Ultralow Distortion, Wide Bandwidth Voltage Feedback Op Amps

AD9631/AD9632

FEATURES

Wide bandwidth
  AD9631, G = +1
  AD9632, G = +2
  Small signal
    AD9631, 320 MHz
    AD9632, 250 MHz
  Large signal (4 V p-p)
    AD9631, 175 MHz
    AD9632, 180 MHz
Ultralow distortion (SFDR), low noise
  −113 dBc typical @ 1 MHz
  −95 dBc typical @ 5 MHz
  −72 dBc typical @ 20 MHz
  46 dBm third-order intercept @ 25 MHz
  7.0 nV/√Hz spectral noise density
High speed
  Slew rate: 1300 V/µs
  Settling time to 0.01%, 2 V step: 16 ns
  ±3 V to ±5 V supply operation
  17 mA supply current

APPLICATIONS

ADC input driver
Differential amplifiers
IF/RF amplifiers
Pulse amplifiers
Professional video
DAC current to voltage
Baseband and video communications
Pin diode receivers
Active filters/integrators/log amps

GENERAL DESCRIPTION

The AD9631/AD9632 are very high speed and wide bandwidth amplifiers. The AD9631 is unity gain stable. The AD9632 is stable at gains of 2 or greater. Using a voltage feedback architecture, the exceptional settling time, bandwidth, and low distortion of the AD9631/AD9632 meet the requirements of many applications that previously depended on current feedback amplifiers. Its classical op amp structure works much more predictably in many designs.
PIN CONFIGURATION

Figure 1. 8-Lead PDIP (N) and SOIC (R) Packages

A proprietary design architecture has produced an amplifier that combines many of the best characteristics of both current feedback and voltage feedback amplifiers. The AD9631/AD9632 exhibit exceptionally fast and accurate pulse response (16 ns to 0.01%) as well as extremely wide small signal and large signal bandwidth and ultralow distortion. The AD9631 achieves −72 dBc at 20 MHz, 320 MHz small signal bandwidth, and 175 MHz large signal bandwidths.

These characteristics position the AD9631/AD9632 ideally for driving flash as well as high resolution ADCs. Additionally, the balanced high impedance inputs of the voltage feedback architecture allow maximum flexibility when designing active filters.

The AD9631/AD9632 are offered in the industrial (−40°C to +85°C) temperature range. They are available in PDIP and SOIC.

MAXIMUM POWER DISSIPATION

The maximum power that can be safely dissipated by these devices is limited by the associated rise in junction temperature. The maximum safe junction temperature for plastic encapsulated devices is determined by the glass transition temperature of the plastic, approximately 150°C. Exceeding this limit temporarily may cause a shift in parametric performance due to a change in the stresses exerted on the die by the package. Exceeding a junction temperature of 175°C for an extended period can result in device failure.

While the AD9631 and AD9632 are internally short circuit protected, this may not be sufficient to guarantee that the maximum junction temperature (150°C) is not exceeded under all conditions. To ensure proper operation, it is necessary to observe the maximum power derating curves.

Figure 4. Maximum Power Dissipation vs. Temperature

ESD CAUTION

ESD (electrostatic discharge) sensitive device. Charged devices and circuit boards can discharge without detection. Although this product features patented or proprietary protection circuitry, damage may occur on devices subjected to high energy ESD. Therefore, proper ESD precautions should be taken to avoid performance degradation or loss of functionality.

THEORY OF OPERATION

GENERAL

The AD9631/AD9632 are wide bandwidth, voltage feedback amplifiers. Because their open-loop frequency response follows the conventional 6 dB/octave roll-off, their gain bandwidth product is basically constant. Increasing their closed-loop gain results in a corresponding decrease in small signal bandwidth. This can be observed by noting the bandwidth specification between the AD9631 (gain of +1) and AD9632 (gain of +2). The AD9631/AD9632 typically maintain 65° of phase margin. This high margin minimizes the effects of signal and noise peaking.

FEEDBACK RESISTOR CHOICE

The value of the feedback resistor is critical for optimum performance on the AD9631 (gain of +1) and less critical as the gain increases. Therefore, this section is specifically targeted at the AD9631.

At the minimum stable gain (+1), the AD9631 provides optimum dynamic performance with $R_F = 140\ \Omega$. This resistor acts as a parasitic suppressor only against damped RF oscillations that can occur due to lead (input, feedback) inductance and parasitic capacitance. This value of R_F provides the best combination of wide bandwidth, low parasitic peaking, and fast settling time.

In fact, for the same reasons, place a 100 Ω to 130 Ω resistor in series with the positive input for other AD9631 noninverting and all AD9631 inverting configurations. The correct connection is shown in Figure 59 and Figure 60.

Figure 59. Noninverting Operation
Figure 60. Inverting Operation

When the AD9631 is used in the transimpedance (I to V) mode, such as in photodiode detection, the value of R_F and diode capacitance (C_I) are usually known. Generally, the value of R_F selected will be in the kΩ range, and a shunt capacitor (C_F) across R_F will be required to maintain good amplifier stability. The value of C_F required to maintain optimal flatness (<1 dB peaking) and settling time can be estimated by

$$C_F \cong \left[\left(2\omega_O C_I R_F - 1\right)/\omega_O{}^2 R_F{}^2\right]^{\frac{1}{2}}$$

where:
ω_O is equal to the unity gain bandwidth product of the amplifier in rad/sec.
C_I is the equivalent total input capacitance at the inverting input.

Typically $\omega_O = 800 \times 10^6$ rad/sec (see Figure 19).

As an example, choosing $R_F = 10$ kΩ and $C_I = 5$ pF requires C_F to be 1.1 pF (Note that C_I includes both source and parasitic circuit capacitance). The bandwidth of the amplifier can be estimated using C_F:

$$f_{3dB} \cong \frac{1.6}{2\pi R_F C_F}$$

Figure 61. Transimpedance Configuration

For general voltage gain applications, the amplifier bandwidth can be closely estimated as

$$f_{3dB} \cong \frac{\omega_O}{2\pi\left(1 + R_F / R_G\right)}$$

This estimation loses accuracy for gains of +2/−1 or lower due to the damping factor of the amplifier. For these low gain cases, the bandwidth will actually extend beyond the calculated value (see Figure 17 and Figure 29).

As a general rule, Capacitor C_F will not be required if

$$\left(R_F \| R_G\right) \times C_I \le \frac{NG}{4\omega_O}$$

where NG is the noise gain $(1 + R_F/R_G)$ of the circuit. For most voltage gain applications, this should be the case.

PULSE RESPONSE

Unlike a traditional voltage feedback amplifier, where the slew speed is dictated by its front end dc quiescent current and gain bandwidth product, the AD9631/AD9632 provide on-demand current that increases proportionally to the input step signal amplitude. This results in slew rates (1300 V/μs) comparable to wideband current feedback designs. This, combined with relatively low input noise current (2.0 pA/√Hz), gives the AD9631/AD9632 the best attributes of both voltage and current feedback amplifiers.

LARGE SIGNAL PERFORMANCE

The outstanding large signal operation of the AD9631 and AD9632 is due to a unique, proprietary design architecture. To maintain this level of performance, the maximum 550 V × MHz product must be observed (for example, @ 100 MHz, $V_{OUT} \leq$ 5.5 V p-p).

POWER SUPPLY BYPASSING

Adequate power supply bypassing can be critical when optimizing the performance of a high frequency circuit. Inductance in the power supply leads can form resonant circuits that produce peaking in the amplifier's response. In addition, if large current transients must be delivered to the load, then bypass capacitors (typically greater than 1 μF) will be required to provide the best settling time and lowest distortion. A parallel combination of at least 4.7 μF, and between 0.1 μF and 0.01 μF, is recommended. Some brands of electrolytic capacitors will require a small series damping resistor ≈4.7 Ω for optimum results.

DRIVING CAPACITIVE LOADS

The AD9631/AD9632 were designed primarily to drive non-reactive loads. If driving loads with a capacitive component is desired, the best frequency response is obtained by the addition of a small series resistance as shown in Figure 62. Figure 63 shows the optimum value for R_{SERIES} vs. capacitive load. It is worth noting that the frequency response of the circuit when driving large capacitive loads will be dominated by the passive roll-off of R_{SERIES} and C_L.
Figure 62. Driving Capacitive Loads
Figure 63. Recommended R_{SERIES} vs. Capacitive Load

APPLICATIONS INFORMATION

The AD9631/AD9632 are voltage feedback amplifiers well suited for applications such as photodetectors, active filters, and log amplifiers. The wide bandwidth (320 MHz), phase margin (65°), low current noise (2.0 pA/√Hz), and slew rate (1300 V/μs) of the devices give higher performance capabilities to these applications over previous voltage feedback designs.

With a settling time of 16 ns to 0.01% and 11 ns to 0.1%, the devices are an excellent choice for DAC I/V conversion. The same characteristics along with low harmonic distortion make them a good choice for ADC buffering/amplification. With superb linearity at relatively high signal frequencies, the AD9631/AD9632 are ideal drivers for ADCs up to 12 bits.

OPERATION AS A VIDEO LINE DRIVER

The AD9631/AD9632 have been designed to offer outstanding performance as video line drivers. The important specifications of differential gain (0.02%) and differential phase (0.02°) meet the most exacting HDTV demands for driving video loads.
Figure 64. Video Line Driver

ACTIVE FILTERS

The wide bandwidth and low distortion of the AD9631/AD9632 are ideal for the realization of higher bandwidth active filters. These characteristics, while being more common in many current feedback op amps, are offered in the AD9631/AD9632 in a voltage feedback configuration. Many active filter configurations are not realizable with current feedback amplifiers.

A multiple feedback active filter requires a voltage feedback amplifier and is more demanding of op amp performance than other active filter configurations, such as the Sallen-Key. In general, the amplifier should have a bandwidth that is at least 10 times the bandwidth of the filter if problems due to phase shift of the amplifier are to be avoided.

Figure 65 is an example of a 20 MHz low-pass multiple feedback active filter using an AD9632.
Figure 65. Active Filter Circuit

Choose

F_O = cutoff frequency = 20 MHz

α = damping ratio = $1/Q$ = 2

H = absolute value of circuit gain = $\left| \dfrac{-R4}{R1} \right| = 1$

Then

$$k = 2\pi F_O C1$$

$$C2 = \frac{4C1(H+1)}{\alpha^2}$$

$$R1 = \frac{\alpha}{2HK}$$

$$R3 = \frac{\alpha}{2K(H+1)}$$

$$R4 = H(R1)$$

ANALOG-TO-DIGITAL CONVERTER (ADC) DRIVER

As ADCs move toward higher speeds with higher resolutions, there becomes a need for high performance drivers that will not degrade the analog signal to the converter. It is desirable from a system's standpoint that the ADC be the element in the signal chain that ultimately limits overall distortion. Figure 66 is such an example.
Figure 66. *AD9631 Used as Driver for an ADC Signal Chain*

LAYOUT CONSIDERATIONS

The specified high speed performance of the AD9631/AD9632 requires careful attention to board layout and component selection. Proper RF design techniques and low-pass parasitic component selection are mandatory.

The PCB should have a ground plane covering all unused portions of the component side of the board to provide a low impedance path. Remove the ground plane from the area near the input pins to reduce stray capacitance.

Use chip capacitors for supply bypassing (see Figure 59 and Figure 60). Connect one end to the ground plane, and the other within 1/8 inch of each power pin. Connect an additional large (0.47 μF to 10 μF) tantalum electrolytic capacitor in parallel, though not necessarily so close, to supply current for fast, large signal changes at the output.

The feedback resistor should be located close to the inverting input pin to keep the stray capacitance at this node to a minimum. Capacitance variations of less than 1 pF at the inverting input will significantly affect high speed performance.

Use stripline design techniques for long signal traces (greater than about 1 inch). These should be designed with a characteristic impedance of 50 Ω or 75 Ω and be properly terminated at each end.

AD9631ARZ	−40°C to +85°C	8-Lead Standard Small Outline Package [SOIC_N]	R-8
AD9631ARZ-REEL	−40°C to +85°C	8-Lead Standard Small Outline Package [SOIC_N]	R-8
AD9631ARZ-REEL7	−40°C to +85°C	8-Lead Standard Small Outline Package [SOIC_N]	R-8
AD9631AR-EBZ		AD9631 Evaluation Board	
AD9631ACHIPS		Die	
AD9632ANZ	−40°C to +85°C	8-Lead Plastic Dual In-Line Package [PDIP]	N-8
AD9632AR	−40°C to +85°C	8-Lead Standard Small Outline Package [SOIC_N]	R-8
AD9632ARZ	−40°C to +85°C	8-Lead Standard Small Outline Package [SOIC_N]	R-8
AD9632ARZ-REEL	−40°C to +85°C	8-Lead Standard Small Outline Package [SOIC_N]	R-8
AD9632ARZ-REEL7	−40°C to +85°C	8-Lead Standard Small Outline Package [SOIC_N]	R-8
AD9632AR-EBZ		AD9632 Evaluation Board	

[1] Z = RoHS Compliant Part.
