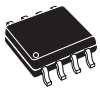
TS555

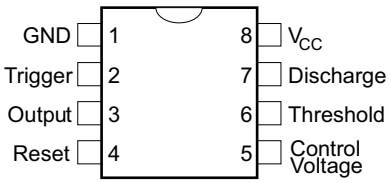
Low-power single CMOS timer

Datasheet - production data



SO8
(plastic micropackage)

Pin connections
(top view)



Description

The TS555 is a single CMOS timer with very low consumption:

($I_{cc(TYP)}$ TS555 = 110 µA at V_{CC} = +5 V versus $I_{cc(TYP)}$ NE555[a] = 3 mA),

and high frequency:

($f_{f(max.)}$ TS555 = 2.7 MHz versus $f_{(max)}$ NE555[a] = 0.1 MHz).

Timing remains accurate in both monostable and astable mode.

The TS555 provides reduced supply current spikes during output transitions, which enable the use of lower decoupling capacitors compared to those required by bipolar NE555[a].

With the high input impedance ($10^{12}\Omega$), timing capacitors can also be minimized.

Features

- Very low power consumption:
  - 110 µA typ at V_{CC} = 5 V
  - 90 µa typ at V_{CC} = 3 V
- High maximum astable frequency of 2.7 MHz
- Pin-to-pin functionally-compatible with bipolar NE555[a]
- Wide voltage range: +2 V to +16 V
- Supply current spikes reduced during output transitions
- High input impedance: $10^{12}\ \Omega$
- Output compatible with TTL, CMOS and logic MOS

a. Terminated product

Contents

1 Absolute maximum ratings and operating conditions

Table 1. Absolute maximum ratings

Symbol	Parameter	Value	Unit
V_{CC}	Supply voltage	+18	V
I_{OUT}	Output current	± 100	mA
R_{thja}	Thermal resistance junction to ambient (1)	125	°C/W
R_{thjc}	Thermal resistance junction to case (1)	40	
T_j	Junction temperature	+150	°C
T_{stg}	Storage temperature range	-65 to +150	
ESD	Human body model (HBM)(2)	1500	V
	Machine model (MM)(3)	200	
	Charged device model (CDM)(4)	1000	

1. Short-circuits can cause excessive heating. These values are typical and specified for a four layers PCB.
2. Human body model: a 100 pF capacitor is charged to the specified voltage, then discharged through a 1.5kΩ resistor between two pins of the device. This is done for all couples of connected pin combinations while the other pins are floating.
3. Machine model: a 200 pF capacitor is charged to the specified voltage, then discharged directly between two pins of the device with no external series resistor (internal resistor < 5 Ω). This is done for all couples of connected pin combinations while the other pins remain floating.
4. Charged device model: all pins plus package are charged together to the specified voltage and then discharged directly to the ground.

Table 2. Operating conditions

Symbol	Parameter	Value	Unit
V_{CC}	Supply voltage	2 to 16	V
I_{OUT}	Output sink current Output source current	10 50	mA
T_{oper}	Operating free air temperature range	-40 to +125	°C

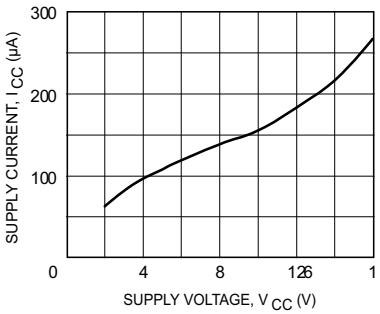
Figure 3. Supply current (per timer) versus supply voltage

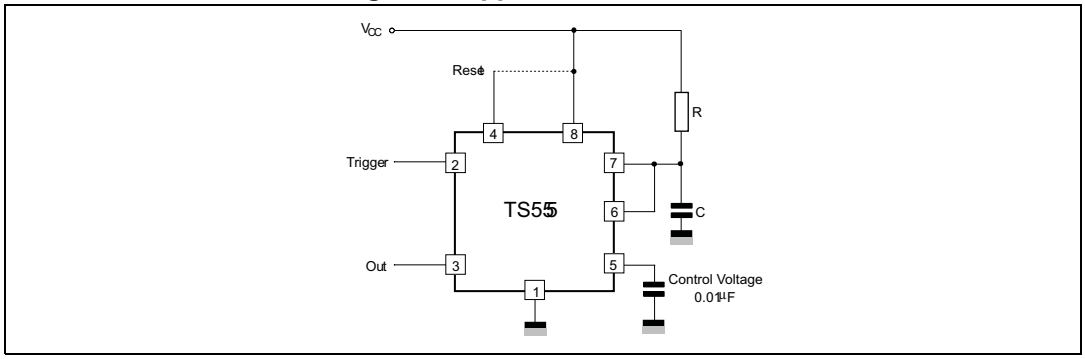


4 Application information

4.1 Monostable operation

In monostable mode, the timer operates like a one-shot generator. The external capacitor is initially held discharged by a transistor inside the timer, as shown in *Figure 4*.

Figure 4. Application schematic



The circuit triggers on a negative-going input signal when the level reaches 1/3 V_{CC}. Once triggered, the circuit remains in this state until the set time has elapsed, even if it is triggered again during this interval. The duration of the output HIGH state is given by $t = 1.1\ R\ x\ C$.

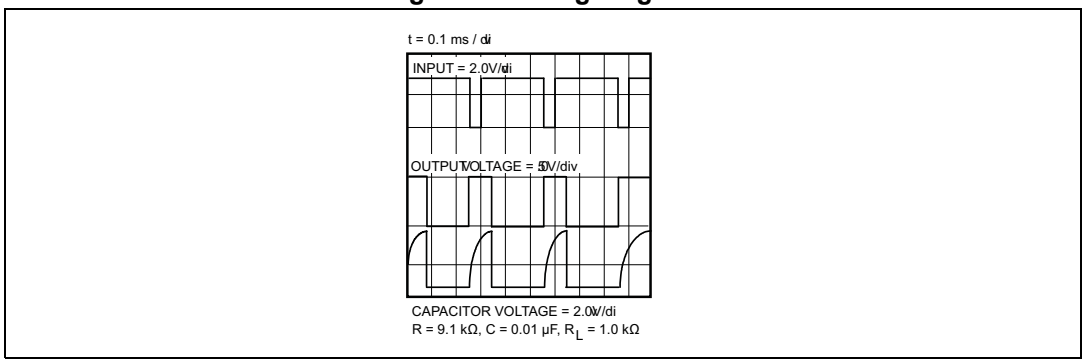
Since the charge rate and threshold level of the comparator are both directly proportional to the supply voltage, the timing interval is independent of the supply. Applying a negative pulse simultaneously to the reset terminal (pin 4) and the trigger terminal (pin 2) during the timing cycle discharges the external capacitor and causes the cycle to start over. The timing cycle then starts on the positive edge of the reset pulse. While the reset pulse is applied, the output is driven to the LOW state.

When a negative trigger pulse is applied to pin 2, the flip-flop is set, releasing the short circuit across the external capacitor and driving the output HIGH. The voltage across the capacitor increases exponentially with the time constant $\tau = R\ x\ C$.

When the voltage across the capacitor equals 2/3 V_{CC}, the comparator resets the flip-flop which then discharges the capacitor rapidly and drives the output to its LOW state. *Figure 5* shows the actual waveforms generated in this mode of operation.

When reset is not used, it should be tied high to avoid any false triggering.

Figure 5. Timing diagram



4.2 Astable operation

When the circuit is connected as shown in *Figure 6* (pins 2 and 6 connected) it triggers itself and runs as a multi-vibrator. The external capacitor charges through R_A and R_B and discharges through R_B only. Therefore, the duty cycle may be precisely set by the ratio of these two resistors.

In the astable mode of operation, C charges and discharges between 1/3 V_{CC} and 2/3 V_{CC}. As in the triggered mode, the charge and discharge times, and therefore frequency, are independent of the supply voltage.

Figure 6. Application schematic

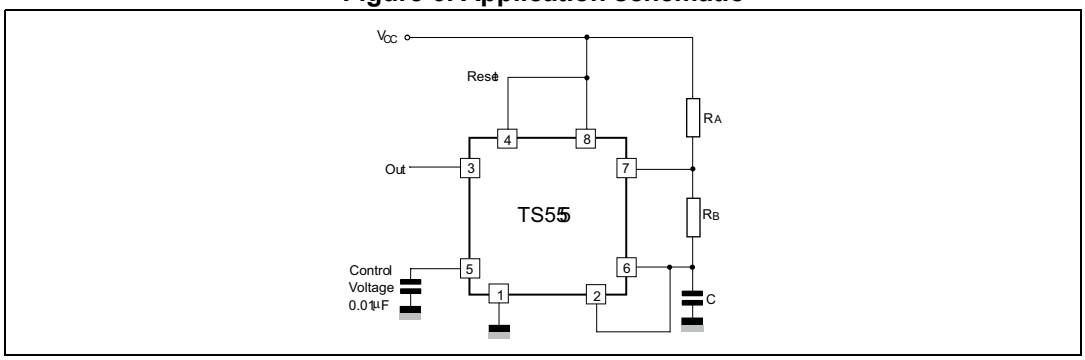


Figure 7 shows actual waveforms generated in this mode of operation.

The charge time (output HIGH) is given by:

$$t1 = 0.693\ (R_A + R_B)\ C$$

The discharge time (output LOW) by:

$$t2 = 0.693\ x\ R_B\ x\ C$$

Thus the total period T is given by:

$$T = t1 + t2 = 0.693\ (R_A + 2R_B)\ C$$

The frequency of oscillation is then:

$$f = \frac{1}{T} = \frac{1.44}{(RA + 2RB)C}$$

The duty cycle is given by:

$$D = \frac{RB}{RA + 2RB}$$
