## Programmable Current Limit High-Side Switch

## General Description

The MIC2544A and MIC2548A are integrated, high-side power switches optimized for low loss DC power switching and other power management applications, including Advanced Configuration and Power Interface (ACPI). The MIC2544A/48A is a cost-effective, highly integrated solution that requires few external components to satisfy USB and ACPI requirements.
Load current management features include a precision resistor-programmable output current-limit and a soft-start circuit which minimizes inrush current when the switch is enabled. Thermal shutdown, along with current-limit, protects the switch and the attached device.
The MIC2544A/48A's open-drain flag output is used to indicate current-limiting or thermal shutdown to a local controller. The MIC2548A has an additional internal latch which turns the output off upon thermal shutdown providing robust fault control. The enable signal is compatible with both 3 V and 5 V logic, and is also used as the thermal shutdown latch reset for the MIC2548A
The MIC2544A and MIC2548A are available in active-high and active-low enable versions in the 8 -pin SOIC (small-outline integrated circuit) and 8-pin MSOP (micro-small-outline package).

## Features

- 2.7 V to 5.5 V input
- Adjustable current-limit up to 1.5 A
- Reverse current flow blocking (no "body diode")
- $90 \mu \mathrm{~A}$ typical on-state supply current
- $1 \mu \mathrm{~A}$ typical off-state supply current
- $120 \mathrm{~m} \Omega$ maximum on-resistance
- Open-drain fault flag
- Thermal shutdown
- Thermal shutdown output latch (MIC2548A)
- 2 ms (slow) turn-on and fast turn-off
- Available with active-high or active-low enable

## Applications

- USB power distribution
- PCI bus power switching
- Notebook PC
- ACPI power distribution
- PC card hot swap applications
- Inrush current-limiting

## Typical Application

Typical Advanced Configuration and Power Interface (ACPI) Application

## Notes:

1. Exceeding the absolute maximum rating may damage the device.
2. The device is not guaranteed to function outside its operating rating.
3. Devices are ESD sensitive. Handling precautions recommended. Human body model, 1.5 k in series with 100 pF .
4. Off is $\leq 0.8 \mathrm{~V}$ and on is $\geq 2.4 \mathrm{~V}$ for the MIC2544A-1 and MIC2548A-1. Off is $\geq 2.4 \mathrm{~V}$ and on is $\leq 0.8 \mathrm{~V}$ for the MIC2544A-2 and MIC2548A-2. The enable input has about 200 mV of hysteresis.
5. Guaranteed by design but not production tested.
6. Current limit threshold is determined by $I_{\text {LIMIT }}=\frac{230 \mathrm{~V}}{R_{\text {SET }}}$, where $R_{\text {SET }}$ is in ohms.

The following applies unless otherwise noted: MIC2544A-1, $\mathrm{T}_{\mathrm{A}}=25^{\circ} \mathrm{C}, \mathrm{V}_{\mathrm{IN}}=5.0 \mathrm{~V}, \mathrm{R}_{\text {SET }}=232 \Omega, \mathrm{C}_{\text {OUT }}=10 \mu \mathrm{~F}$.

## Functional Characteristics (Continued)

## Functional Characteristics (Continued)

## Functional Characteristics (Continued)

## Block Diagram

## Functional Description

The MIC2544A and MIC2548A are high-side N-channel switches available with either active-high or active-low enable inputs. Fault conditions turn-off or inhibit turn-on of the output transistor and activate the open-drain error flag transistor making it sink current-to-ground.

## Input and Output

IN is the power supply connection to the logic circuitry and the drain of the output MOSFET. OUT is the source of the output MOSFET. In a typical circuit, current flows from IN to OUT toward the load. If VOUT is greater than VIN, current will flow from OUT to IN since the switch is bidirectional when enabled.
The output MOSFET and driver circuitry are also designed to allow the MOSFET source to be externally forced to a higher voltage than the drain ( $\mathrm{V}_{\text {OUt }}>\mathrm{V}_{\text {IN }}$ ) when the switch is disabled. In this situation, the MIC2544A/48A avoids undesirable current flow from OUT to IN. Both OUT pins must be connected together.

## Thermal Shutdown

Thermal shutdown shuts off the output MOSFET and signals the fault flag if the die temperature exceeds $150^{\circ} \mathrm{C} .5^{\circ} \mathrm{C}$ of hysteresis prevents the switch from turning on until the die temperature drops to $145^{\circ} \mathrm{C}$. Over-temperature detection functions only when the
switch is enabled.
The MIC2548A features an internal latch which causes the part to remain off after thermal shutdown until a reset pulse is provided via the enable pin (pin 1). While in current-limit, the thermal shutdown latch prevents on/off cycling of the output.
Refer to Figures 2a and 2 b for timing diagram. The flag remains low until reset.

## Enable Input

EN must be driven logic high or logic low, or be pulled high or low for a clearly defined input. Floating the input may cause unpredictable operation. EN should not be allowed to go negative with respect to GND, and $\mathrm{V}_{\text {EN }}$ should be less than or equal to $\mathrm{V}_{\mathbb{I}}$.

## Setting $\mathrm{I}_{\text {Limit }}$

The MIC2544A/2548A's current limit is user programmable and controlled by a resistor connected between the $\mathrm{l}_{\text {Limit }}$ pin and ground. The value of this resistor is determined by the following equation:

$$
I_{\text {LIMIT }}=\frac{\text { CurrentLimitFactor(CLF) }}{R_{S E T}}
$$

or

$$
\mathrm{R}_{\mathrm{SET}}=\frac{\text { CurrentLimitFactor }(\mathrm{V})}{\mathrm{I}_{\text {LIMIT }}(\mathrm{A})}
$$

For example: $\quad$ Set $\mathrm{I}_{\text {Limit }}=1.0 \mathrm{~A}$
Looking in the Electrical specifications we will find CLF at LIMIT $=1 \mathrm{~A}$.

| Min | Typ | Max | Units |
| :---: | :---: | :---: | :---: |
| 184 | 230 | 276 | V |

Table 1. $C L F$ at $l_{\text {LIMIt }}=1 \mathrm{~A}$
For the sake of this example, we will say the typical value of CLF at an $\mathrm{I}_{\text {out }}$ of 1 A is 230 V . Applying the equation above:

$$
\begin{aligned}
& \mathrm{R}_{\mathrm{SET}}(\Omega)=\frac{230 \mathrm{~V}}{1.0 \mathrm{~A}}=230 \Omega \\
& R_{\mathrm{SET}}=232 \Omega
\end{aligned}
$$

(the closest standard $1 \%$ value)
Designers should be aware that variations in the measured $\mathrm{I}_{\text {LIMIT }}$ for a given $\mathrm{R}_{\text {SET }}$ resistor, will occur because of small differences between individual ICs (inherent in silicon processing) resulting in a spread of $\mathrm{I}_{\text {LIMIT }}$ values. In the example above a typical value of CLF was used to calculate $\mathrm{R}_{\text {SET }}$. One can determine $\mathrm{I}_{\text {LIMIT }}$ 's spread by using the minimum and maximum values of CLF and the calculated value of $R_{\text {SET }}$.

$$
\begin{aligned}
& \text { LIMIT_MIN }=\frac{184 \mathrm{~V}}{232 \Omega}=0.79 \mathrm{~A} \\
& I_{\text {LIMIT_MAX }}=\frac{276 \mathrm{~V}}{232 \Omega}=1.19 \mathrm{~A}
\end{aligned}
$$

Giving one a maximum $\mathrm{L}_{\text {LImit }}$ variation over-temperature of:

| $I_{\text {LIMIT_MIN }}$ | LIMIT_TYP | ILIMIT_MAX |
| :---: | :---: | :---: |
| 0.79A (-21\%) | 1.0A | 1.19A (+19\%) |

| I_OUT | R_SET | I_OUT_Min | I_OUT_Max |
| :---: | :---: | :---: | :---: |
| 0.2 | 1150 | 0.140 | 0.260 |
| 0.3 | 767 | 0.210 | 0.390 |
| 0.4 | 575 | 0.280 | 0.520 |
| 0.5 | 460 | 0.350 | 0.650 |
| 0.6 | 383 | 0.480 | 0.720 |
| 0.7 | 329 | 0.560 | 0.840 |
| 0.8 | 288 | 0.640 | 0.960 |
| 0.9 | 256 | 0.720 | 1.080 |
| 1 | 230 | 0.800 | 1.200 |
| 1.1 | 209 | 0.880 | 1.320 |
| 1.2 | 192 | 0.960 | 1.440 |
| 1.3 | 177 | 1.040 | 1.560 |
| 1.4 | 164 | 1.120 | 1.680 |
| 1.5 | 153 | 1.200 | 1.800 |

Table 2. MIC2544A/2548A R SET Table

## Short-Circuit Protection

In the event of a short circuit, the output current will fold back to approximately $70 \%$ of the short-circuit currentlimit.

## Fault Flag

FLG is an N-channel, open-drain MOSFET output. The fault flag is active (low) for current-limit or thermal shutdown conditions. The flag output MOSFET is capable of sinking a 10 mA load to typically 100 mV above ground. The FLG response delay time $t_{D}$ is typically $5 \mu$ s.

## Application Information

## Supply Filtering

A minimum $1 \mu \mathrm{~F}$ bypass capacitor from IN -to-GND, located near the MIC2544A and MIC2548A, is strongly recommended to control supply transients. Without a bypass capacitor, an output short may cause sufficient ringing on the input (from supply lead inductance) to damage internal control circuitry. An additional $22 \mu \mathrm{~F}$ input capacitor placed close to the IC is required if a bulk input capacitor is further than 3 inches away from the IC.
Input transients must not exceed the absolute maximum supply voltage ( $\mathrm{V}_{\mathbb{I N} \text { max }}=6 \mathrm{~V}$ ) even for a short duration.

Figure 3. Supply Bypassing

## Power Dissipation

The device's junction temperature depends upon several factors such as the load, PCB layout, ambient temperature, and package type. Equations that can be used to calculate power dissipation and junction temperature are found below.
Calculation of power dissipation can be accomplished by the following equation:

$$
P_{D}=R_{D S(o n)} \times\left(l_{\text {loUT }}\right)^{2}
$$

To relate this to junction temperature, the following equation can be used:

$$
T_{j}=P_{D} \times \theta_{J A}+T_{A}
$$

where:
$T_{j}=$ junction temperature
$T_{A}=$ ambient temperature
$\theta_{\mathrm{JA}}=$ is the thermal resistance of the package

## Transient Over Current Filter

The inrush current from the connection of a heavy capacitive load may cause the fault flag to fall for $10 \mu \mathrm{~s}$ to $200 \mu \mathrm{~s}$ while the switch is in a constant-current mode, charging the capacitance, as shown in Figure 4.

Figure 4. Flag Glitch with $\mathrm{C}_{\text {out }}=\mathbf{1 2 0 \mu F}$
Adding an optional series resistor-capacitor ( $\mathrm{R}_{\text {SET2 }}$ ), in parallel with $\mathrm{R}_{\mathrm{SET}}$, and as shown in Figure 8, allows the transient current-limit to be set to a different value than steady-state. A typical USB hot-plug inrush is 2A to 3A for $10 \mu \mathrm{~s}$ to $20 \mu \mathrm{~s}$. If $\mathrm{R}_{\text {SET }}$ is $309 \Omega$ ( 525 mA ), an $\mathrm{R}_{\text {SET2 }}$ of $100 \Omega(2.3 \mathrm{~A})$ and $\mathrm{C}_{\text {SET }}$ of $1 \mu \mathrm{~F}(\mathrm{RC}=100 \mu \mathrm{~s})$ allows transient surge of 3 A to pass for $100 \mu$ s without tripping the over current flag (FLG), as shown in Figure 5.

Figure 5. ILIMIT Filter with $\mathrm{C}_{\text {out }}=120 \mu \mathrm{~F}$

Figure 6 circuit can also be used to filter out transient FLG assertion. The value of the RC time constant should be selected to match the length of transient. Figure 7 shows the FLAG pin waveform due to the inrush of current surge.

Figure 6. Flag Filter Circuit

Figure 7. Flag Filter with $\mathrm{C}_{\text {out }}=100 \boldsymbol{\mu}$

## USB Power Distribution

The MIC2544A is ideal for meeting USB power distribution requirements. Figure 8 depicts a USB Host application. RSET should be set to a value providing a current-limit $>500 \mathrm{~mA}$.
The accurate current-limit of the MIC2544A will reduce power supply current requirements. Also, fast reaction to short circuit faults prevent voltage droop in mobile PC applications.

## Printed Circuit Board Hot-Plug

The MIC2544A/48A are ideal inrush current-limiters suitable for hot-plug applications. Due to the integrated charge pump, the MIC2544A/48A presents high impedance when off and slowly becomes low impedance as it turns on. This "soft start" feature effectively isolates power supplies from highly capacitive loads by reducing inrush current during hot-plug events. Figure 9 shows how the MIC2544A may be used in a hot-plug application.

Figure 8. USB Host Application
Note: MSOP package option uses pin 5 for ILIM. Pin 4 is not connected (NC). Bold lines indicate 0.1 " wide, 1-oz. copper high-current traces.
