CMOS Dual 8-Bit Buffered Multiplying DAC

## AD7528

## FEATURES

On-Chip Latches for Both DACs
+5 V to +15 V Operation
DACs Matched to 1\%
Four Quadrant Multiplication
TTL/CMOS Compatible
Latch Free (Protection Schottkys not Required)
APPLICATIONS
Digital Control of:
Gain/Attenuation
Filter Parameters
Stereo Audio Circuits
X-Y Graphics

## GENERAL DESCRIPTION

The AD7528 is a monolithic dual 8-bit digital/analog converter featuring excellent DAC-to-DAC matching. It is available in skinny $0.3^{\prime \prime}$ wide 20 -lead DIPs and in 20-lead surface mount packages.
Separate on-chip latches are provided for each DAC to allow easy microprocessor interface.
Data is transferred into either of the two DAC data latches via a common 8-bit TTL/CMOS compatible input port. Control input $\overline{\mathrm{DAC} \mathrm{A}} / \mathrm{DAC} \mathrm{B}$ determines which DAC is to be loaded. The AD7528's load cycle is similar to the write cycle of a random access memory and the device is bus compatible with most 8 -bit microprocessors, including 6800, 8080, 8085, Z80.
The device operates from $\mathrm{a}+5 \mathrm{~V}$ to +15 V power supply, dissipating only 20 mW of power.

Both DACs offer excellent four quadrant multiplication characteristics with a separate reference input and feedback resistor for each DAC.

## PRODUCT HIGHLIGHTS

1. DAC-to-DAC matching: since both of the AD7528 DACs are fabricated at the same time on the same chip, precise matching and tracking between DAC A and DAC B is inherent. The AD7528's matched CMOS DACs make a whole new range of applications circuits possible, particularly in the audio, graphics and process control areas.
2. Small package size: combining the inputs to the on-chip DAC latches into a common data bus and adding a $\overline{\mathrm{DAC} \mathrm{A}} / \mathrm{DAC} \mathrm{B}$ select line has allowed the AD7528 to be packaged in either a small 20-lead DIP, SOIC or PLCC.

## CAUTION:

1. ESD sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subjected to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts.
2. Do not insert this device into powered sockets. Remove power before insertion or removal.

## TERMINOLOGY

## Relative Accuracy

Relative accuracy or endpoint nonlinearity is a measure of the maximum deviation from a straight line passing through the endpoints of the DAC transfer function. It is measured after adjusting for zero and full scale and is normally expressed in LSBs or as a percentage of full scale reading.

## Differential Nonlinearity

Differential nonlinearity is the difference between the measured change and the ideal 1 LSB change between any two adjacent codes. A specified differential nonlinearity of $\pm 1$ LSB max over the operating temperature range ensures monotonicity.

## Gain Error

Gain error or full-scale error is a measure of the output error between an ideal DAC and the actual device output. For the

AD7528, ideal maximum output is $\mathrm{V}_{\mathrm{REF}}-1$ LSB. Gain error of

## Output Capacitance

Capacitance from OUT A or OUT B to AGND.

## Digital to Analog Glitch Impulse

The amount of charge injected from the digital inputs to the analog output when the inputs change state. This is normally specified as the area of the glitch in either pA-secs or nV-secs depending upon whether the glitch is measured as a current or voltage signal. Glitch impulse is measured with $\mathrm{V}_{\text {REF }} \mathrm{A}$, $\mathrm{V}_{\text {REF }} \mathrm{B}=$ AGND.

## Propagation Delay

This is a measure of the internal delays of the circuit and is defined as the time from a digital input change to the analog output current reaching $90 \%$ of its final value.

## Channel-to-Channel Isolation

The proportion of input signal from one DAC's reference input which appears at the output of the other DAC, expressed as a ratio in dB .

## Digital Crosstalk

The glitch energy transferred to the output of one converter due to a change in digital input code to the other converter. Specified in nV secs.

## INTERFACE LOGIC INFORMATION

DAC Selection:
Both DAC latches share a common 8-bit input port. The control input $\overline{\mathrm{DAC} \mathrm{A}} / \mathrm{DAC} \mathrm{B}$ selects which DAC can accept data from the input port.

## Mode Selection:

Inputs $\overline{\mathrm{CS}}$ and $\overline{\mathrm{WR}}$ control the operating mode of the selected DAC. See Mode Selection Table below.

## Write Mode:

When $\overline{\mathrm{CS}}$ and $\overline{\mathrm{WR}}$ are both low the selected DAC is in the write mode. The input data latches of the selected DAC are transparent and its analog output responds to activity on DB0-DB7.

## Hold Mode:

The selected DAC latch retains the data which was present on DB0-DB7 just prior to $\overline{\mathrm{CS}}$ or $\overline{\mathrm{WR}}$ assuming a high state. Both analog outputs remain at the values corresponding to the data in their respective latches.

Mode Selection Table

| $\overline{\overline{\text { DAC A}} / \mathbf{D A C ~ B ~}}$ | $\overline{\mathbf{C S}}$ | $\overline{\mathbf{W R}}$ | DAC A | DAC B |
| :--- | :--- | :--- | :--- | :--- |
| L | L | L | WRITE | HOLD |
| H | L | L | HOLD | WRITE |
| X | H | X | HOLD | HOLD |
| X | X | H | HOLD | HOLD |

L = Low State; H = High State; X = Don't Care.

## WRITE CYCLE TIMING DIAGRAM

## CIRCUIT INFORMATION-D/A SECTION

The AD7528 contains two identical 8-bit multiplying D/A converters, DAC A and DAC B. Each DAC consists of a highly stable thin film R-2R ladder and eight N-channel current steering switches. A simplified D/A circuit for DAC A is shown in

Figure 1. Simplified Functional Circuit for DAC A

Figure 1. An inverted R-2R ladder structure is used, that is, binary weighted currents are switched between the DAC output and AGND thus maintaining fixed currents in each ladder leg independent of switch state.

## EQUIVALENT CIRCUIT ANALYSIS

Figure 2 shows an approximate equivalent circuit for one of the AD7528's D/A converters, in this case DAC A. A similar equivalent circuit can be drawn for DAC B. Note that AGND (Pin 1) is common for both DAC A and DAC B.
The current source $I_{\text {LEAKAGE }}$ is composed of surface and junction leakages and, as with most semiconductor devices, approximately doubles every $10^{\circ} \mathrm{C}$. The resistor $\mathrm{R}_{\mathrm{O}}$ as shown in Figure 2 is the equivalent output resistance of the device which varies with input code (excluding all 0 s code) from 0.8 R to $2 \mathrm{R} . \mathrm{R}$ is typically $11 \mathrm{k} \Omega$. $\mathrm{C}_{\text {OUT }}$ is the capacitance due to the N -channel switches and varies from about 50 pF to 120 pF depending upon the digital input. $g\left(V_{\text {REF }} A, N\right)$ is the Thevenin equivalent voltage generator due to the reference input voltage $V_{\text {REF }} A$ and the transfer function of the R-2R ladder.

Figure 2. Equivalent Analog Output Circuit of DAC A

## CIRCUIT INFORMATION-DIGITAL SECTION

The input buffers are simple CMOS inverters designed such that when the AD 7528 is operated with $\mathrm{V}_{\mathrm{DD}}=5 \mathrm{~V}$, the buffer converts TTL input levels ( 2.4 V and 0.8 V ) into CMOS logic levels. When $\mathrm{V}_{\mathrm{IN}}$ is in the region of 2.0 volts to 3.5 volts the input buffers operate in their linear region and pass a quiescent current, see Figure 3. To minimize power supply currents it is recommended that the digital input voltages be as close to the supply rails ( $\mathrm{V}_{\mathrm{DD}}$ and DGND ) as is practically possible.
The AD7528 may be operated with any supply voltage in the range $5 \leq \mathrm{V}_{\mathrm{DD}} \leq 15$ volts. With $\mathrm{V}_{\mathrm{DD}}=+15 \mathrm{~V}$ the input logic levels are CMOS compatible only, i.e., 1.5 V and 13.5 V .

Figure 3. Typical Plots of Supply Current, IDD vs. Logic Input Voltage $V_{I N}$, for $V_{D D}=+5 \mathrm{~V}$ and +15 V

NOTES:
${ }^{1}$ R1, R2 AND R3, R4 USED ONLY IF GAIN ADJUSTMENT IS REQUIRED.
SEE TABLE III FOR RECOMMENDED VALUES.
${ }^{2} \mathrm{C} 1, \mathrm{C} 2$ PHASE COMPENSATION ( $10 \mathrm{pF}-15 \mathrm{pF}$ ) IS REQUIRED WHEN USING HIGH SPEED AMPLIFIERS TO PREVENT RINGING OR OSCILLATION.

Figure 4. Dual DAC Unipolar Binary Operation (2 Quadrant Multiplication); See Table I

NOTES:
${ }^{1}$ R1, R2 AND R3, R4 USED ONLY IF GAIN ADJUSTMENT IS REQUIRED. SEE TABLE III FOR RECOMMENDED VALUES.
ADJUST R1 FOR $V_{\text {OUT }} A=0 V$ WITH CODE 10000000 IN DAC A LATCH.
ADJUST R3 FOR $\mathrm{V}_{\text {OUT }} \mathrm{B}=0 \mathrm{O}$ WITH CODE 10000000 IN DAC B LATCH.
2MATCHING AND TRACKING IS ESSENTIAL FOR RESISTOR PAIRS
R6, R7 AND R9, R10.
${ }^{3} \mathrm{C} 1$, C2 PHASE COMPENSATION ( $10 \mathrm{pF}-15 \mathrm{pF}$ ) MAY BE REQUIRED IF A1/A3 IS A HIGH SPEED AMPLIFIER.

Figure 5. Dual DAC Bipolar Operation (4 Quadrant Multiplication); See Table II

Table I. Unipolar Binary Code Table

| DAC Latch Contents <br> MSB LSB | Analog Output <br> (DAC A or DAC B) |
| :--- | :--- |
| 11111111 | $-V_{I N}\left(\frac{255}{256}\right)$ |
| 10000001 | $-V_{I N}\left(\frac{129}{256}\right)$ |
| 10000000 | $-V_{I N}\left(\frac{128}{256}\right)=-\frac{V_{I N}}{2}$ |
| 01111111 | $-V_{I N}\left(\frac{127}{256}\right)$ |
| 00000001 | $-V_{I N}\left(\frac{1}{256}\right)$ |
| 00000000 | $-V_{I N}\left(\frac{0}{256}\right)=0$ |

Note: 1 LSB $=\left(2^{-8}\right)\left(V_{I N}\right)=\frac{1}{256}\left(V_{I N}\right)$

Table II. Bipolar (Offset Binary) Code Table

| DAC Latch Contents MSB LSB | Analog Output (DAC A or DAC B) |
| :---: | :---: |
| 11111111 | $+V_{I N}\left(\frac{127}{128}\right)$ |
| 10000001 |  |
| 10000000 | 0 |
| 01111111 | $-V_{I N}\left(\frac{1}{128}\right)$ |
| 00000001 | $-V_{I N}\left(\frac{127}{128}\right)$ |
| 00000000 | $-V_{I N}\left(\frac{128}{128}\right)$ |
| Note: $1 \mathrm{LSB}=\left(2^{-7}\right)\left(V_{\text {IN }}\right)=\frac{1}{128}\left(V_{\text {IN }}\right)$ |  |

Table III. Recommended Trim Resistor
Values vs. Grade

| Trim <br> Resistor | J/A/S | K/B/T | L/C/U |

| R2; R4 | 330 | 150 | 82 |

## APPLICATIONS INFORMATION

## Application Hints

To ensure system performance consistent with AD7528 specifications, careful attention must be given to the following points:

1. GENERAL GROUND MANAGEMENT: AC or transient voltages between the AD7528 AGND and DGND can cause noise injection into the analog output. The simplest method of ensuring that voltages at AGND and DGND are equal is to tie AGND and DGND together at the AD7528. In more complex systems where the AGND-DGND intertie is on the backplane, it is recommended that diodes be connected in inverse parallel between the AD7528 AGND and DGND pins (1N914 or equivalent).
2. OUTPUT AMPLIFIER OFFSET: CMOS DACs exhibit a code-dependent output resistance which in turn causes a code-dependent amplifier noise gain. The effect is a codedependent differential nonlinearity term at the amplifier output which depends on $V_{O S}$ ( $\mathrm{V}_{\text {OS }}$ is amplifier input offset voltage). This differential nonlinearity term adds to the $\mathrm{R} / 2 \mathrm{R}$ differential nonlinearity. To maintain monotonic operation, it is recommended that amplifier $\mathrm{V}_{\text {OS }}$ be no greater than $10 \%$ of 1 LSB over the temperature range of interest.
3. HIGH FREQUENCY CONSIDERATIONS: The output capacitance of a CMOS DAC works in conjunction with the amplifier feedback resistance to add a pole to the open loop response. This can cause ringing or oscillation. Stability can be restored by adding a phase compensation capacitor in parallel with the feedback resistor.

## DYNAMIC PERFORMANCE

The dynamic performance of the two DACs in the AD7528 will depend upon the gain and phase characteristics of the output amplifiers together with the optimum choice of the PC board layout and decoupling components. Figure 6 shows the relation

Figure 6. Channel-to-Channel Isolation

Figure 7. Suggested PC Board Layout for AD7528 with AD644 Dual Op Amp
ship between input frequency and channel to channel isolation. Figure 7 shows a printed circuit layout for the AD7528 and the AD644 dual op amp which minimizes feedthrough and crosstalk.

## SINGLE SUPPLY APPLICATIONS

The AD7528 DAC R-2R ladder termination resistors are connected to AGND within the device. This arrangement is particularly convenient for single supply operation because AGND may be biased at any voltage between DGND and $\mathrm{V}_{\mathrm{DD}}$. Figure 8 shows a circuit which provides two +5 V to +8 V analog outputs by biasing AGND +5 V up from DGND. The two DAC reference inputs are tied together and a reference input voltage is obtained without a buffer amplifier by making use of the constant and matched impedances of the DAC A and DAC B reference inputs. Current flows through the two DAC R-2R ladders into $R 1$ and $R 1$ is adjusted until the $V_{\text {REF }} A$ and $V_{\text {REF }} B$ inputs are at +2 V . The two analog output voltages range from +5 V to +8 V for DAC codes 00000000 to 11111111 .

Figure 8. AD7528 Single Supply Operation
Figure 9 shows DAC A of the AD7528 connected in a positive reference, voltage switching mode. This configuration is useful in that $\mathrm{V}_{\text {OUT }}$ is the same polarity as $\mathrm{V}_{\text {IN }}$ allowing single supply operation. However, to retain specified linearity, $\mathrm{V}_{\text {IN }}$ must be in the range 0 V to +2.5 V and the output buffered or loaded with a high impedance, see Figure 10. Note that the input voltage is connected to the DAC OUT A and the output voltage is taken from the $D A C V_{\text {REF }} A$ pin.

## PROGRAMMABLE WINDOW COMPARATOR

Figure 13. Digitally Programmable Window Comparator (Upper and Lower Limit Detector)

In the circuit of Figure 13 the AD7528 is used to implement a programmable window comparator. DACs A and B are loaded with the required upper and lower voltage limits for the test, respectively. If the test input is not within the programmed limits, the pass/fail output will indicate a fail (logic zero).

## PROGRAMMABLE STATE VARIABLE FILTER

In this state variable or universal filter configuration (Figure 14) DACs A1 and B1 control the gain and Q of the filter characteristic while DACs A2 and B2 control the cutoff frequency, $\mathrm{f}_{\mathrm{C}}$. DACs A2 and B2 must track accurately for the simple expression for $\mathrm{f}_{\mathrm{C}}$ to hold. This is readily accomplished by the AD7528. Op amps are $2 \times$ AD644. C3 compensates for the effects of op amp gain bandwidth limitations.

The filter provides low pass, high pass and band pass outputs and is ideally suited for applications where microprocessor control of filter parameters is required, e.g., equalizer, tone controls, etc.
Programmable range for component values shown is $\mathrm{f}_{\mathrm{C}}=0 \mathrm{kHz}$ to 15 kHz and $\mathrm{Q}=0.3$ to 4.5 .

Figure 14. Digitally Controlled State Variable Filter

## CIRCUIT EQUATIONS

$C 1=C 2, R 1=R 2, R 4=R 5$

$$
f_{C}=\frac{1}{2 \pi R 1 C 1}
$$

$$
Q=\frac{R 3}{R 4} \times \frac{R_{F}}{R_{F B B 1}}
$$

$$
A_{O}=-\frac{R_{F}}{R_{S}}
$$

NOTE
DAC Equivalent Resistance Equals
$\frac{256 \times(\text { DAC Ladder Resistance })}{\text { DAC Digital Code }}$

## DIGITALLY CONTROLLED DUAL TELEPHONE

## ATTENUATOR

In this configuration the AD7528 functions as a 2-channel digitally controlled attenuator. Ideal for stereo audio and telephone signal level control applications. Table IV gives input codes vs. attenuation for a 0 dB to 15.5 dB range.

$$
\text { Input Code }=256 \times 10 \exp \left(-\frac{\text { Attenuation, } d B}{20}\right)
$$

Figure 15. Digitally Controlled Dual Telephone Attenuator

Table IV. Attenuation vs. DAC A, DAC B Code for the Circuit of Figure 15

| Attn. dB | DAC Input Code | Code In Decimal | Attn. dB | DAC Input Code | Code In Decimal |
| :---: | :---: | :---: | :---: | :---: | :---: |
