## Data Sheet

## FEATURES

Low power amplifiers provide low noise and low distortion, ideal for xDSL modem receiver
Wide supply range: $+5 \mathrm{~V}, \pm 2.5 \mathrm{~V}$ to $\pm 12 \mathrm{~V}$ voltage supply
Low power consumption: $\mathbf{4 . 0 \mathrm { mA } / \mathrm { Amp }}$
Voltage feedback
Ease of Use
Lower total noise (insignificant input current noise contribution compared to current feedback amps)
Low noise and distortion
2.5 nV/ $\sqrt{\mathrm{Hz}}$ voltage noise @ 100 kHz
$1.2 \mathrm{pA} / \sqrt{ } \mathrm{Hz}$ current noise
MTPR <-66 dBc (G = +7)
SFDR 110 dB @ 200 kHz
High speed
130 MHz bandwidth ( -3 dB ), $\mathbf{G}=+1$
Settling time to $0.1 \%$, 68 ns
$50 \mathrm{~V} / \mu \mathrm{s}$ slew rate
High output swing: $\pm 10.1 \mathrm{~V}$ on $\pm 12 \mathrm{~V}$ supply
Low offset voltage, $\mathbf{1 . 5} \mathbf{~ m V}$ typical

## APPLICATIONS

Receiver for ADSL, VDSL, HDSL, and proprietary xDSL systems
Low noise instrumentation front end
Ultrasound preamps
Active filters
16-bit ADC buffers

## GENERAL DESCRIPTIONS

The AD8022 consists of two low noise, high speed, voltage feedback amplifiers. Each amplifier consumes only 4.0 mA of quiescent current, yet has only $2.5 \mathrm{nV} / \sqrt{ } \mathrm{Hz}$ of voltage noise. These dual amplifiers provide wideband, low distortion performance, with high output current optimized for stability when driving capacitive loads. Manufactured on ADI's high voltage generation of XFCB bipolar process, the AD8022 operates on a wide range of supply voltages. The AD8022 is available in both an 8-lead MSOP and an 8-lead SOIC. Fast over voltage recovery and wide bandwidth make the AD8022 ideal as the receive channel front end to an ADSL, VDSL, or proprietary xDSL transceiver design.

In an xDSL line interface circuit, the AD8022's op amps can be configured as the differential receiver from the line transformer or as independent active filters.

| Supply Voltage (+ $\mathrm{V}_{\mathrm{s}}$ to $-\mathrm{V}_{\mathrm{s}}$ ) | 26.4 V |
| Internal Power Dissipation ${ }^{1}$ |  |
| $\quad$ 8-Lead SOIC (R) | 1.6 W |
| $\quad$ 8-Lead MSOP (RM) | 1.2 W |
| Input Voltage (Common Mode) | $\pm \mathrm{V}_{\mathrm{s}}$ |
| Differential Input Voltage | $\pm 0.8 \mathrm{~V}$ |
| Output Short-Circuit Duration | Observe Power Derating Curves |
| Storage Temperature Range | $-65^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$ |
| Operating Temperature Range <br> $\quad$ (A Grade) | $-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$ |
| Lead Temperature Range | $300^{\circ} \mathrm{C}$ |
| $\quad$ (Soldering 10 sec) |  |

[^1]Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only; functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

## MAXIMUM POWER DISSIPATION

The maximum power that can be safely dissipated by the AD8022 is limited by the associated rise in junction temperature. The maximum safe junction temperature for plastic encapsulated devices is determined by the glass transition temperature of the plastic, approximately $150^{\circ} \mathrm{C}$. Temporarily exceeding this limit may cause a shift in parametric performance due to a change in the stresses exerted on the die by the package. Exceeding a junction temperature of $175^{\circ} \mathrm{C}$ for an extended period can result in device failure.

While the AD8022 is internally short-circuit protected, this may not be sufficient to guarantee that the maximum junction temperature $\left(150^{\circ} \mathrm{C}\right)$ is not exceeded under all conditions. To ensure proper operation, it is necessary to observe the maximum power derating curves.

Figure 3. Maximum Power Dissipation vs. Temperature

## ESD CAUTION

ESD (electrostatic discharge) sensitive device. Electrostatic charges as high as 4000 V readily accumulate on the human body and test equipment and can discharge without detection. Although this product features proprietary ESD protection circuitry, permanent damage may occur on devices subjected to high energy electrostatic discharges. Therefore, proper ESD precautions are recommended to avoid performance degradation or loss of functionality.

## THEORY OF OPERATION

The AD8022 is a voltage-feedback op amp designed especially for ADSL or other applications requiring very low voltage and current noise along with low supply current, low distortion, and ease of use.

The AD8022 is fabricated on Analog Devices' proprietary eXtra-Fast Complementary Bipolar (XFCB) process, which enables the construction of PNP and NPN transistors with similar fTs in the 4 GHz region. The process is dielectrically isolated to eliminate the parasitic and latch-up problems caused by junction isolation. These features enable the construction of high frequency, low distortion amplifiers with low supply currents.

Figure 38. Simplified Schematic

As shown in Figure 38, the AD8022 input stage consists of an NPN differential pair in which each transistor operates a $300 \mu \mathrm{~A}$ collector current. This gives the input devices a high transconductance and therefore gives the AD8022 a low input noise of $2.5 \mathrm{nV} / \sqrt{ } \mathrm{Hz} @ 100 \mathrm{kHz}$. The input stage drives a folded cascode that consists of a pair of PNP transistors. These PNPs then drive a current mirror that provides a differential input to single-ended output conversion. The output stage provides a high current gain of 10,000 so that the AD8022 can maintain a high dc open-loop gain, even into low load impedances.

## APPLICATIONS

The low noise AD8022 dual xDSL receiver amplifier is specifically designed for the dual differential receiver amplifier function within xDSL transceiver hybrids, as well as other low noise amplifier applications. The AD8022 can be used in receiving modulated signals including discrete multitone (DMT) on either end of the subscriber loop. Communication systems designers can be challenged when designing an xDSL modem transceiver hybrid capable of receiving the smallest signals embedded in noise that inherently exists on twisted-pair phone lines. Noise sources include near-end crosstalk (NEXT), far-end crosstalk (FEXT), background, and impulse noise, all of which are fed, to some degree, into the receiver front end. Based on a Bellcore noise survey, the background noise level for typical twisted-pair telephone loops is $-140 \mathrm{dBm} / \sqrt{ } \mathrm{Hz}$ or $31 \mathrm{nV} / \sqrt{ } \mathrm{Hz}$. It is therefore important to minimize the noise added by the receiver amplifiers to preserve as much signal-tonoise ratio (SNR) as possible. With careful transceiver hybrid design, using the AD8022 dual, low noise, receiver amplifier to maintain power density levels lower than $-140 \mathrm{dBm} / \sqrt{ } \mathrm{Hz}$ in ADSL modems is easily achieved.

## DMT MODULATION AND MULTITONE POWER RATIO (MTPR)

ADSL systems rely on discrete multitone DMT modulation to carry digital data over phone lines. DMT modulation appears in the frequency domain as power contained in several individual frequency subbands, sometimes referred to as tones or bins, each of which is uniformly separated in frequency. (See Figure 24 to Figure 27 for MTPR results while the AD8022 receives DMT driving 800 mV rms across a $500 \Omega$ differential load.) A uniquely encoded quadrature amplitude modulation (QAM) signal occurs at the center frequency of each subband or tone. Difficulties exist when decoding these subbands if a QAM signal from one subband is corrupted by the QAM signal(s) from other subbands, regardless of whether the corruption comes from an adjacent subband or harmonics of other subbands. Conventional methods of expressing the output signal integrity of line receivers, such as spurious-free dynamic range (SFDR), single tone harmonic distortion (THD), twotone intermodulation distortion (IMD), and third-order intercept (IP3), become significantly less meaningful when amplifiers are required to process DMT and other heavily modulated waveforms. A typical xDSL downstream DMT signal can contain as many as 256 carriers (subbands or tones) of QAM signals. MTPR is the relative difference between the measured power in a typical subband (at one tone or carrier) vs. the power at another subband specifically selected to contain no QAM data.

In other words, a selected subband (or tone) remains open or void of intentional power (without a QAM signal) yielding an
empty frequency bin. MTPR, sometimes referred to as the empty bin test, is typically expressed in dBc , similar to expressing the relative difference between single tone fundamentals and second or third harmonic distortion components. Measurements of MTPR are typically made at the output of the receiver directly across the differential load. Other components aside, the receiver function of an ADSL transceiver hybrid is affected by the turns ratio of the selected transformers within the hybrid design. Since a transformer reflects the secondary voltage back to the primary side by the inverse of the turns ratio, $1 / \mathrm{N}$, increasing the turns ratio on the secondary side reduces the voltage across the primary side inputs of the differential receiver. Increasing the turns ratio of the transformers can inadvertently cause a reduction of the SNR by reducing the received signal strength.

## CHANNEL CAPACITY AND SNR

The efficiency of an ADSL system in delivering the digital data embedded in the DMT signals can be compromised when the noise power of the transmission system increases. Figure 39 shows the relationship between SNR and the relative maximum number of bits per tone or subband while maintaining a bit error rate at $10^{-7}$ errors per second.

Figure 39. ADSL DMT SNR vs. Bits/Tone

## POWER SUPPLY AND DECOUPLING

The AD8022 should be powered with a good quality (that is, low noise) dual supply of $\pm 12 \mathrm{~V}$ for the best overall performance. The AD8022 circuit also functions at voltages lower than $\pm 12 \mathrm{~V}$. Careful attention must be paid to decoupling the power supply pins. A pair of $10 \mu \mathrm{~F}$ capacitors located in near proximity to the AD8022 is required to provide good decoupling for lower frequency signals. In addition, $0.1 \mu \mathrm{~F}$ decoupling capacitors should be located as close to each of the power supply pins as is physically possible.

## LAYOUT CONSIDERATIONS

As is the case with all high speed amplifiers, careful attention to printed circuit board layout details prevent associated board parasitics from becoming problematic. Proper RF design technique is mandatory. The PCB should have a ground plane covering all unused portions of the component side of the board to provide a low impedance return path. Removing the ground plane from the area near the input signal lines reduces stray capacitance. Chip capacitors should be used for supply bypassing. One end of the capacitor should be connected to the ground plane, and the other should be connected no more than $1 / 8$ inch away from each supply pin. An additional large ( $0.47 \mu \mathrm{~F}$ to $10 \mu \mathrm{~F}$ ) tantalum capacitor should be connected in parallel, although not necessarily as close, in order to supply current for fast, large signal changes at the AD8022 output. Signal lines connecting the feedback and gain resistors should be as short as possible, minimizing the inductance and stray capacitance associated with these traces. Locate termination resistors and loads as close as possible to the input(s) and output, respectively. Adhere to stripline design techniques for long signal traces (greater than about 1 inch). Following these generic guidelines improves the performance of the AD8022 in all applications.

## OUTLINE DIMENSIONS

gure 44. 8-Lead Mini Small Outline Package [MSOP]
(RM-8)—Dimensions shown in millimeters

## ORDERING GUIDE

| Model $^{1}$ | Temperature Range | Package Description | Package Option |
| :--- | :--- | :--- | :--- |
| AD8022AR | $-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$ | 8 -Lead SOIC_N | R-8 |
| AD8022ARZ | $-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$ | 8 -Lead SOIC_N | R-8 |
| AD8022ARZ-REEL | $-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$ | 8 -Lead SOIC_N | R-8 |
| AD8022ARZ-REEL7 | $-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$ | 8 -Lead SOIC_N | R-8 |
| AD8022ARMZ | $-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$ | 8 -Lead MSOP | RM-8 |
| AD8022ARMZ-REEL | $-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$ | 8 -Lead MSOP | RM-8 |
| AD8022ARMZ-REEL7 | $-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$ | 8 -Lead MSOP | RM-8 |
| AD8022ARM-EBZ |  | Evaluation Board |  |
| AD8022AR-EBZ | Evaluation Board |  |  |
