CYDMX064A16/CYDMX064B16

16 K/8 K/4 K × 16 MoBL[®] ADM

Asynchronous Dual-Port Static RAM

Features

- True dual-ported memory block that allow simultaneous independent access
 - One port with dedicated time multiplexed address and data (ADM) interface
 - One port configurable to standard SRAM or time multiplexed address and data interface
- 16 K/8 K/4 K × 16 memory configuration
- High speed access
 - 65 ns or 90 ns ADM interface
 - 40 ns or 60 ns standard SRAM interface
- Fully asynchronous operation
- Port independent 1.8 V, 2.5 V, and 3.0 V IOs
- Ultra low operating power
 - Active: I_{CC} = 15 mA (typical) at 90 ns
 - Active: I_{CC} = 25 mA (typical) at 65 ns
 - Standby: I_{SB3} = 2 μA (typical)
- Port independent power-down
- On-chip arbitration logic
- Mailbox interrupt for port to port communication
- Input Read and Output Drive registers
- Upper byte and lower byte control
- Small package: 6 × 6 mm, 100-ball Pb-free BGA
- Industrial temperature range

Block Diagram

Notes

1. A13-A0 for CYDMX256A16 and CYDMX256B16; A12-A0 for CYDMX128A16 and CYDMX128B16; and A11-A0 for CYDMX064A16 and CYDMX064B16.
2. IRR1 and IRR2 not available for CYDMX256A16 and CYDMX256B16.

Notes

3. This pin is A13 for CYDMX256A16 and CYDMX256B16.
4. This pin is DNU for CYDMX064A16 and CYDMX064B16.
5. This pin is DNU for CYDMX256A16 and CYDMX256B16.
6. DNU pins are "do not use" pins. No trace or power component can be connected to these pins.

Pin Definitions

Left Port	Right Port	Description
CS#L	CS#R	Chip select
WE#L	WE#R	Read/Write Enable
OE#L	OE#R	Output Enable
	A0–A13	Address (A0–A11 for 4K device; A0–A12 for 8K device; A0–A13 for 16K device)
	MSEL	Right port interface mode select (0: Standard SRAM; 1: Address/Data Mux)
IOL0–IOL15	IOR0–IOR15	Address/Data Bus Input/Output
ADV#L	ADV#R	Address Latch Enable; ADV#R only use when R-port is in ADM mode
UB#L	UB#R	Upper byte select (IO8–IO15)
LB#L	LB#R	Lower byte select (IO0–IO7)
INT#L	INT#R	Interrupt Flag
BUSY#L	BUSY#R	Busy Flag
SFEN#		Special Function Enable Signal
IRR0–IRR1		Input signals for input read registers for CYDMX128A16, CYDMX128B16, CYDMX064A16 and CYDMX064B16; IRR0 is DNU and IRR1 is A13 for CYDMX256A16 and CYDMX256B16.
ODR0–ODR4		Output signals for output drive registers; These are open drained outputs.
V _{CC}		Core power supply
GND		Ground
VDDIOL		Left port IO power supply
VDDIOR		Right port IO power supply
DNU		No Connect; Do not connect trace or power component to these pins.

Functional Description

The CYDMX256A16, CYDMX128A16, CYDMX064A16, CYDMX256B16, CYDMX128B16, and CYDMX064B16 are low power CMOS 16K/8K/4K × 16 dual-port static RAMs. The two ports are: one dedicated time multiplexed address and data (ADM) interface and one configurable standard SRAM or ADM interface. The two ports permit independent, asynchronous read and write access to any memory locations. Each port has independent control pins: Chip Select (CS#), Write Enable (WE#), and Output Enable (OE#). Two output flags are provided on each port (BUSY# and INT#). BUSY# flag is triggered when the port is trying to access the same memory location currently being accessed by the other port. The Interrupt flag (INT#) permits communication between ports or systems by means of a mailbox. Power-down feature is controlled independently on each port by a Chip Select (CS#) pin.

The CYDMX256A16, CYDMX128A16, CYDMX064A16, CYDMX256B16, CYDMX128B16, and CYDMX064B16 are available in 100-ball 0.5-mm pitch Ball Grid Array (BGA) packages. Application areas include interprocessor and multiprocessor designs, communications status buffering, and dual-port video and graphics memory.

Power Supply

The core voltage (V_{CC}) can be 1.8 V, 2.5 V, or 3.0 V, as long as it is lower than or equal to the IO voltage. Each port operates on

independent IO voltages. This is determined by what is connected to the V_{DDIOL} and V_{DDIOR} pins. The supported IO standards are 1.8 V and 2.5 V LVCMOS and 3.0 V LVTTTL.

ADM Interface Read or Write Operation

This description is applicable to both the left ADM port and right port configured as an ADM port.

Three control signals, ADV#, WE#, and CS# are used to perform the read and write operations. Address signals are first applied to the IO bus along with CS# LOW. The addresses are loaded from the IO bus in response to the rising edge of the Address Latch Enable (ADV#) signal. It is necessary to meet the setup (t_{AVDS}) and hold (t_{AVDH}) times given in the AC specifications with valid address information to properly latch the addresses.

After the address signals are latched in, a read operation is issued when WE# stays HIGH. The IO bus becomes High Z when the address signals meet t_{AVDH}. The read data is driven on the IO bus t_{OE} after the OE# is asserted LOW, and held until t_{HZOE} or t_{HZCS} after the rising edge of OE# or CS#, whichever comes first.

A write operation is issued when WE# is asserted LOW. The write data is applied to the IO bus right after address meets the hold time (t_{AVDH}). And write data is written with the rising edge of either WE# or CS#, whichever comes first, and meets data setup (t_{SD}) and hold (t_{HD}) times.

Standard SRAM Interface Read or Write Operation

This description is applicable to the right access port configured as standard SRAM port. Read and write operations with standard SRAM interface configuration is the same as the ADM port except addresses are presented on the A bus. Operation is controlled by CS#, OE#, and WE#. A read operation is issued when WE# is asserted HIGH. A write operation is issued when WE# is asserted LOW. The IO bus is the destination for read data and the source for write data when the read operation is issued. However, write data must be driven to IO when the write operation is issued.

Byte Select Operation

The fundamental word size is 16 bits. Each word is broken up into two 8-bit bytes. Each port has two active LOW byte enables: UB# and LB#. Activating or deactivating the byte enables alters the result of read and write operations to the port. During a write, byte enable asserted HIGH inhibits the corresponding byte to be updated in the addressed memory location. During a read, both byte enables are inputs to the asynchronous output enable control logic. When a byte enable is asserted HIGH, the corresponding data byte is tristated. Subsequently, when the byte enable is asserted LOW, the corresponding data byte is driven with the read data.

Chip Select Operation

Each port has one active LOW chip select signal, CS#. CS# must be asserted LOW for the port to be considered active. To issue a valid read or write operation, the chip select input must be asserted LOW throughout the read or write cycle. When CS# is deasserted HIGH during a write, if t_{WRL} , t_{SD} , and t_{HD} are not met, the contents of the addressed location is not altered.

An automatic power-down feature controlled by deactivating the chip select (CS# HIGH) permits the on-chip circuitry of each port to enter a very low standby power mode.

Output Enable Operation

Each port has one output enable signal, OE#. When OE# is asserted HIGH, IO bus is tri-stated after t_{HZOE} . When OE# is asserted LOW, control of the IO bus is assumed by the asynchronous output enable logic (the logic is controlled by inputs WE#, CS#, UB#, and LB#).

Mailbox Interrupts

The upper two memory locations are used for message passing. The highest memory location (0xFFF for CYDMX064A16 and CYDMX064B16, 0x1FFF for CYDMX128A16 and CYDMX128B16, and 0x3FFF for CYDMX256A16 and CYDMX256B16) is the mailbox for the right port. The second highest memory location (0xFFE for CYDMX064A16 and CYDMX064B16, 0x1FFE for CYDMX128A16 and CYDMX128B16, and 0x3FFE for CYDMX256A16 and CYDMX256B16) is the mailbox for the left port. When one port writes to the opposite port's mailbox, an interrupt signal is generated to the opposite port. The interrupt

resets when the owner reads the contents of its own mailbox. The message written to the mailbox is user defined.

Each port reads the other port's mailbox without resetting the interrupt. The active state of the busy signal (to a port) prevents the port from setting the interrupt to the winning port. Also, an active busy to a port prevents that port from reading its own mailbox and resetting the interrupt to it.

On power-up, both interrupts are set by default. An initialization program must be run to reset the interrupts.

If an application does not require message passing, do not connect the interrupt pin to the processor's interrupt request input pin.

Arbitration Logic

The CYDMX256A16, CYDMX128A16, CYDMX064A16, CYDMX256B16, CYDMX128B16, and CYDMX064B16 provide on-chip arbitration to resolve simultaneous memory location access (collision). If both ports' CS# signals are asserted and an address match occurs within each other, the busy logic determines which port has access. If t_{PS} is violated, one of the two ports gains permission to the location, but it is not predictable which port gets the permission. BUSY# is asserted t_{BLA} after an address match or t_{BLC} after CS# is taken LOW.

Input Read Register

The Input Read Register (IRR) feature is available only for CYDMX128A16, CYDMX128B16, CYDMX064A16, and CYDMX064B16 devices. When SFEN# = V_{IL} , the IRR captures the status of two external devices connected to the Input Read pins (IRR0 and IRR1) to address location 0x0000. Address 0x0000 is not available for standard memory accesses when SFEN# = V_{IL} . When SFEN# = V_{IH} , address 0x0000 is available for normal memory accesses. Either port accesses the contents of IRR with normal read operation from address 0x0000. During reads from the IRR, IO<1:0> are valid bits and IO<15:2> are don't care. The IRR inputs are 1.8 V and 2.5 V LVCMOS or 3.0 V LVTTTL, depending on the core voltage supply (V_{CC}).

Output Drive Register

The Output Drive Register (ODR) determines the state of up to five external binary state devices by providing a path to V_{SS} for the external circuit. These outputs are open drain. The five external devices operates at different voltages ($1.5 V \leq V_{DDIO} \leq 3.5 V$) but the combined current cannot exceed 40 mA (8 mA maximum for each external device). The status of the ODR bits are set using standard write accesses from either port to address 0x0001 with a '1' corresponding to on and '0' corresponding to off. The status of the ODR bits are read with a normal read access to address 0x0001. When SFEN# = V_{IL} , the ODR is active and address 0x0001 is not available for memory accesses. When SFEN# = V_{IH} , the ODR is inactive and address 0x0001 is used for standard accesses. During reads and writes to ODR, IO<4:0> are valid and IO<15:5> are don't care.

Architecture

The CYDMX256A16, CYDMX128A16, CYDMX064A16, CYDMX256B16, CYDMX128B16, and CYDMX064B16 consist of an array of 16K, 8K, and 4K words of 16 dual-ported SRAM cells, IO, address lines, and control signals (CS#, ADV#, OE#, and WE#). Between the two access ports, one is a dedicated time multiplexed address and data interface; the other is a pin selectable port to either standard SRAM or time multiplexed

address and data interface. Independent control signals for each port permit simultaneous access to any location in memory. To handle the situation of writing and reading to the same location, a BUSY# pin is provided on each port. For port to port communication, an Interrupt (INT#) pin is also available on each port.

Table 1. ADM Interface Read/Write with Byte Select Operations

ADV#	CS#	WE#	OE#	UB#	LB#	IO0 - IO15	Mode
X	H	X	X	X	X	High Z	Deselected or power-down

Notes

7. 0x3FFF for CYDMX256A16 and CYDMX256B16, 0x1FFF for CYDMX128A16 and CYDMX128B16, 0x3FFF for CYDMX064A16 and CYDMX064B16.
8. 0x3FFE for CYDMX256A16 and CYDMX256B16, 0x1FFE for CYDMX128A16 and CYDMX128B16, 0x3FFE for CYDMX064A16 and CYDMX064B16.
9. If it meets tPS, "L" if the CS# and address of the opposite port become stable BEFORE the current port; "H" if the CS# and address of the opposite port become stable AFTER the current port. If tPS is not met, either BUSY#L or BUSY#R results "L". BUSY#L and BUSY#R cannot be "L" simultaneously.
10. Write operations to the left port are internally ignored when BUSY#L is driving LOW regardless of actual logic level on the pin; Write operations to the right port are internally ignored when BUSY#R is driving LOW regardless of actual logic level on the pin.
11. SFEN# = V_{IL} for IRR reads.
12. UB# or LB# = V_{IL}. If LB# = V_{IL}, then IO<7:0> are valid. If UB# = V_{IL} then IO<15:8> are valid.
13. LB# must be active (LB# = V_{IL}) for these bits to be valid.
14. SFEN# active when either CS#L = V_{IL} or CS#R = V_{IL}. It is inactive when CS#L = CS#R = V_{IH}.
15. SFEN# = V_{IL} for ODR reads and writes.
16. Output enable must be low (OE# = V_{IL}) during reads for valid data to be output.
17. During ODR writes data is also written to the memory.

Maximum Ratings

Exceeding maximum ratings^[18] may shorten the useful life of the device. User guidelines are not tested.

Storage Temperature -65 °C to +150 °C
 Ambient Temperature with Power Applied -55 °C to +125 °C
 Supply Voltage to Ground Potential.....-0.5 V to +3.3 V
 DC Voltage Applied to Outputs in High Z State -0.5 V to V_{CC} + 0.5 V

DC Input Voltage^[19].....-0.5 V to V_{CC} + 0.5 V
 Output Current into Outputs (LOW)..... 90 mA
 Static Discharge Voltage..... > 2000 V
 Latch up Current..... > 200 mA

Operating Range

Range	Ambient Temperature	V _{CC}
Industrial	-40 °C to +85 °C	1.8 V ± 100 mV 2.5 V ± 100 mV 3.0 V ± 300 mV
