## FEATURES

Low power: $\mathbf{4 0} \boldsymbol{\mu} \mathrm{A}$ supply current (maximum)
Low input currents
1 pA input bias current
0.5 pA input offset current

High CMRR: $\mathbf{1 1 0 ~ d B ~ C M R R , ~ G ~ = ~} \mathbf{1 0 0}$
Space-saving MSOP
Zero input crossover distortion
Rail-to-rail input and output
Gain set with single resistor
Operates from 1.8 V to 5.5 V

## APPLICATIONS

## Medical instrumentation

 Low-side current sensePortable devices

## ABSOLUTE MAXIMUM RATINGS

Table 4.

| Parameter | Rating |
| :--- | :--- |
| Supply Voltage | 6 V |
| Power Dissipation | See Figure 3 |
| Output Short-Circuit Current | 55 mA |
| Input Voltage (Common Mode) | $\pm \mathrm{V}_{\mathrm{S}}$ |
| Differential Input Voltage | $\pm \mathrm{V}_{\mathrm{S}}$ |
| Storage Temperature Range | $-65^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$ |
| Operating Temperature Range | $-40^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$ |
| Lead Temperature (Soldering, 10 sec) | $300^{\circ} \mathrm{C}$ |
| Junction Temperature | $140^{\circ} \mathrm{C}$ |
| ӨJA (4-Layer JEDEC Standard Board) |  |
| $\quad$ 8-Lead MSOP | $135^{\circ} \mathrm{C} / \mathrm{W}$ |
| Package Glass Transition Temperature |  |
| $\quad$ 8-Lead MSOP | $140^{\circ} \mathrm{C}$ |
| ESD |  |
| $\quad$ Human Body Model | 2 kV |
| Charge Device Model | 1 kV |
| Machine Model | 200 V |

Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only; functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

## MAXIMUM POWER DISSIPATION

The maximum safe power dissipation in the package of the AD8236 is limited by the associated rise in junction temperature $\left(\mathrm{T}_{\mathrm{J}}\right)$ on the die. The plastic encapsulating the die locally reaches the junction temperature. At approximately $140^{\circ} \mathrm{C}$, which is the glass transition temperature, the plastic changes its properties. Even temporarily exceeding this temperature limit may change the stresses that the package exerts on the die, permanently shifting the parametric performance of the AD8236.
The still-air thermal properties of the package and $\operatorname{PCB}\left(\theta_{\mathrm{J}}\right)$, the ambient temperature $\left(\mathrm{T}_{\mathrm{A}}\right)$, and the total power dissipated in the package $\left(\mathrm{P}_{\mathrm{D}}\right)$ determine the junction temperature of the die. The junction temperature is calculated as

$$
T_{J}=T_{A}+\left(P_{D} \times \theta_{\mathrm{JA}}\right)
$$

The power dissipated in the package $\left(\mathrm{P}_{\mathrm{D}}\right)$ is the sum of the quiescent power dissipation and the power dissipated in the package due to the load drive for all outputs. The quiescent power is the voltage between the supply pins $\left(\mathrm{V}_{\mathrm{s}}\right)$ times the quiescent current ( I s ). Assuming the load ( $\mathrm{R}_{\mathrm{L}}$ ) is referenced to midsupply, the total drive power is $\mathrm{V}_{\mathrm{s}} / 2 \times$ Iout, some of which is dissipated in the package and some in the load (Vout $\times$ Iout $)$.

The difference between the total drive power and the load power is the drive power dissipated in the package.

$$
\begin{aligned}
& P_{D}=\text { Quiescent Power }+(\text { Total Drive Power }- \text { Load Power }) \\
& P_{D}=\left(V_{S} \times I_{S}\right)+\left(\frac{V_{S}}{2} \times \frac{V_{O U T}}{R_{L}}\right)-\frac{V_{O U T}^{2}}{R_{L}}
\end{aligned}
$$

RMS output voltages should be considered. If $\mathrm{R}_{\mathrm{L}}$ is referenced to $-\mathrm{V}_{\mathrm{s}}$, as in single-supply operation, the total drive power is $\mathrm{V}_{\mathrm{s}} \times$ Iout. If the rms signal levels are indeterminate, consider the worst case, when $V_{\text {out }}=\mathrm{V}_{\mathrm{S}} / 4$ for $\mathrm{R}_{\mathrm{L}}$ to midsupply

$$
P_{D}=\left(V_{S} \times I_{S}\right)+\frac{\left(V_{S} / 4\right)^{2}}{R_{L}}
$$

In single-supply operation with $\mathrm{R}_{\mathrm{L}}$ referenced to $-\mathrm{V}_{\mathrm{S}}$, worst case is $V_{\text {out }}=V_{s} / 2$.

Airflow increases heat dissipation, effectively reducing $\theta_{\mathrm{IA}}$. In addition, more metal directly in contact with the package leads from metal traces, through holes, ground, and power planes reduces the $\theta_{\mathrm{JA}}$.

Figure 3 shows the maximum safe power dissipation in the package vs. the ambient temperature for the 8 -lead MSOP on a 4 -layer JEDEC standard board. $\theta_{\mathrm{JA}}$ values are approximations.

Figure 3. Maximum Power Dissipation vs. Ambient Temperature

## ESD CAUTION

ESD (electrostatic discharge) sensitive device. Charged devices and circuit boards can discharge without detection. Although this product features patented or proprietary protection circuitry, damage may occur on devices subjected to high energy ESD. Therefore, proper ESD precautions should be taken to avoid performance degradation or loss of functionality.

## AD8236

## PIN CONFIGURATION AND FUNCTION DESCRIPTIONS

Figure 4. Pin Configuration

Table 5. Pin Function Descriptions

| Pin No. | Mnemonic | Description |
| :--- | :--- | :--- |
| 1 | - IN | Negative Input Terminal (True Differential Input) |
| 2,3 | $R_{G}$ | Gain Setting Terminals (Place Resistor Across the RG Pins) |
| 4 | $+\mathbb{N}$ | Positive Input Terminal (True Differential Input) |
| 5 | $-V_{S}$ | Negative Power Supply Terminal |
| 6 | REF | Reference Voltage Terminal (Drive This Terminal with a Low Impedance Voltage Source to Level-Shift the Output) |
| 7 | $V_{o u t}$ | Output Terminal |
| 8 | $+V_{S}$ | Positive Power Supply Terminal |

## AD8236

## THEORY OF OPERATION

The AD8236 is a monolithic, 2-op-amp instrumentation amplifier. It was designed for low power, portable applications where size and low quiescent current are paramount. For example, it has a rail-to-rail input and output stage to offer more dynamic range when operating on low voltage batteries. Unlike traditional rail-to-rail input amplifiers that use a complementary differential pair stage and suffer from nonlinearity, the AD8236 uses a novel architecture to internally boost the supply rail, allowing the amplifier to operate rail to rail yet still deliver a low 0.5 ppm of nonlinearity. In addition, the 2 -op-amp instrumentation amplifier architecture offers a wide operational common-mode voltage range. Additional information is provided in the CommonMode Input Voltage Range section. Precision, laser-trimmed resistors provide the AD8236 with a high CMRR of 86 dB (minimum) at $\mathrm{G}=5$ and gain accuracy of $0.05 \%$ (maximum).

## BASIC OPERATION

The AD8236 amplifies the difference between its positive input $(+\mathrm{IN})$ and its negative input (-IN). The REF pin allows the user to level-shift the output signal. This is convenient when interfacing to a filter or analog-to-digital converter (ADC). The basic setup is shown in Figure 35. Figure 37 shows an example configuration for operating the AD8236 with dual supplies. The equation for the AD8236 is as follows:

$$
V_{\text {out }}=G \times(V I N P-V I N M)+V R E F
$$

If no gain setting resistor is installed, the default gain, $G$, is 5 . The Gain Selection section describes how to program the gain, G .

Figure 35. Basic Setup

## GAIN SELECTION

Placing a resistor across the $\mathrm{R}_{\mathrm{G}}$ terminals sets the gain of the AD8236, which can be calculated by referring to Table 6 or by using the gain equation

$$
R_{G}=\frac{420 \mathrm{k} \Omega}{G-5}
$$

Table 6. Gains Achieved Using 1\% Resistors

| $\mathbf{1 \%}$ Standard Table Value of $\mathbf{R}_{\mathbf{G}}(\boldsymbol{\Omega})$ | Calculated Gain |
| :--- | :--- |
| 422 k | 6.0 |
| 210 k | 7.0 |
| 140 k | 8.0 |
| 105 k | 9.0 |

The AD8236 defaults to $\mathrm{G}=5$ when no gain resistor is used. Gain accuracy is determined by the absolute tolerance of $\mathrm{R}_{\mathrm{G}}$. The TC of the external gain resistor increases the gain drift of the instrumentation amplifier. Gain error and gain drift are at a minimum when the gain resistor is not used.

## LAYOUT

Careful board layout maximizes system performance. In applications that need to take advantage of the low input bias current of the AD8236, avoid placing metal under the input path to minimize leakage current.

## Grounding

The output voltage of the AD8236 is developed with respect to the potential on the reference terminal, REF. To ensure the most accurate output, the trace from the REF pin should either be connected to the AD8236 local ground (see Figure 37) or connected to a voltage that is referenced to the AD8236 local ground (Figure 35).

## REFERENCE TERMINAL

The reference terminal, REF, is at one end of a $210 \mathrm{k} \Omega$ resistor (see Figure 34). The output of the instrumentation amplifier is referenced to the voltage on the REF terminal; this is useful when the output signal needs to be offset to voltages other than common. For example, a voltage source can be tied to the REF pin to level-shift the output so that the AD8236 can interface with an ADC. The allowable reference voltage range is a function of the gain, common-mode input, and supply voltages. The REF pin should not exceed either $+\mathrm{V}_{s}$ or $-\mathrm{V}_{s}$ by more than 0.5 V .
For best performance, especially in cases where the output is not measured with respect to the REF terminal, source impedance to the REF terminal should be kept low because parasitic resistance can adversely affect CMRR and gain accuracy. Figure 36 demonstrates how an op amp is configured to provide a low source impedance to the REF terminal when a midscale reference voltage is desired.

Figure 36. Driving the REF Pin

## POWER SUPPLY REGULATION AND BYPASSING

The AD8236 has high power supply rejection ration (PSRR). However, for optimal performance, a stable dc voltage should be used to power the instrumentation amplifier. Noise on the supply pins can adversely affect performance. As in all linear circuits, bypass capacitors must be used to decouple the amplifier.
A $0.1 \mu \mathrm{~F}$ capacitor should be placed close to each supply pin. A $10 \mu \mathrm{~F}$ tantalum capacitor can be used further away from the part (see Figure 37). In most cases, it can be shared by other precision integrated circuits.

## AD8236

Figure 38. Creating an $I_{B I A S}$ Path

## INPUT BIAS CURRENT RETURN PATH

The AD8236 input bias current is extremely small at less than 10 pA . Nonetheless, the input bias current must have a return path to common. When the source, such as a transformer, cannot provide a return current path, one should be created (see Figure 38).

## INPUT PROTECTION

All terminals of the AD8236 are protected against ESD. In addition, the input structure allows for dc overload conditions a diode drop above the positive supply and a diode drop below the negative supply. Voltages beyond a diode drop of the supplies cause the ESD diodes to conduct and enable current to flow through the diode. Therefore, an external resistor should be used in series with each of the inputs to limit current for voltages above + Vs. In either scenario, the AD8236 safely handles a continuous 6 mA current at room temperature.
For applications where the AD8236 encounters extreme overload voltages, as in cardiac defibrillators, external series resistors and low leakage diode clamps, such as BAV199Ls, FJH1100s, or SP720s, should be used.

## RF INTERFERENCE

RF rectification is often a problem in applications where there are large RF signals. The problem appears as a small dc offset voltage. The AD8236, by its nature, has a 3.1 pF gate capacitance, $\mathrm{C}_{\mathrm{G}}$, at each input. Matched series resistors form a natural low-pass filter that reduces rectification at high frequency (see Figure 39). The relationship between external, matched series resistors and the internal gate capacitance is expressed as

$$
\begin{aligned}
& \text { FilterFreq }_{\text {DIFF }}=\frac{1}{2 \pi R C_{G}} \\
& \text { FilterFreq }_{C M}=\frac{1}{2 \pi R C_{G}}
\end{aligned}
$$

Figure 39. RFI Filtering Without External Capacitors

To eliminate high frequency common-mode signals while using smaller source resistors, a low-pass RC network can be placed at the input of the instrumentation amplifier (see Figure 40). The filter limits the input signal bandwidth according to the following relationship:

$$
\begin{aligned}
& \text { FilterFreq }_{\text {DIFF }}=\frac{1}{2 \pi R\left(2 C_{D}+C_{C}+C_{G}\right)} \\
& \text { FilterFreq }_{C M}=\frac{1}{2 \pi R\left(C_{C}+C_{G}\right)}
\end{aligned}
$$

Mismatched $\mathrm{C}_{\mathrm{c}}$ capacitors result in mismatched low-pass filters. The imbalance causes the AD8236 to treat what would have been a common-mode signal as a differential signal. To reduce the effect of mismatched external $C_{C}$ capacitors, select a value of $C_{D}$ greater than 10 times $\mathrm{C}_{\mathrm{c}}$. This sets the differential filter frequency lower than the common-mode frequency.

Figure 40. RFI Suppression

## COMMON-MODE INPUT VOLTAGE RANGE

The common-mode input voltage range is a function of the input voltages, reference voltage, supplies, and the output of Internal Op Amp A. Figure 34 shows the internal nodes of the AD8236. Figure 20 to Figure 23 show the common-mode voltage ranges for typical supply voltages and gains.

If the supply voltages and reference voltage is not represented in Figure 20 to Figure 23, the following methodology can be used to calculate the acceptable common-mode voltage range:

1. Adhere to the input, output, and reference voltage ranges shown in Table 2 and Table 3.
2. Calculate the output of the internal op amp, A. The following equation calculates this output:
$A=\frac{5}{4}\left(V_{C M}-\frac{V_{D I F F}}{2}\right)-\frac{52.5 \mathrm{k} \Omega}{\mathrm{R}_{\mathrm{G}}} V_{D I F F}-\frac{V_{\text {REF }}}{4}$
where:
$V_{\text {DIFF }}$ is defined as the difference in input voltages,
$V_{\text {DIff }}=$ VINP - VINM.
$V_{C M}$ is defined as the common mode voltage,
$\mathrm{V}_{\mathrm{CM}}=(\mathrm{VINP}+\mathrm{VINM}) / 2$.
If no gain setting resistor, $\mathrm{R}_{\mathrm{G}}$, is installed, set $\mathrm{R}_{\mathrm{G}}$ to infinity.
3. Keep A within 10 mV of either supply rail. This is valid over the $-40^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$ temperature range.
$-V_{s}+10 \mathrm{mV}<A<+V_{s}-10 \mathrm{mV}$

## APPLICATIONS INFORMATION <br> AC-COUPLED INSTRUMENTATION AMPLIFIER

An integrator can be tied to the AD8236 in feedback to create a high-pass filter as shown in Figure 41. This circuit can be used to reject dc voltages and offsets. At low frequencies, the impedance of the capacitor, C, is high. Therefore, the gain of the integrator is high. DC voltage at the output of the AD8236 is inverted and gained by the integrator. The inverted signal is injected back into the REF pin, nulling the output. In contrast, at high frequencies, the integrator has low gain because the impedance of C is low. Voltage changes at high frequencies are inverted but at a low gain. The signal is injected into the REF pins, but it is not enough to null the output. At very high frequencies, the capacitor appears as a short. The op amp is at unity gain. High frequency signals are, therefore, allowed to pass.
When a signal exceeds $\mathrm{f}_{\text {HIGH-PASS }}$, the AD8236 outputs the highpass filtered input signal.

## LOW POWER HEART RATE MONITOR

The low power and small size of the AD8236 make it an excellent choice for heart rate monitors. As shown in Figure 42, the AD8236 measures the biopotential signals from the body. It rejects common-mode signals and serves as the primary gain stage set at $\mathrm{G}=5$. The $4.7 \mu \mathrm{~F}$ capacitor and the $100 \mathrm{k} \Omega$ resistor set the -3 dB cutoff of the high-pass filter that follows the instrumentation amplifier. It rejects any differential dc offsets that may develop from the half-cell overpotential of the electrode.
A secondary gain stage, set at $G=403$, amplifies the ECG signal, which is then sent into a second-order, low-pass, Bessel filter with -3 dB cutoff at 48 Hz . The $324 \Omega$ resistor and $1 \mu \mathrm{~F}$ capacitor serve as an antialiasing filter. The $1 \mu \mathrm{~F}$ capacitor also serves as a charge reservoir for the ADC's switched capacitor input stage.

This circuit was designed and tested using the AD8609, low power, quad op amp. The fourth op amp is configured as a Schmitt trigger to indicate if the right arm or left arm electrodes fall off the body. Used in conjunction with the $953 \mathrm{k} \Omega$ resistors at the inputs of the AD8236, the resistors pull the inputs apart when the electrodes fall off the body. The Schmitt trigger sends an active low signal to indicate a leads off condition.

The reference electrode (right leg) is set tied to ground. Likewise, the shield of the electrode cable is also tied to ground. Some portable heart rate monitors do not have a third electrode. In such cases, the negative input of the AD8236 can be tied to GND.
Note that this circuit is shown, solely, to demonstrate the capability of the AD8236. Additional effort must be made to ensure compliance with medical safety guidelines.
