balun
the presence of multi GHz mixing products, it will distort. A band limiting filter would provide suppression from those products beyond the capability of the amplifier, as well as limit the noise bandwidth, however the settling of the filter can be an issue. The LTC2158, at 310Msps only allows 1.5 ns settling time for any driver that is disturbed by these transients.

This approach of removing the filter between the ADC and driver amplifier offers many advantages. It opens the opportunity to precede the amplifier with switchable bandpass filters, without any need to change the critical network between the drive amplifier and ADC. The trans-
mission line distances shown in the schematic are part of the design, and are devised such that there are no impedance discontinuities, and therefore no reflections, in the distances between 75 ps to 200ps from the ADC. End termination can be immediately prior to, or preferably after the ADC, and the amplifier should either be within the 75ps inner boundary, or outside the 200ps distance. Similarly, any shunt capacitor or resonator, including the large pads required by some inductors with more than a small fraction of 1 pF, incorporated into a filter, should not be in this range of distances from the ADC where reflections will impair performance. Transformers with large

## APPLICATIONS InFORMATION

pads should be avoided within these distances.
A 100 nH shunt inductor at the ADC input approximates the complex conjugate of the ADC sampling circuit, and in doing so, improves powertransfer and suppresses the low frequency difference products produced by direct sampling ADCs. If the entire frequency range from 300 MHz to 1 GHz were of interest, a 100nH inductor at the input is acceptable, but if interest is only in higher frequencies, performance would be better if the input inductor is reduced in value. If lower frequencies are of interest, a higher value up to some 200nH may be practical, but beyond that range the SRF of the inductor becomes an issue. As this inductor is placed at different distances either before or after the ADC inputs, the optimal value may change. In all cases, it should be within 50ps of the ADC inputs. End termination may be more than 200ps distant if after the ADC. If the end termination were perfect, it could be at any distance after the ADC. To terminate the input path after the ADC,
place the termination resistors on the back of the PCB. If the input signal path is buried or on the back of the PCB, termination resistors should be placed on the top of the PCB to properly terminate after the ADC.

Although the ADC is isolated by a driver amplifier, care must be taken when filtering at the amplifier input. Much like MESFETs, high frequency mixing products are handled well by the LTC6430. However, if there is no band limiting after the LTC6430, these mixing products, reduced by reverse isolation but subsequently reflected from a filter prior to the LTC6430 and reamplified, can cause distortion. In such cases, the network will then be sensitive to transmission line lengths and impedance characteristics of the filter prior to the LTC6430. Diplexers or absorptive filters can produce more robust results. An absorptive filter or diplexer-like structure after the amplifier reduces the sensitivity to the network prior to the amplifier, but the same constraints previously outlined apply to the filter.

## APPLICATIONS INFORMATION

## 50MHz to 1000MHz CATV Push-Pull Amplifier: $75 \Omega$ Input and $75 \Omega$ Output

Figure 10. CATV Amplifier: $75 \Omega$ Input and $75 \Omega$ Output

Wide bandwidth, excellent linearity and low output noise makes the LTC6430-15 an exceptional candidate for CATV amplifier applications.

As expected, the LTC6430-15 works well in a push-pull circuit to cover the entire 40MHz to 1000MHz CATV band. Using readily available SMT baluns, the LTC6430-15 offers high linearity and low noise across the whole CATV band. Remarkably, this performance is achieved with only 800 mW of power at 5 V . Its low power dissipation greatly reduces the heat sinking requirements relative to traditional "block" CATV amplifiers.
The native LTC6430-15 device is well matched to $100 \Omega$ differential impedance at both the input and the output. Therefore, we can employ 1:1.33 surface mount (SMT) baluns to transform its native $100 \Omega$ impedance to the standard $75 \Omega$ CATV impedance, while retaining all the exceptional characteristics of the LTC6430-15. In addition, the balun's excellent phase balance and the 2nd order linearity of the LTC6430-15 combine to further suppress 2nd order products across the entire CATV band. As with any wide bandwidth application, care must be taken when
selecting a choke. An SMT wire wound ferrite core inductor was chosen for its low series resistance, high self resonant frequency (SRF) and compact size. An input stability network is not required for this application as the balun presents a low impedance to the LTC6430-15's input at Iow frequencies. Our resulting push-pull CATV amplifier circuit is simple, compact, completely SMT and extremely power efficient.

The LTC6430-15 push-pull circuit has 14.1 dB of gain with $\pm 0.4 \mathrm{~dB}$ of flatness across the entire 50 MHz to 1000 MHz band. It sports an OIP3 of 46dBm and a noise figure of only 4.5 dB . The CTB and CSO measurements have not been taken as of this writing.

These characteristics make the LTC6430-15 an ideal amplifier for head-end cable modem applications or CATV distribution amplifiers. The circuit is shown in Figure 10, with $75 \Omega$ " F " connectors at both input and output. The evaluation board may be loaded with either $75 \Omega$ "F" connectors, or $75 \Omega$ BNC connectors, depending on the users preference. Please note that the use of substandard connectors can limit usable bandwidth of the circuit.

## TYPICAL APPLICATIONS

$50 \Omega$ Input/Output Balanced Amplifier

16-Bit ADC Driver

## LTC6430-15

TYPICAL APPLICATIONS
$75 \Omega$ 50MHz to 1000 MHz CATV Amplifier

## PACKAGE DESCRIPTION

Please refer to http://www.linear.com/designtools/packaging/ for the most recent package drawings.

UF Package
24-Lead Plastic QFN ( $4 \mathrm{~mm} \times 4 \mathrm{~mm}$ )
(Reference LTC DWG \# 05-08-1697 Rev B)

RECOMMENDED SOLDER PAD PITCH AND DIMENSIONS

BOTTOM VIEW—EXPOSED PAD PIN 1 NOTCH

NOTE:

1. DRAWING PROPOSED TO BE MADE A JEDEC PACKAGE OUTLINE MO-220 VARIATION (WGGD-X)-TO BE APPROVED
2. DRAWING NOT TO SCALE
3. ALL DIMENSIONS ARE IN MILLIMETERS
4. DIMENSIONS OF EXPOSED PAD ON BOTTOM OF PACKAGE DO NOT INCLUDE

MOLD FLASH. MOLD FLASH, IF PRESENT, SHALL NOT EXCEED 0.15 mm ON ANY SIDE, IF PRESENT
5. EXPOSED PAD SHALL BE SOLDER PLATED
6. SHADED AREA IS ONLY A REFERENCE FOR PIN 1 LOCATION ON THE TOP AND BOTTOM OF PACKAGE

## Wideband Balanced Amplifier

## RELATED PARTS

| PART NUMBER | DESCRIPTION | COMMENTS |
| :---: | :---: | :---: |
| Fixed Gain IF Amplifiers/ADC Drivers |  |  |
| LTC6431-15 | $50 \Omega$ Gain Block IF Amplifier | Single-Ended Version of LTC6431-15, 15.5dB Gain, 47dBm OIP3 at 240 MHz into a $50 \Omega$ Load |
| LTC6417 | 1.6GHz Low Noise High Linearity Differential Buffer/ ADC Driver | OIP3 $=41 \mathrm{dBm}$ at 300 MHz , Can Drive 50W Differential Output High Speed Voltage Clamping Protects Subsequent Circuitry |
| LTC6400-8/LTC6400-14/ <br> LTC6400-20/LTC6400-26 | 1.8GHz Low Noise, Low Distortion Differential ADC Drivers | -71 dBc IM3 at $240 \mathrm{MHz} 2 \mathrm{~V}_{\mathrm{p}-\mathrm{p}}$ Composite, $\mathrm{I}_{\mathrm{S}}=90 \mathrm{~mA}, \mathrm{~A}_{\mathrm{V}}=8 \mathrm{~dB}, 14 \mathrm{~dB}$, 20dB, 26dB |
| LTC6401-8/LTC6401-14/ <br> LTC6401-20/LTC6401-26 | 1.3GHz Low Noise, Low Distortion Differential ADC Drivers | -74 dBc IM3 at $140 \mathrm{MHz} 2 \mathrm{~V}_{\mathrm{P}-\mathrm{p}}$ Composite, $\mathrm{I}_{\mathrm{S}}=50 \mathrm{~mA}, \mathrm{~A}_{V}=8 \mathrm{~dB}, 14 \mathrm{~dB}$, $20 \mathrm{~dB}, 26 \mathrm{~dB}$ |
| $\begin{aligned} & \text { LT6402-6/LT6402-12/ } \\ & \text { LT6402-20 } \end{aligned}$ | 300MHz Differential Amplifier/ADC Drivers | -71 dBc IM3 at $20 \mathrm{MHz} 2 \mathrm{~V}_{\text {P-p }}$ Composite, $\mathrm{A}_{\mathrm{V}}=6 \mathrm{~dB}, 12 \mathrm{~dB}, 20 \mathrm{~dB}$ |
| LTC6410-6 | 1.4GHz Differential IF Amplifier with Configurable Input Impedance | OIP3 $=36 \mathrm{dBm}$ at 70 MHz , Flexible Interface to Mixer IF Port |
| LTC6416 | 2GHz, 16-Bit Differential ADC Buffer | $\begin{aligned} & -72 \mathrm{dBc} \text { IM2 at } 300 \mathrm{MHz} 2 \mathrm{~V}_{\mathrm{p}-\mathrm{p}} \text { Composite, } \mathrm{I}_{\mathrm{S}}=42 \mathrm{~mA}, \mathrm{eN}=2.8 \mathrm{nV} / \sqrt{\mathrm{Hz}}, \\ & \left.\mathrm{~A}_{\mathrm{V}}=0 \mathrm{~dB}, 300 \mathrm{MHz}\right\} 0.1 \mathrm{~dB} \text { Bandwidth } \end{aligned}$ |
| LTC6420-20 | Dual 1.8GHz Low Noise, Low Distortion Differential ADC Drivers | Dual Version of the LTC6400-20, $A_{V}=20 \mathrm{~dB}$ |
| Variable Gain IF Amplifiers/ADC Drivers |  |  |
| LT6412 | 800MHz, 31dB Range Analog-Controlled VGA | OIP3 $=35 \mathrm{dBm}$ at 240MHz, Continuously Adjustable Gain Control |

## Baseband Differential Amplifiers

| LTC6409 | $1.1 \mathrm{nV} / \sqrt{\mathrm{Hz}}$ Single Supply Differential Amplifier/ADC Driver | 88 dB SFDR at 100 MHz , AC- or DC-Coupled Inputs |
| :---: | :---: | :---: |
| LTC6406 | 3GHz Rail-to-Rail Input Differential Amplifier/ ADC Driver | -65 dBc IM3 at $50 \mathrm{MHz} 2 \mathrm{~V}_{\text {P-p }}$ Composite, Rail-to-Rail Inputs, $\mathrm{eN}=1.6 \mathrm{nV} / \sqrt{\mathrm{Hz}}, 18 \mathrm{~mA}$ |
| LTC6404-1/LTC6404-2 | Low Noise Rail-to-Rail Output Differential Amplifier/ ADC Driver | 16-Bit SNR, SFDR at 10MHz, Rail-to-Rail Outputs, eN $=1.5 \mathrm{nV} / \sqrt{\mathrm{Hz}}$, LTC6404-1 Is Unity-Gain Stable, LTC6404-2 Is Gain-of-Two Stable |
| LTC6403-1 | Low Noise Rail-to-Rail Output Differential Amplifier/ ADC Driver | 16-Bit SNR, SFDR at 3MHz, Rail-to-Rail Outputs, eN $=2.8 \mathrm{nV} / \sqrt{\mathrm{Hz}}$ |
| High Speed ADCs |  |  |
| LTC2208/LTC2209 | 16-Bit, 13Msps/160Msps ADC | 74dBFS Noise Floor, SFDR > 89dB at 140MHz, 2.25Vp-p Input |
| LTC2259-16 | 16-Bit, 80Msps ADC, Ultralow Power | 72 dBFS Noise Floor, SFDR > 82dB at 140MHz, 2.00Vp-p Input |
| $\begin{aligned} & \text { LTC2160-14/LTC2161-14/ } \\ & \text { LTC2162-14 } \end{aligned}$ | 14-bit, 25Msps/40Msps/60Msps ADC Low Power | 76.2 dBFS Noise Floor, SFDR > 84dB at 140MHz, 2.00V ${ }_{\text {P-p }}$ Input |
| LTC2155-14/LTC2156-14/ <br> LTC2157-14/LTC2158-14 | 14-bit, 170Msps/210Msps/250Msps/310Msps ADC 2-Channel | 69dBFS Noise Floor, SFDR > 80dB at 140MHz, 1.50Vp-p Input, $>1 \mathrm{GHz}$ Input BW |
| LTC2216 | 16-Bit, 80Msps ADC | 79dBFS Noise Floor, SFDR > 91dB at 140MHz, 75Vp-p Input |
