# 10-Port, Constant-Current LED Driver and I/O Expander with PWM Intensity Control 

## General Description

The MAX6946/MAX6947 |²C-/SMBus ${ }^{\text {TM }}$-compatible, serial-interfaced peripherals provide microprocessors with $10 \mathrm{I} / \mathrm{O}$ ports rated to 7 V .
Each port can be configured as a 2.5 mA to 20 mA con-stant-current LED driver (static or PWM), a 1.25 mA to 10 mA constant-current LED driver (static or PWM), an open-drain logic output, or an overvoltage-protected Schmitt logic input.
Analog and switching LED intensity control includes individual 8-bit PWM control per output, individual 1-bit analog current control (half/full scale) per output, and a global 3-bit DAC current control that applies to all LED outputs.

The MAX6946/MAX6947 can stagger the PWM timing of the 10-port outputs in consecutively phased $45^{\circ}$ increments. Staggering the outputs spreads the PWM load currents over time in eight steps, helping to even out the power-supply current and reduce the RMS current. For a similar part with an $\mathrm{SPI}^{\top \mathrm{TM}}{ }_{-} / \mathrm{QSPI}^{\mathrm{TM}}{ }^{-/ /}$or MICROWIRE ${ }^{\mathrm{TM}}{ }_{-}$ compatible interface, refer to the MAX6966/MAX6967 data sheet.

## Applications

Cellular Phones
Portable Equipment
RGB LED Drivers

LCD Backlights Keypad Backlights LED Status Indicators

Typical Operating Circuit

SMBus is a trademark of Intel Corp.
SPI and QSPI are trademarks of Motorola, Inc.
MICROWIRE is a trademark of National Semiconductor Corp.

Features

- 2.25 V to 3.6 V Operation
- I/O Ports Default to High Impedance (LEDs Off) on Power-Up
- I/O Port Inputs Are Overvoltage Protected to 7V
- I/O Port Outputs Are 7V-Rated Open-Drain, 10mA or 20mA Constant-Current Static/PWM LED Drivers, or Open-Drain Logic Outputs
- I/O Ports Support Hot Insertion
- Individual 8-Bit PWM Intensity Control for Each LED
$\overline{\text { RST }}$ Input Clears Serial Interface and Can Exit Shutdown (Warm Start)
- MAX6946 OSC Input Allows for External PWM Clock Input
- MAX6947 ADO Input Selects from Two Slave Addresses
- Auto Ramp-Up Out of Shutdown, and Up to 4s Hold-Off Before Ramp-Down into Shutdown
- $0.8 \mu \mathrm{~A}$ (typ) Shutdown Current
- $-40^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$ Temperature Range
- Tiny WLP Package (4 x 4 Grid)

Ordering Information

| PART | PIN-PACKAGE | PKG <br> CODE |
| :--- | :--- | :--- |
| MAX6946ATE + | 16 TQFN-EP* | T1633-4 |
| MAX6946CAWE + | 16 WLP | W162B2-1 |
| MAX6947ATE + | 16 TQFN-EP* | T1633-4 |

+Denotes a lead-free package.
*EP = Exposed pad.
Note: All devices are specified over the $-40^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$ operating temperature range.

Pin Configurations

# 10-Port, Constant-Current LED Driver and I/O Expander with PWM Intensity Control 

## ABSOLUTE MAXIMUM RATINGS

VDD to GND $\qquad$ ... $\qquad$ .-0.3V to +4 V
SCL, SDA, ADO, $\overline{\text { RST }}$, OSC to GND $-0.3 V$ to +6 V
P0 to P9 to GND -0.3V to +8 V
DC Current into P0 to P9 ................................................... 24 mA
DC Current into SDA. .10 mA
$\overline{\text { RST Sink Current }}$
.10 mA
Total GND Current 280 mA

Stresses beyond those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

## ELECTRICAL CHARACTERISTICS

( $\mathrm{V}_{\mathrm{DD}}=2.25 \mathrm{~V}$ to $3.6 \mathrm{~V}, \mathrm{~T}_{\mathrm{A}}=\mathrm{T}_{\mathrm{MIN}}$ to $\mathrm{T}_{\mathrm{MAX}}$, unless otherwise noted. Typical values are at $\mathrm{V}_{\mathrm{DD}}=3.3 \mathrm{~V}, \mathrm{~T}_{\mathrm{A}}=+25^{\circ} \mathrm{C}$.) (Note 1)

| PARAMETER | SYMBOL | CONDITIONS |  | MIN | TYP | MAX | UNITS |

| $\overline{\text { RST }}$ Rising Edge to MAX6946/MAX6947 ACK to Ensure Reset Run | trstrun | Reset Run enabled, enabled | internal oscillator | 5.6 |  |  | ms |

Note 1: All parameters are tested at $\mathrm{T}_{\mathrm{A}}=+25^{\circ} \mathrm{C}$. Specifications over temperature are guaranteed by design.
Note 2: Port current is factory trimmed to meet a median sink current of 20 mA and 10 mA over all ports. The $\Delta \mathrm{l}$ OUT specification guarantees current matching between parts.
Note 3: A master device must provide a hold time of at least 300ns for the SDA signal (referred to $\mathrm{V}_{\mathrm{IL}}$ of the SCL signal) in order to bridge the undefined region of SCL's falling edge.
Note 4: Not production tested. Guaranteed by design.
Note 5: $\mathrm{C}_{b}=$ total capacitance of one bus line in picoFarads; tR and tF are measured between $0.3 \times \mathrm{V}_{\mathrm{DD}}$ and $0.7 \times \mathrm{V}_{\mathrm{DD}}$.
Note 6: $\operatorname{ISINK} \leq 6 \mathrm{~mA}$.
Note 7: Guaranteed by design. Input filters on the SDA and SCL inputs suppress noise spikes of less than 50 ns.

# 10-Port, Constant-Current LED Driver and I/O Expander with PWM Intensity Control 

## Detailed Description

The MAX6946/MAX6947 general-purpose input/output (GPIO) peripherals provide $10 \mathrm{I} / \mathrm{O}$ ports, PO to P9, controlled through an $1^{2} \mathrm{C}$-compatible serial interface. Use the 10 I/O ports as logic inputs, open-drain logic outputs, or constant-current sinks in any combination. Ports withstand 7 V independent of the MAX6946/ MAX6947s' supply voltage whether used as logic inputs, logic outputs, or constant-current sinks.
The MAX6946/MAX6947 feature shutdown and standby modes for low-power dissipation. The I/O ports feature pulse-width modulation (PWM) of the outputs and can stagger the PWM timing of the 10 port outputs in consecutively phased $45^{\circ}$ increments. The I/O ports also feature ramp-up and ramp-down controls.
The MAX6946/MAX6947 feature a $\overline{\mathrm{RST}}$ input to halt any serial-interface transmission and bring the device out of shutdown.
Open-drain logic outputs require external pullup resistors to provide the logic-high reference. Ports configured as open-drain logic outputs have a relatively weak sink capability, but are still adequate for normal logiclevel outputs. The weak drive means that the short-circuit current is low enough that inadvertently driving an LED from a port configured as a logic output is unlikely to damage the LED.
The MAX6946 features a fixed ${ }^{2}$ C C slave address of 0100000 and provides an OSC input to accept an external PWM clock input as an alternative to the internal PWM clock.
The MAX6947 features an AD0 input that uses two-level logic to select from two ${ }^{2} \mathrm{C}$ slave addresses. The MAX6947 always uses the internal PWM clock.

## Register Structure

The MAX6946/MAX6947 contain 22 internal registers (see Table 1). Use registers $0 \times 00$ to $0 \times 09$ to individually control ports PO to P9. Registers 0x0A to 0x0D allow more than one port control register to be written with the same data to simplify software. Registers $0 \times 0 E$ and OxOF do not store data, but return the port input status when read. Registers $0 \times 10$ to $0 \times 15$ configure and control the device operation.

Table 1. Register Address Map

| DESCRIPTION | $\begin{aligned} & \text { ADDRESS } \\ & \text { CODE } \\ & \text { (HEX) } \end{aligned}$ | AUTOINCREMENT ADDRESS |
| :---: | :---: | :---: |
| Port P0 output level or PWM | 0x00 | $0 \times 01$ |
| Port P1 output level or PWM | 0x01 | 0x02 |
| Port P2 output level or PWM | 0x02 | $0 \times 03$ |
| Port P3 output level or PWM | 0x03 | 0x04 |

| Output current ISET98 | $0 \times 14$ | $0 \times 15$ |
| Global current | 0x15 | $0 \times 10$ |
| Factory reserved; do not write to this register | 0x7D | - |

## 10-Port, Constant-Current LED Driver and I/O Expander with PWM Intensity Control

Configuration Register (0x10)
Use the configuration register to select PWM phasing between outputs, test fade status, enable hardware startup from shutdown, and select shutdown or run mode (Table 2).

Initial Power-Up
All control registers reset upon power-up (Table 3). Power-up status sets I/O ports PO to P9 to high impedance, and puts the device into shutdown. The MAX6946/MAX6947 powers up in shutdown.

Table 2. Configuration Register (0x10)

| REGISTER BIT | DESCRIPTION | VALUE | FUNCTION |
| :---: | :---: | :---: | :---: |
| D7 | OSC enable* | 0 | Internal oscillator enabled as PWM clock source |
|  |  | 1 | External oscillator input enabled as PWM clock source |
| D6 | RSTPOR options | 0 | $\overline{\text { RST }}$ does not change register data |
|  |  | 1 | $\overline{\mathrm{RST}}$ resets registers to POR (power-on reset) state |
| D5 | PWM stagger | 0 | PWM outputs are in phase |
|  |  | 1 | PWM outputs stagger phase |
| D4 | Hold-off status** | 0 | Device not in hold-off |
|  |  | 1 | Device in hold-off |
| D3 | Fade-off status** | 0 | Device not in fade-off |
|  |  | 1 | Device in fade-off |
| D2 | Ramp-up status** | 0 | Device not in ramp-up |
|  |  | 1 | Device in ramp-up |
| D1 | $\overline{\text { RST }}$ RUN enable | 0 | Reset Run disabled |
|  |  | 1 | Reset Run enabled |
| D0 | RUN enable | 0 | Shutdown mode |
|  |  | 1 | Run mode |

*The OSCEN bit applies only to the MAX6946. OSCEN is always 0 for the MAX6947, and the MAX6947 ignores writes to the OSCEN bit.
**Read-only bits.

## Table 3. Initial Power-Up Register Status

| DESCRIPTION | POWER-UP CONDITION | ADDRESS CODE (HEX) | REGISTER BIT |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  |  | D7 | D6 | D5 | D4 | D3 | D2 | D1 | D0 |
| Port P0-P9 output level or PWM | Port 0-9 high impedance | 0x00-0x09 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 |
| Configuration | Shutdown mode, Reset Run disabled | $0 \times 10$ | 0/1* | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| Ramp-down/hold-off | Fade/hold-off disabled | 0x11 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| Ramp-up | Disabled | $0 \times 12$ | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| Output current ISET70 | IPEAK $=10 \mathrm{~mA}$ for ports P7-P0 | $0 \times 13$ | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| Output current ISET98 | IPEAK $=10 \mathrm{~mA}$ for ports P9, P8 | $0 \times 14$ | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| Global current | Full current | $0 \times 15$ | 0 | 0 | 0 | 0 | 0 | 1 | 1 | 1 |

*Value is 0 for MAX6947 and 1 for MAX6946 bit.

## 10-Port, Constant-Current LED Driver and I/O Expander with PWM Intensity Control

I/O Ports
The MAX6946/MAX6947 contain 10 I/O ports. Configure the 10 I/O ports as logic inputs, open-drain logic outputs, or constant-current sinks in any combination. Table 4 shows a detailed description of the individual port configuration registers $0 \times 00$ through $0 \times 09$. Use registers $0 \times 00-0 \times 09$ to individually assign each port as a logic input, open-drain logic output or con-stant-current sink (see the PWM Intensity Control and

Phasing section). The I/O ports are high impedance without $V_{D D}$ applied and remain high impedance upon power-up.
Figure 1 shows the I/O port structure of the MAX6946/ MAX6947. I/O ports P0 to P9 default to high impedance on power-up, so LEDs or other port loads connected draw no current. Ports used as inputs do not load their source signals.

Figure 1. Simplified Schematic of I/O Ports
Table 4. Individual Port Configuration Options (Port Output Registers 0x00-0x09)

| PORT TYPE | OUTPUT REGISTER CODE | RUN MODE (CONFIGURATION REGISTER BIT D0 $=1$ ) | SHUTDOWN (CONFIGURATION REGISTER BIT DO = 0) | APPLICATION NOTES |
| :---: | :---: | :---: | :---: | :---: |
| Low-logic output | $0 \times 00$ | Logic-low output, | t constant current | Lowest supply current, unaffected by shutdown |
| High-logic output | $0 \times 01$ | Logic-high output with external pullup resistor; otherwise, high impedance |  |  |
| Logic input |  | CMOS logic input |  |  |
| Constantcurrent static sink output | $0 \times 02$ | Static constant-current sink output | High impedance | Full constant-current drive with no PWM |
| Constantcurrent PWM output | 0x03-0xFE | $0 \times 03=3 / 256$ PWM duty cycle $0 x F E=254 / 256$ PWM duty cycle |  | Adjustable constant current |
| LED off | 0xFF | Logic-high output with external pullup resistor; otherwise, high impedance |  | LED off |

# 10-Port, Constant-Current LED Driver and I/O Expander with PWM Intensity Control 

Ports Configured as Outputs
The global-current register sets the full (maximum) con-stant-current sink into an I/O port configured as an output (Table 5). Each output port's individual constantcurrent sink can set to either half or full scale of the global current by the output-current registers (Table 6). By default, maximum current is 20 mA , hence the default maximum half current is 10 mA .
Set each output port's individual constant-current sink to either half scale or full scale of the global current.

Use the output-current registers to set the individual currents (Table 6). Set the global current by the globalcurrent register (Table 5).
Set each output current individually to best suit the maximum operating current of an LED load, or even adjust on the fly to double the effective intensity control range of each output. The individual current selection is 10 mA (half) or 20 mA (full) when setting the global-current register to its maximum value.

## Table 5. Global-Current Register Format (0x15)

| DESCRIPTION | REGISTER BIT |  |  |  |  |  |  |  |

## 10-Port, Constant-Current LED Driver and I/O Expander with PWM Intensity Control

PWM Intensity Control and Phasing
The MAX6946/MAX6947 use an internal 32kHz oscillator to generate PWM timing for LED intensity control. The MAX6946 also features an OSC input to allow for an external clock for generating PWM timing for LED intensity control. Select the PWM clock source for the MAX6946 with configuration register bit D7 (Table 2). The MAX6947 powers up configured to use the internal 32 kHz oscillator by default. The MAX6946 powers up configured to use the external clock source by default.
A PWM period comprises 256 cycles of the nominal 32kHz PWM clock (Figure 2). Individually set the ports' PWM duty cycle between $3 / 256$ and $254 / 256$. See Table 4 for port register settings.
Configure PWM timing by setting the stagger bit in the configuration register (Table 2), either with output staggering or without. Clearing the stagger bit causes all outputs using PWM to switch at the same time using
the timing shown in Figure 2. All outputs, therefore, draw load current at the exactly same time for the same PWM setting. This means that if, for example, all outputs are set to $0 \times 80$ (128/256 duty cycle), the current draw would be zero (all loads off) for half the time, and full (all loads on) for the other half.
Setting the stagger bit causes the PWM timing of the 10 port outputs to stagger by 32 counts of the 256 -count PWM period (i.e., $1 / 8$ th), distributing the port output switching points across the PWM period (Figure 3). Staggering reduces the di/dt output-switching transient on the supply and also reduces the peak/mean current requirement.
Set or clear the stagger bit during shutdown. Changing the stagger bit during normal operation can cause a transient flicker in any PWM-controlled LEDs because of the fundamental PWM timing changes.

Figure 2. Static and PWM Constant-Current Waveforms

# 10-Port, Constant-Current LED Driver and I/O Expander with PWM Intensity Control 

## Ports Configured as Inputs

Configure a port as a logic input by writing $0 \times 01$ to the port's output register (Table 4). Reading an input port register returns the logic levels from the I/O ports configured as a logic input (Table 7). The input port register returns logic 0 in the appropriate bit position for a port not configured as a logic input.
The input port's registers are read only. The MAX6946/ MAX6947 ignore a write to input ports register.

## $\overline{R S T}$ Input

The active-low $\overline{\text { RST }}$ input operates as a reset that voids any current ${ }^{2}{ }^{2} \mathrm{C}$ transaction involving the MAX6946/ MAX6947, forcing the devices into the ${ }^{2} \mathrm{C}$ stop condition. Use the D6 bit in the configuration register to configure $\overline{R S T}$ to reset all the internal registers to the power-on reset state (Tables 2 and 3). The RST input is overvoltage tolerant to 6 V .
The MAX6946/MAX6947 ignore all ${ }^{2} \mathrm{C}$ bus activity while $\overline{\text { RST }}$ remains low. The MAX6946/MAX6947 use this feature to minimize supply current in power-critical applications by effectively disconnecting the MAX6946/ MAX6947 from the bus during idle periods. RST also operates as a bus multiplexer, allowing multiple MAX6946/MAX6947s to use the same I ${ }^{2}$ C slave address. Drive only one MAX6946/MAX6947 RST input high at any time to use $\overline{\mathrm{RST}}$ as a bus multiplexer.

The MAX6946/MAX6947 feature a Reset Run option so that simply taking the $\overline{\mathrm{RST}}$ input high brings the driver out of shutdown in addition to its normal function of enabling the devices' ${ }^{2} \mathrm{C}$ interface.

Standby Mode and Operating Current Configuring all the ports as logic inputs or outputs (all output registers set to value $0 \times 00$ or $0 \times 01$ ) or LED off (output register set to value 0xFF) puts the MAX6946/ MAX6947 into standby mode. Put the MAX6946/ MAX6947 into standby mode for lowest supply-current consumption.
Setting a port as a constant-current output increases the operating current (output register set to a value between $0 \times 02$ and $0 \times F E$ ), even if a load is not applied to the port. The MAX6946/MAX6947 enable an internal current mirror to provide the accurate constant-current sink. Enabling the internal current mirror increases the devices' supply current. Each output contains a gated mirror, and each mirror is only enabled when required. In PWM mode, the current mirror is only turned on for the output's on-time. This means that the operating current varies as constant-current outputs are turned on and off through the serial interface, as well as by the PWM intensity control.

Figure 3. Staggered PWM Waveform

## 10-Port, Constant-Current LED Driver and I/O Expander with PWM Intensity Control

Shutdown Mode
In shutdown mode, all ports configured as constantcurrent outputs (output register set to a value between $0 \times 02$ and 0xFE) are switched off, and these outputs go high impedance as if their registers were set to value 0xFF. Ports configured as logic inputs or outputs (output registers set to value $0 \times 00$ or $0 \times 01$ ) are unaffected (Table 4). This means that any ports used for GPIOs are still fully operational in shutdown mode, and port inputs can be read and output ports can be toggled at any time using the serial interface. Use the MAX6946/ MAX6947 for a mix of logic inputs, logic outputs, and PWM LED drivers, and only the LED drivers turn off automatically in shutdown.
Put the MAX6946/MAX6947 into shutdown mode by clearing the run bit (bit D0) in the configuration register (0x10) (Table 2). Exit shutdown by setting the run bit high through the serial interface or by using the Reset Run option (see the Reset Run Option section). Configure and control the MAX6946/MAX6947 normally through the serial interface in shutdown mode. All registers are accessible in shutdown mode, and shutdown mode does not change any register values.

Changing a port from static logic-low ( $0 \times 00$ ) or static logic-high ( $0 \times 01$ ) to a constant-current value (0x02-0xFE) in shutdown mode turns that output off (logic-high or high impedance) like any other constantcurrent outputs in shutdown. The new constant-current output starts just like any other constant-current outputs when exiting shutdown.
Changing a port from a constant-current value ( $0 \times 02-0 \times F E$ ) to static logic-low ( $0 \times 00$ ) or static logichigh ( $0 \times 01$ ) in shutdown causes that output to set to the value as a GPIO output. The new GPIO output is unaffected just like any other GPIO output when exiting shutdown.

Ramp-Up and Ramp-Down Controls The MAX6946/MAX6947 provide controls that allow the output currents to ramp down into shutdown (rampdown), and ramp up again out of shutdown (ramp-up) (Figures 4 and 5). Ramp-down comprises a programmable hold-off delay that also maintains the outputs at full current for a time before the programmed fade-off time. After the hold-off delay, the output currents ramp down.

Figure 4. Ramp-Up Behavior

Figure 5. Ramp-Down, Hold-Off, and Fade-Off Behavior

## 10-Port, Constant-Current LED Driver and I/O Expander with PWM Intensity Control

Figure 6. Output Fade DAC (Global Current $=0 \times 07$ )

The ramp-down register sets the hold-off and fade-off times and allows disabling of hold-off and fade-off (zero delay), if desired (Table 8). The ramp-up register sets the ramp-up time and allows disabling of ramp-up (zero delay), if desired (Table 9). The configuration register contains three status bits that identify the condition of the MAX6946/MAX6947, hold-off, fade-off, or ramp-up (Table 2). The configuration register also enables or disables ramp-up. One write command to the configuration register can put the MAX6946/MAX6947 into shutdown (using hold-off and fade-off settings in the fade register) and one read command to the configuration register can determine whether the Reset Run is enabled for restart, and whether the MAX6946/MAX6947 will use ramp-up on restart.

## Table 8. Ramp-Down Register Format (0X11)

| DESCRIPTION | REGISTER BIT |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | D7 | D6 | D5 | D4 | D3 | D2 | D1 | D0 |

| 1/16s ramp-up to full current coming out from shutdown | $X$ | $X$ | $X$ | $X$ | $X$ | 0 | 0 | 1 |
| $1 / 8$ s ramp-up to full current coming out from shutdown | $X$ | $X$ | $X$ | $X$ | $X$ | 0 | 1 | 0 |
| $1 / 4$ s ramp-up to full current coming out from shutdown | $X$ | $X$ | $X$ | $X$ | $X$ | 0 | 1 | 1 |
| $1 / 2$ s ramp-up to full current coming out from shutdown | $X$ | $X$ | $X$ | $X$ | $X$ | 1 | 0 | 0 |
| 1s ramp-up to full current coming out from shutdown | $X$ | $X$ | $X$ | $X$ | $X$ | 1 | 0 | 1 |
| 2s ramp-up to full current coming out from shutdown | $X$ | $X$ | $X$ | $X$ | $X$ | 1 | 1 | 0 |
| 4s ramp-up to full current coming out from shutdown | $X$ | $X$ | $X$ | $X$ | $X$ | 1 | 1 | 1 |

Ramp-up and ramp-down use the PWM clock for timing. When using the external oscillator make sure the oscillator runs until the end of the sequence. The internal oscillator always runs during a fade sequence, even if none of the ports use PWM.
The ramp-up and ramp-down circuit operates a 3-bit DAC. The DAC adjusts the internal current reference used to set the constant-current outputs in a similar manner to the global-current register (Table 5). The MAX6946/MAX6947 scale the master current reference so all output constant-current and PWM settings adjust at the same ratio with respect to each other. This means the LEDs always fade at the same rate even if with different intensity settings.
The maximum port output current set by the global-current register (Table 5) also sets the point during rampdown that the current starts falling, and the point during ramp-up that the current stops rising. Figure 7 shows the ramp waveforms that occur with different globalcurrent register settings.

Reset Run Option
The MAX6946/MAX6947 feature a Reset Run option so that simply taking the RST input high brings the driver out of shutdown in addition to its normal function of enabling the MAX6946/MAX6947s' ${ }^{2} \mathrm{C}$ interface. This provides an alternative method of bringing the driver out of shutdown to writing to the configuration register through the serial interface. The Reset Run timing uses the PWM clock, either the internal nominal 32 kHz oscillator or a user-provided clock fed into the OSC input (MAX6946 only).
After enabling the Reset Run option, the MAX6946/ MAX6947 use the rising edge on RST, followed by no ${ }^{12}$ C interface activity to the MAX6946/MAX6947 for 128 to 129 periods of the PWM clock to trigger the Reset

Figure 7. Global Current Modifies Fade Behavior
Run option. If this timeout period elapses without the MAX6946/MAX6947 acknowledging an I ${ }^{2}$ C transaction, the run bit (DO) in the configuration register sets, bringing the driver out of shutdown and activating any programmed ramp-up. If RST pulses high for less than this timeout period to trigger a Reset Run, the MAX6946/ MAX6947 ignore the pulse, and the MAX6946/MAX6947 continue to wait for a suitable trigger.
Cancel the Reset Run trigger by transmitting an $\mathrm{I}^{2} \mathrm{C}$ communication to the MAX6946/MAX6947 before the timeout period elapses. The trigger cancels when the MAX6946/MAX6947 acknowledge the ${ }^{2} \mathrm{C}$ (ransaction

# 10-Port, Constant-Current LED Driver and I/O Expander with PWM Intensity Control 

and requires sending at least the MAX6946/MAX6947s' ${ }^{2} \mathrm{C}$ slave address. When using the internal oscillator, the minimum timeout period is $127 / 45000$ equal to 2.822 ms . When using an external oscillator for the PWM clock, the timeout period is 127/OSC. The shortest time period allowed is 1.27 ms ; this number corresponds to the maximum OSC frequency of 100 kHz . When using the internal oscillator, the minimum ${ }^{2} \mathrm{C}$ clock speed that guarantees a successful start bit and eight data bits ( 9 bits total) within the minimum timeout period is $9 / 5.66 \mathrm{~ms}$ equal to 1590 Hz . Canceling the Reset Run trigger clears the Reset Run bit (D1) in the configuration register, disabling Reset Run. The run bit (D0) in the configuration register remains cleared, so the driver remains in shutdown.

## OSC Input

The MAX6946 can use an external clock of up to 100 kHz instead of the internal 32 kHz oscillator. Connect the external clock to the OSC input and set the OSC bit in the configuration register to enable the MAX6946 to use the external clock (Table 2).

## Serial Interface

## Serial Addressing

The MAX6946/MAX6947 operate as a slave that sends and receives data through an $\mathrm{I}^{2} \mathrm{C}$-compatible, 2-wire interface. The interface uses a serial-data line (SDA) and a serial-clock line (SCL) to achieve bidirectional communication between master(s) and slave(s). A master (typically a microcontroller) initiates all data transfers to and from the MAX6946/MAX6947 and generates the SCL clock that synchronizes the data transfer (Figure 8).
The MAX6946/MAX6947 SDA line operates as both an input and an open-drain output. A pullup resistor, typically $4.7 \mathrm{k} \Omega$, is required on SDA. The MAX6946/ MAX6947 SCL line operates as an input. A pullup resistor, typically $4.7 \mathrm{k} \Omega$, is required on SCL if there are multiple masters on the 2-wire interface, or if the master in a single-master system has an open-drain SCL output.
Each transmission consists of a START condition (Figure 9) sent by a master, followed by the MAX6946/ MAX6947 7-bit slave address plus the R/W bit, a register address byte, one or more data bytes, and finally a STOP condition (Figure 9).

Figure 8. 2-Wire Serial Interface Timing Details

## 10-Port, Constant-Current LED Driver and I/O Expander with PWM Intensity Control

Table 10. MAX6946/MAX6947 Slave Addresses

| MAX6947 | SLAVE ADDRESS |
| :---: | :---: |
| AD0 $=$ GND | 0100000 |
| AD0 $=V_{D D}$ | 0100100 |
| MAX6946 | 0100000 |

## Start and Stop Conditions

Both SCL and SDA remain high when the interface is not busy. A master signals the beginning of a transmission with a START (S) condition by transitioning SDA from high to low while SCL is high. When the master finishes communicating with the slave, it issues a STOP (P) condition by transitioning SDA from low to high while SCL is high. The bus is then free for another transmission (Figure 9).

Bit Transfer
One data bit is transferred during each clock pulse. The data on SDA must remain stable while SCL is high (Figure 10).

Acknowledge
Any bytes received after the command byte are data bytes. The first data byte goes into the internal register of the MAX6946/MAX6947 selected by the command byte (Figure 11). If multiple data bytes are transmitted before a STOP condition is detected, these bytes are generally stored in subsequent MAX6946/MAX6947 internal registers because the command byte autoincrements (Table 1).

## Message Format for Reading

Read from the MAX6946/MAX6947 using the MAX6946/MAX6947s' internally stored command byte as an address pointer the same way the stored command byte is used as an address pointer for a write. The pointer autoincrements after each data byte is read using the same rules as for a write (Table 1). Thus, a read is initiated by first configuring the MAX6946/ MAX6947s' command byte by performing a write (Figures 12 and 13). The master can now read n con-

Figure 9. Start and Stop Conditions

Figure 10. Bit Transfer

Figure 11. Acknowledge
secutive bytes from the MAX6946/MAX6947 with the first data byte being read from the register addressed by the initialized command byte (Figure 14). When performing read-after-write verification, remember to reset the command byte's address because the stored command byte address has been autoincremented after the write (Table 1).

## 10-Port, Constant-Current LED Driver and I/O Expander with PWM Intensity Control

Figure 12. Command Byte Received

Figure 13. Command and Single Data Byte Received

Figure 14. n Data Bytes Received

Operation with Multiple Masters
If the MAX6946/MAX6947 operates on a 2 -wire interface with multiple masters, a master reading the MAX6946/MAX6947 should use a repeated start between the write. This sets the MAX6946/MAX6947 address pointer, and the read(s) that takes the data from the location(s) (Table 1). This is because it is possible for master 2 to take over the bus after master 1 has set up the MAX6946/MAX6947s' address pointer, then master 1's delayed read can be from an unexpected location.

## Command Address Autoincrementing

The command address stored in the MAX6946/ MAX6947 increments through the grouped register functions after each data byte is written or read (Table 1).

## Applications Information

Port Input and I2C Interface-Level Translation from Higher or Lower Logic Voltages The MAX6946/MAX6947s' ${ }^{2}$ C interface (SDA, SCL) and ${ }^{12} \mathrm{C}$ slave address select input ADO (MAX6947 only), PWM clock input OSC (MAX6946 only), and reset input $\overline{\text { RST }}$ are overvoltage protected to +6 V , independent of VDD. The 10 I/O ports P0-P9 are overvoltage protected to +8 V independent of $\mathrm{V}_{\mathrm{DD}}$. This allows the MAX6946/ MAX6947 to operate from one supply voltage, such as 3.3 V , while driving the $\mathrm{I}^{2} \mathrm{C}$ interface and/or some of the $10 \mathrm{I} / \mathrm{O}$ as inputs from a higher logic level, such as 5 V .

# 10-Port, Constant-Current LED Driver and I/O Expander with PWM Intensity Control 

Hot Insertion
The $\overline{\operatorname{RST}}, \mathrm{SCL}$, and ADO inputs and SDA remain high impedance with up to +6 V asserted on them when the MAX6946/MAX6947 power down (VDD = OV). I/O ports PO to P9 remain high impedance with up to +8 V asserted on them when the MAX6946/MAX6947 power down. Use the MAX6946/MAX6947 in hot-swap applications.

## Differences Between the MAX6946 and MAX6947

The MAX6946 features the OSC input, allowing the device to use an external clock as the PWM clock source. The MAX6946 features a fixed ${ }^{2}$ C slave address of 0100000. The MAX6947 features an AD0 input, allowing two unique ${ }^{2} \mathrm{C}$ addresses (Table 10). The MAX6947 always uses the internal 32 kHz oscillator as the PWM clock source.

## Driving LEDs into Brownout

The MAX6946/MAX6947 correctly regulate the con-stant-current outputs, provided there is a minimum voltage drop across the port output. This port output voltage is the difference between the load (typically LED) supply and the load voltage drop (LED forward voltage). If the LED supply drops so that the minimum port output voltage is not maintained, the driver output stages brownout and the load current falls. The minimum port voltage is approximately 0.5 V at 10 mA sink current and approximately 1 V at 20 mA sink current.
Operating the LEDs directly from a battery supply can cause brownouts. For example, the LED supply voltage is a single rechargeable lithium-ion battery with a maximum terminal voltage of 4.2 V on charge, 3.4 V to 3.7 V
most of the time, and down to 3 V when discharged. In this scenario, the LED supply falls significantly below the brownout point when the battery is at end-of-life voltage (3V).
Figure 15 shows the typical current sink by a LITEON LTST-C170TBKT 3.0V blue LED as the LED supply voltage is varied from 2.5 V to 7 V . The LED currents shown are for ports programmed for 10 mA and 20 mA constant current, swept over a 2.5 V to 7 V LED supply voltage range. It can be seen that the LED forward voltage falls with current, allowing the LED current to fall gracefully, not abruptly, in brownout. In practice, the LED current drops to 6 mA to 7 mA at a 3 V LED supply voltage, this is acceptable performance at end-of-life in many backlight applications.

Output-Level Translation
The open-drain output architecture allows the ports to level translate the outputs to higher or lower voltages than the MAX6946/MAX6947 supply. Use an external pullup resistor on any output to convert the high-impedance, logic-high condition to a positive voltage level. Connect the resistor to any voltage up to 7 V . When using a pullup on a constant-current output, select the resistor value to sink no more than a few hundred micramps in logic-low condition. This ensures that the current sink output saturates close to GND. For interfacing CMOS inputs, a pullup resistor value of $220 \mathrm{k} \Omega$ is a good starting point. Use a lower resistance to improve noise immunity in applications where power consumption is less critical, or where a faster rise time is needed for a given capacitive load.

Figure 15. LED Brownout

# 10-Port, Constant-Current LED Driver and I/O Expander with PWM Intensity Control 

Using Stagger with Fewer Ports
The stagger option, when selected, applies to all ports configured as constant-current outputs. The 10 ports' PWM cycles are separated to eight evenly spaced start positions (Figure 3). Optimize phasing when using fewer than 10 ports as constant-current outputs by allocating the ports with the most appropriate start positions. If using eight constant-current outputs, choose PO-P7 because these all have different PWM start positions. If using four constant-current outputs, choose PO, P2, P4, P6 or P1, P3, P5, P7 because their PWM start positions are evenly spaced. In general, choose the ports that spread the PWM start positions as evenly as possible. This optimally spreads out the current demand from the ports' load supply.

## Generating a Shutdown/Run Output

The MAX6946/MAX6947 can use an I/O port to automatically generate a shutdown/run output. The shutdown/run output is active low when the MAX6946/ MAX6947 are in run mode, hold-off, fade-off, or rampup, and goes high automatically when the devices finally enter shutdown after fade-off. Programming the port's output register to value $0 \times 02$ puts the output into static constant-current mode (Table 4). Program the port's output current register to half current (Table 6) to minimize operating current. Connect a $220 \mathrm{k} \Omega$ pullup resistor to this port.
In run mode, the output port goes low, approaching OV, as the port's static constant current saturates trying to sink a higher current than the $220 \mathrm{k} \Omega$ pullup resistor can source.

In shutdown mode, the output goes high impedance together with any other constant-current outputs. This output remains low during ramp-up and fade-down sequences because the current drawn by the $220 \mathrm{k} \Omega$ pullup resistor is much smaller than the available output constant current, even at the lowest fade current step.

Driving Load Currents Higher than 20mA The MAX6946/MAX6947 can drive loads needing more than 20 mA , like high-current white LEDs, by paralleling outputs. For example, consider a white LED that requires 70 mA . Drive this LED using the ports P0-P3 connected in parallel (shorted together). Configure three of the ports for full current (20mA) and configure the last port for half current $(10 \mathrm{~mA})$ to meet the 70 mA requirement. Control the four ports simultaneously with one write access using register 0x0B (Table 1). Note that because the output ports are current limiting, they do not need to switch simultaneously to ensure safe current sharing.

## Power-Supply Considerations

The MAX6946/MAX6947 operate with a power-supply voltage of 2.25 V to 3.6 V . Bypass the power supply to GND with a $0.1 \mu \mathrm{~F}$ ceramic capacitor as close as possible to the device.

NOTES:

1. DIMENSIONING \& TOLERANCING CONFORM TO ASME Y14.5M-1994.
2. ALL DIMENSIONS ARE IN MILLIMETERS. ANGLES ARE IN DEGREES.
3. N IS THE TOTAL NUMBER OF TERMINALS.
4. THE TERMINAL \#1 IDENTIFIER AND TERMINAL NUMBERING CONVENTION SHALL CONFORM TO JESD 95-1 SPP-012. DETAILS OF TERMINAL \#1 IDENTIFIER ARE OPTIONAL, BUT MUST BE LOCATED WITHIN THE ZONE INDICATED. THE TERMINAL \# 1 IDENTIFIER MAY BE EITHER A MOLD OR MARKED FEATURE
5. DIMENSION b APPLIES TO METALLIZED TERMINAL AND IS MEASURED BETWEEN 0.20 mm AND 0.25 mm FROM TERMINAL TIP
6. ND AND NE REFER TO THE NUMBER OF TERMINALS ON EACH D AND E SIDE RESPECTIVELY DEPOPULATION IS POSSIBLE IN A SYMMETRICAL FASHION.
7. COPLANARITY APPLIES TO THE EXPOSED HEAT SINK SLUG AS WELL AS THE TERMINALS
8. DRAWING CONFORMS TO JEDEC MO22O REVISION C.
@ marking is for package orientation reference only.
9. NUMBER OF LEADS SHOWN ARE FOR REFERENCE ONLY.
10. WARPAGE NOT TO EXCEED 0.10 mm .

-DRAWING NOT TO SCALE-
