

Compact and versatile three-phase and three-sense motor driver

Datasheet - production data

**Features**

- Operating voltage from 7 to 45 V
- Maximum output current 1.5 A_{rms}
- R_{DSon} HS + LS = 1 Ω typ.
- Supporting both single and three shunts architectures
- Current control with adjustable OFF time
- Current sensing based on external shunt resistors
- Flexible driving methodology user settable between 6 inputs (high side and low side driving) and 3 inputs (direct PWM driving)
- FOC compatible thanks to three shunts sensing topology support
- Full protections set
 - Non-dissipative overcurrent protection
 - Short-circuit protection
 - Undervoltage lockout
 - Thermal shutdown
 - Interlocking function
- Low standby current consumption

Applications

- Industrial robotics
- Medical and health care
- Factory automation end-points
- Home appliances
- Small pumps
- Server, computing and general purpose FANs
- Office and home automation

Description

The STSPIN830 is a compact and versatile field oriented control FOC ready three-phase motor driver. It integrates in a very small 4 x 4 mm QFN package, both the control logic and a fully protected low R_{DSon} triple half-bridge power stage.

Thanks to a dedicated MODE input pin the device offers the freedom to decide whether to drive it through 6 inputs (one for each power switch) or a more common 3 PWM direct driving inputs.

The STSPIN830 supports both single and three shunts architectures and embeds a PWM current controller based on user settable values of reference voltage and OFF time.

The devices can be forced in a low consumption state reducing the total current consumption down to less than 45 μA.

As with all other devices from the STSPIN family, the STSPIN830 integrates a complete set of protections for the power stages (non-dissipative overcurrent, thermal shutdown, short-circuit, undervoltage lockout and interlocking) making it a bulletproof solution for the new wave of demanding industrial applications.

1. Refer to [Section 5.2: Logic inputs](#) for more details.

5 Functional description

The STSPIN830 is a three-phase motor driver integrating a PWM current limiter and a power stage composed of three fully-protected half-bridges.

5.1 Power supply and standby

The device is supplied through the VS pins, the two pins **must** be at the same voltage.

At power-up the power stage is disabled and the FAULT pin is forced low until the VS voltage rise above the $V_{StH(ON)}$ threshold.

If the VS fall below the $V_{StH(ON)} - V_{StH(HYST)}$ value the power stage is immediately disabled and the FAULT pins are forced low.

Figure 3. UVLO protection management

The device provides a low consumption mode which is set by forcing the STBY\RESET input below the V_{STBYL} threshold.

When the device is in standby status the power stage is disabled (outputs are at high impedance) and the supply to the integrated control circuitry is strongly reduced. When the device leaves the standby status, all the control circuitry is reset to power-up condition.

5.2 Logic inputs

The STSPIN830 offers two alternative methods to drive the power stage, which can be selected by setting the status of MODE pin.

If MODE pin is set low (connected to GND) the output of each full bridge is controlled by the respective ENx and INx inputs.

If MODE pin is set high the output of each full bridge is controlled by the respective INxH and INxL inputs.

In both cases the status of the power bridge is also determined by the PWM current limiter as indicated in [Section 5.3](#).

Note: The MODE pin status must not be changed whilst the device is operational.

When the ENFAULT input is forced low the power stage is immediately disabled (all MOSFETs are turned off). The pin is also used as FAULT indication through the integrated open-drain MOSFET as described in [Section 5.4 on page 16](#) and [Section 5.5 on page 20](#).

Table 7. ENx and INx inputs truth table (MODE = 'L')

MODE	ENFAULT	ENx	INx	OUTx	'x' half-bridge condition
0	0	X ⁽¹⁾	X ⁽¹⁾	High Z ⁽²⁾	Disabled
0	1	0	X ⁽¹⁾	High Z ⁽²⁾	Disabled
0	1	1	0	GND	LS on
0	1	1	1	VS	HS on

1. X: don't care.

2. High Z: high impedance.

Table 8. INxL and INxH inputs truth table (MODE = 'H')

MODE	ENFAULT	INxH	INxL	OUTx	'x' half-bridge condition
1	0	X ⁽¹⁾	X ⁽¹⁾	High Z ⁽²⁾	Disabled
1	1	0	0	High Z ⁽²⁾	Disabled
1	1	0	1	GND	LS on
1	1	1	0	VS	HS on
1	1	1	1	High Z ⁽²⁾	Disabled (interlocking)

1. X: don't care.

2. High Z: high impedance.

5.3 PWM current limiter

The device implements a PWM current limiter.

The load current is sensed through the SNS pin monitoring the voltage drop across an external resistor connected between the source of the low side power MOSFET (SENSEx pins) and ground.

The voltage of the SNS pin (V_{SNS}) is compared to the reference voltage pin (V_{REF}).

When $V_{SNS} > V_{REF}$ the current limiter is triggered, the OFF time is started and all the power outputs are disabled (high impedance) until the end of count of the timer.

During current decays the inputs values are ignored until the system returns to ON condition (decay time expired).

The reference voltage value, V_{REF} , has to be selected according the load current target value (peak value) and sense resistors value.

Equation 1

$$V_{REF} = R_{SENSE} \times I_{LOAD,peak}$$

The choice of sense resistors value must be take into account two main issues:

- The sensing resistor dissipates energy and provides dangerous negative voltages on the SENSE pins during the current recirculation. For this reason the resistance of this component should be kept low (using multiple resistors in parallel will help obtaining the required power rating with standard resistors).
- The lower is the R_{SENSE} value, the higher is the peak current error due to noise on V_{REF} pin and to the input offset of the current sense comparator: too small values of R_{SENSE} must be avoided.

Figure 4. PWM current limit sequence example

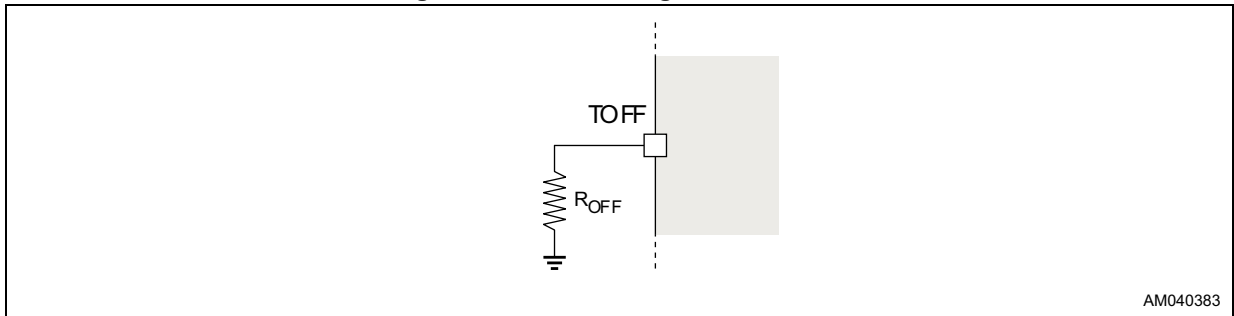

AM040382

Note: When the voltage on the SNS pin exceeds the absolute ratings, a fault condition is triggered and the ENFAULT output is forced low.

TOFF adjustment

The OFF time is adjusted through an external resistor connected between the TOFF pin and ground as shown in [Figure 5](#).

Figure 5. OFF time regulation circuit

The relation between the OFF time and the external resistor value is shown in the graph of [Figure 6](#). The value typically ranges from 10 μ s to 150 μ s.

The recommended value for R_{OFF} is in the range between 5 k Ω and 180 k Ω .

Figure 6. OFF time vs R_{OFF} value

5.4 Device protections

5.4.1 Overcurrent and short-circuit protections

The device embeds circuitry to protect each power MOSFET against the overload and short-circuit conditions (short-circuit to ground, short-circuit to VS and short-circuit between outputs).

When the overcurrent or the short-circuit protection is triggered the power stage is disabled and the EN\FAULT input is forced low through the integrated open drain MOSFET discharging the external C_{EN} capacitor.

The power stage is kept disabled and the open drain MOSFET is kept ON until the EN\FAULT input falls below the V_{RELEASE} threshold, then the C_{EN} capacitor is charged through the external R_{EN} resistor.

Figure 7. Overcurrent and short-circuit protections management

The total disable time after an overcurrent event is set sizing properly the external network connected to EN\FAULT pin (refer to [Figure 8](#)) and it is the sum of the discharging and charging time of the C_{EN} capacitor:

Equation 2

$$t_{DIS} = t_{discharge} + t_{charge}$$

Considering $t_{\text{discharge}}$ is normally significantly lower than t_{charge} , its contribution is negligible and the disable time is almost equal to t_{charge} only:

Equation 3

$$t_{\text{DIS}} \cong R_{\text{EN}} \times C_{\text{EN}} \times I_n \frac{(V_{\text{DD}} - R_{\text{EN}} \times I_{\text{PD}}) - V_{\text{RELEASE}}}{(V_{\text{DD}} - R_{\text{EN}} \times I_{\text{PD}}) - V_{\text{IH}}}$$

Where V_{DD} is the pull-up voltage of the R_{EN} resistor.

The recommended value for R_{EN} and C_{EN} are respectively 39 kΩ and 10 nF that allow obtaining 300 μs disable time.

Figure 8. Disable time versus R_{EN} and C_{EN} values ($V_{\text{DD}} = 3.3 \text{ V}$)

Figure 9. Overcurrent threshold versus temperature (normalized at 25 °C)

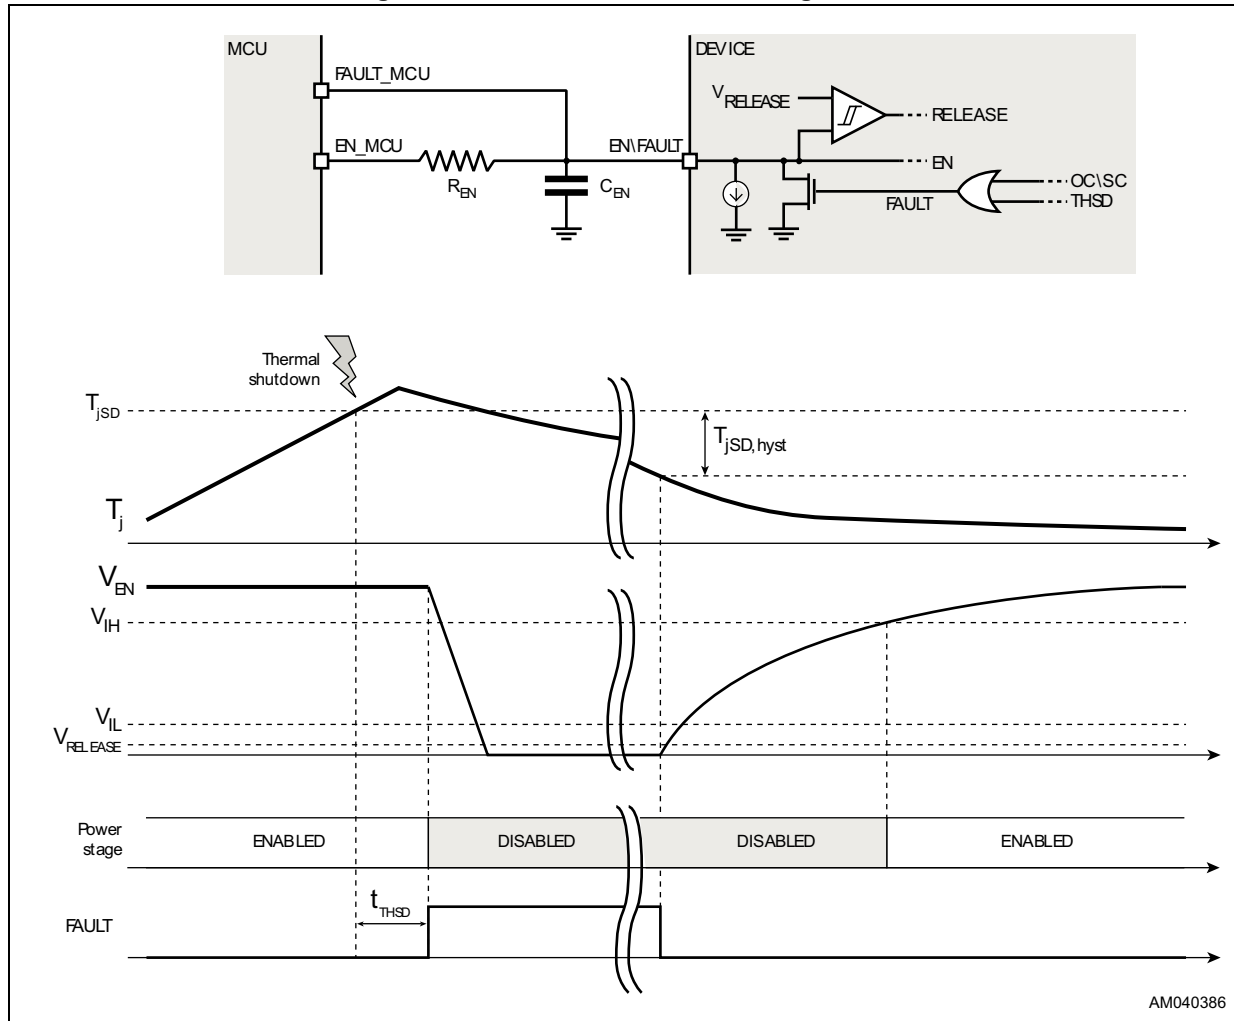

5.4.2 Thermal shutdown

The device embeds circuitry to protect it from overtemperature conditions.

When the thermal shutdown temperature is reached the power bridge are disabled and the EN\FAULT input is forced low through the integrated open drain MOSFET (refer to [Figure 10](#)).

The protection and the EN\FAULT output is released when the IC temperature returns below a safe operating value ($T_{jSD} - T_{jSD,Hyst}$).

Figure 10. Thermal shutdown management

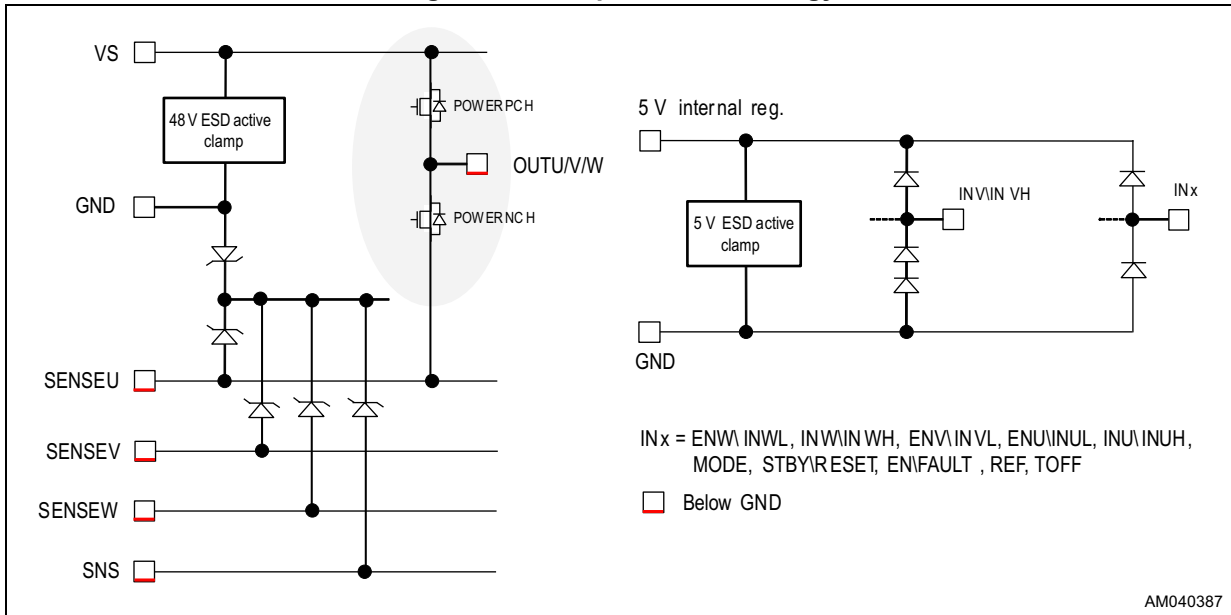

5.4.3 Blanking time

The device provides a blanking time t_{BLANK} after each power MOSFET commutation to prevent false triggering of protections and current limiter.

During blanking time the protections (overcurrent, short-circuit, thermal shutdown) and the comparator of the current limiter are inhibit.

5.5 ESD protection strategy

Figure 11. ESD protection strategy

6 Typical applications

R_{EN}	39 k Ω
C_{STBY}	1 nF
R_{STBY}	18 k Ω
R_{OFF}	10 k Ω ($T_{OFF} \cong 13 \mu$ s)

Figure 12. Typical application schematic with single shunt

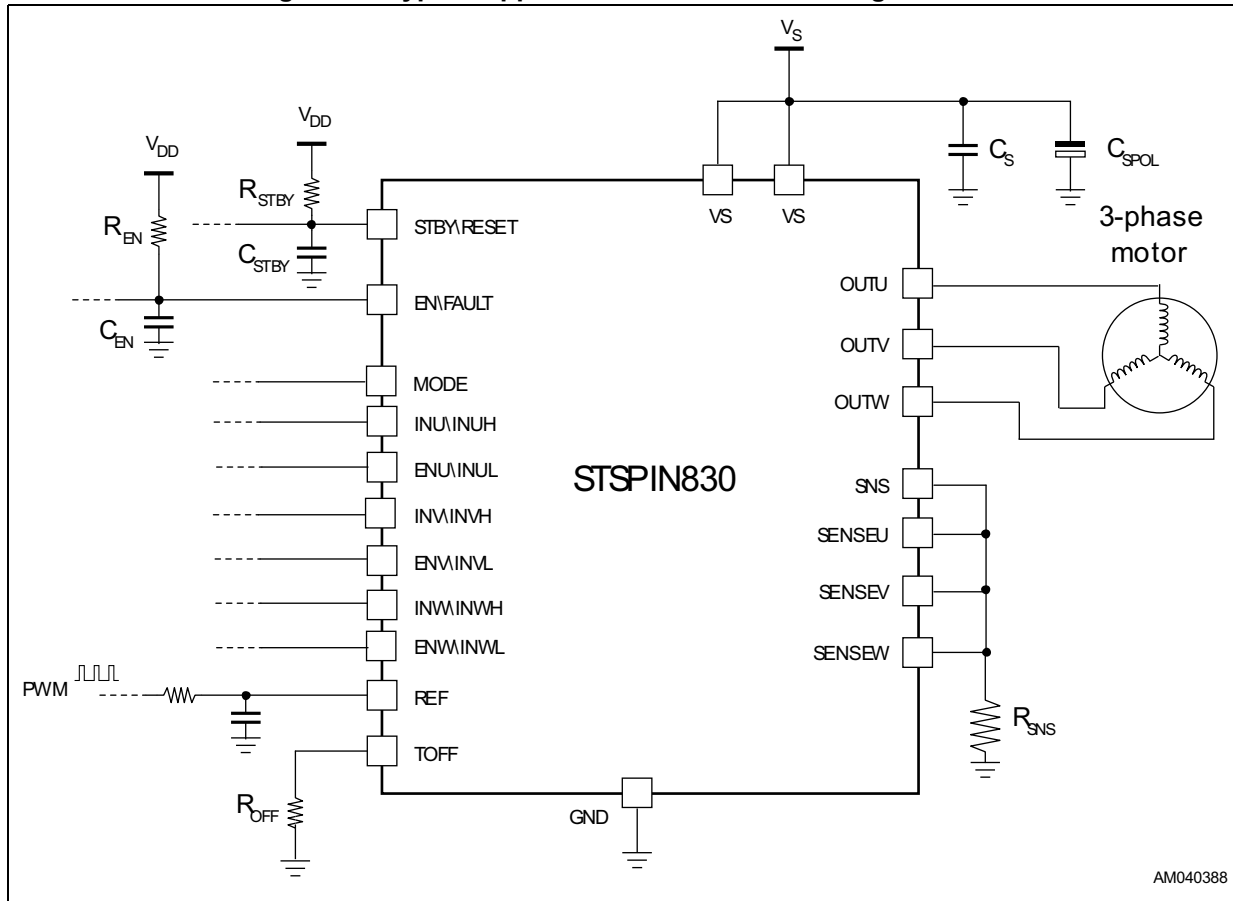

Figure 13. Typical application schematic with triple shunt

7 Layout recommendations

The STSPIN830 integrates the power stage; in order to improve the thermal dissipation, the exposed pad must be connected to the ground plane on the bottom layer using multiple vias equally spaced. This ground plane acts as a heatsink, for this reason it should be as wide as possible.

The voltage supply V_S must be stabilized and filtered with a ceramic bypass capacitor, typically 330 nF. It must be placed on the same side and as close as possible to V_S pin in order to reject high frequency noise components on the supply. A bulk capacitor could also be required (typically a 33 μ F). The connection between the power supply connector and the V_S pins must be as short as possible using wide traces.

In order to ensure the best ground connection between the STSPIN830 and the other components, a GND plane surrounding the device is recommended.

A capacitor between REF pins and ground should be positioned as near as possible to the device in order to filter the noise and stabilize the reference voltage.

Several vias should be positioned as near as possible each sense resistor connecting them to the ground plane on the bottom layer. In this way, both the GND planes provide a path for the current flowing into the power stage.

The path between the ground of the shunt resistors and the ceramic bypass capacitor of the device is critical; for this reason it must be as short as possible minimizing parasitic inductances that can cause voltage spikes on SENSE and OUT pins.

The OUT pins and the VS nets can be routed using the bottom layer, it is recommended to use two vias for output connections.

Figure 14. PCB layout example with triple shunt (top layer)

In case of single shunt configuration take special care for the SENSE and SNS pins connection.

As suggested in *Figure 15* and *Figure 16*, the shunt resistor can be placed in the top layer close to SENSEU and SNS pins with a wide copper area and vias. The connection with other sense pins (SENSEV and SENSEW) can be routed in the bottom layer taking care to maximize the track area and add more vias near to the pins.

Figure 15. PCB layout example with single shunt (top layer)

Figure 16. PCB layout example with single shunt (bottom layer)

8 Package information

In order to meet environmental requirements, ST offers these devices in different grades of ECOPACK® packages, depending on their level of environmental compliance. ECOPACK® specifications, grade definitions and product status are available at: www.st.com. ECOPACK® is an ST trademark.
