Data Sheet

AD4030-24/AD4032-24

24-Bit, 2 MSPS/500 kSPS, SAR ADCs

FEATURES

- High performance
  - Throughput: 2 MSPS (AD4030-24) or 500 kSPS (AD4032-24) options
  - INL: ±0.9 ppm maximum from −40°C to +125°C
  - SNR: 108.4 dB typical
  - THD: −127 dB typical
  - NSD: −169 dBFS/Hz typical
- Low power
  - 30 mW at 2 MSPS
  - 10 mW at 500 kSPS
  - 3 mW at 10 kSPS
- Easy Drive™ features reduce system complexity
  - Low 1.2 µA input current for dc inputs at 2 MSPS
  - Wide common-mode input range: $-(1/128) \times V_{REF}$ to $+(129/128) \times V_{REF}$
- Flexible external reference voltage range: 4.096 V to 5 V
  - Accurate integrated reference buffer with 2 µF bypass capacitor
- Programmable block averaging filter with up to 2^{16} decimation
  - Extended sample resolution to 30 bits
  - Overrange and synchronization bits
- Flexi-SPI digital interface
  - 1, 2, or 4 SDO lanes allows slower SCK
  - Echo clock mode simplifies use of digital isolator
  - Compatible with 1.2 V to 1.8 V logic
- 7 mm × 7 mm, 64-Ball CSP_BGA package with internal supply and reference capacitors to help reduce system footprint

APPLICATIONS

- Automatic test equipment
- Digital control loops
- Medical instrumentation
- Seismology
- Semiconductor manufacturing
- Scientific instrumentation

FUNCTIONAL BLOCK DIAGRAM

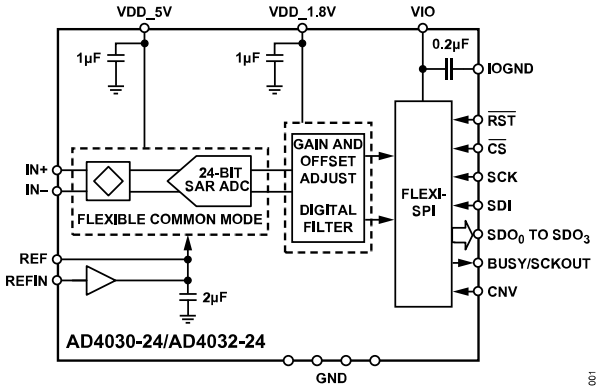

Figure 1. Functional Block Diagram

GENERAL DESCRIPTION

The AD4030-24/AD4032-24 are 2 MSPS or 500 kSPS successive approximation register (SAR), analog-to-digital converters (ADC) with Easy Drive™. With a guaranteed maximum ±0.9 ppm integral nonlinearity (INL) and no missing codes at 24-bits, the AD4030-24/AD4032-24 achieve unparalleled precision from −40°C to +125°C. Figure 1 shows the functional architecture of the AD4030-24/AD4032-24.

A low drift, internal precision reference buffer eases voltage reference sharing with other system circuitry. The AD4030-24/AD4032-24 offer a typical dynamic range of 109 dB when using a 5 V reference. The low noise floor enables signal chains requiring less gain and lower power. A block averaging filter with programmable decimation ratio can increase dynamic range up to 155.5 dB. The wide differential input and common mode ranges allow inputs to use the full $\pm V_{REF}$ range without saturating, simplifying signal conditioning requirements and system calibration. The improved settling of the Easy Drive analog inputs broadens the selection of analog front-end components compatible with the AD4030-24/AD4032-24. Both single-ended and differential signals are supported.

The versatile Flexi-SPI serial peripheral interface (SPI) eases host processor and ADC integration. A wide data clocking window, multiple SDO lanes, and optional dual data rate (DDR) data clocking can reduce the serial clock to 10 MHz while operating at a sample rate of 2 MSPS or 500 kSPS. Echo clock mode and ADC host clock mode relax the timing requirements and simplify the use of digital isolators.

The 7 mm × 7 mm, 64-Ball CSP_BGA package of the AD4030-24/AD4032-24 integrates all critical power supply and reference bypass capacitors, reducing the footprint and system component count, and lessening sensitivity to board layout.

TEMPERATURE RANGE					
Specified Performance	T_{MIN} to T_{MAX}	−40		+125	°C

[1] The acquisition phase is the time available for the input sampling capacitors to acquire a new input with the ADC running at a throughput rate of 2 MSPS for the AD4030-24 or 500 kSPS for the AD4032-24.

[2] See the low frequency noise plot in Figure 24. 1/f noise is canceled internally by auto-zeroing. Noise spectral density is substantially uniform from dc to $f_S/2$.

[3] When VIO < 1.4 V, Bit IO2X must be set to 1. See the Output Driver Register section.

TIMING SPECIFICATIONS

VDD_5V = 5.4 V, VDD_1.8V = 1.8 V, VIO = 1.8 V, REFIN = 5 V, input common mode = 2.5 V, f_S = 2 MSPS for the AD4030-24 or 500 kSPS for the AD4032-24, and all specifications are T_{MIN} to T_{MAX}, unless otherwise noted. Typical values are at T_A = 25°C. See Figure 2 for the timing voltage levels. For VIO < 1.4 V, Bit IO2X must be set to 1.

Table 2. Digital Timing Interface

ABSOLUTE MAXIMUM RATINGS

Table 8.

Parameter	Rating
Analog Inputs	
IN+, IN−, REFIN to GND	−0.3 V to VDD_5V + 0.3 V
Supply Voltage	
VDD_5V, REF to GND	−0.3 V to +6.0 V
VDD_1.8V, VIO to GND	−0.3 V to +2.1 V
Digital Inputs to GND	−0.3 V to VIO + 0.3 V
CNV to GND	−0.3 V to VIO + 0.3 V
Digital Outputs to GND	−0.3 V to VIO + 0.3 V
Storage Temperature Range	−55°C to +150°C
Operating Junction Temperature Range	−40°C to +125°C
Maximum Reflow (Package Body) Temperature	260°C

Stresses at or above those listed under Absolute Maximum Ratings may cause permanent damage to the product. This is a stress rating only; functional operation of the product at these or any other conditions above those indicated in the operational section of this specification is not implied. Operation beyond the maximum operating conditions for extended periods may affect product reliability.

THERMAL RESISTANCE

Thermal performance is directly linked to printed circuit board (PCB) design and operating environment. Careful attention to PCB thermal design is required.

Table 9. Thermal Resistance

Package Type	θ_{JA}	θ_{JC}	Unit
05-08-1797	35	16	°C/W

ELECTROSTATIC DISCHARGE (ESD) RATINGS

The following ESD information is provided for handling of ESD-sensitive devices in an ESD protected area only.

Human body model (HBM) per ANSI/ESDA/JEDEC JS-001.

Field induced charged device model (FICDM) per ANSI/ESDA/JEDEC JS-002.

ESD Ratings for AD4030-24/AD4032-24

Table 10. AD4030-24/AD4032-24, 64-Ball CSP_BGA

ESD Model	Withstand Threshold (kV)	Class
HBM	4	3A
FICDM	1.25	C3

ESD CAUTION

ESD (electrostatic discharge) sensitive device. Charged devices and circuit boards can discharge without detection. Although this product features patented or proprietary protection circuitry, damage may occur on devices subjected to high energy ESD. Therefore, proper ESD precautions should be taken to avoid performance degradation or loss of functionality.

PIN CONFIGURATION AND FUNCTION DESCRIPTIONS

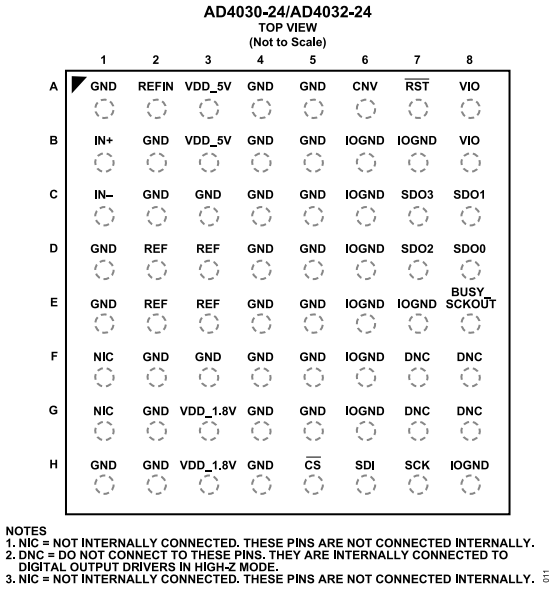

Figure 11. Pin Configuration

Table 11. Pin Function Descriptions

Pin No.	Mnemonic	Type[1]	Description
A1, A4, A5, B2, B4, B5, C2 to C5, D1, D4, D5, E1, E4, E5, F2 to F5, G2, G4, G5, H1, H2, H4	GND	P	Power Supply Ground.
A2	REFIN	AI	Buffered Reference Input. When using the internal reference buffer, drive REFIN with 4.096 V to 5 V (referred to ground). To disable the reference buffer, tie REFIN to ground and drive REF with 4.096 V to 5 V.
A3, B3	VDD_5V	P	5 V Power Supply. The range of VDD_5V depends on the reference value, 5.3 V to 5.5 V for a 5 V reference, and 4.75 V to 5.25 V for a 4.096 V reference. This pin has a 1 µF bypass capacitor inside the package.
A6	CNV	DI	Convert Input. A rising edge on this input powers up the device and initiates a new conversion. This signal must have low jitter to achieve the specified performance of the ADC. Logic levels are determined by the VIO pin.
A7	$\overline{\text{RST}}$	DI	Reset Input (Active Low). Asynchronous device reset.
A8, B8	VIO	P	Input/Output Interface Digital Power. Nominally, this pin is at the same supply as the host interface (1.8 V, 1.5 V, or 1.2 V). This pin has a 0.2 µF bypass capacitor inside the package. For VIO < 1.4 V, Bit IO2X of the output driver register must be set to 1.
B1	IN+	AI	Positive Analog Input.
B6, B7, C6, D6, E6, E7, F6, G6, H8	IOGND	P	VIO Ground. Connect to the same ground plane as all GND pins.
C1	IN−	AI	Negative Analog Input.
C7	SDO3	DO	Serial Data Output. The conversion result is output on this pin. It is synchronized to SCK.
C8	SDO1	DO	Serial Data Output. The conversion result is output on this pin. It is synchronized to SCK.
D2, D3, E2, E3	REF	AI	Optional Unbuffered Reference Input. Drive REF with 4.096 V to 5 V (referred to ground). This pin has a 2 µF bypass capacitor inside the package. When using the internal reference buffer, do not connect REF.
D7	SDO2	DO	Serial Data Output. The conversion result is output on this pin. It is synchronized to SCK.
D8	SDO0	DO	Serial Data Output. The conversion result is output on this pin. It is synchronized to SCK.
E8	BUSY_SCKOUT	DO	BUSY Indicator in SPI Clocking Mode. This pin goes high at the start of a new conversion and returns low when the conversion has finished. Logic levels are determined by the VIO pin. When SCKOUT is enabled, this pin function is either an echo of the incoming SCK from the host controller or a clock sourced by the internal oscillator.

PIN CONFIGURATION AND FUNCTION DESCRIPTIONS

Table 11. Pin Function Descriptions

Pin No.	Mnemonic	Type[1]	Description
F1	NIC		Not Internally Connected. These pins are not connected internally.
F7, F8, G7, G8	DNC		Do Not Connect to These Pins. They are internally connected to digital output drivers in high-Z mode.
G1	NIC		Not Internally Connected. These pins are not connected internally.
G3, H3	VDD_1.8V	P	1.8 V Power Supply. The range of VDD_1.8V is 1.71 V to 1.89 V. This pin has a 1 µF bypass capacitor inside the package.
H5	$\overline{CS}$	DI	Chip Select Input (Active Low).
H6	SDI	DI	Serial Data Input.
H7	SCK	DI	Serial Data Clock Input. When the device is selected ($\overline{CS}$ = low), the conversion result is shifted out by this clock.

[1] AI is analog input, P is power, DI is digital input, and DO is digital output.

TYPICAL PERFORMANCE CHARACTERISTICS

VDD_5V = 5.4 V, VDD_1.8V = 1.8 V, VIO = 1.8V, REFIN = 5 V, input common mode = 2.5 V, f_S = 2 MSPS for the AD4030-24 or 500 kSPS for the AD4032-24, and all specifications T_{MIN} to T_{MAX}, unless otherwise noted. Typical values are at T_A = 25°C.

TERMINOLOGY

INTEGRAL NONLINEARITY ERROR (INL)

INL is the deviation of each individual code from a line drawn from negative full scale through positive full scale. The point used as negative full scale occurs ½ LSB before the first code transition. Positive full scale is defined as a level 1½ LSB beyond the last code transition. The deviation is measured from the middle of each code to the true straight line (see Figure 40).

DIFFERENTIAL NONLINEARITY ERROR (DNL)

In an ideal ADC, code transitions are 1 LSB apart. DNL is the maximum deviation from this ideal value. It is often specified in terms of resolution for which no missing codes are guaranteed.

ZERO ERROR (ZE)

Zero error is the difference between the ideal midscale voltage, 0 V, and the actual voltage producing the midscale output code, 0 LSB.

GAIN ERROR (GE)

The first transition (from 100 ... 00 to 100 ... 01) occurs at a level ½ LSB above nominal negative full scale. The last transition (from 011 … 10 to 011 … 11) occurs for an analog voltage 1½ LSB below the nominal full scale. The gain error is the deviation of the difference between the actual level of the last transition and the actual level of the first transition from the difference between the ideal levels.

SPURIOUS-FREE DYNAMIC RANGE (SFDR)

SFDR is the difference, in decibels (dB), between the rms amplitude of a full-scale input signal and the peak spurious signal.

EFFECTIVE NUMBER OF BITS (ENOB)

ENOB is a measurement of the resolution with a sine wave input. It is related to SINAD as follows: ENOB = (SINADdB − 1.76)/6.02. ENOB is expressed in bits.

TOTAL HARMONIC DISTORTION (THD)

THD is the ratio of the rms sum of the first five harmonic components to the rms value of a full-scale input signal and is expressed in decibels.

DYNAMIC RANGE (DR)

Dynamic range is the rms voltage of a full-scale sine wave to the total rms voltage of the noise measured. The value for dynamic range is expressed in decibels. It is measured with a signal at −60 dBFS so that it includes all noise sources and DNL artifacts.

SIGNAL-TO-NOISE RATIO (SNR)

SNR is the ratio of the rms voltage of a full-scale sine wave to the rms sum of all other spectral components below the Nyquist frequency, excluding harmonics and dc. The value for SNR is expressed in decibels.

SIGNAL-TO-NOISE-AND-DISTORTION (SINAD) RATIO

SINAD is the ratio of the rms voltage of a full-scale sine wave to the rms sum of all other spectral components that are less than the Nyquist frequency, including harmonics but excluding dc. The value of SINAD is expressed in decibels.

APERTURE DELAY

Aperture delay is the measure of the acquisition performance and is the time between the rising edge of the CNV input and when the input signal is held for a conversion.

TRANSIENT RESPONSE

Transient response is the time required for the ADC to acquire a full-scale input step to ±1 LSB accuracy.

COMMON-MODE REJECTION RATIO (CMRR)

CMRR is the ratio of the power in the ADC output at the frequency, f, to the power of a 4.5 V p-p sine wave applied to the input common-mode voltage of frequency, f.

$$CMRR \text{ (dB)} = 10\times \log(P_{ADC\_IN}/P_{ADC\_OUT})$$

where:
P_{ADC_IN} is the common-mode power at the frequency, f, applied to the inputs.
P_{ADC_OUT} is the power at the frequency, f, in the ADC output.

POWER SUPPLY REJECTION RATIO (PSRR)

PSRR is the ratio of the power in the ADC output at the frequency, f, to the power of a 200 mV p-p sine wave applied to the ADC VDD supply of frequency, f.

$$PSRR \text{ (dB)} = 10 \times \log(P_{VDD\_IN}/P_{ADC\_OUT})$$

where:
P_{VDD_IN} is the power at the frequency, f, at the VDD pin.
P_{ADC_OUT} is the power at the frequency, f, in the ADC output.

THEORY OF OPERATION

Figure 39 shows the basic functions of the AD4030-24/AD4032-24 .

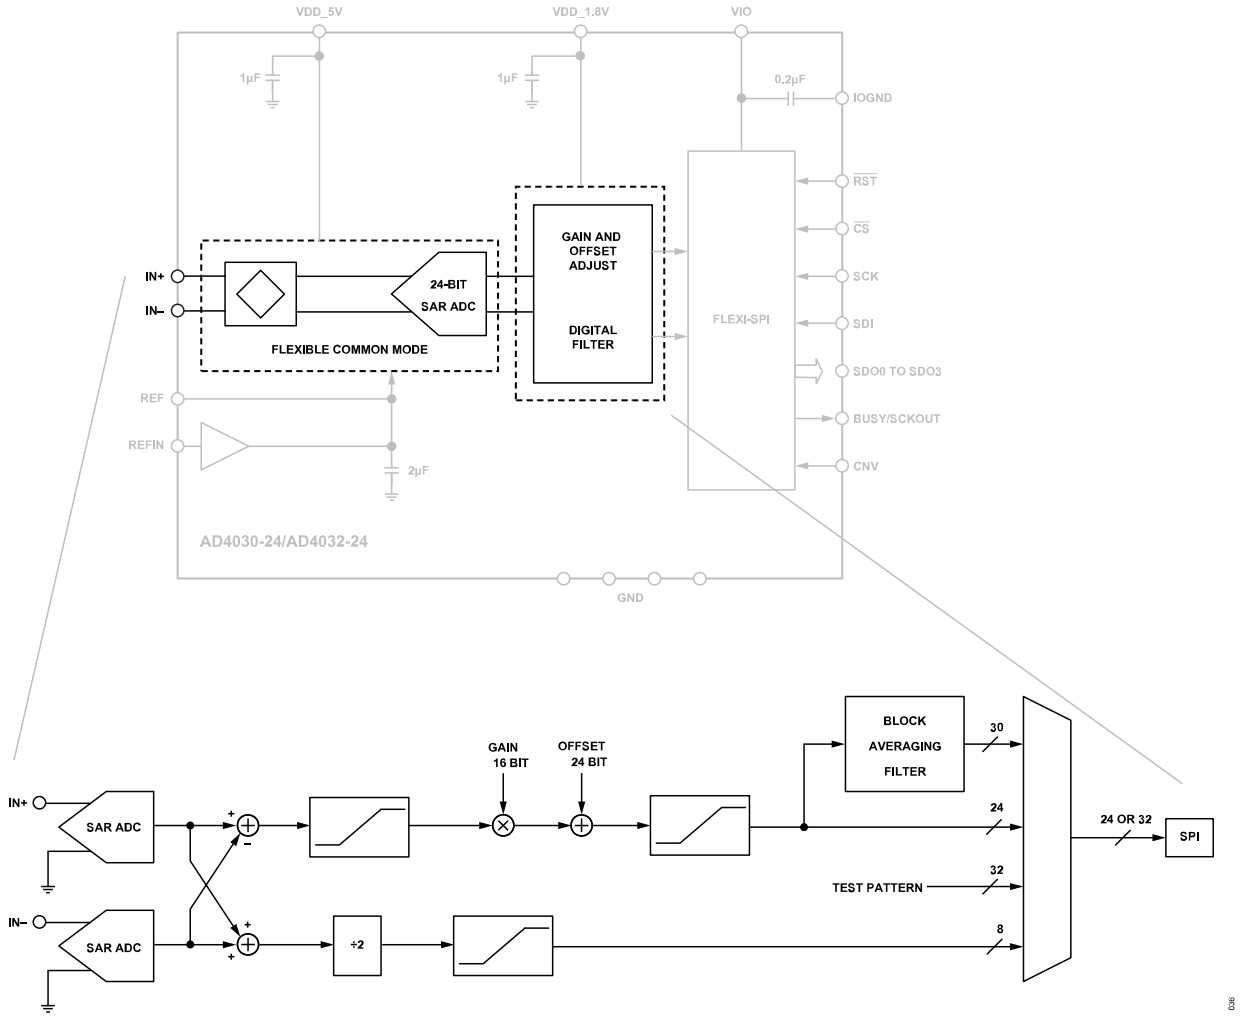

Figure 39. AD4030-24/AD4032-24 Functional Block Diagram and Signal Processing Architecture

OVERVIEW

The AD4030-24/AD4032-24 are low noise, low power, high speed, 24-bit successive approximation register (SAR) ADCs. The AD4030-24 is capable of converting 2,000,000 samples per second (2 MSPS), and the AD4032-24 is capable of converting 500,000 samples per second (500 kSPS). It offers several analog and digital features to ease system design. The analog features include a wide common-mode range that eases level shifting requirements as well as an extended fully differential input range of ±(65/64) × V_{REF}, easing the margin requirements on signal conditioning.

The AD4030-24/AD4032-24 have an integrated reference buffer with an integrated decoupling capacitor to minimize the external components on board. The on-chip track-and-hold circuitry does not exhibit any pipeline delay or latency, making this circuitry ideal for control loops and high speed applications. The digital features include offset correction, gain adjustment, and averaging, which offload the host processor. The user can configure the device for one of several output code formats (see the Summary of Selectable Output Data Formats section).

The AD4030-24/AD4032-24 use a Flexi-SPI, allowing the data to be accessed via multiple SPI lanes, which relaxes clocking requirements for the host SPI controller. An echo clock mode is also available to assist in data clocking, simplifying the use of isolated data interfaces. The AD4030-24/AD4032-24 has a valid first conversion after exiting power-down mode. The architecture achieves ±0.9 ppm INL maximum, with no missing codes at 24 bits and 108.4 dB SNR. The AD4030-24 dissipates only 30 mW at 2 MSPS.

CONVERTER OPERATION

The AD4030-24/AD4032-24 operate in two phases, acquisition phase and conversion phase. In the acquisition phase, the internal track-and-hold circuitry is connected to each input pin (IN+, IN−) and samples the voltage on each pin independently. Issuing a

THEORY OF OPERATION

rising edge pulse on the CNV pin initiates a conversion. The rising edge pulse on the CNV pin also asserts the BUSY signal to indicate a conversion in progress. At the end of the conversion, the BUSY signal is deasserted. The conversion result is a 24-bit code representing the input voltage difference and an 8-bit code representing the input common-mode voltage. Depending on the device configuration, this conversion result can be processed digitally and latched into the internal output register. The acquisition circuit on each input pin is also precharged to the previous sample voltage, which minimizes the kick-back charge to the input driver. The host processor retrieves the output code via the SDO pins that are internally connected to the internal output register.

TRANSFER FUNCTION

In the default configuration, the AD4030-24/AD4032-24 digitizes the full-scale difference voltage of 2 × V_{REF} into 2^{24} levels, resulting in an LSB size of 0.596 µV with V_{REF} = 5 V. Note that 1 LSB at 24 bits is approximately 0.06 ppm. The ideal transfer function is shown in Figure 40. The differential output data is in twos complement format. Table 12 summarizes the mapping of input voltages to differential output codes.

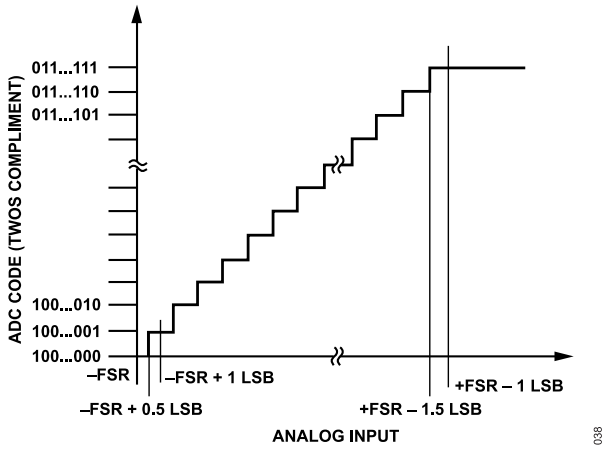

Figure 40. ADC Ideal Transfer Function for the Differential Output Codes (FSR Is Full-Scale Range)

Table 12. Input Voltage to Output Code Mapping

Description	Analog Input Voltage Difference	Digital Output Code (Twos Complement, Hex)
FSR − 1LSB	(8388607 × V_{REF})/(8388608)	0x7FFFFF
Midscale + 1LSB	V_{REF}/(8388608)	0x000001
Midscale	0 V	0x000000
Midscale − 1LSB	−V_{REF}/(8388608)	0xFFFFFF
−FSR + 1LSB	−(8388607 × V_{REF})/(8388608)	0x800001
−FSR	− V_{REF}	0x800000

ANALOG FEATURES

The AD4030-24/AD4032-24 has a precharging circuit as part of the internal track-and-hold circuitry, which charges the internal sampling capacitors to the previously sampled input voltage. This reduces the charge kickback, making the precharge circuit on the analog input of the AD4030-24/AD4032-24 easier to drive than other conventional SAR ADCs. The reduced kickback, combined with a longer acquisition phase, means reduced settling requirements on the driving amplifier. This combination also allows the use of larger resistor values, which are beneficial for improving amplifier stability. Furthermore, the bandwidth of the RC filter is reduced, resulting in lower noise and/or power consumption of the signal chain.

The common-mode voltage is not restricted except by the absolute voltage range for each input (from −1/128 × V_{REF} to 129/128 × V_{REF}). The analog inputs can be modeled by the equivalent circuit shown in Figure 41. In the acquisition phase, each input pin has approximately 116 pF input capacitance (C_{IN}) from the sampling capacitor in series with 19 Ω on resistance (R_{ON}) of the sampling switch. During conversion phase, each input has the capacitance of the input pin (C_{PIN}), which is about 4 pF. Any signal that is common to both inputs is reduced by the common-mode rejection of the ADC. During conversion, the analog inputs draw only a small leakage current.

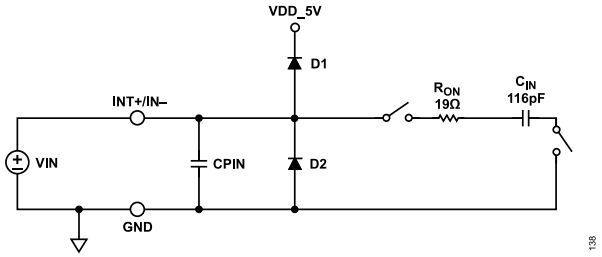

Figure 41. Equivalent Circuit for the AD4030-24/AD4032-24 Differential Analog Input

Each input is sampled independently. The conversion results do not saturate assuming each of the inputs are within the specified full-scale input range. Note that digital domain saturation occurs if the digital offset and digital gain parameters are configured to map the conversion result to numeral values that exceed the full-scale digital range (-2^{23} to $+2^{23}-1$ for the 24-bit word). An input voltage difference up to ±(65/64) × V_{REF} can be captured and converted without saturation by setting the digital gain parameter to a value < 1.

The slew rate at the analog input pins must be less than 400 V/µs during the acquisition phase and less than 30 V/µs at the sampling moment to ensure good performance. This can be ensured by choosing values for the external RC circuit that allow the RC time-constant to be more than 12.5 ns (R × C > 12.5e-9).

DIGITAL SAMPLE PROCESSING FEATURES

The AD4030-24/AD4032-24 supports several digital and data processing features that can be applied to the signal samples. These features are enabled and disabled via the control registers of the AD4030-24/AD4032-24. Figure 39 contains a signal processing architecture block diagram showing the available digital and data processing features.

THEORY OF OPERATION

Full-Scale Saturation

The conversion results saturate digitally (before any post-processing) when either or both inputs exceed the analog limits specified herein. After applying offset and gain scaling, the results are truncated to 24-bit representation (saturating at maximum 0x7FFFFF and minimum 0x800000). Care must be taken to avoid unintentional saturation, especially when applying digital offset and/or gain scaling. See the Digital Offset Adjust and Digital Gain sections for more details on the use of these features.

Common-Mode Output

When the host controller writes 0x1 or 0x2 to the OUT_DATA_MD bit field of the modes register (see the Modes Register section), an 8-bit code representing the input common-mode voltage is appended to the 16-bit or 24-bit code representing the input voltage difference. The LSB size of the 8-bit code is $V_{REF}/256$. The 8-bit code saturates at 0 and 255 when the common mode input voltage is 0 V and V_{REF}, respectively. The 8-bit code is not affected by digital offset and gain scaling, which is applied only to the code representing the input voltage difference.

Block Averaging

The AD4030-24/AD4032-24 provide a block averaging filter (SINC1) with programmable block length 2^N, N = 1, 2, 3, …, 16. The filter is reset after processing each block of 2^N samples. The filter is enabled by writing 0x3 to the OUT_DATA_MD bit field of the modes register (see the Modes Register section) as well as a value (1 ≤ N ≤ 16) to the AVG_VAL bit field in the averaging mode register (see the Averaging Mode Register section). In this configuration, the output sample word is 32 bits. The 30 most significant bits (MSBs) represent the numerical value of the 24-bit codes averaged in blocks of 2^N samples. The automatic scaling allows the 24 MSBs of the 30-bit code are equal to the 24-bit codes when averaging blocks of constant values. The 31st bit (OR) is an overrange warning bit that is high when one or more samples in the block are subject to saturation. The 32nd bit (SYNC) is high once every 2^N conversion cycles to indicate when the average values are updated at the end of each block of samples. See the Digital Sample Processing Features section for more information.

The effective data rate in averaging mode is $f_{CNV}/2^N$. The reset value of N in the AVG_VAL bit field is 0x00 (no averaging). Figure 57 shows an example timing diagram in averaging mode. Figure 42 shows the frequency response of the filter for an N = 1, 2, 3, 4, 5.

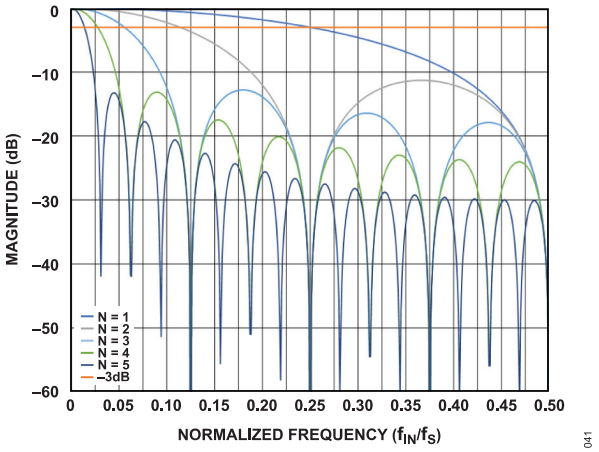

Figure 42. Frequency Response Examples for the Block Averaging Filter

Digital Offset Adjust

The ADC can be programmed to add a 24-bit signed offset value to the sample data (see the Register Details section). When adding an offset to the samples, it is possible to cause the sample data to saturate numerically. The user must take this into account when using the offset feature. The default value is 0x000000. See the Offset Registers section for more details.

Digital Gain

The ADC can be programmed to apply a 16-bit unsigned digital gain (Register 0x1C and Register 0x1D) to the digital samples (see the Register Details section). The gain is applied to each sample based on the following equation:

$$Code_{OUT} = Code_{IN} \times (USER\_GAIN/0x8000)$$

where:

0x0000 ≤ USER_GAIN ≤ 0xFFFF.

The effective gain range is 0 to 1.99997. Note that applying gain to the samples may cause numerical saturation. The default value is 0x8000 (gain = 1). To measure input voltage differences exceeding $\pm V_{REF}$, set the gain less than the unity to avoid the numerical saturation of the 24-bit, 16-bit, or 30-bit output differential codes. See the Gain Registers section for more details.

Test Pattern

To facilitate functional testing and debugging of the SPI, the host controller can write a 32-bit test pattern to the AD4030-24/AD4032-24 (see the Test Pattern Registers section). The value written to the test pattern registers is output using the normal sample cycle timing. The 32-bit test pattern output mode is enabled by writing 0x4 to the OUT_DATA_MD bit field of the modes register (see the Modes Register section). The default value stored in the test pattern registers is 0x5A5A0F0F.

THEORY OF OPERATION

Summary of Selectable Output Data Formats

Figure 43 summarizes the output data formats that are available on the AD4030-24/AD4032-24, which are selected in the modes register (see the Modes Register section). Note that the OR and SYNC flags are each 1-bit.

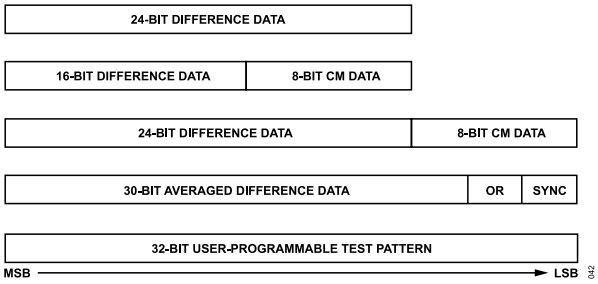

Figure 43. Summary of Selectable Output Sample Formats

APPLICATIONS INFORMATION

TYPICAL APPLICATION DIAGRAMS

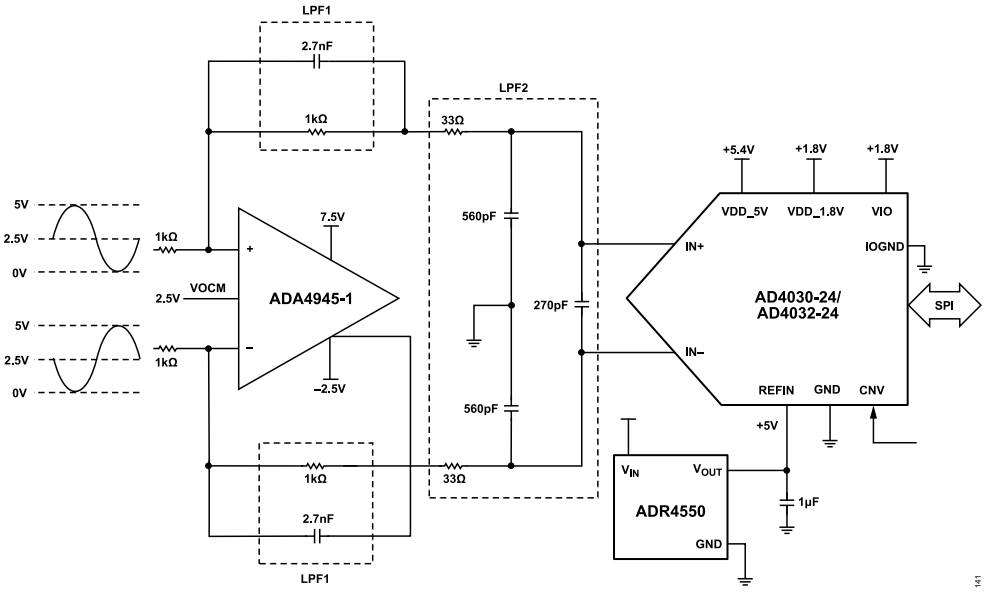

Figure 44. Differential Driver Analog Front End

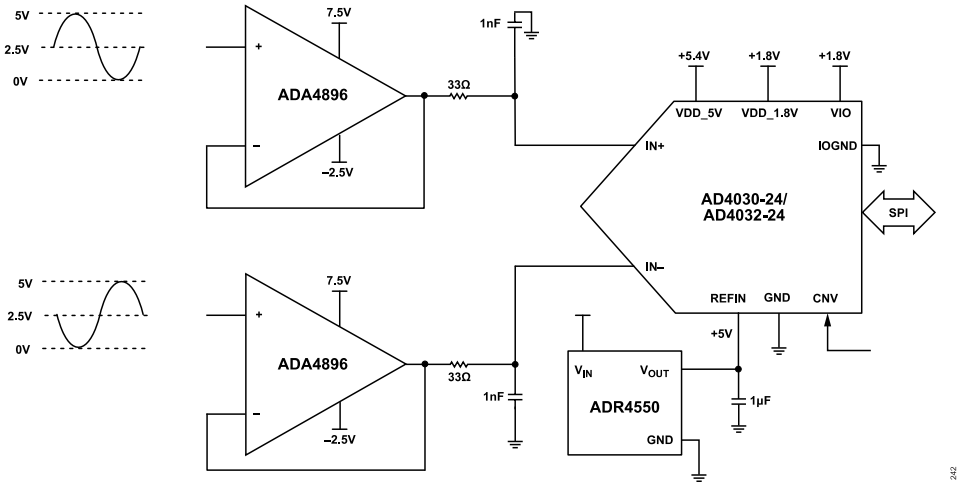

Figure 45. Unity Gain Dual Buffer Configuration

ANALOG FRONT-END DESIGN

Driver Amplifier Choice

Figure 44 shows two examples for driving the AD4030-24/AD4032-24. Either can be combined with an upstream stage that provides additional signal conditioning. Both can accommodate single-ended or differential inputs. To take advantage of the SNR and THD performance of the AD4030-24/AD4032-24, it is important to choose a driver amplifier that has low enough noise and THD sufficient to meet the application requirements. In addition to the amplifiers shown in Figure 44, the LTC6227 is another driver option. Analog Devices offers several companion driver amplifiers that can be found on the ADC drivers web page.

REFERENCE CIRCUITRY DESIGN

The AD4030-24/AD4032-24 require an external reference to define its input range. This reference must be 4.096 V to 5 V. An optimal choice for the reference is the ADR4550 or ADR4540. These ADCs have several features that reduce the charge pulled from the reference, making the AD4030-24/AD4032-24 much easier to use than other ADCs. For most applications, the reference can drive the REFIN pin, which has an internal precision buffer that isolates the reference from the ADC circuitry. The buffer has a high input impedance and small input current (5 nA typical) that allows multiple ADCs to share a common reference. An RC circuit between the reference and the REFIN pin can be used to filter

APPLICATIONS INFORMATION

reference noise (see Figure 46). Suggested values are 100 Ω < R < 1 kΩ, and C ≥ 10 µF.

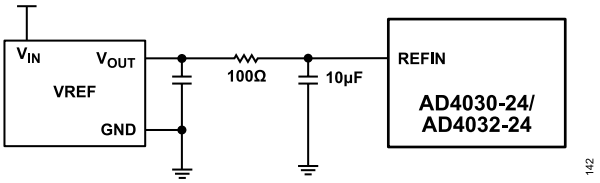

Figure 46. Reference with Noise Filter

For the best possible gain error, the internal buffer can be disabled (REFIN = 0 V) and an external reference can be used to drive the REF pins. The current drawn by the REF pins is small (<2 µA) and depends on the sample rate and output code (see Figure 30). An internal 2 µF capacitor on the REF pins provides optimal reference bypassing and simplifies PCB design by reducing component count and layout sensitivity.

In applications where a burst of samples is taken after idling for long periods, as shown in Figure 47, the reference current (I_{REF}) quickly goes from approximately 0 µA to a maximum of 1.8 µA at 2 MSPS from approximately 0 µA to 0.5 µA at 500 kSPS. This step in dc current draw triggers a transient response in the reference that must be considered because any deviation in the reference output voltage affects the accuracy of the output code. If the reference is driving the REFIN pins, the internal buffer is able to handle these transitions (see Figure 28). When the REF pins are being driven with no external buffer, and the transient response of the reference is important, the fast settling LTC6655LN-5 reference is recommended.

Figure 47. CNV Waveform Showing Burst Sampling

APPLICATIONS INFORMATION

DEVICE RESET

The AD4030-24/AD4032-24 provide two options for performing a device reset using the serial interface. A hardware reset is initiated by pulsing the voltage on the $\overline{RST}$ pin low. A software reset is initiated by setting both the SW_RESET and SW_RESETX bits in the Interface Configuration A register to 1 in the same write instruction (see the Interface Configuration A Register section).

Performing a hardware or software reset asserts the RESET_OCCURRED bit in the digital diagnostics register (see the Digital Diagnostics Register section). The RESET_OCCURRED bit is cleared by writing the bit with a 1. RESET_OCCURRED can be used by the digital host to confirm that the AD4030-24/AD4032-24 has executed a device reset.

The AD4030-24/AD4032-24 is designed to generate a power-on reset (POR) when VDD_5V and VDD_1.8V are first applied. A POR resets the state of the user configuration registers and asserts the RESET_OCCURRED bit. If VDD_5V or VDD_1.8V drops to less than its specified operating range, a POR occurs. It is recommended to perform a hardware or software reset after a POR.

Figure 48 shows the timing diagram for performing a device reset using the $\overline{RST}$ input. The minimum $\overline{RST}$ pulse width is 50 ns, represented by $t_{RESETPW}$ in Figure 48 and Table 1. A reset must be performed no sooner than 3 ms after the power supplies are valid and stable (this delay is represented by t_{RESET_DELAY} in Figure 48 and Table 1).

After a hardware or software reset, no SPI commands or conversions can be started for 750 µs.

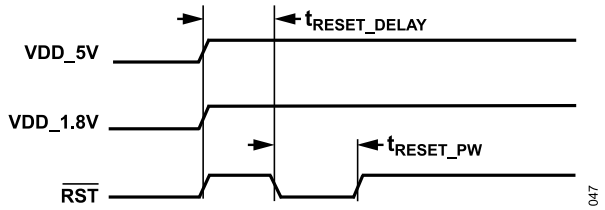

Figure 48. Power-On Reset (POR) Timing

POWER SUPPLIES

The AD4030-24/AD4032-24 do not have any specific power supply sequencing requirements. Care must be taken to adhere to the maximum voltage relationships described in the Absolute Maximum Ratings section. The voltage range for the VDD_5V supply depends on the chosen reference voltage (see the Specifications table, Internal Reference Buffer, or Externally Overdriven Reference). Figure 49 shows the minimum and maximum values for VDD_5V with respect to REFIN and REF. VDD_5V voltage values more than the maximum or less than the minimum result in either damage to the device or degraded performance.

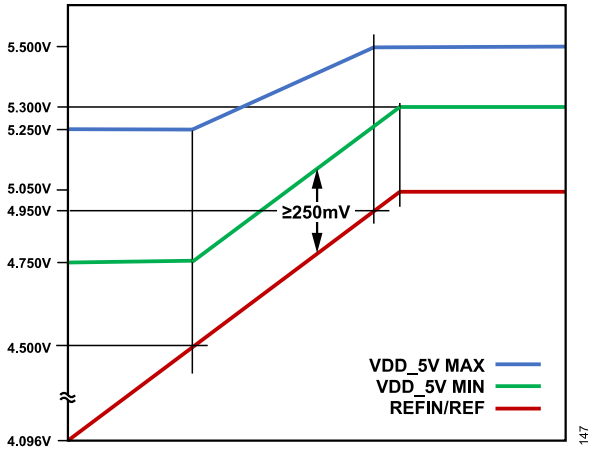

Figure 49. VDD_5V Minimum and Maximum Values for REFIN/REF

The AD4030-24/AD4032-24 have a POR circuit that resets the AD4030-24/AD4032-24 at initial power-up or whenever VDD_5V or VDD_1.8V drops to less than its specified operating range.

Note that the VDD_5V and the VDD_1.8V supplies have internal 1 µF bypass capacitors inside the package, while VIO has an internal 0.2 µF bypass capacitor. These internal capacitors reduce bill of materials (BOM) count and solution size. If the bulk supply bypass capacitors are not close to the ADC, external capacitors can be added next to the ADC. The minimum rise time for all supplies is 100 µs.

Power Consumption States

During a conversion, the power consumption rate of the AD4030-24/AD4032-24 is at its highest. When the conversion is complete, it enters a standby state and much of the internal circuitry is powered down, and current consumption drops to less than 20% relative to the conversion state. To ensure full accuracy, some circuitry, including the reference buffer, remains powered on during the standby state.

The device can be placed into a lower power shutdown state during periods when the convert clock is idle by writing 0x3 to the OPERATING_MODES bit field of the device configuration register (see the Device Configuration Register section) . The default value of this bit field is [00] for normal operating mode. In the shutdown state, the current consumption typically drops to less than 10 µA.

Shutdown Mode

When the ADC enters shutdown mode, the internal reference buffer is disabled and a 500 Ω switch connects the REFIN pins to the REF pin (unless the REFIN pin is grounded and the REF pins are externally driven). This keeps the 2 µF capacitor on the REF pins charged up to allow fast recovery when the ADC exits shutdown mode. Because of this keep-alive switch, there is some charge injected to the REFIN pin when the ADC enters shutdown mode

APPLICATIONS INFORMATION

(400 pC) and exits shutdown mode (5 pC). When exiting shutdown mode, the REF pins are accurate after 30 µs.

SERIAL INTERFACE

The AD4030-24/AD4032-24 support a multilane SPI serial digital interface with a common bit clock (SCK). The flexible VIO pins supply allows the AD4030-24/AD4032-24 to communicate with any digital logic operating between 1.2 V and 1.8 V. However, for the VIO pins levels less than 1.4 V, the IO2X bit in the output driver register must be set to 1 (see the Output Driver Register section). The serial output data is clocked out on up to 4 SDO lanes (see Figure 50). An echo clock mode that is synchronous with the output data is available to ease timing requirements when using isolation on the digital interface. A host clock mode is also available and uses an internal oscillator to clock out the data bits. The SPI Clocking Mode section, Echo Clock Mode section, Host Clock Mode section, Single Data Rate section, Dual Data Rate section, 1-Lane Output Data Clocking Mode section, 2-Lane Output Data Clocking Mode section, 4-Lane Output Data Clocking Mode section, and Data Output Modes Summary section describe the operation of the AD4030-24/AD4032-24 SPI.

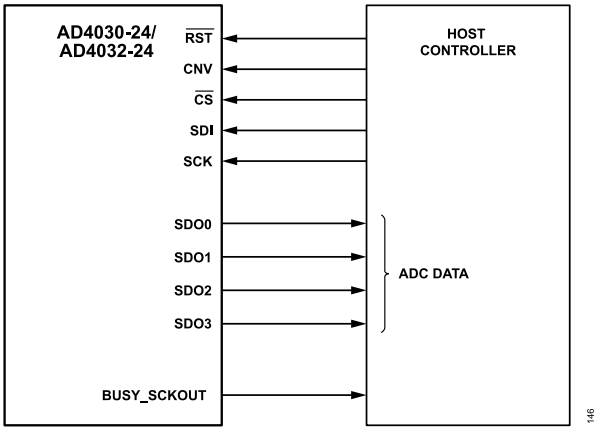

Figure 50. AD4030-24/AD4032-24 Multilane SPI

SPI SIGNALS

The SPI is a multilane interface that is used to both configure the ADC as well as retrieve sampled data. It consists of the following signals:

- $\overline{CS}$ (input) (chip select). $\overline{CS}$ must be set to low to initiate and enable a data transfer to or from the SDI pins or SDOx pins of the ADC. $\overline{CS}$ timing for reading sample data can be moderated by observing the state of the BUSY pin. For echo clock mode and host clock mode, $\overline{CS}$ timing must be controlled by the host processor because the BUSY_SCKOUT pin is used as the bit clock output for these clocking modes.
- SDI (input). Serial data input stream from the host controller to the ADC. The SDI signal is only used when writing data into one of the user registers of the AD4030-24/AD4032-24.
- CNV (input). The CNV signal is sourced by the host controller and initiates a sample conversion. The frequency of the CNV signal determines the sampling rate of the AD4030-24/AD4032-24. The maximum frequency of the CNV clock is 2 MSPS.
- SCK (input). Serial data clock sourced by the host controller. The maximum SCK rate supported for output data transfer is 100 MHz. For register reads and writes, the maximum SCK rate is 86 MHz for the VIO pins > 1.71 V, and 81 MHz for 1.14 V ≤ the VIO pins < 1.71 V.
- SDO0 through SDO3 (outputs). Data lanes to the host controller. The number of active data lanes can be either 1, 2, or 4 lanes (see Table 14). The number of data lanes is configured in the Modes Register section.
- BUSY_SCKOUT (output). The behavior of the BUSY_SCKOUT pin is dependent on the selected clocking mode. Table 13 defines the behavior of the BUSY_SCKOUT pin for each clocking mode.

Table 13. BUSY_SCKOUT Pin Behavior vs. Clocking Mode

Clocking Mode	Behavior
SPI Clocking Mode	Valid BUSY_SCKOUT pin signal for the ADC conversion status. The busy signal on the BUSY_SCKOUT pin goes high when a conversion is triggered by the CNV signal. The busy signal on the BUSY_SCKOUT pin goes low when the conversion is complete.
Echo Clock Mode	Bit clock. The BUSY_SCKOUT pin is a delayed version of SCK input.
Host Clock Mode	Bit clock. The BUSY_SCKOUT pin sources the clock signal from the internal oscillator.

Register Access Mode

The AD4030-24/AD4032-24 offer programmable user registers that are used to configure the device as outlined in the Registers section. By default, at power-up, the device is in conversion mode. Therefore, to access the user registers, a special access command must be sent by the host controller over the SPI, as shown in Figure 5. When this register access command is sent over the SPI, the device enters the register configuration mode. To read back the values from one of the user registers listed in the Registers section, the host controller must send the pattern shown in Figure 4. To write to one of the user registers, the host controller must send the pattern shown in Figure 3. In either case (read/write), the host controller must always issue 24 clock pulses on SCK line and pull $\overline{CS}$ low for the entire transaction.

After writing to/reading from the appropriate user registers, the host controller must exit the register configuration mode by writing 0x01 to register address 0x0014 as detailed in the EXIT configuration mode register. An algorithm for register read/write access is as follows:

1. Perform a read back from a dummy register address 0x3FFF, to enter the register configuration mode.
2. Read back from or write to the desired user register addresses.
3. Exit the register configuration mode by writing 0x01 to register address 0x0014. Exiting register configuration mode causes the register updates to take effect.

SERIAL INTERFACE

Stream Mode

The AD4030-24/AD4032-24 also offer a way to perform bulk register read/write transactions, while the AD4030-24/AD4032-24 is in register configuration mode. To perform bulk read/write registers transactions, $\overline{CS}$ must be kept low and SCK pulses must be issued in multiples of 8 as each register is only one byte (8 bits) wide. In stream mode, only address decrementing is allowed, meaning that the user can read back from/write to the initial register address and register addresses that are directly below the initial register address. It is recommended that register accesses in stream mode be applied to register blocks with contiguous addresses. However, it is possible to address registers that are not present in the register map. To do so, simply write all zeros to these registers, or, when reading back, simply discard the contents read from these registers, since it is random data. See the Registers section to see which register address is valid and continuous. For example, to read back a 24-bit offset value in one shot, the user must issue 24 SCK pulses starting from Register Address 0x0018. Figure 51 shows timing diagram for bulk read starting at a given address.

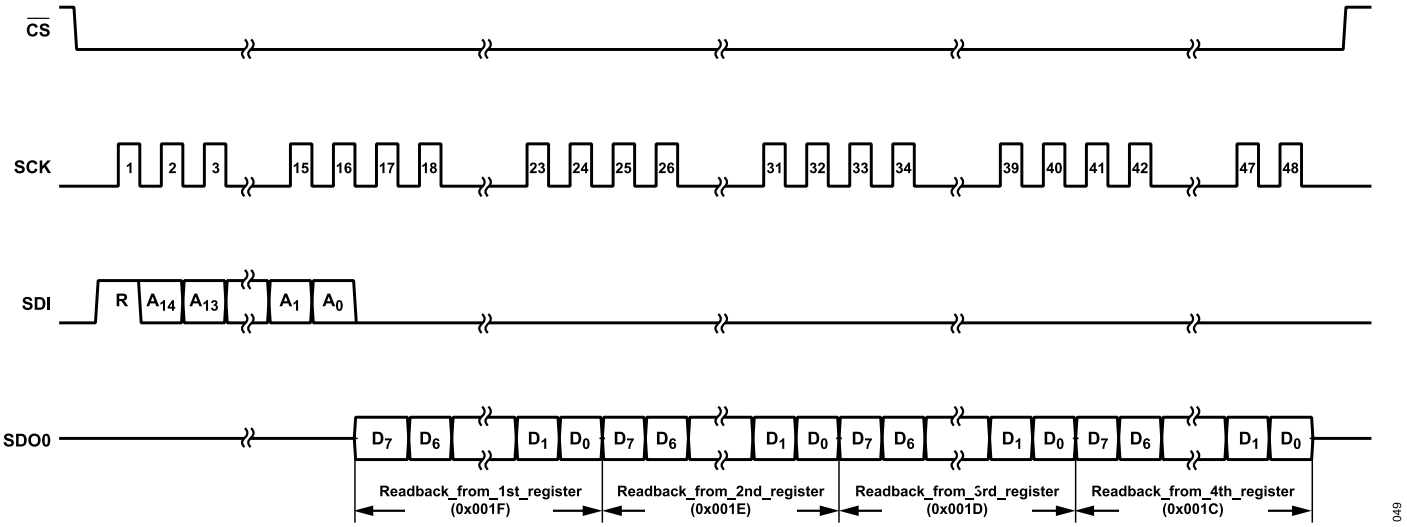

Figure 51. Stream Mode Bulk Register Read Back Operation

SERIAL INTERFACE

SAMPLE CONVERSION TIMING AND DATA TRANSFER

A conversion is started on the rising edge of the CNV signal, as shown in Figure 52. Once the conversion is complete, $\overline{CS}$ can be asserted, which causes the current conversion result to be loaded into the output shift register.

Referring to Figure 52, there are two optional data transfer zones for sample N. Zone 1 represents the use case where $\overline{CS}$ is asserted immediately following the de-assertion of BUSY signal for the sample N conversion (in SPI conversion mode), or after 300 ns for echo and host clock modes. For Zone 1, the available time to read out sample N is given by the following:

Zone 1 Data Read Window = $t_{CYC} - t_{CONV} - t_{QUIET\_CNV\_ADV}$

For example, if f_{CNV} is 2 MSPS (t_{CYC} = 500 ns) and using the typical value of t_{CONV} (282 ns), the available window width is 198.4 ns (= 500 ns – 282 ns – 19.6 ns).

Zone 2 represents the case where assertion of $\overline{CS}$ to read Sample N is delayed until after the conversion for Sample N + 1 is initiated.

To prevent data corruption, a quiet zone must be observed before and after each rising edge of the CNV signal, as shown in Figure 52. The quiet zone immediately before the rising edge of CNV is $t_{QUIET\_CNV\_ADV}$ and is equal to 19.6 ns. The quiet zone immediately after the rising edge of CNV is $t_{QUIET\_CNV\_DELAY}$ and is equal to 9.8 ns. Assuming that the $\overline{CS}$ is asserted immediately after the quiet zone around the rising edge of CNV, the amount of time available to clock out the data is the following:

Zone 2 Data Read Window = $t_{CYC} - t_{QUIET\_CNV\_DELAY} - t_{QUIET\_CNV\_ADV}$

For example, if f_{CNV} is 2 MSPS (t_{CYC} = 500 ns) and using the typical value of t_{CONV} (282 ns), the available window width is 470.6 ns (= 500 ns – 9.8 ns – 19.6 ns). The Zone 2 transfer window is longer than the Zone 1 window, which can enable the use of a slower SCK on the SPI and ease the timing requirements for the interface. When using Zone 2 for the data transfer, it is recommended to assert $\overline{CS}$ immediately after the quiet zone. However, Zone 2 must be asserted at least 25 ns before the falling edge of BUSY for Sample N + 1. If not, Sample N is overwritten with Sample N + 1.

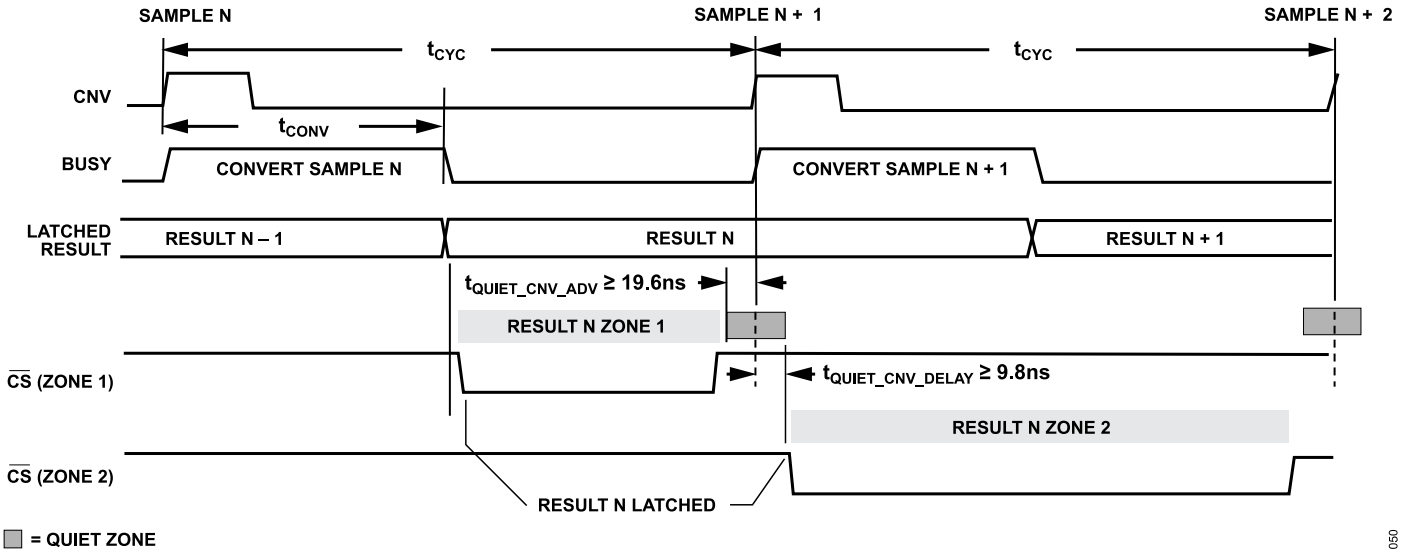

Figure 52. Example Timing for Data Transfer Zones

SERIAL INTERFACE

CLOCKING MODES

This section covers the various clocking modes supported by the AD4030-24/AD4032-24 SPI. These modes are available for 1-lane, 2-lanes, and 4-lanes. The clocking mode is configured in the modes register (see Table 16 for register descriptions).

SPI Clocking Mode

SPI clocking mode is the default clocking mode of the AD4030-24/AD4032-24 and is equivalent to a host-sourced bit clock (SCK), in which the host controller uses its own clock to latch the output data. The SPI-compatible clocking mode is enabled by writing 0x0 to the CLK_MD bit field of the modes register (see the Modes Register section). The interface connection is as shown in Figure 50. In this mode, the BUSY_SCKOUT pin signal is valid and indicates the completion of a conversion (high to low transition of the BUSY_SCKOUT pin). A simplified sample cycle is shown in Figure 53. When not in averaging mode, if the host controller does not use the BUSY_SCKOUT pin signal to detect the completion of a conversion and instead uses an internal timer to retrieve the data, the host controller must wait at least 300 ns after the rising edge of the CNV pulse before asserting $\overline{CS}$ low. When operating in block averaging mode, the host controller must assert $\overline{CS}$ low no sooner than 300 ns after the rising edge of the CNV pulse for the last sample in the block.

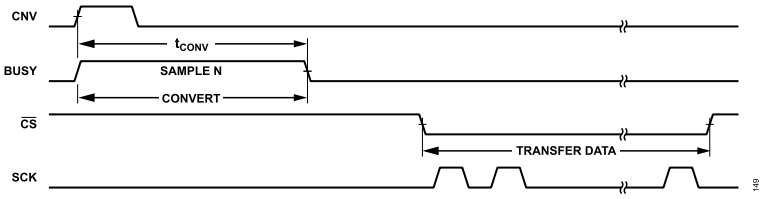

Figure 53. Typical Sample Cycle for SPI Clocking Mode

SERIAL INTERFACE

Echo Clock Mode

Figure 54 shows the signal connections for the echo clock mode. The echo clock mode is enabled by writing 0x1 to the CLK_MD bit field of the modes register (see the Modes Register section). In this mode, the BUSY_SCKOUT pin cannot be used to detect a conversion completion. The BUSY_SCKOUT pin becomes a bit clock output and is sourced by looping through the SCK of the host controller to the BUSY_SCKOUT pin (with some fixed delay, 5.4 ns to 7.9 ns, depending on the voltage of the VIO pins). To begin retrieving the conversion data in nonaveraging mode, the host controller must assert $\overline{CS}$ low no sooner than 300 ns after the rising edge of the CNV pulse. When the ADC is configured for block averaging mode, the host controller must assert $\overline{CS}$ low no sooner than 300 ns after the rising edge of the CNV pulse for the last sample in the block. Example timing diagrams are shown in the Data Clocking Requirements and Timing section. When echo clock mode is enabled, the BUSY_SCKOUT pin is aligned with the SDOx pins transitions, making the data and clock timing insensitive to asymmetric propagation delays in the paths of the SDOx pins and SCK pins.

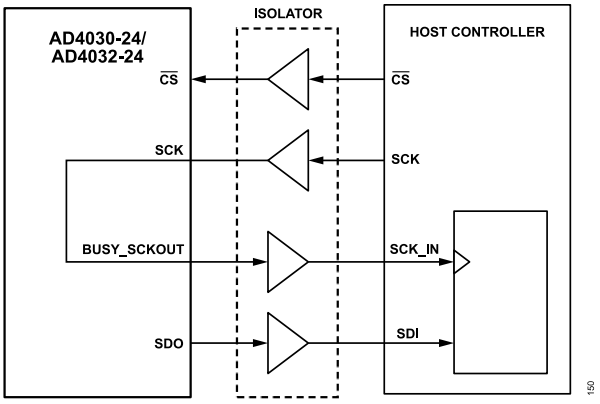

Figure 54. Echo Clock Mode Signal Path Diagram

Host Clock Mode

When enabled, host clock mode uses the internal oscillator as the bit clock source. The host clock mode is enabled by writing 0x2 to the CLK_MD bit field of the modes register. The bit clock frequency can be programmed in the OSC_DIV bit field in the internal oscillator register, with available divisor values of 1, 2, or 4 (see the Internal Oscillator Register section). Figure 55 shows the signal connections for the host clock mode. In this mode, the BUSY_SCKOUT pin provides the bit clock output and cannot be used to detect a conversion completion. The AD4030-24/AD4032-24 automatically calculate the number of clock pulses required to clock out the conversion data based on word size, number of active lanes, and choice of single data rate mode or dual data rate mode. The number of clock pulses can be read from the OSC_LIMIT bit field of the internal oscillator register. The SCK_IN from the host must not be active. When retrieving the conversion data in nonaveraging mode, the host must not assert $\overline{CS}$ low sooner than 300 ns after the rising edge of the CNV pulse. When the ADC is configured in averaging mode for 2^N averages, the host must not assert $\overline{CS}$ low sooner than 300 ns after the rising edge of the CNV pulse for the last sample in the block.

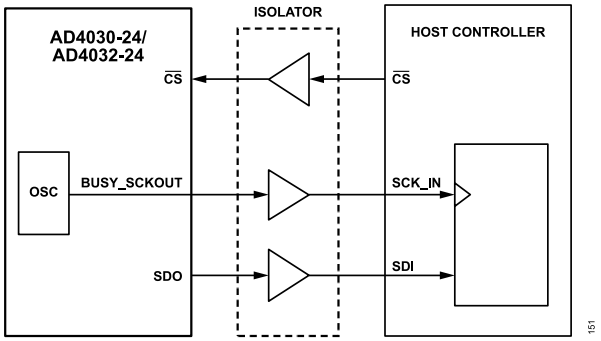

Figure 55. Host Clock Mode Signal Path Example

Single Data Rate

Single data rate clocking (SDR), in which one bit (per active lane) is clocked out during a single clock cycle, is supported for all output configurations and sample formats (see Table 14). The SDR clocking mode is enabled by default at power-up or can be enabled by writing 0 to the DDR_MD bit of the modes register (see the Modes Register section).

Dual Data Rate

Dual data rate (DDR) mode (two data bit transitions per clock cycle per active lane) is available only for host clock mode and echo clock mode.

The DDR clocking mode is enabled by writing 1 to the DDR_MD bit of the modes register (see the Modes Register section). The DDR mode uses half the number of SCK pulses to clock out conversion data in comparison to SDR mode.

1-Lane Output Data Clocking Mode

1-lane is the default output data clocking mode at power-up. The 1-lane output data clocking mode is enabled by writing 0x0 to the LANE_MD bit of the modes register (see the Modes Register section). The active lane is SDO0. Example timing diagrams for 1-lane mode using SPI clocking mode, echo clock mode, and host clock mode are in the Data Clocking Requirements and Timing section.

2-Lane Output Data Clocking Mode

When 2-lane output data clocking mode is enabled, the sample word bits are split between two SDO lanes. Figure 58 shows how the bits are allocated between the lanes for 2-lane mode. The bit arrangement is the same for SPI clock mode, echo clock mode, and host clock mode. 2-lane output data clocking mode is enabled by writing 0x1 to the LANE_MD bit of the modes register (see

SERIAL INTERFACE

the Modes Register section). The host controller must recombine the data coming from the SDO lanes to reconstruct the original sample word. The number of SCK pulses required to clock out the conversion data is reduced by one-half with respect to the 1-lane mode. Table 14 lists the active SDO lanes for 2-lane mode. Example timing diagrams for 2-lane mode using SPI clock mode, echo clock mode, and host clock mode are in the Data Clocking Requirements and Timing section.

4-Lane Output Data Clocking Mode

When 4-lane output data clocking mode is enabled, the sample word bits are split between four SDO lanes. Figure 59 shows how the bits are allocated between the lanes for 4-lane mode. The bit arrangement is the same for SPI clock mode, echo clock mode, and host clock mode. 4-lane output data clocking mode is enabled by writing 0x2 to the LANE_MD bit of the modes register (see the Modes Register section). The host controller must recombine the data coming from the SDO lanes to reconstruct the original sample word. The number of SCK pulses required to clock out the conversion data is reduced by one-fourth with respect to the 1-lane output data clocking. The active SDO lanes for 4-lane mode are shown in Table 14. Example timing diagrams for 4-lane mode using SPI clock mode, echo clock mode, and host clock mode are in the Data Clocking Requirements and Timing section.

Data Output Modes Summary

Table 14 is a summary of the supported data output modes of the AD4030-24/AD4032-24.

Table 14. AD4030-24/AD4032-24 Supported Data Output Modes

Number of Lanes	Active SDO Lanes	Clock Mode	Supported Data Clocking Mode	Output Sample Data-Word Length
1	SDO0	SPI	SDR only	24 or 32
		Echo	SDR and DDR	24 or 32
		Host	SDR and DDR	24 or 32
2	SDO0, SDO1	SPI	SDR only	24 or 32
		Echo	SDR and DDR	24 or 32
		Host	SDR and DDR	24 or 32
4	SDO0, SDO1, SDO2, SDO3	SPI	SDR only	24 or 32
		Echo	SDR and DDR	24 or 32
		Host	SDR and DDR	24 or 32

SERIAL INTERFACE

DATA CLOCKING REQUIREMENTS AND TIMING

Basic and Averaging Conversion Cycles

Figure 56 shows the basic conversion cycle for a single sample. This cycle applies to SPI clocking mode. When using echo clock mode and host clock mode, the BUSY_SCKOUT pin function is disabled and the bit clock is sourced on the BUSY_SCKOUT pin. The data transfer must meet the requirements described in the Sample Conversion Timing and Data Transfer section.

Table 15 contains the minimum and maximum values for the conversion timing parameters, which apply to all clocking modes.

Table 15. Conversion Cycle Timing Parameters

Parameter	Min	Max
t_{CNVH}	10 ns	No specific maximum
t_{CNVL}	20 ns	No specific maximum
t_{CONV}	264 ns	300 ns

The duration of the data transfer period is dependent on the sample resolution, number of active lanes, SCK frequency, and data clocking mode (SDR or DDR). The nominal value of the transfer duration is given by

$$Data\ \ Transfer\ \ Duration = t_{TRANS} = \frac{N_{BITS}}{M_{LANES}} \times \frac{1}{f_{SCK}} \times \frac{1}{K}\ \ seconds$$

where:
N_{BITS} = number of bits to clock out
M_{LANES} = number of lanes used to clock out the data (1, 2, or 4)
f_{SCK} = SCK clock frequency, in Hz
K = 1 (SDR only, DDR not available for SPI mode clocking)

For a given f_{SCK}, number of data lanes, sample word size, and SDR/DDR mode, the minimum sample period when using Zone 1 for the data transfer is as follows:

Minimum Zone 1 Sample Period:

$$t_{CYC} \geq \left(\frac{N_{BITS}}{M_{LANES} \times f_{SCK} \times K}\right) + t_{CONV} + t_{QUIET\_CNV\_ADV}$$

The minimum sample period when using Zone 2 for data transfer is as follows:

$$t_{CYC} \geq \left(\frac{N_{BITS}}{M_{LANES} \times f_{SCK} \times K}\right) + t_{QUIET\_CNV\_DELAY} + t_{QUIET\_CNV\_ADV}$$

Figure 57 shows a typical conversion cycle when the averaging mode is active and SPI clocking mode is being used. The BUSY signal is asserted for a number of CNV clock periods that are equal to the configured number of samples to be averaged. The averaged sample is available when the BUSY signal is deasserted. Like nonaveraged mode, if the configured clocking mode is either echo clock or host clock, the BUSY signal is replaced by the output bit clock (SCKOUT). The host controller must manage the timing for asserting $\overline{CS}$.

4-Lane, SDR Mode

Figure 59 shows a conversion cycle for 4-lane data output using SDR clocking mode. See the 4-Lane Output Data Clocking Mode section for more information.

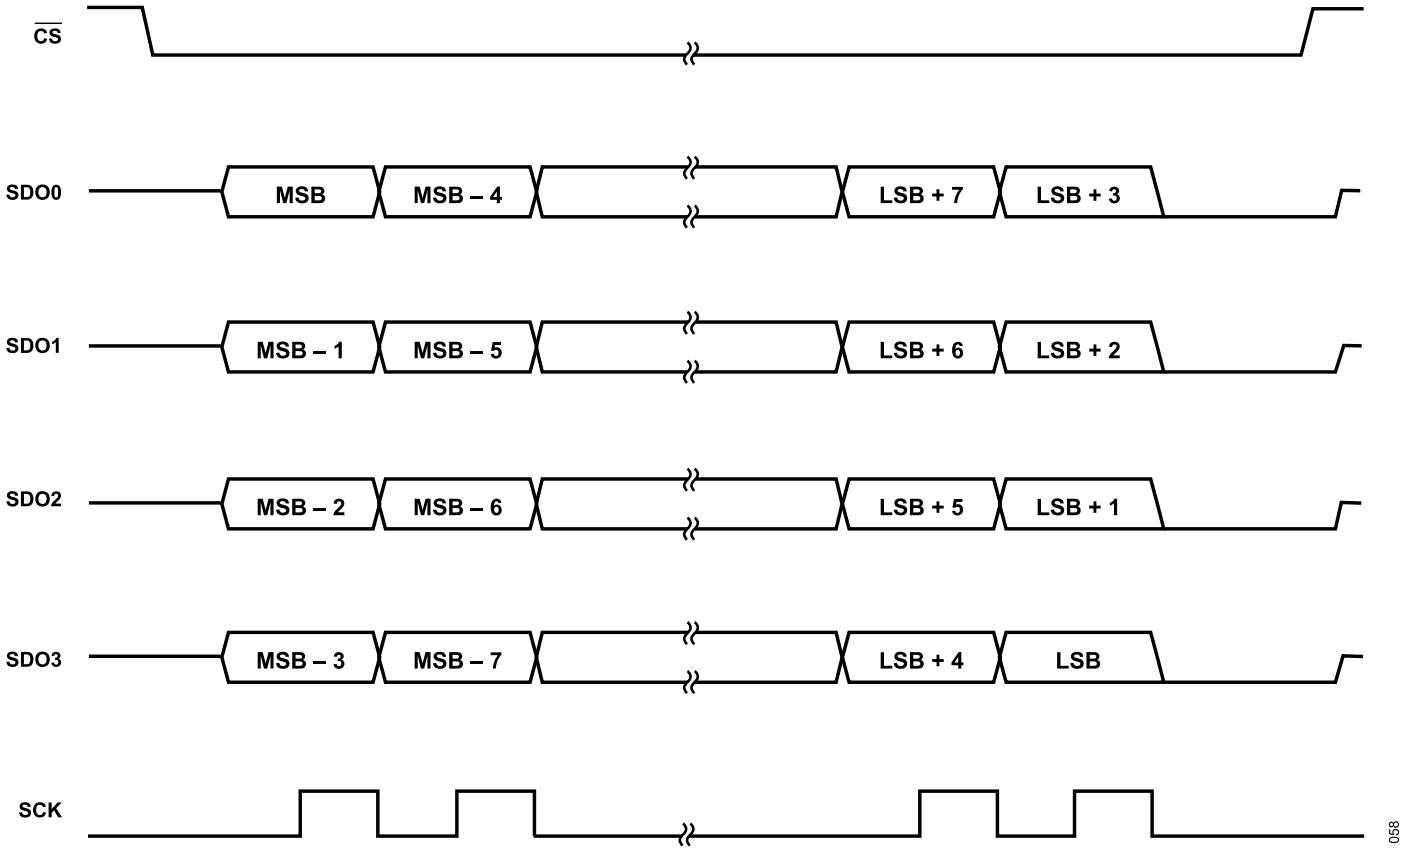

Figure 59. 4-Lane, SDR Timing Diagram

SERIAL INTERFACE

Echo Clock Timing Diagrams

1-Lane, SDR Mode, Echo Clock Mode

Figure 7 shows the timing relationships for SDR mode (1-bit per SCK period) in 1-lane echo clock mode. The timing relationships between the signals apply to both 24-bit and 32-bit sample word formats.

SCKOUT is a delayed version of the incoming SCK. The delay (t_{DSDO}) has a maximum value of 5.6 ns (at VIO > 1.71 V). Changes in SDOx logic states are aligned to the rising edges of SCKOUT. The clock and data edge alignments are the same for 1-lane, 2-lane, and 4-lane output data modes.

1-Lane, DDR Mode, Echo Clock Mode

Figure 8 shows the timing relationships for DDR mode (2-bit transitions per SCKOUT period) in 1-lane mode echo clock mode. The timing relationships between the signals apply to both 24-bit and 32-bit sample word formats.

Similar to SDR mode, SCKOUT is a delayed version of the incoming SCK. Changes in SDOx logic states are aligned to both rising and falling edges of SCKOUT.

Host Clock Mode Timing

1-Lane, Host Clock Mode, SDR

Figure 9 shows the timing relationships for host clock mode when using SDR mode and 1-lane mode. Similar to echo clock mode, the clock rising edges are aligned to the data bit transitions. The frequency of SCKOUT signal is controlled by the OSC_DIV value programmed in the internal oscillator register (see the Internal Oscillator Register section).

1-Lane, Host Clock Mode, DDR

Figure 10 shows the timing relationships for host clock mode when using DDR. Similar to echo clock mode, the rising and falling clock edges are aligned to the data bit transitions. The frequency of SCKOUT signal is controlled by the OSC_DIV value programmed in the internal oscillator register (see the Internal Oscillator Register section).

LAYOUT GUIDELINES

The following layout guidelines are recommended to achieve maximum performance of the AD4030-24/AD4032-24:

- The AD4030-24/AD4032-24 contain internal 1 µF bypass capacitors for VDD_5V and VDD_1.8V, and VIO contains an internal 0.2 µF capacitor. Therefore, no external bypass capacitors are required, which saves on board space, bill of materials count, and reduces layout sensitivity.
- It is recommended to have all the analog signals flow in from the left side of the AD4030-24/AD4032-24 and all the digital signals to flow in and out from the right side of the AD4030-24/AD4032-24 because this helps isolate analog signals from digital signals.
- Use a solid ground plane under the AD4030-24/AD4032-24 and connect all the analog ground (GND) pins and digital ground (IOGND) pins to the shared ground plane to avoid formation of ground loops.
- Traces routed to either the REFIN pin or REF pins must be isolated and shielded from other signals. Avoid routing signals beneath the reference trace (REFIN or REF). The REF pins are connected to an internal 2 µF capacitor, eliminating the need to place a decoupling capacitor on the output of the external reference buffer. If a noise reduction filter is placed between the output of the reference (or buffer) and the chosen reference input, it must be placed as close as possible to the AD4030-24/AD4032-24.

REGISTERS

The AD4030-24/AD4032-24 have programmable user registers that are used to configure the device. These registers can be accessed while the AD4030-24/AD4032-24 is in register configuration mode. Table 16 contains the complete list of the AD4030-24/AD4032-24 user registers and bit fields in the registers. The Register Details section contains details about the functions of each of the bit fields. The access mode specifies whether the register is comprised only of read-only bits (R) or a mix of read-only and read/write bits (R/W). Read-only bits cannot be overwritten by an SPI write transaction, but read/write bits can.

Table 16. AD4030-24/AD4032-24 Register Summary

EXIT CONFIGURATION MODE REGISTER

Address: 0x14, Reset: 0x00, Name: EXIT_CFG_MD

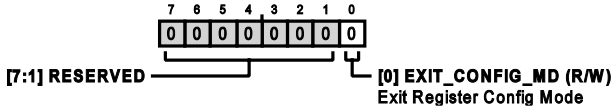

Table 30. Bit Descriptions for EXIT_CFG_MD

Bits	Bit Name	Description	Reset	Access
[7:1]	RESERVED	Reserved.	0x0	R
0	EXIT_CONFIG_MD	Exit Register Config Mode. Write 1 to exit register configuration mode. Self clearing upon $\overline{CS}$ = 1.	0x0	R/W

AVERAGING MODE REGISTER

Address: 0x15, Reset: 0x00, Name: AVG

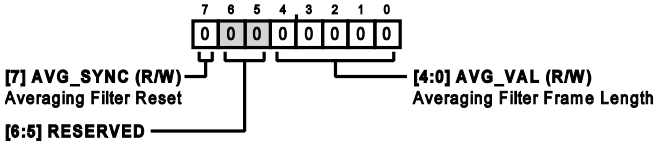

Table 31. Bit Descriptions for AVG

Bits	Bit Name	Description	Reset	Access
7	AVG_SYNC	Averaging Filter Reset. 1 = reset, self clearing.	0x0	R/W
[6:5]	RESERVED	Reserved.	0x0	R
[4:0]	AVG_VAL	Averaging Filter Block Length, 2^N. 0x00 = no averaging. 0x01 = 2^1 samples. 0x02 = 2^2 samples. 0x03 = 2^3 samples. 0x04 = 2^4 samples. 0x05 = 2^5 samples. … 0x0F = 2^{15} samples. 0x10 = 2^{16} samples. 0x11 through 0x1F = invalid.	0x0	R/W

REGISTER DETAILS

OFFSET REGISTERS

Address: 0x16, Reset: 0x00, Name: OFFSET_LB

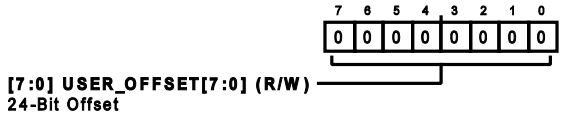

Table 32. Bit Descriptions for OFFSET_LB

Bits	Bit Name	Description	Reset	Access
[7:0]	USER_OFFSET[7:0]	24-Bit Offset. Twos complement (signed). $1\ LSB = \frac{V_{REF}}{2^{23}}/GAIN.$	0x0	R/W

Address: 0x17, Reset: 0x00, Name: OFFSET_MB

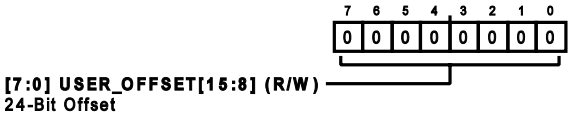

Table 33. Bit Descriptions for OFFSET_MB

Bits	Bit Name	Description	Reset	Access
[7:0]	USER_OFFSET[15:8]	24-Bit Offset. Twos complement (signed). $1\ LSB = \frac{V_{REF}}{2^{23}}/GAIN.$	0x0	R/W

Address: 0x18, Reset: 0x00, Name: OFFSET_HB

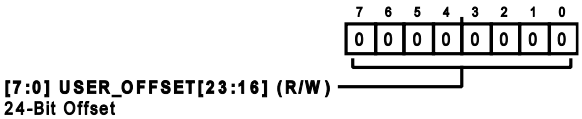

Table 34. Bit Descriptions for OFFSET_HB

Bits	Bit Name	Description	Reset	Access
[7:0]	USER_OFFSET[23:16]	24-Bit Offset. Twos complement (signed). $1\ LSB = \frac{V_{REF}}{2^{23}}/GAIN.$	0x0	R/W

GAIN REGISTERS

Address: 0x1C, Reset: 0x00, Name: GAIN_LB

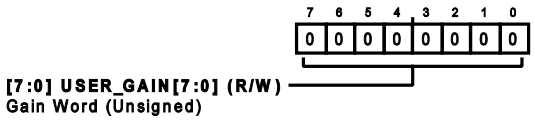

Table 35. Bit Descriptions for GAIN_LB

Bits	Bit Name	Description	Reset	Access
[7:0]	USER_GAIN[7:0]	Gain Word (Unsigned). Multiplier Output = Input × Gain Word/0x8000. Maximum Effective Gain = 0xFFFF/0x8000 = 1.99997.	0x0	R/W

Address: 0x1D, Reset: 0x80, Name: GAIN_HB

REGISTER DETAILS

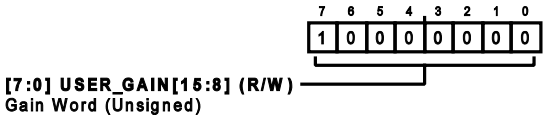

Table 36. Bit Descriptions for GAIN_HB

Bits	Bit Name	Description	Reset	Access
[7:0]	USER_GAIN[15:8]	Gain Word (Unsigned). Multiplier Output = Input × Gain Word/0x8000. Maximum Effective Gain = 0xFFFF/0x8000 = 1.99997.	0x80	R/W

MODES REGISTER

Address: 0x20, Reset: 0x00, Name: MODES

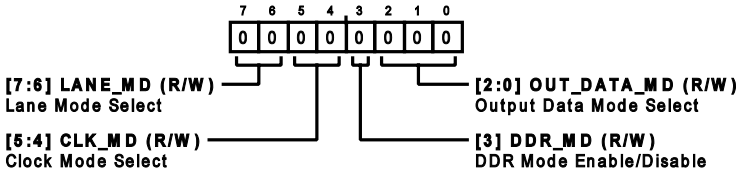

Table 37. Bit Descriptions for MODES

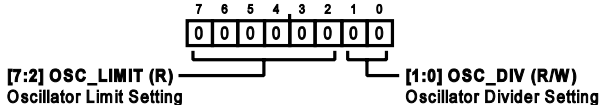
Bits	Bit Name	Description	Reset	Access
[7:6]	LANE_MD	Lane Mode Select. 00 = one lane. 01 = two lanes. 10 = four lanes. 11 = invalid setting.	0x0	R/W
[5:4]	CLK_MD	Clock Mode Select. 00 = SPI clocking mode. 01 = echo clock mode. 10 = host clock mode. 11 = invalid setting.	0x0	R/W
3	DDR_MD	DDR Mode Enable/Disable. 0 = SDR. 1 = DDR (only valid for echo clock mode and host clock mode).	0x0	R/W
[2:0]	OUT_DATA_MD	Output Data Mode Select. 000 = 24-bit differential data. 001 = 16-bit differential data + 8-bit common-mode data. 010 = 24-bit differential data + 8-bit common-mode data. 011 = 30-bit averaged differential data + OR bit + SYNC bit. 100 = 32-bit test data pattern (TEST_DATA_PAT).	0x0	R/W

INTERNAL OSCILLATOR REGISTER

Address: 0x21, Reset: 0x00, Name: OSCILLATOR



REGISTER DETAILS

Table 38. Bit Descriptions for OSCILLATOR

Bits	Bit Name	Description	Reset	Access
[7:2]	OSC_LIMIT	Oscillator Limit Setting. Oscillator is limited to this number of clock pulses plus one. Automatically calculated by the AD4030-24 based on the data-word size, number of active SDO lanes, and data rate mode (SDR or DDR).	0x0	R
[1:0]	OSC_DIV	Oscillator Divider Setting. 00 = no divide (divide by 1). 01 = divide by 2. 10 = divide by 4. 11 = invalid setting.	0x0	R/W

OUTPUT DRIVER REGISTER

Address: 0x22, Reset: 0x00, Name: IO

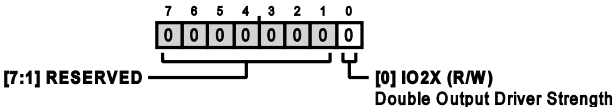


Table 39. Bit Descriptions for IO

Bits	Bit Name	Description	Reset	Access
[7:1]	RESERVED	Reserved.	0x0	R
0	IO2X	Double Output Driver Strength. 1 = double output driver strength. 0 = normal output driver strength.	0x0	R/W

TEST PATTERN REGISTERS

Address: 0x23, Reset: 0x0F, Name: TEST_PAT_BYTE0

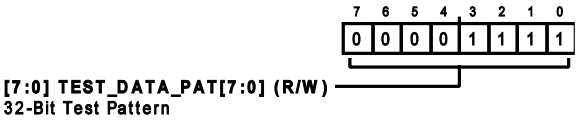

Table 40. Bit Descriptions for TEST_PAT_BYTE0

Bits	Bit Name	Description	Reset	Access
[7:0]	TEST_DATA_PAT[7:0]	32-Bit Test Pattern. Applied when OUT_DATA_MD = 4.	0xF	R/W

Address: 0x24, Reset: 0x0F, Name: TEST_PAT_BYTE1

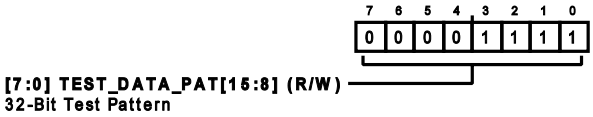

Table 41. Bit Descriptions for TEST_PAT_BYTE1

Bits	Bit Name	Description	Reset	Access
[7:0]	TEST_DATA_PAT[15:8]	32-Bit Test Pattern. Applied when OUT_DATA_MD = 4.	0xF	R/W

Address: 0x25, Reset: 0x5A, Name: TEST_PAT_BYTE2

REGISTER DETAILS

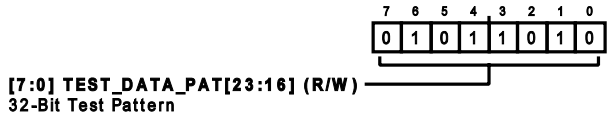

Table 42. Bit Descriptions for TEST_PAT_BYTE2

Bits	Bit Name	Description	Reset	Access
[7:0]	TEST_DATA_PAT[23:16]	32-Bit Test Pattern. Applied when OUT_DATA_MD = 4.	0x5A	R/W

Address: 0x26, Reset: 0x5A, Name: TEST_PAT_BYTE3

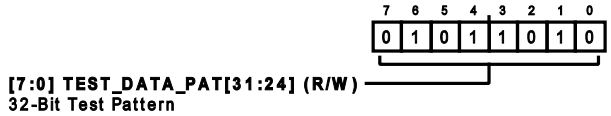

Table 43. Bit Descriptions for TEST_PAT_BYTE3

Bits	Bit Name	Description	Reset	Access
[7:0]	TEST_DATA_PAT[31:24]	32-Bit Test Pattern. Applied when OUT_DATA_MD = 4.	0x5A	R/W

DIGITAL DIAGNOSTICS REGISTER

Address: 0x34, Reset: 0x40, Name: DIG_DIAG

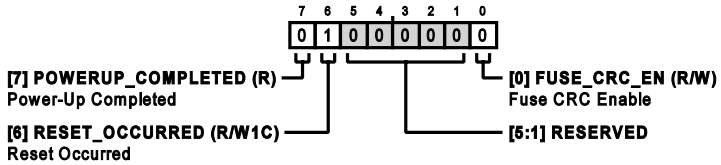

Table 44. Bit Descriptions for DIG_DIAG

Bits	Bit Name	Description	Reset	Access
7	POWERUP_COMPLETED	Power-Up Completed. 1 = power-up completed. Self clearing.	0x0	R
6	RESET_OCCURRED	Reset Occurred. This bit is set to 1 upon a reset event. Write 1 to clear (useful for detecting brownouts).	0x1	R/W1C
[5:1]	RESERVED	Reserved.	0x0	R
0	FUSE_CRC_EN	Fuse CRC Enable. Write a 1 to force recheck of CRC.	0x0	R/W

DIGITAL ERRORS REGISTER

Address: 0x35, Reset: 0x00, Name: DIG_ERR

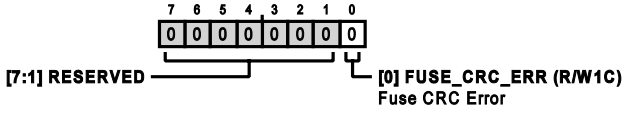

Table 45. Bit Descriptions for DIG_ERR

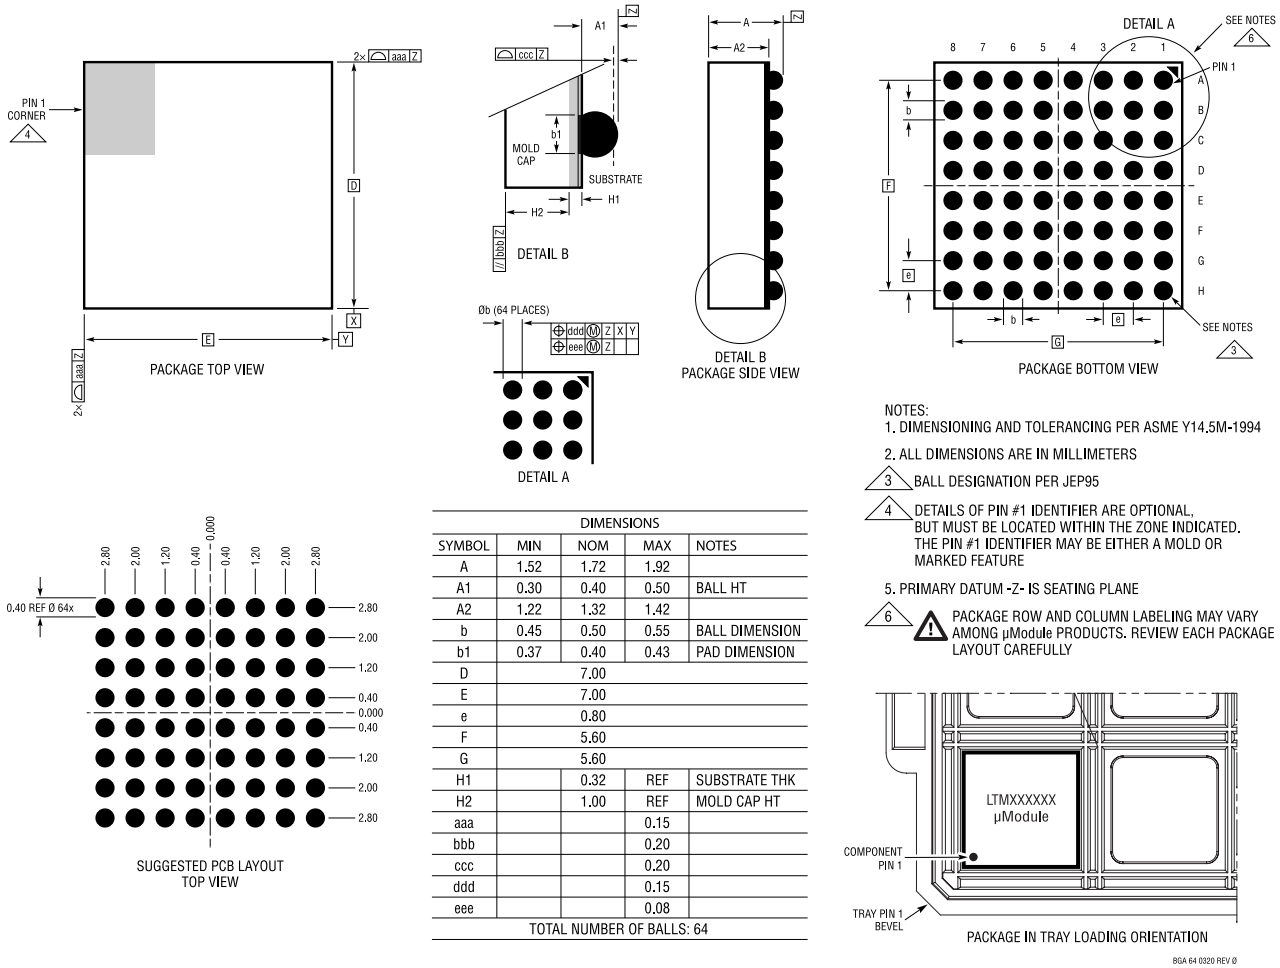
Bits	Bit Name	Description	Reset	Access
[7:1]	RESERVED	Reserved.	0x0	R
0	FUSE_CRC_ERR	Fuse CRC Error. This bit is set to 1 upon a fuse CRC error. Write 1 to clear.	0x0	R/W1C

OUTLINE DIMENSIONS



DIMENSIONS				
SYMBOL	MIN	NOM	MAX	NOTES
A	1.52	1.72	1.92	
A1	0.30	0.40	0.50	BALL HT
A2	1.22	1.32	1.42	
b	0.45	0.50	0.55	BALL DIMENSION
b1	0.37	0.40	0.43	PAD DIMENSION
D		7.00		
E		7.00		
e		0.80		
F		5.60		
G		5.60		
H1		0.32	REF	SUBSTRATE THK
H2		1.00	REF	MOLD CAP HT
aaa			0.15	
bbb			0.20	
ccc			0.20	
ddd			0.15	
eee			0.08	
TOTAL NUMBER OF BALLS: 64				

NOTES:
1. DIMENSIONING AND TOLERANCING PER ASME Y14.5M-1994
2. ALL DIMENSIONS ARE IN MILLIMETERS
3. BALL DESIGNATION PER JEP95
4. DETAILS OF PIN #1 IDENTIFIER ARE OPTIONAL, BUT MUST BE LOCATED WITHIN THE ZONE INDICATED. THE PIN #1 IDENTIFIER MAY BE EITHER A MOLD OR MARKED FEATURE
5. PRIMARY DATUM -Z- IS SEATING PLANE
6. PACKAGE ROW AND COLUMN LABELING MAY VARY AMONG µModule PRODUCTS. REVIEW EACH PACKAGE LAYOUT CAREFULLY

Figure 60. 64-Ball Chip Scale Package Ball Grid Array [CSP_BGA]
(05-08-1797)
Dimensions shown in millimeters

Updated: May 10, 2022

ORDERING GUIDE

Model[1]	Temperature Range	Package Description	Packing Quantity	Package Option
AD4030-24BBCZ	-40°C to +125°C	64-Ball CSP-BGA (7 mm x 7 mm x 1.72 mm)	Tray, 260	05-08-1797
AD4030-24BBCZ-RL	-40°C to +125°C	64-Ball CSP-BGA (7 mm x 7 mm x 1.72 mm)	Reel, 2000	05-08-1797
AD4032-24BBCZ	-40°C to +125°C	64-Ball CSP-BGA (7 mm x 7 mm x 1.72 mm)	Tray, 260	05-08-1797
AD4032-24BBCZ-RL	-40°C to +125°C	64-Ball CSP-BGA (7 mm x 7 mm x 1.72 mm)	Reel, 2000	05-08-1797

[1] Z = RoHS Compliant Part.

EVALUATION BOARDS

Evaluation Board[1, 2]	Description
EVAL-AD4030-24-KTZ	Evaluation Kit
EVAL-AD4030-24FMCZ	Evaluation Board

[1] Z = RoHS Compliant Part.

[2] The EVAL-AD4030-24-KTZ and EVAL-AD4030-24FMCZ can be used to evaluate the AD4032-24.
