

# Build in EQ Function 25W Class-D Audio Amplifier With AGC function

## **General Description**

The LPA2100 is a mono efficient, digital amplifier power stage for driving speakers up to  $25W/4\Omega$ . The LPA2100 integrates AGC(automatic gain control)circuit for a NCN(Non-Crack Noise) technical in application without damaging speaker when a high power signal occurs. When function failed happened to input capacitor, the chip will cut off the output circuit through detecting the input signal to protect speaker. The LPA2100 device is fully protected against faults with short-circuit protection and thermal protection as well as over-voltage and DC protection. Faults are reported back to the processor to prevent devices form being damaged during overload conditions.

## **Order Information**

# **Applications**

- Mini-Micro Component, Speaker Bar, Docks
- ♦ After-Market Automotive
- ♦ Consumer Audio Applications, CRT TV
- ♦ Portable Bluetooth Speaker
- ♦ Cellular and Smart mobile phone
- ♦ Square Speaker

## **Features**

- 15W Output at 0.1% THD with a 4Ω Load and12.0V
   PVCC for amplifier
- ♦ Wide voltage range: 4.5V~15V
- Integrated 2 degree AGC circuit
- Integrated Self-Protection Circuits Including Over-Voltage, Under-Voltage, Over-Temperature, DC-Detect, and Short Circuit
- Multiple Switching Frequencies
  - AM Avoidance
  - Master/Slave Synchronization
  - ➤ Up to 450KHz Switching Frequency
- ♦ High Efficient Class-D Operation: >90%
- Indication for NCN(Non-Crack Noise)
- ♦ Pb-Free Package

## **Applications Information**(for Amplifier)

#### Gain

The gain of the LPA2100 is set by an external two resistor and multiplied by an internal 10 fold amplification.

AV= ( Rf1/Rin1 ) \*10=(Rf2/Rin2)\*10 Gain=20lgAV

#### AGC For NCN

The LPA2100 integrates an automatic gain control technology to achieve NCN(Non-Crack Noise). The circuit could set different NCN degree by different resistance divider applying to CTRL/SLV to protect speaker as showed below.R1+R2 should less than 100K. Also, the voltage on CTRL/SLV set the Master/Slave synchronization mode. When circuit set master synchronization mode, chip will output a 500KHz frequency pulse signal through SYNC pin. If circuit used as Slave mode, chip can receive a pulse signal from 300KHz to 700KHz.

The function of NCN(Non-Crack Noise) needs two key processes: Detection of Crack and Suppression gain. When an overload signal applied to speaker, chip will suppress the gain of circuit through real-time detection output signal in a certain time. The suppression will be stronger until the output signal fall to the available range with a stable balance between the signal and suppression. In the same way, the suppression will be weaker when the input signal amplitude decreases.

Sheet.1 NCN function and Master/Slave synchronization

Voltage on CTRL/SLV	NCN	Master/Slave
CTRL/SLV < 1/6 VDD	Disabled	Master
1/6 VDD < CTRL/SLV < 2/6 VDD	2degree	Master
2/6 VDD < CTRL/SLV < 3/6 VDD	1degree	Master
3/6 VDD < CTRL/SLV < 4/6 VDD	Disabled	Slave
4/6 VDD < CTRL/SLV < 5/6 VDD	2degree	Slave
CTRL/SLV > 5/6 VDD	1degree	Slave

Note: 1degree: Detection delay time: 45ms, release of suppression: 2.6s;

2degree: Detection delay time: 10ms , release of suppression: 1.2s;

#### Shutdown operation

In order to reduce power consumption while not in use, the LPA2100 contains shutdown circuitry to turn off the amplifier's bias circuitry. This shutdown feature turns the amplifier off when logic low is applied to the EN pin. By switching the EN pin connected to GND, the LPA2100 supply current draw will be minimized in idle mode.

#### Power supply decoupling

The LPA2100 is a high performance CMOS audio amplifier that requires adequate power supply decoupling to ensure the output THD and PSRR a low as possible. Power supply decoupling affects low response. Optimum decoupling frequency achieved by using two capacitors of different types targeting to different types of noise on the power supply leads. For higher frequency transients, spikes, or digital hash on the line, good low а equivalent-series-resistance (ESR) ceramic capacitor, typically 1.0µF, works best, placing it as close as possible to the device VDD terminal. For filtering lower- frequency noise signals, a large capacitor of 20µF (ceramic) and a capacitor of

LPA2100-00 Version 1.0 May.-2016 Email: marketing@lowpowersemi.com www.lowpowersemi.com Page 14 of 20

Preliminary Datasheet LPA2100

220uF(electrolytic) are recommended, placing them near the audio power amplifier.

#### **Short Circuit Protection (SCP)**

The LPA2100 has short circuit protection circuitry on the outputs to prevent damage to the device when output-to-output or output-to-GND short occurs. When a short circuit is detected on the outputs, the outputs are disabled immediately. If the short was removed, the device activates again.

#### Signal Frequency suppress

The LPA2100 has an OPP/N pin which is the negative output of amplifier as show below. With R2 and C2, we can suppress high frequency part of signal. And the low frequency part of signal could be attenuated by R1 and C1.

$$f_{H} = \frac{1}{2\pi R_{1}C_{1}} ; f_{L} = \frac{1}{2\pi R_{2}C_{2}}$$

$$C2$$

$$Rin$$

$$R2$$

$$R3$$

$$VIN$$

#### **Over Temperature Protection**

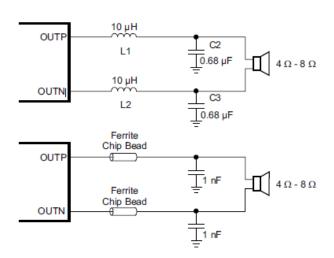

Thermal protection on the LPA2100 prevents the device from damage when the internal die temperature exceeds 150°C. There is a 15 degree tolerance on this trip point from device to device. Once the die temperature exceeds the thermal set point, the device outputs are disabled. This is not a latched fault. The thermal fault is cleared once the temperature of the die is reduced by 30°C. This large hysteresis will prevent motor boating sound well and the device begins normal operation at this point without external system intervention.

#### How to reduce EMI

A simple solution is to put an additional capacitor at

power supply terminal for power line. The traces from amplifier to speakers should design as short as we can. The LPA2100 has been tested with a simple ferrite bead filter for a variety of applications. The LPA2100 EVM passes FCC class-B specifications under these conditions using twisted speaker wires. The size and type of ferrite bead can be selected to meet application requirements. Also, the filter capacitor can be increased if necessary with some impact on efficiency. There may be a few circuit instances where it is necessary to add a complete LC reconstruction filter. These circumstances might occur if there are nearby circuits which are sensitive to noise. In these cases a classic second order Butterworth filter similar to those shown in the figures below can be used.

Some systems have little power supply decoupling from the AC line but are also subject to line conducted interference (LCI) regulations. These include systems powered by "wall warts" and "power bricks." In these cases, LC reconstruction filters can be the lowest cost means to pass LCI tests. Common mode chokes using low frequency ferrite material can also be effective at preventing line conducted interference.

LPA2100-00 Version 1.0 May.-2016 Email: marketing@lowpowersemi.com

## **PCB** Layout notices

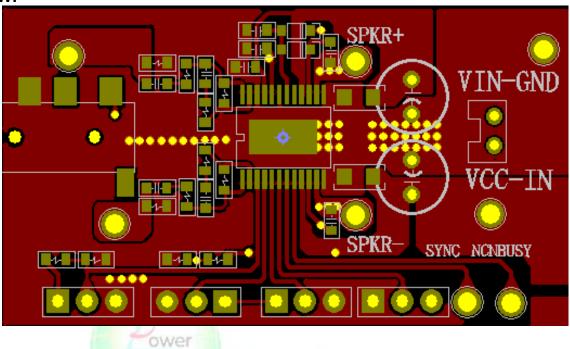

- 1, In the path of the power supply, plus a 1uF and a 10uF to ground high-frequency filter capacitor. These caps can be connected to the thermal pad directly for an excellent ground connection. Consider adding a small, good quality low ESR ceramic capacitor may achieve better sound effects.
- 2, Large (470  $\mu$ F or greater) bulk power supply decoupling capacitors should be placed near the LPA2100 on the PVCC supplies. Local, high-frequency bypass capacitors should be placed as close to the PVCC pins as possible.
- 3, The power line, ground line and filter capacitor and bypass capacitors as close to the chip's pins, remember not to put the capacitor on the back of the board, through tiny holes through the jumper even over. Keep the current loop from each of the outputs through the ferrite bead and the small filter cap and back to PGND as small and tight as possible. The size of this current loop determines its effectiveness as an antenna.
- 4, Power, ground, and a large current line must try to be wide enough, if you want to add vias, the number of through-holes must be at least 6. The thermal pad must be soldered to the PCB for proper thermal performance and optimal reliability.
- 5, GND and VDD should be put independently, high-power signals to avoid interference.
- 6, If you want to pursue as large as the effect of power, a large selection of speakers or sound chamber with low resistance (such as  $3.6\Omega$ ) speakers, or added to improve the supply voltage.
- 7, Including the line between large current cell and chip, the inductor should be as close and short as possible to chip for a high performance. Adding a coil to this pin would be helpful for EMI certification. If there is a high standards needed in LPA2100 application, we could add a coil and capacitor between chip and speaker constituting a LC filter which coil would be 100MHz,  $600\Omega$  and its DCI beyond 4A placing as close as possible to chip, the capacitor should be 1nF connecting the PGND.
- 8, The position under the amplifier chip on the board must be added vents and large areas of exposed copper and tin to enhance heat dissipation.
- 9, In case of fixed gain and meeting demand, it should make C<sub>IN</sub> small as possible as we can because it constitute a high through filter with Rin which cutoff frequency is 1/2\*3.414\*Cin\*Rin. A high capacitance cap could make POP worse.
