## Dual 12-Bit, High Bandwidth, Multiplying DAC with 4-Quadrant Resistors and Parallel Interface

## Data Sheet

## FEATURES

10 MHz multiplying bandwidth
On-chip 4-quadrant resistors allow flexible output ranges
INL of $\pm 1$ LSB
40-lead LFCSP package
2.5 V to 5.5 V supply operation
$\pm 10 \mathrm{~V}$ reference input
21.3 MSPS update rate

Extended temperature range: $-\mathbf{4 0}{ }^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$
4-quadrant multiplication
Power-on reset
$0.5 \mu \mathrm{~A}$ typical current consumption
Guaranteed monotonic
Readback function

## APPLICATIONS

## Portable battery-powered applications

Waveform generators
Analog processing
Instrumentation applications
Programmable amplifiers and attenuators
Digitally controlled calibration
Programmable filters and oscillators
Composite video
Ultrasound
Gain, offset, and voltage trimming

## GENERAL DESCRIPTION

The AD5405 ${ }^{1}$ is a CMOS, 12 -bit, dual-channel, current output digital-to-analog converter (DAC). This device operates from a 2.5 V to 5.5 V power supply, making it suited to battery-powered and other applications.

Because of manufacturing with a CMOS submicron process, the device offers excellent 4-quadrant multiplication characteristics, with large signal multiplying bandwidths of up to 10 MHz .

The applied external reference input voltage ( $\mathrm{V}_{\text {REF }}$ ) determines the full-scale output current. An integrated feedback resistor ( $\mathrm{R}_{\mathrm{FB}}$ ) provides temperature tracking and full-scale voltage output when combined with an external I to V precision amplifier. This device also contains the 4 -quadrant resistors necessary for bipolar operation and other configuration modes.
This DAC uses data readback, allowing the user to read the contents of the DAC register via the DB pins. On power-up, the internal register and latches fill with 0 s , and the DAC outputs are at zero scale.

The AD5405 has a $6 \mathrm{~mm} \times 6 \mathrm{~mm}$, 40-lead LFCSP package.

## SPECIFICATIONS

$\mathrm{V}_{\mathrm{DD}}=2.5 \mathrm{~V}$ to $5.5 \mathrm{~V}, \mathrm{~V}_{\text {Ref }}=10 \mathrm{~V}$, Iout2 $=0 \mathrm{~V}$. Temperature range for Y version: $-40^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$. All specifications $\mathrm{T}_{\mathrm{MIN}}$ to $\mathrm{T}_{\mathrm{MAX}}$, unless otherwise noted. DC performance is measured with OP177, and ac performance is measured with AD8038, unless otherwise noted.

## Data Sheet

## TIMING CHARACTERISTICS

All input signals are specified with $\operatorname{tr}=\mathrm{tf}=1 \mathrm{~ns}\left(10 \%\right.$ to $90 \%$ of $\left.\mathrm{V}_{\mathrm{DD}}\right)$ and timed from a voltage level of $\left(\mathrm{V}_{\mathrm{IL}}+\mathrm{V}_{\mathrm{IH}}\right) / 2 . \mathrm{V}_{\mathrm{DD}}=2.5 \mathrm{~V}$ to 5.5 V , $\mathrm{V}_{\text {REF }}=10 \mathrm{~V}$, IouT2 $=0 \mathrm{~V}$, temperature range for Y version: $-40^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$. All specifications $\mathrm{T}_{\text {MIN }}$ to $\mathrm{T}_{\text {MAX, }}$ unless otherwise noted.

Table 2. ${ }^{1}$

| Parameter | Limit at $\mathrm{T}_{\text {min }}$, $\mathrm{T}_{\text {MAX }}$ | Unit | Test Conditions/Comments |
| :---: | :---: | :---: | :---: |
| Write Mode |  |  |  |
| $\mathrm{t}_{1}$ | 0 | ns min | $\mathrm{R} / \overline{\mathrm{W}}$ to $\overline{\mathrm{CS}}$ setup time |
| $\mathrm{t}_{2}$ | 0 | ns min | R/ $\bar{W}$ to $\overline{C S}$ hold time |

| $\mathrm{t}_{12}$ | 5 | ns typ | Data access time |
|  | 35 | ns max |  |
| $t_{13}$ | 5 | ns typ | Bus relinquish time |
|  | 10 | ns max |  |
| Update Rate | 21.3 | MSPS | Consists of $\overline{C S}$ min high time, $\overline{C S}$ low time, and output voltage settling time |

${ }^{1}$ Guaranteed by design and characterization, not subject to production test.

Figure 2. Timing Diagram

Figure 3. Load Circuit for Data Timing Specifications

## ABSOLUTE MAXIMUM RATINGS

Transient currents of up to 100 mA do not cause SCR latch-up. $\mathrm{T}_{\mathrm{A}}=25^{\circ} \mathrm{C}$, unless otherwise noted.

Table 3.

| Parameter | Rating |
| :--- | :--- |
| V $_{\text {DD }}$ to GND | -0.3 V to +7 V |
| $\mathrm{~V}_{\text {REF }}, \mathrm{V}_{\text {REF }} B, R_{\text {FB }}, \mathrm{R}_{\text {FB }} \mathrm{B}$ to GND | -12 V to +12 V |
| lout1, lout2 to GND | -0.3 V to +7 V |
| Logic Inputs and Output ${ }^{1}$ | -0.3 V to $\mathrm{V}_{\mathrm{DD}}+0.3 \mathrm{~V}$ |
| Operating Temperature Range |  |
| $\quad$ Automotive (Y Version) | $-40^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$ |
| Storage Temperature Range | $-65^{\circ} \mathrm{C}$ to $+150^{\circ} \mathrm{C}$ |
| Junction Temperature | $150^{\circ} \mathrm{C}$ |
| 40-lead LFCSP, $\theta_{\mathrm{JA}}$ Thermal Impedance | $30^{\circ} \mathrm{C} / \mathrm{W}$ |
| Lead Temperature, Soldering (10 sec) | $300^{\circ} \mathrm{C}$ |
| Infrared (IR) Reflow, Peak Temperature | $235^{\circ} \mathrm{C}$ |
| $\quad$ (<20 sec) |  |

${ }^{1}$ Overvoltages at DBx, $\overline{\mathrm{LDAC}}, \overline{\mathrm{CS}}$, and $\mathrm{R} / \overline{\mathrm{W}}$ are clamped by internal diodes.

Stresses at or above those listed under Absolute Maximum Ratings may cause permanent damage to the product. This is a stress rating only; functional operation of the product at these or any other conditions above those indicated in the operational section of this specification is not implied. Operation beyond the maximum operating conditions for extended periods may affect product reliability.

## ESD CAUTION

|  | ESD (electrostatic discharge) sensitive device. <br> Charged devices and circuit boards can discharge <br> without detection. Although this product features <br> patented or proprietary protection circuitry, damage <br> may occur on devices subjected to high energy ESD. <br> Therefore, proper ESD precautions should be taken to <br> avoid performance degradation or loss of functionality. |
| :--- | :--- |

## PIN CONFIGURATION AND FUNCTION DESCRIPTIONS

## NOTES

1. NIC = NOT INTERNALLY CONNECTED.
2. EXPOSED PAD MUST BE CONNECTED TO GROUND.

Figure 4. Pin Configuration
Table 4. Pin Function Descriptions

| Pin No. | Mnemonic | Description |
| :---: | :---: | :---: |
| 1 to 4 | $\begin{aligned} & \text { R1A, R2A, } \\ & \text { R2_3A, R3A } \end{aligned}$ | DAC A 4-Quadrant Resistors. Allow a number of configuration modes, including bipolar operation with minimum of external components. |
| 5,26 | $\mathrm{V}_{\text {ref }} \mathrm{A}, \mathrm{V}$ 恠B | DAC Reference Voltage Input Terminals. |
| 6 | DGND | Digital Ground Pin. |
| 7 | $\overline{\text { LDAC }}$ | Load DAC Input. Allows asynchronous or synchronous updates to the DAC output. The DAC is asynchronously updated when this signal goes low. Alternatively, if this line is held permanently low, an automatic or synchronous update mode is selected whereby the DAC is updated on the rising edge of $\overline{C S}$. |
| 8 | DAC $\bar{A} / \mathrm{B}$ | Selects DAC A or B. Low selects DAC A, and high selects DAC B. |
| 9,34 to 37 | NIC | Not internally connected. |
| 10 to 21 | DB11 to DB0 | Parallel Data Bits 11 through 0. |
| 22 | $\overline{C S}$ | Chip Select Input. Active low. Used in conjunction with $R / \bar{W}$ to load parallel data to the input latch or to read data from the DAC register. Edge sensitive; when pulled high, the DAC data is latched. |
| 23 | R/W | Read/Write. When low, used in conjunction with $\overline{\mathrm{CS}}$ to load parallel data. When high, used in conjunction with $\overline{\mathrm{CS}}$ to read back contents of DAC register. |
| 24 | $\overline{\mathrm{CLR}}$ | Active Low Control Input. Clears DAC output and input and DAC registers. |
| 25 | $V_{\text {DD }}$ | Positive Power Supply Input. These devices can be operated from a supply of 2.5 V to 5.5 V . |
| 27 to 30 | $\begin{aligned} & \text { R3B, R2_3B, } \\ & \text { R2B, R1B } \end{aligned}$ | DAC B 4-Quadrant Resistors. Allow a number of configuration modes, including bipolar operation with a minimum of external components. |
| 31,40 | $\mathrm{R}_{\text {FB }} B, \mathrm{R}_{\text {FB }} A$ | External Amplifier Output. |
| 32 | lout2B | DAC A Analog Ground. This pin typically ties to the analog ground of the system, but can be biased to achieve single-supply operation. |
| 33 | lout1B | DAC B Current Outputs. |
| 38 | lout1A | DAC A Current Outputs. |
| 39 | lout2A | DAC A Analog Ground. This pin typically ties to the analog ground of the system, but can be biased to achieve single-supply operation. |
|  | EPAD | Exposed pad must be connected to ground. |

## TERMINOLOGY

## Relative Accuracy (Endpoint Nonlinearity)

A measure of the maximum deviation from a straight line passing through the endpoints of the DAC transfer function. It is measured after adjusting for zero and full scale and is normally expressed in LSBs or as a percentage of the full-scale reading.

## Differential Nonlinearity

The difference in the measured change and the ideal 1 LSB change between two adjacent codes. A specified differential nonlinearity of -1 LSB maximum over the operating temperature range ensures monotonicity.

## Gain Error (Full-Scale Error)

A measure of the output error between an ideal DAC and the actual device output. For this DAC, ideal maximum output is $\mathrm{V}_{\text {Ref }}-1 \mathrm{LSB}$. The gain error of the DAC is adjustable to zero with an external resistance.

## Output Leakage Current

The current that flows into the DAC ladder switches when they are turned off. For the Iour 1 terminal, it can be measured by loading all 0 s to the DAC and measuring the Iout 1 current. Minimum current flows into the Iout 2 line when the DAC is loaded with all 1 s .

## Output Capacitance

Capacitance from Iour 1 or Iout 2 to AGND.

## Output Current Settling Time

The amount of time for the output to settle to a specified level for a full-scale input change. For this device, it is specified with a $100 \Omega$ resistor to ground.

## Digital-to-Analog Glitch Impulse

The amount of charge injected from the digital inputs to the analog output when the inputs change state. This is typically specified as the area of the glitch in either pA-sec or $\mathrm{nV}-\mathrm{sec}$, depending on whether the glitch is measured as a current or voltage signal.

## Digital Feedthrough

When the device is not selected, high frequency logic activity on the device's digital inputs is capacitively coupled through the device and produces noise on the Iout pins and, subsequently, on the following circuitry. This noise is digital feedthrough.

## Multiplying Feedthrough Error

The error due to capacitive feedthrough from the DAC reference input to the DAC Iour 1 terminal when all 0 s are loaded to the DAC.

## Digital Crosstalk

The glitch impulse transferred to the outputs of a DAC in response to a full-scale code change (all 0 s to all 1 s , or vice versa) in the input register of another DAC. It is expressed in nV-sec.

## Analog Crosstalk

The glitch impulse transferred to the output of one DAC due to a change in the output of another DAC. It is measured by loading one of the input registers with a full-scale code change (all 0 s to all 1 s , or vice versa) while keeping LDAC high and then pulsing LDAC low and monitoring the output of the DAC whose digital code has not changed. The area of the glitch is expressed in nV -sec.

## Channel to Channel Isolation

The portion of input signal from a DAC reference input that appears at the output of the other DAC. It is expressed in decibels.

## Total Harmonic Distortion (THD)

The DAC is driven by an ac reference. The ratio of the rms sum of the harmonics of the DAC output to the fundamental value is the THD. Usually only the lower-order harmonics are included, such as the second to the fifth harmonics.

$$
T H D=20 \log \frac{\sqrt{\mathrm{~V}_{2}^{2}+\mathrm{V}_{3}{ }^{2}+\mathrm{V}_{4}^{2}+\mathrm{V}_{5}^{2}}}{\mathrm{~V}_{1}}
$$

## Intermodulation Distortion (IMD)

The DAC is driven by two combined sine wave references of frequencies fa and fb . Distortion products are produced at sum and difference frequencies of $\mathrm{mfa} \pm \mathrm{nfb}$, where $\mathrm{m}, \mathrm{n}=0$, $1,2,3 \ldots$ Intermodulation terms are those for which m or n is not equal to 0 . The second-order terms include ( $\mathrm{fa}+\mathrm{fb}$ ) and $(f a-f b)$, and the third-order terms are $(2 f a+f b),(2 f a-f b)$, $(f+2 f a+2 f b)$, and ( $\mathrm{fa}-2 \mathrm{fb}$ ). IMD is defined as $I M D=20 \log \frac{(r m s ~ s u m ~ o f ~ t h e ~ s u m ~ a n d ~ d i f f ~ d i s t o r t i o n ~ p r o d u c t s)}{r m s ~ a m p l i t u d e ~ o f ~ t h e ~ f u n d a m e n t a l ~}$

## Compliance Voltage Range

The maximum range of (output) terminal voltage for which the device provides the specified characteristics.

## GENERAL DESCRIPTION DAC SECTION

The AD5405 is a 12-bit, dual-channel, current-output DAC consisting of a standard inverting R-2R ladder configuration. Figure 31 shows a simplified diagram for a single channel of the AD5405. The feedback resistor $\mathrm{R}_{\mathrm{FB}} \mathrm{A}$ has a value of 2R. The value of R is typically $10 \mathrm{k} \Omega$ (with a minimum of $8 \mathrm{k} \Omega$ and a maximum of $13 \mathrm{k} \Omega$ ). If Iout 1 A and Iour 2 A are kept at the same potential, a constant current flows into each ladder leg, regardless of digital input code. Therefore, the input resistance presented at $V_{\text {ReF }} A$ is always constant.

Figure 31. Simplified Ladder Configuration
Access is provided to the $\mathrm{V}_{\text {ref }}, \mathrm{R}_{\mathrm{fb}}$, Iout 1 , and Iout 2 terminals of the DAC, making the device extremely versatile and allowing it to be configured for several operating modes, such as unipolar output, bipolar output, or single-supply mode.

## CIRCUIT OPERATION

## Unipolar Mode

Using a single operational amplifier, this DAC can easily be configured to provide 2-quadrant multiplying operation or a unipolar output voltage swing, as shown in Figure 32.

## NOTES

1. SIMILAR CONFIGURATION FOR DAC B.
2. C1 PHASE COMPENSATION (1pF TO 2pF) MAY BE REQUIRED

IF A1 IS A HIGH SPEED AMPLIFIER.
Figure 32. Unipolar Operation

When an output amplifier is connected in unipolar mode, the output voltage is given by

$$
V_{\text {OUT }}=-V_{\text {REF }} \times D / 2^{n}
$$

where:
$D$ is the fractional representation, in the range of 0 to 4,095 , of the digital word loaded to the DAC.
$n$ is the resolution of the DAC.
With a fixed 10 V reference, the circuit shown in Figure 32 gives a unipolar 0 V to -10 V output voltage swing. When $\mathrm{V}_{\mathrm{IN}}$ is an ac signal, the circuit performs 2-quadrant multiplication.
Table 5 shows the relationship between digital code and the expected output voltage for unipolar operation.

Table 5. Unipolar Code

| Digital Input | Analog Output (V) |
| :--- | :--- |
| 111111111111 | $-V_{\text {REF }}(4,095 / 4,096)$ |
| 100000000000 | $-V_{\text {REF }}(2,048 / 4,096)=-V_{\text {REF }} / 2$ |
| 000000000001 | $-V_{\text {REF }}(1 / 4,096)$ |
| 000000000000 | $-V_{\text {REF }}(0 / 4,096)=0$ |

## Bipolar Operation

In some applications, it may be necessary to generate full 4-quadrant multiplying operation or a bipolar output swing. This can be easily accomplished by using another external amplifier, as shown in Figure 33.

Figure 33. Bipolar Operation (4-Quadrant Multiplication)
When in bipolar mode, the output voltage is given by

$$
V_{\text {OUT }}=\left(V_{R E F} \times D / 2^{n-1}\right)-V_{\text {REF }}
$$

where:
$D$ is the fractional representation, in the range of 0 to 4095 , of the digital word loaded to the DAC.
$n$ is the number of bits.
When $\mathrm{V}_{\text {IN }}$ is an ac signal, the circuit performs 4-quadrant multiplication.
Table 6 shows the relationship between the digital code and the expected output voltage for bipolar operation.

Table 6. Bipolar Code

| Digital Input | Analog Output (V) |
| :--- | :--- |
| 111111111111 | $+V_{\text {REF }}(4,095 / 4,096)$ |
| 100000000000 | 0 |
| 000000000001 | $-V_{\text {REF }}(4,095 / 4,096)$ |
| 000000000000 | $-V_{\text {REF }}(4,096 / 4,096)$ |

## Stability

In the I-to-V configuration, the Iout of the DAC and the inverting node of the operational amplifier must be connected as close as possible, and proper printed circuit board (PCB) layout techniques must be used. Because every code change corresponds to a step function, gain peaking may occur if the operational amplifier has limited gain bandwidth product (GBP) and there is excessive parasitic capacitance at the inverting node. This parasitic capacitance introduces a pole into the open-loop response, which can cause ringing or instability in the closed-loop applications circuit.

An optional compensation capacitor, C 1 , can be added in parallel with $\mathrm{R}_{\mathrm{FB}} \mathrm{A}$ for stability, as shown in Figure 32 and Figure 33. Too small a value of C 1 can produce ringing at the output, whereas too large a value can adversely affect the settling time. C 1 can be found empirically, but 1 pF to 2 pF is generally adequate for the compensation.

## SINGLE-SUPPLY APPLICATIONS

## Voltage Switching Mode of Operation

Figure 34 shows the DAC operating in the voltage switching mode. The reference voltage, $\mathrm{V}_{\text {IN }}$, is applied to the $\mathrm{I}_{\text {out }} 1 \mathrm{~A}$ pin, Iout 2 A is connected to AGND, and the output voltage is available at the $V_{\text {ReF }} A$ terminal. In this configuration, a positive reference voltage results in a positive output voltage, making single-supply operation possible. The output from the DAC is voltage at a constant impedance (the DAC ladder resistance). Therefore, an operational amplifier is necessary to buffer the output voltage. The reference input no longer sees a constant input impedance, but one that varies with code. Therefore, the voltage input must be driven from a low impedance source.

NOTES

1. SIMILAR CONFIGURATION FOR DAC B.
2. C1 PHASE COMPENSATION (1pF TO 2pF) MAY BE REQUIRED IF A1 IS A HIGH SPEED AMPLIFIER.

Figure 34. Single-Supply Voltage-Switching Mode

Note that $\mathrm{V}_{\text {IN }}$ is limited to low voltages because the switches in the DAC ladder no longer have the same source drain drive voltage. As a result, their on resistance differs and degrades the integral linearity of the DAC. Also, VIN must not go negative by more than 0.3 V , or an internal diode turns on, causing the device to exceed the maximum ratings. In this type of application, the full range of multiplying capability of the DAC is lost.

## ADDING GAIN

In applications where the output voltage must be greater than $\mathrm{V}_{\text {IN }}$, gain can be added with an additional external amplifier, or it can be achieved in a single stage. Consider the effect of temperature coefficients of the thin film resistors of the DAC. Simply placing a resistor in series with the $\mathrm{R}_{F B}$ resistor causes mismatches in the temperature coefficients, resulting in larger gain temperature coefficient errors. Instead, the circuit of Figure 35 shows the recommended method for increasing the gain of the circuit. R1, R2, and R3 can have similar temperature coefficients, but they need not match the temperature coefficients of the DAC. This approach is recommended in circuits where gains of greater than 1 are required. Note that $\mathrm{R}_{\mathrm{FB}} \gg \mathrm{R} 2 / / \mathrm{R} 3$ and a gain error percentage of $100 \times(\mathrm{R} 2 / / \mathrm{R} 3) / \mathrm{R}_{\mathrm{FB}}$ must be taken into consideration.

Figure 35. Increasing Gain of Current Output DAC

## DIVIDER OR PROGRAMMABLE GAIN ELEMENT

Current steering DACs are very flexible and lend themselves to many applications. If this type of DAC is connected as the feedback element of an operational amplifier and $R_{F B} A$ is used as the input resistor, as shown in Figure 36, the output voltage is inversely proportional to the digital input fraction, D.

For $D=1-2^{-n}$, the output voltage is

Figure 36. Current Steering DAC Used as a Divider or Programmable Gain Element
As D is reduced, the output voltage increases. For small values of the digital fraction $D$, it is important to ensure that the amplifier does not saturate and that the required accuracy is met. For example, an 8 -bit DAC driven with the binary code $0 \times 10$ (0001 0000 )-that is, 16 decimal-in the circuit of Figure 36 can cause the output voltage to be 16 times $\mathrm{V}_{\text {IN }}$. However, if the DAC has a linearity specification of $\pm 0.5 \mathrm{LSB}, \mathrm{D}$ can have a weight in the range of $15.5 / 256$ to $16.5 / 256$ so that the possible output voltage is in the range of $15.5 \mathrm{~V}_{\text {IN }}$ to $16.5 \mathrm{~V}_{\text {IN }}$-an error of $3 \%$, even though the DAC itself has a maximum error of $0.2 \%$.
DAC leakage current is also a potential error source in divider circuits. The leakage current must be counterbalanced by an opposite current supplied from the operational amplifier through the DAC. Because only a fraction, $D$, of the current into the $\mathrm{V}_{\text {REF }}$ terminal is routed to the Iout 1 terminal, the output voltage changes as follows:

Output Error Voltage Due to DAC Leakage $=($ Leakage $\times R) / D$
where $R$ is the DAC resistance at the $V_{\text {REF }}$ terminal.
For a DAC leakage current of $10 \mathrm{nA}, \mathrm{R}=10 \mathrm{k} \Omega$, and a gain (that is, $1 / \mathrm{D}$ ) of 16 , the error voltage is 1.6 mV .

## REFERENCE SELECTION

When selecting a reference for use with the AD5405 and other devices in this series of current output DACs, pay attention to the output voltage temperature coefficient specification of the reference. This parameter not only affects the full-scale error, but also can affect the linearity (INL and DNL) performance. The reference temperature coefficient must be consistent with the system accuracy specifications. For example, an 8-bit system required to hold its overall specification to within 1 LSB over the temperature range $0^{\circ} \mathrm{C}$ to $50^{\circ} \mathrm{C}$ dictates that the maximum system drift with temperature must be less than $78 \mathrm{ppm} /{ }^{\circ} \mathrm{C}$. A 12 -bit system with the same temperature range to overall specification within 2 LSBs requires a maximum drift of $10 \mathrm{ppm} /{ }^{\circ} \mathrm{C}$. Choosing a precision reference with low output temperature coefficient minimizes this error source. Table 7 lists some references available from Analog Devices, Inc., that are suitable for use with this range of current output DACs.

## AMPLIFIER SELECTION

The primary requirement for the current steering mode is an amplifier with low input bias currents and low input offset voltage. Because of the code dependent output resistance of the DAC, the input offset voltage of an operational amplifier is multiplied by the variable gain of the circuit. A change in this noise gain between two adjacent digital fractions produces a step change in the output voltage due to the amplifier's input offset voltage. This output voltage change is superimposed on the desired change in output between the two codes and gives rise to a differential linearity error, which, if large enough, could cause the DAC to be nonmonotonic.

The input bias current of an operational amplifier also generates an offset at the voltage output because of the bias current flowing in the feedback resistor, $\mathrm{R}_{\mathrm{FB}}$. Most operational amplifiers have input bias currents low enough to prevent significant errors in 12-bit applications.
Common-mode rejection of the operational amplifier is important in voltage switching circuits, because it produces a code dependent error at the voltage output of the circuit. Most operational amplifiers have adequate common-mode rejection for use at 12-bit resolution.
If the DAC switches are driven from true wideband, low impedance sources (VIN and AGND), they settle quickly. Consequently, the slew rate and settling time of a voltage-switching DAC circuit is determined largely by the output operational amplifier. To obtain minimum settling time in this configuration, minimize capacitance at the $\mathrm{V}_{\text {ref }}$ node (the voltage output node in this application) of the DAC. This is done by using low input capacitance buffer amplifiers and careful board design.
Most single-supply circuits include ground as part of the analog signal range, which in turn requires an amplifier that can handle rail-to-rail signals. Analog Devices offers a wide range of singlesupply amplifiers, as listed in Table 8 and Table 9.

## PARALLEL INTERFACE

Data is loaded into the AD5405 in a 12-bit parallel word format. Control lines $\overline{C S}$ and $\mathrm{R} / \overline{\mathrm{W}}$ allow data to be written to or read from the DAC register. A write event takes place when $\overline{\mathrm{CS}}$ and $\mathrm{R} / \overline{\mathrm{W}}$ are brought low, data available on the data lines fills the shift register, and the rising edge of $\overline{\mathrm{CS}}$ latches the data and transfers the latched data-word to the DAC register. The DAC latches are not transparent; therefore, a write sequence must consist of a falling and rising edge on $\overline{\mathrm{CS}}$ to ensure that data is loaded into the DAC register and that its analog equivalent is reflected on the DAC output. A read event takes place when $\mathrm{R} / \overline{\mathrm{W}}$ is held high and $\overline{\mathrm{CS}}$ is brought low. Data is loaded from the DAC register, goes back into the input register, and is output onto the data line, where it can be read back to the controller for verification or diagnostic purposes. The input and DAC registers of these devices are not transparent; therefore, a falling and rising edge of $\overline{\mathrm{CS}}$ is required to load each data-word.

## MICROPROCESSOR INTERFACING

## ADSP-21xx Processors to AD5405 Interface

Figure 37 shows the AD5405 interfaced to the ADSP-21xx series of DSPs as a memory-mapped device. A single wait state may be necessary to interface the AD5405 to the ADSP-21xx, depending on the clock speed of the DSP. The wait state can be programmed via the data memory wait state control register of the ADSP-21xx (see the ADSP-21xx family user manual for details).

Figure 37. ADSP-21xx to AD5405 Interface

## 8xC51 to AD5405 Interface

Figure 38 shows the interface between the AD5405 and the 8 xC 51 family of DSPs. To facilitate external data memory access, the address latch enable (ALE) mode is enabled. The low byte of the address is latched with this output pulse during access to the external memory. AD0 to AD7 are the multiplexed low order addresses and data bus; they require strong internal pull-ups when emitting 1s. During access to external memory, A8 to A15 are the high order address bytes. Because these ports are open drained, they also require strong internal pull-ups when emitting 1 s .

Figure 38. 8xC51 to AD5405 Interface

## ADSP-BF504 to ADSP-BF592 Device Family to AD5405 Interface

Figure 39 shows a typical interface between the AD5405 and the ADSP-BF504 to ADSP-BF592 family of DSPs. The asynchronous memory write cycle of the processor drives the digital inputs of the DAC. The $\overline{\mathrm{AMS}} \mathrm{x}$ line is actually four memory select lines. Internal ADDR lines are decoded into $\overline{\mathrm{AMS}}_{3-0}$; these lines are then inserted as chip selects. The rest of the interface is a standard handshaking operation.

Figure 39. ADSP-BF504 to ADSP-BF592 Device Family to AD5405 Interface

## PCB LAYOUT AND POWER SUPPLY DECOUPLING

In any circuit where accuracy is important, careful consideration of the power supply and ground return layout helps to ensure the rated performance. The PCB on which the AD5405 is mounted must be designed so the analog and digital sections are separated and confined to certain areas of the board. If the DAC is in a system where multiple devices require an AGND to DGND connection, the connection must be made at one point only. The star ground point must be established as close as possible to the device.
These DACs must have ample supply bypassing of $10 \mu \mathrm{~F}$ in parallel with $0.1 \mu \mathrm{~F}$ on the supply located as close as possible to the package, ideally right up against the device. The $0.1 \mu \mathrm{~F}$ capacitor must have low effective series resistance (ESR) and low effective series inductance (ESI), like the common ceramic types of capacitors that provide a low impedance path to ground at high frequencies, to handle transient currents due to internal logic switching. Low ESR $1 \mu \mathrm{~F}$ to $10 \mu \mathrm{~F}$ tantalum or electrolytic capacitors must also be applied at the supplies to minimize transient disturbance and filter out low frequency ripple.

Components, such as clocks, that produce fast switching signals must be shielded with digital ground to avoid radiating noise to other parts of the board, and they must never run near the reference inputs.
Avoid crossover of digital and analog signals. Traces on opposite sides of the board must run at right angles to each other. This reduces the effects of feedthrough on the board.
A microstrip technique is by far the best, but its use is not always possible with a double-sided board. In this technique, the component side of the board is dedicated to the ground plane, and signal traces are placed on the soldered side.
It is good practice to use compact, minimum lead length PCB layout design. Leads to the input must be as short as possible to minimize IR drops and stray inductance.
The PCB metal traces between $V_{\text {Ref }}$ and RFB must also be matched to minimize gain error. To maximize high frequency performance, the I-to-V amplifier must be located as close as possible to the device.

[^0]:    ${ }^{1}$ U.S. Patent Number 5,689,257

[^1]:    ${ }^{1}$ Guaranteed by design and characterization, not subject to production test.

[^2]:    ${ }^{1} \mathrm{RU}=\mathrm{TSSOP}, \mathrm{CP}=\mathrm{LFCSP}, \mathrm{RM}=\mathrm{MSOP}, \mathrm{UJ}=\mathrm{TSOT}$.

[^3]:    ${ }^{1} \mathrm{Z}=$ RoHS Compliant Part.
