## Data Sheet

## FEATURES

Fully differential
Low noise
2.25 nV/ $\sqrt{ } \mathrm{Hz}$
$2.1 \mathrm{pA} / \sqrt{ } \mathrm{Hz}$
Low harmonic distortion
98 dBc SFDR at 1 MHz
85 dBc SFDR at 5 MHz
72 dBc SFDR at $\mathbf{2 0} \mathbf{~ M H z}$
High speed
$410 \mathrm{MHz}, 3 \mathrm{~dB}$ BW ( $\mathbf{G}=1$ )
$800 \mathrm{~V} / \mu \mathrm{s}$ slew rate
45 ns settling time to $0.01 \%$
69 dB output balance at 1 MHz
80 dB dc CMRR
Low offset: $\pm 0.5 \mathrm{mV}$ maximum
Low input offset current: $0.5 \mu \mathrm{~A}$ maximum
Differential input and output
Differential-to-differential or single-ended-to-differential operation
Rail-to-rail output
Adjustable output common-mode voltage
Wide supply voltage range: 5 V to 12 V
Available in a small SOIC package and an 8-lead LFCSP

## APPLICATIONS

ADC drivers to 18 bits
Single-ended-to-differential converters
Differential filters
Level shifters
Differential PCB drivers
Differential cable drivers

## GENERAL DESCRIPTION

The AD8139 is an ultralow noise, high performance differential amplifier with rail-to-rail output. With its low noise, high SFDR, and wide bandwidth, it is an ideal choice for driving analog-to-digital converters (ADCs) with resolutions to 18 bits. The AD8139 is easy to apply, and its internal common-mode feedback architecture allows its output common-mode voltage to be controlled by the voltage applied to one pin. The internal feedback loop also provides outstanding output balance as well as suppression of even-order harmonic distortion products. Fully differential and single-ended-to-differential gain configurations are easily realized by the AD8139. Simple external feedback networks consisting of four resistors determine the closed-loop gain of the amplifier.

NIC = NO INTERNAL CONNECTION. .
Figure 2. 8-Lead LFCSP

The AD8139 is manufactured on the proprietary Analog Devices, Inc., second-generation XFCB process, enabling it to achieve low levels of distortion with input voltage noise of only $2.25 \mathrm{nV} / \sqrt{ } \mathrm{Hz}$.
The AD8139 is available in an 8-lead SOIC package with an exposed paddle (EP) on the underside of its body and a $3 \mathrm{~mm} \times$ 3 mm LFCSP. It is rated to operate over the temperature range of $-40^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$.

## ABSOLUTE MAXIMUM RATINGS

Table 3.

| Parameter | Rating |
| :--- | :--- |
| Supply Voltage | 12 V |
| Vocm | $\pm \mathrm{V}_{\mathrm{S}}$ |
| Power Dissipation | See Figure 4 |
| Input Common-Mode Voltage | $\pm \mathrm{V}_{\mathrm{S}}$ |
| Storage Temperature Range | $-65^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$ |
| Operating Temperature Range | $-40^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$ |
| Lead Temperature (Soldering 10 sec$)$ | $300^{\circ} \mathrm{C}$ |
| Junction Temperature | $150^{\circ} \mathrm{C}$ |

Stresses at or above those listed under Absolute Maximum Ratings may cause permanent damage to the product. This is a stress rating only; functional operation of the product at these or any other conditions above those indicated in the operational section of this specification is not implied. Operation beyond the maximum operating conditions for extended periods may affect product reliability.

## THERMAL RESISTANCE

$\theta_{J A}$ is specified for the worst-case conditions, that is, $\theta_{\mathrm{JA}}$ is specified for device soldered in circuit board for surface-mount packages.

Table 4.

| Package Type | $\boldsymbol{\theta}_{\mathrm{JA}}$ | Unit |
| :--- | :--- | :--- |
| 8-Lead SOIC with EP/4-Layer | 70 | ${ }^{\circ} \mathrm{C} / \mathrm{W}$ |
| 8-Lead LFCSP/4-Layer | 70 | ${ }^{\circ} \mathrm{C} / \mathrm{W}$ |

## Maximum Power Dissipation

The maximum safe power dissipation in the AD8139 package is limited by the associated rise in junction temperature $\left(\mathrm{T}_{\mathrm{J}}\right)$ on the die. At approximately $150^{\circ} \mathrm{C}$, which is the glass transition temperature, the plastic changes its properties. Even temporarily exceeding this temperature limit can change the stresses that the package exerts on the die, permanently shifting the parametric performance of the AD8139. Exceeding a junction temperature of $175^{\circ} \mathrm{C}$ for an extended period can result in changes in the silicon devices potentially causing failure.

The power dissipated in the package $\left(\mathrm{P}_{\mathrm{D}}\right)$ is the sum of the quiescent power dissipation and the power dissipated in the package due to the load drive for all outputs. The quiescent power is the voltage between the supply pins $\left(\mathrm{V}_{\mathrm{s}}\right)$ times the quiescent current ( $\mathrm{I}_{\mathrm{s}}$ ). The load current consists of differential and common-mode currents flowing to the load, as well as currents flowing through the external feedback networks and the internal common-mode feedback loop. The internal resistor tap used in the common-mode feedback loop places a $1 \mathrm{k} \Omega$ differential load on the output. RMS output voltages should be considered when dealing with ac signals.
Airflow reduces $\theta_{J A}$. In addition, more metal directly in contact with the package leads from metal traces, through holes, ground, and power planes reduce the $\theta_{\mathrm{JA}}$.
Figure 4 shows the maximum safe power dissipation in the package vs. the ambient temperature for the exposed paddle (EP) 8-lead SOIC ( $\left.\theta_{\mathrm{JA}}=70^{\circ} \mathrm{C} / \mathrm{W}\right)$ and the 8-lead LFCSP $\left(\theta_{\mathrm{IA}}=70^{\circ} \mathrm{C} / \mathrm{W}\right)$ on a JEDEC standard 4-layer board. $\theta_{\mathrm{J} A}$ values are approximations.

Figure 4. Maximum Power Dissipation vs. Temperature for a 4-Layer Board

## ESD CAUTION

ESD (electrostatic discharge) sensitive device. Charged devices and circuit boards can discharge without detection. Although this product features patented or proprietary protection circuitry, damage may occur on devices subjected to high energy ESD Therefore, proper ESD precautions should be taken to avoid performance degradation or loss of functionality.

## PIN CONFIGURATIONS AND FUNCTION DESCRIPTIONS

NOTES

1. NIC = NO INTERNAL CONNECTION.
2. SOLDER THE EXPOSED PADDLE ON THE BACK OF THE PACKAGE TO THE GROUND PLANE OR TO
A POWER PLANE. A POWER PLANE.
Figure 5. 8-Lead SOIC Pin Configuration
Table 5. Pin Function Descriptions

| Pin No. | Mnemonic | Description |
| :---: | :---: | :---: |
| 1 | -IN | Inverting Input. |
| 2 | Vocm | An internal feedback loop drives the output common-mode voltage to be equal to the voltage applied to the Vocm pin, provided the operation of the amplifier remains linear. |
| 3 | V+ | Positive Power Supply Voltage. |
| 4 | +OUT | Positive Side of the Differential Output. |
| 5 | -OUT | Negative Side of the Differential Output. |
| 6 | V- | Negative Power Supply Voltage. |
| 7 | NIC | No Internal Connection. |
| 8 | +IN | Noninverting Input. |
| 0 | EP | Exposed Paddle. Solder the exposed paddle on the back of the package to the ground plane or to a power plane. |

## TYPICAL PERFORMANCE CHARACTERISTICS

Unless otherwise noted, differential gain $=+1, \mathrm{R}_{\mathrm{G}}=\mathrm{R}_{\mathrm{F}}=200 \Omega, \mathrm{R}_{\mathrm{L}, \mathrm{dm}}=1 \mathrm{k} \Omega, \mathrm{V}_{\mathrm{S}}= \pm 5 \mathrm{~V}, \mathrm{~T}_{\mathrm{A}}=25^{\circ} \mathrm{C}, \mathrm{V}_{\text {ocm }}=0 \mathrm{~V}$. Refer to the basic test circuit in Figure 57 for the definition of terms.

## THEORY OF OPERATION

The AD8139 is a high speed, low noise differential amplifier fabricated on the Analog Devices second-generation extra fast complementary bipolar (XFCB) process. It is designed to provide two closely balanced differential outputs in response to either differential or single-ended input signals. Differential gain is set by external resistors, similar to traditional voltagefeedback operational amplifiers. The common-mode level of the output voltage is set by a voltage at the Vосм pin and is independent of the input common-mode voltage. The AD8139 has an H -bridge input stage for high slew rate, low noise, and low distortion operation and rail-to-rail output stages that provide maximum dynamic output range. This set of features allows for convenient single-ended-to-differential conversion, a common need to take advantage of modern high resolution ADCs with differential inputs.

## TYPICAL CONNECTION AND DEFINITION OF TERMS

Figure 59 shows a typical connection for the AD8139, using matched external $\mathrm{R}_{\mathrm{F}} / \mathrm{R}_{\mathrm{G}}$ networks. The differential input terminals of the AD8139, $\mathrm{V}_{\mathrm{AP}}$ and $\mathrm{V}_{\mathrm{AN}}$, are used as summing junctions. An external reference voltage applied to the V OCм terminal sets the output common-mode voltage. The two output terminals, $\mathrm{V}_{\mathrm{OP}}$ and $\mathrm{V}_{\mathrm{ON}}$, move in opposite directions in a balanced fashion in response to an input signal.

Figure 59. Typical Connection
The differential output voltage is defined as

$$
\begin{equation*}
V_{O, d m}=V_{O P}-V_{O N} \tag{1}
\end{equation*}
$$

Common-mode voltage is the average of two voltages. The output common-mode voltage is defined as

$$
\begin{equation*}
V_{O, c m}=\frac{V_{O P}+V_{O N}}{2} \tag{2}
\end{equation*}
$$

## Output Balance

Output balance is a measure of how well $V_{\text {OP }}$ and $V_{\text {ON }}$ are matched in amplitude and how precisely they are $180^{\circ}$ out of phase with each other. It is the internal common-mode feedback loop that forces the signal component of the output common-mode towards zero, resulting in the near perfectly balanced differential
outputs of identical amplitude and exactly $180^{\circ}$ out of phase. The output balance performance does not require tightly matched external components, nor does it require that the feedback factors of each loop be equal to each other. Low frequency output balance is limited ultimately by the mismatch of an on-chip voltage divider, which is trimmed for optimum performance.
Output balance is measured by placing a well-matched resistor divider across the differential voltage outputs and comparing the signal at the midpoint of the divider with the magnitude of the differential output. By this definition, output balance is equal to the magnitude of the change in output common-mode voltage divided by the magnitude of the change in output differential-mode voltage:

$$
\begin{equation*}
\text { Output Balance }=\left|\frac{\Delta V_{O, c m}}{\Delta V_{O, d m}}\right| \tag{3}
\end{equation*}
$$

The block diagram of the AD8139 in Figure 60 shows the external differential feedback loop ( $\mathrm{R}_{\mathrm{F}} / \mathrm{R}_{\mathrm{G}}$ networks and the differential input transconductance amplifier, $G_{\text {DIFF }}$ ) and the internal common-mode feedback loop (voltage divider across $\mathrm{V}_{\mathrm{OP}}$ and $\mathrm{V}_{\mathrm{ON}}$ and the common-mode input transconductance amplifier, $\left.\mathrm{G}_{\mathrm{CM}}\right)$. The differential negative feedback drives the voltages at the summing junctions $\mathrm{V}_{\mathrm{AN}}$ and $\mathrm{V}_{\mathrm{AP}}$ to be essentially equal to each other.

$$
\begin{equation*}
V_{A N}=V_{A P} \tag{4}
\end{equation*}
$$

The common-mode feedback loop drives the output commonmode voltage, sampled at the midpoint of the two $500 \Omega$ resistors, to equal the voltage set at the Vocm terminal. This ensures that

$$
\begin{equation*}
V_{O P}=V_{O C M}+\frac{V_{O, d m}}{2} \tag{5}
\end{equation*}
$$

and

$$
\begin{equation*}
V_{O N}=V_{O C M}-\frac{V_{O, d m}}{2} \tag{6}
\end{equation*}
$$

## APPLICATIONS INFORMATION

## ESTIMATING NOISE, GAIN, AND BANDWIDTH WITH MATCHED FEEDBACK NETWORKS

## Estimating Output Noise Voltage

The total output noise is calculated as the root-sum-squared total of several statistically independent sources. Because the sources are statistically independent, the contributions of each must be individually included in the root-sum-square calculation. Table 6 lists recommended resistor values and estimates of bandwidth and output differential voltage noise for various closed-loop gains. For most applications, $1 \%$ resistors are sufficient.

Table 6. Recommended Values of Gain-Setting Resistors and Voltage Noise for Various Closed-Loop Gains

| Gain | $\mathbf{R}_{\mathbf{G}}(\mathbf{\Omega})$ | $\mathbf{R}_{\mathbf{F}}(\mathbf{\Omega})$ | $\mathbf{3 ~ d B}$ <br> Bandwidth $(\mathbf{M H z})$ | Total Output <br> Noise (nV/JHz) |
| :--- | :--- | :--- | :--- | :--- |
| 1 | 200 | 200 | 400 | 5.8 |
| 2 | 200 | 400 | 160 | 9.3 |
| 5 | 200 | 1 k | 53 | 19.7 |
| 10 | 200 | 2 k | 26 | 37 |

The differential output voltage noise contains contributions from the input voltage noise and input current noise of the AD8139 as well as those from the external feedback networks.

The contribution from the input voltage noise spectral density is computed as

$$
\begin{equation*}
V o \_n 1=v_{n}\left(1+\frac{R_{F}}{R_{G}}\right) \text {, or equivalently, } v_{n} / \beta \tag{7}
\end{equation*}
$$

where $v_{n}$ is defined as the input-referred differential voltage noise. This equation is the same as that of traditional op amps.
The contribution from the input current noise of each input is computed as

$$
\begin{equation*}
V o \_n 2=i_{n}\left(R_{F}\right) \tag{8}
\end{equation*}
$$

where $i_{n}$ is defined as the input noise current of one input. Each input needs to be treated separately because the two input currents are statistically independent processes.
The contribution from each $R_{G}$ is computed as

$$
\begin{equation*}
V o \_n 3=\sqrt{4 k T R_{G}}\left(\frac{R_{F}}{R_{G}}\right) \tag{9}
\end{equation*}
$$

This result can be intuitively viewed as the thermal noise of each $\mathrm{R}_{\mathrm{G}}$ multiplied by the magnitude of the differential gain.
The contribution from each $R_{F}$ is computed as

$$
\begin{equation*}
V o \_n 4=\sqrt{ } 4 k T R_{F} \tag{10}
\end{equation*}
$$

## Voltage Gain

The behavior of the node voltages of the single-ended-todifferential output topology can be deduced from the previous definitions. Referring to Figure 59, $\left(\mathrm{C}_{\mathrm{F}}=0\right)$ and setting $\mathrm{V}_{\mathrm{IN}}=0$, one can write

$$
\begin{align*}
& \frac{V_{I P}-V_{A P}}{R_{G}}=\frac{V_{A P}-V_{O N}}{R_{F}}  \tag{11}\\
& V_{A N}=V_{A P}=V_{O P}\left(\frac{R_{G}}{R_{F}+R_{G}}\right) \tag{12}
\end{align*}
$$

Solving the above two equations and setting $\mathrm{V}_{\text {IP }}$ to $\mathrm{V}_{\mathrm{i}}$ gives the gain relationship for $\mathrm{V}_{\mathrm{O}, \mathrm{dm}} / \mathrm{V}_{\mathrm{i}}$.

$$
\begin{equation*}
V_{O P}-V_{O N}=V_{O, d m}=\frac{R_{F}}{R_{G}} V_{i} \tag{13}
\end{equation*}
$$

An inverting configuration with the same gain magnitude can be implemented by simply applying the input signal to $\mathrm{V}_{\mathrm{IN}}$ and setting $\mathrm{V}_{\text {IP }}=0$. For a balanced differential input, the gain from $V_{I N, d m}$ to $V_{o, d m}$ is also equal to $R_{F} / R_{G}$, where $V_{I N, d m}=V_{I P}-V_{I N}$.

## Feedback Factor Notation

When working with differential amplifiers, it is convenient to introduce the feedback factor $\beta$, which is defined as

$$
\begin{equation*}
\beta=\frac{R_{G}}{R_{F}+R_{G}} \tag{14}
\end{equation*}
$$

This notation is consistent with conventional feedback analysis and is very useful, particularly when the two feedback loops are not matched.

## Input Common-Mode Voltage

The linear range of the $\mathrm{V}_{\mathrm{AN}}$ and $\mathrm{V}_{\mathrm{AP}}$ terminals extends to within approximately 1 V of either supply rail. Because $\mathrm{V}_{\mathrm{AN}}$ and $\mathrm{V}_{\mathrm{AP}}$ are essentially equal to each other, they are both equal to the input common-mode voltage of the amplifier. Their range is indicated in the Specifications tables as input common-mode range. The voltage at $\mathrm{V}_{\mathrm{AN}}$ and $\mathrm{V}_{\mathrm{AP}}$ for the connection diagram in Figure 59 can be expressed as

$$
\begin{align*}
& V_{A N}=V_{A P}=V_{A C M}= \\
& \left(\frac{R_{F}}{R_{F}+R_{G}} \times \frac{\left(V_{I P}+V_{I N}\right)}{2}\right)+\left(\frac{R_{G}}{R_{F}+R_{G}} \times V_{O C M}\right) \tag{15}
\end{align*}
$$

where $V_{A C M}$ is the common-mode voltage present at the amplifier input terminals.
Using the $\beta$ notation, Equation 15 can be written as follows:

$$
\begin{equation*}
V_{A C M}=\beta V_{O C M}+(1-\beta) V_{I C M} \tag{16}
\end{equation*}
$$

or equivalently,

$$
\begin{equation*}
V_{A C M}=V_{I C M}+\beta\left(V_{O C M}-V_{I C M}\right) \tag{17}
\end{equation*}
$$

where $V_{I C M}$ is the common-mode voltage of the input signal, that is, $V_{I C M}=V_{I P}+V_{I N} / 2$.

For proper operation, the voltages at $\mathrm{V}_{\mathrm{AN}}$ and $\mathrm{V}_{\mathrm{AP}}$ must stay within their respective linear ranges.

## Calculating Input Impedance

The input impedance of the circuit in Figure 59 depends on whether the amplifier is being driven by a single-ended or a differential signal source. For balanced differential input signals, the differential input impedance ( $\mathrm{R}_{\mathrm{IN}, \mathrm{dm}}$ ) is simply

$$
\begin{equation*}
R_{I N, d m}=2 R_{G} \tag{18}
\end{equation*}
$$

For a single-ended signal (for example, when $\mathrm{V}_{\text {IN }}$ is grounded and the input signal drives $\mathrm{V}_{\text {IP }}$ ), the input impedance becomes

$$
\begin{equation*}
R_{I N}=\frac{R_{G}}{1-\frac{R_{F}}{2\left(R_{G}+R_{F}\right)}} \tag{19}
\end{equation*}
$$

The input impedance of a conventional inverting op amp configuration is simply $\mathrm{R}_{\mathrm{G}}$, but it is higher in Equation 19 because a fraction of the differential output voltage appears at the summing junctions, $\mathrm{V}_{\mathrm{AN}}$ and $\mathrm{V}_{\mathrm{AP}}$. This voltage partially bootstraps the voltage across the input resistor $\mathrm{R}_{\mathrm{G}}$, leading to the increased input resistance.

## Input Common-Mode Swing Considerations

In some single-ended-to-differential applications, when using a single-supply voltage, attention must be paid to the swing of the input common-mode voltage, $\mathrm{V}_{\mathrm{ACM}}$.

Consider the case in Figure 61, where $\mathrm{V}_{\text {IN }}$ is 5 V p-p swinging about a baseline at ground, and $\mathrm{V}_{\text {REF }}$ is connected to ground.
The circuit has a differential gain of 1.6 and $\beta=0.38$. V ICM has an amplitude of 2.5 V p-p and is swinging about ground. Using the results in Equation 16, the common-mode voltage at the inputs of the AD8139, $\mathrm{V}_{\mathrm{ACM}}$, is a 1.5 V p-p signal swinging about a baseline of 0.95 V . The maximum negative excursion of $\mathrm{V}_{\mathrm{Acm}}$ in this case is 0.2 V , which exceeds the lower input common-mode voltage limit.

Figure 61. AD8139 Driving AD7674, 18-Bit, 800 kSPS ADC

One way to avoid the input common-mode swing limitation is to bias $V_{\text {IN }}$ and $V_{\text {ReF }}$ at midsupply. In this case, $\mathrm{V}_{\text {IN }}$ is 5 V p-p swinging about a baseline at 2.5 V , and $\mathrm{V}_{\text {REF }}$ is connected to a low-Z 2.5 V source. VICM now has an amplitude of 2.5 V p-p and is swinging about 2.5 V . Using the results in Equation 17, $\mathrm{V}_{\mathrm{ACM}}$ is calculated to be equal to $\mathrm{V}_{\text {ICM }}$ because $\mathrm{V}_{\text {осм }}=\mathrm{V}_{\text {ICM }}$. Therefore, $\mathrm{V}_{\mathrm{ACM}}$ swings from 1.25 V to 3.75 V , which is well within the input common-mode voltage limits of the AD8139. Another benefit seen in this example is that because $V_{\text {оСм }}=V_{\text {ACM }}=V_{\text {ICM }}$ no wasted common-mode current flows. Figure 62 illustrates how to provide the low- Z bias voltage. For situations that do not require a precise reference, a simple voltage divider suffices to develop the input voltage to the buffer.

Figure 62. Low-Z 2.5 V Buffer
Another way to avoid the input common-mode swing limitation is to use dual power supplies on the AD8139. In this case, the biasing circuitry is not required.

## Bandwidth vs. Closed-Loop Gain

The 3 dB bandwidth of the AD8139 decreases proportionally to increasing closed-loop gain in the same way as a traditional voltage feedback operational amplifier. For closed-loop gains greater than 4, the bandwidth obtained for a specific gain can be estimated as

$$
\begin{equation*}
f-3 \mathrm{~dB}, V_{\text {OUT }, d m}=\frac{R_{G}}{R_{G}+R_{F}} \times(300 \mathrm{MHz}) \tag{20}
\end{equation*}
$$

or equivalently, $\beta(300 \mathrm{MHz})$.
This estimate assumes a minimum $90^{\circ}$ phase margin for the amplifier loop, which is a condition approached for gains greater than 4 . Lower gains show more bandwidth than predicted by the equation due to the peaking produced by the lower phase margin.

## Estimating DC Errors

Primary differential output offset errors in the AD8139 are due to three major components: the input offset voltage, the offset between the $V_{\mathrm{AN}}$ and $\mathrm{V}_{\mathrm{AP}}$ input currents interacting with the feedback network resistances, and the offset produced by the dc voltage difference between the input and output common-mode voltages in conjunction with matching errors in the feedback network.
The first output error component is calculated as

$$
\begin{equation*}
V o_{-} e l=V_{I O}\left(\frac{R_{F}+R_{G}}{R_{G}}\right) \text {, or equivalently as } V_{I O} / \beta \tag{21}
\end{equation*}
$$

where $V_{I O}$ is the input offset voltage. The input offset voltage of the AD8139 is laser trimmed and guaranteed to be less than $500 \mu \mathrm{~V}$.
The second error is calculated as

$$
\begin{equation*}
V o_{-} e 2=I_{I O}\left(\frac{R_{F}+R_{G}}{R_{G}}\right)\left(\frac{R_{G} R_{F}}{R_{F}+R_{G}}\right)=I_{I O}\left(R_{F}\right) \tag{22}
\end{equation*}
$$

where $I_{I O}$ is defined as the offset between the two input bias currents.
The third error voltage is calculated as

$$
\begin{equation*}
V o \_e 3=\Delta e n r \times\left(V_{\text {ICM }}-V_{\text {оСм }}\right) \tag{23}
\end{equation*}
$$

where $\Delta e n r$ is the fractional mismatch between the two feedback resistors.

The total differential offset error is the sum of these three error sources.

## Other Impact of Mismatches in the Feedback Networks

The internal common-mode feedback network still forces the output voltages to remain balanced, even when the $R_{F} / R_{G}$ feedback networks are mismatched. However, the mismatch causes a gain error proportional to the feedback network mismatch.
Ratio-matching errors in the external resistors degrade the ability to reject common-mode signals at the $\mathrm{V}_{\mathrm{AN}}$ and $\mathrm{V}_{\text {IN }}$ input terminals, much the same as with a four-resistor difference amplifier made from a conventional op amp. Ratio-matching errors also produce a differential output component that is equal to the Vосм input voltage times the difference between the feedback factors ( $\beta \mathrm{s}$ ). In most applications using $1 \%$ resistors, this component amounts to a differential dc offset at the output that is small enough to be ignored.

## Driving a Capacitive Load

A purely capacitive load reacts with the bondwire and pin inductance of the AD8139, resulting in high frequency ringing in the transient response and loss of phase margin. One way to minimize this effect is to place a small resistor in series with each output to buffer the load capacitance (see Figure 58 and Figure 63). The resistor and load capacitance form a first-order, low-pass filter; therefore, the resistor value should be as small as possible. In some cases, the ADCs require small series resistors to be added on their inputs.

Figure 63. Frequency Response for Various Capacitive Loads and Series Resistances
The Typical Performance Characteristics that illustrate transient response vs. the capacitive load were generated using series resistors in each output and a differential capacitive load.

## Layout Considerations

Standard high speed PCB layout practices should be adhered to when designing with the AD8139. A solid ground plane is recommended, and good wideband power supply decoupling networks should be placed as close as possible to the supply pins.

To minimize stray capacitance at the summing nodes, the copper in all layers under all traces and pads that connect to the summing nodes should be removed. Small amounts of stray summing-node capacitance cause peaking in the frequency response, and large amounts can cause instability. If some stray summing-node capacitance is unavoidable, its effects can be compensated for by placing small capacitors across the feedback resistors.

## Terminating a Single-Ended Input

Controlled impedance interconnections are used in most high speed signal applications, and they require at least one line termination. In analog applications, a matched resistive termination is generally placed at the load end of the line. This section deals with how to properly terminate a single-ended input to the AD8139.

The input resistance presented by the AD8139 input circuitry is seen in parallel with the termination resistor, and its loading effect must be taken into account. The Thevenin equivalent circuit of the driver, its source resistance, and the termination resistance must all be included in the calculation as well. An exact solution to the problem requires the solution of several simultaneous algebraic equations and is beyond the scope of this data sheet. An iterative solution is also possible and simpler, especially considering the fact that standard $1 \%$ resistor values are generally used.

Figure 64 shows the AD8139 in a unity-gain configuration driving the AD6645, which is a 14 -bit, high speed ADC, and with the following discussion, provides a good example of how to provide a proper termination in a $50 \Omega$ environment.
The termination resistor, $\mathrm{R}_{\mathrm{T}}$, in parallel with the $268 \Omega$ input resistance of the AD8139 circuit (calculated using Equation 19), yields an overall input resistance of $50 \Omega$ that is seen by the signal source. To have matched feedback loops, each loop must have the same $\mathrm{R}_{\mathrm{G}}$ if they have the same $\mathrm{R}_{\mathrm{F}}$. In the input (upper) loop, $\mathrm{R}_{\mathrm{G}}$ is equal to the $200 \Omega$ resistor in series with the (+) input plus the parallel combination of $\mathrm{R}_{\mathrm{T}}$ and the source resistance of $50 \Omega$. In the upper loop, $\mathrm{R}_{\mathrm{G}}$ is therefore equal to $228 \Omega$. The closest standard $1 \%$ value to $228 \Omega$ is $226 \Omega$ and is used for $R_{G}$ in the lower loop. Greater accuracy could be achieved by using two resistors in series to obtain a resistance closer to $228 \Omega$.
Things get more complicated when it comes to determining the feedback resistor values. The amplitude of the signal source generator $\mathrm{V}_{s}$ is two times the amplitude of its output signal when terminated in $50 \Omega$. Therefore, a 2 V p-p terminated amplitude is produced by a 4 V p-p amplitude from VS. The Thevenin equivalent circuit of the signal source and $\mathrm{R}_{T}$ must be used when calculating the closed-loop gain, because in the upper loop, $\mathrm{R}_{\mathrm{G}}$ is split between the $200 \Omega$ resistor and the Thevenin resistance looking back toward the source. The Thevenin voltage of the signal source is greater than the signal source output voltage when terminated in $50 \Omega$ because $\mathrm{R}_{\mathrm{T}}$ must always be greater than $50 \Omega$. In this case, RT is $61.9 \Omega$ and the Thevenin voltage and resistance are 2.2 V p-p and $28 \Omega$, respectively. Now the upper input branch can be viewed as a 2.2 V p-p source in series with $228 \Omega$. Because this is a unity-gain application, a 2 V p-p differential output is required, and RF must therefore be $228 \times$ $(2 / 2.2)=206 \Omega$. The closest standard value to this is $205 \Omega$.

When generating the Typical Performance Characteristics data, the measurements were calibrated to take the effects of the terminations on the closed-loop gain into account.

Because this is a single-ended-to-differential application on a single supply, the input common-mode voltage swing must be checked. From Figure $64, \beta=0.52, \mathrm{~V}_{\text {OCM }}=2.4 \mathrm{~V}$, and $\mathrm{V}_{\text {ICM }}$ is 1.1 V p-p swinging about ground. Using Equation $16, \mathrm{~V}_{\mathrm{ACM}}$ is calculated to be 0.53 V p-p swinging about a baseline of 1.25 V , and the minimum negative excursion is approximately 1 V .

## Exposed Paddle (EP)

The 8-lead SOIC and the 8-lead LFCSP have an exposed paddle on the bottom of the package. To achieve the specified thermal resistance, the exposed paddle must be soldered to one of the PCB planes. The exposed paddle mounting pad should contain several thermal vias within it to ensure a low thermal path to the plane.
