

FEATURES

Stereo analog-to-digital converter (ADC)

- Supports 48 kHz/96 kHz sample rates
- 102 dB dynamic range
- Single-ended input
- Automatic level control

Stereo digital-to-analog converter (DAC)

- Supports 32 kHz/44.1 kHz/48 kHz/96 kHz/192 kHz sample rates
- 101 dB dynamic range
- Single-ended output

Asynchronous operation of ADC and DAC

Stereo sample rate converter (SRC)

- Input/output range: 8 kHz to 192 kHz
- 140 dB dynamic range

Digital interfaces

- Record
- Playback
- Auxiliary record
- Auxiliary playback
- S/PDIF (IEC 60958) input and output
 - Digital interface receiver (DIR)
 - Digital interface transmitter (DIT)
- PLL-based audio MCLK generators
 - Generates required DVDR system MCLKs
- Device control via SPI-compatible serial port
- 64-lead LQFP package

GENERAL DESCRIPTION

The ADAV801 is a stereo audio codec intended for applications such as DVD or CD recorders that require high performance and flexible, cost-effective playback and record functionality. The ADAV801 features Analog Devices, Inc. proprietary, high performance converter cores to provide record (ADC), playback (DAC), and format conversion (SRC) on a single chip. The ADAV801 record channel features variable input gain to allow for adjustment of recorded input levels and automatic level control, followed by a high performance stereo ADC whose digital output is sent to the record interface. The record channel also features level detectors that can be used in feedback loops to adjust input levels for optimum recording. The playback channel features a high performance stereo DAC with independent digital volume control.

FUNCTIONAL BLOCK DIAGRAM

Figure 1.

APPLICATIONS

- DVD-recordable
- All formats
- CD-R/W

The sample rate converter (SRC) provides high performance sample rate conversion to allow inputs and outputs that require different sample rates to be matched. The SRC input can be selected from playback, auxiliary, DIR, or ADC (record). The SRC output can be applied to the playback DAC, both main and auxiliary record channels, and a DIT.

Operation of the ADAV801 is controlled via an SPI-compatible serial interface, which allows the programming of individual control register settings. The ADAV801 operates from a single analog 3.3 V power supply and a digital power supply of 3.3 V with an optional digital interface range of 3.0 V to 3.6 V.

The part is housed in a 64-lead LQFP package and is characterized for operation over the commercial temperature range of -40°C to $+85^{\circ}\text{C}$.

Soldering (10 sec)	300°C

Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only; functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

ESD CAUTION

ESD (electrostatic discharge) sensitive device. Charged devices and circuit boards can discharge without detection. Although this product features patented or proprietary protection circuitry, damage may occur on devices subjected to high energy ESD. Therefore, proper ESD precautions should be taken to avoid performance degradation or loss of functionality.

PIN CONFIGURATION AND FUNCTION DESCRIPTIONS

FUNCTIONAL DESCRIPTION

ADC SECTION

The ADAV801's ADC section is implemented using a second-order multibit (5 bits) Σ - Δ modulator. The modulator is sampled at either half of the ADC MCLK rate (modulator clock = $128 \times f_s$) or one-quarter of the ADC MCLK rate (modulator clock = $64 \times f_s$). The digital decimator consists of a Sinc⁵ filter followed by a cascade of three half-band FIR filters. The Sinc decimates by a factor of 16 at 48 kHz and by a factor of 8 at 96 kHz. Each of the half-band filters decimates by a factor of 2.

Figure 23 shows the details of the ADC section. By default, the ADC assumes that the MCLK rate is 256 times the sample rate. The ADC can be clocked by a number of different clock sources to control the sample rate. MCLK selection for the ADC is set by Internal Clocking Control Register 1 (Address 0x76). The ADC provides an output word of up to 24 bits in resolution in twos complement format. The output word can be routed to either the output ports, the sample rate converter, or the S/PDIF digital transmitter.

Figure 23. Clock Path Control on the ADC

Programmable Gain Amplifier (PGA)

The input of the record channel features a PGA that converts the single-ended signal to a differential signal, which is applied to the analog Σ - Δ modulator of the ADC. The PGA can be programmed to amplify a signal by up to 24 dB in 0.5 dB increments. Figure 24 shows the structure of the PGA circuit.

Figure 24. PGA Block Diagram

Analog Σ - Δ Modulator

The ADC features a second-order, multibit, Σ - Δ modulator. The input features two integrators in cascade followed by a flash converter. This multibit output is directed to a scrambler, followed by a DAC for loop feedback. The flash ADC output is also converted from thermometer coding to binary coding for input as a 5-bit word to the decimator. Figure 25 shows the ADC block diagram.

The ADC also features independent digital volume control for the left and right channels. The volume control consists of 256 linear steps, with each step reducing the digital output codes by 0.39%. Each channel also has a peak detector that records the peak level of the input signal. The peak detector register is cleared by reading it.

Figure 25. ADC Block Diagram

Automatic Level Control (ALC)

The ADC record channel features a programmable automatic level control block. This block monitors the level of the ADC output signal and automatically reduces the gain, if the signal at the input pins causes the ADC output to exceed a preset limit. This function can be useful to maximize the signal dynamic range when the input level is not well defined. The PGA can be used to amplify the unknown signal, and the ALC reduces the gain until the ADC output is within the preset limits. This results in maximum front end gain.

Because the ALC block monitors the output of the ADC, the volume control function should not be used. The ADC volume control scales the results from the ADC, and any distortion caused by the input signal exceeding the input range of the ADC is still present at the output of the ADC, but scaled by a value determined by the volume control register.

The ALC block has two functions, attack mode and recovery mode. Recovery mode consists of three settings: no recovery, normal recovery, and limited recovery. These modes are discussed in the following sections. Figure 26 is a flow diagram of the ALC block. When the ALC has been enabled, any changes made to the PGA or ALC settings are ignored. To change the functionality of the ALC, it must first be disabled. The settings can then be changed and the ALC re-enabled.

Attack Mode

When the absolute value of the ADC output exceeds the level set by the attack threshold bits in ALC Control Register 2, attack mode is initiated. The PGA gain for both channels is reduced by one step (0.5 dB). The ALC then waits for a time determined by the attack timer bits before sampling the ADC output value again. If the ADC output is still above the threshold, the PGA gain is reduced by a further step. This procedure continues until the ADC output is below the limit set by the attack threshold bits. The initial gains of the PGAs are defined by the ADC left PGA gain register and the ADC right PGA gain register, and they can have different values. The ALC subtracts a common gain offset to these values. The ALC preserves any gain difference in dB as defined by these registers. At no time do the PGA gains exceed their initial values. The initial gain setting, therefore, also serves as a maximum value.

The limit detection mode bit in ALC Control Register 1 determines how the ALC responds to an ADC output that exceeds the set limits. If this bit is a 1, both channels must exceed the threshold before the gain is reduced. This mode can be used to prevent unnecessary gain reduction due to spurious noise on a single channel. If the limit detection mode bit is a 0, the gain is reduced when either channel exceeds the threshold.

No Recovery Mode

By default, there is no gain recovery. Once the gain has been reduced, it is not recovered until the ALC is reset, either by toggling the ALCEN bit in ALC Control Register 1 or by writing any value to ALC Control Register 3. The latter option is more efficient because it requires only one write operation to reset the ALC function. No recovery mode prevents volume modulation of the signal caused by adjusting the gain, which can create undesirable artifacts in the signal. The gain can be reduced but not recovered. Therefore, care should be taken that spurious signals do not interfere with the input signal because these might trigger a gain reduction unnecessarily.

Normal Recovery Mode

Normal recovery mode allows for the PGA gain to be recovered, provided that the input signal meets certain criteria. First, the ALC must not be in attack mode, that is, the PGA gain has been reduced sufficiently such that the input signal is below the level set by the attack threshold bits. Second, the output result from the ADC must be below the level set by the recovery threshold bits in the ALC control register. If both of these criteria are met, the gain is recovered by one step (0.5 dB). The gain is incrementally restored to its original value, assuming that the ADC output level is below the recovery threshold at intervals determined by the recovery time bits.

If the ADC output level exceeds the recovery threshold while the PGA gain is being restored, the PGA gain value is held and does not continue restoration until the ADC output level is again below the recovery threshold. Once the PGA gain is restored to its original value, it is not changed again unless the ADC output value exceeds the attack threshold and the ALC then enters attack mode. Care should be taken when using this mode to choose values for the attack and recovery thresholds that prevent excessive volume modulation caused by continuous gain adjustments.

Limited Recovery Mode

Limited recovery mode offers a compromise between no recovery and normal recovery modes. If the output level of the ADC exceeds the attack threshold, attack mode is initiated. When attack mode has reduced the PGA gain to suitable levels, the ALC attempts to recover the gain to its original level. If the ADC output level exceeds the level set by the recovery threshold bits, a counter is incremented (GAINCNTR). This counter is incremented at intervals equal to the recovery time selection, if the ADC has any excursion above the recovery threshold. If the counter reaches its maximum value, determined by the GAINCNTR bits in ALC Control Register 1, the PGA gain is deemed suitable and no further gain recovery is attempted. Whenever the ADC output level exceeds the attack threshold, attack mode is reinitiated and the counter is reset.

Selecting a Sample Rate

The output sample rate of the ADC is always $ADC\ MCLK/256$, as shown in Figure 23. By default, the ADC modulator runs at $ADC\ MCLK/2$. When the ADC MCLK exceeds 12.288 MHz, the ADC modulator should be set to run at $ADC\ MCLK/4$. This is achieved by setting the AMC (ADC Modulator Clock) bit in the ADC Control Register 1. To compensate for the reduced modulator clock speed, a different set of filters are used in the decimator section, ensuring that the sample rate remains the same.

The AMC bit can also be used to boost the THD + N performance of the ADC at the expense of dynamic range. The improvement is typically 0.5 dB to 1.0 dB and works because

selecting the lower modulator rate reduces the amount of digital noise, improving THD + N, but also reduces the oversampling ratio, therefore reducing the dynamic range by a corresponding amount.

For best performance of the ADC, avoid using similar frequency clocks from separate sources in the ADAV801. For example, running the ADC from a 12.288 MHz clock connected to MCLKI and using the PLL to generate a separate 12.288 MHz clock for the DAC can reduce the performance of the ADC. This is due to the interaction of the clocks, which generate beat frequencies that can affect the charge on the switch capacitors of the analog inputs.

Figure 26. ALC Flow Diagram

ADAV801

DAC SECTION

The ADAV801 has two DAC channels arranged as a stereo pair with single-ended analog outputs. Each channel has its own independently programmable attenuator, adjustable in 128 steps of 0.375 dB per step. The DAC can receive data from the playback or auxiliary input ports, the SRC, the ADC, or the DIR. Each analog output pin sits at a dc level of VREF, and swings 1.0 V rms for a 0 dB digital input signal. A single op amp third-order external low-pass filter is recommended to remove high frequency noise present on the output pins. Note that the use of op amps with low slew rate or low bandwidth can cause high frequency noise and tones to fold down into the audio band. Care should be taken in selecting these components.

The FILTD and VREF pins should be bypassed by external capacitors to AGND. The FILTD pin is used to reduce the noise of the internal DAC bias circuitry, thereby reducing the DAC output noise. The voltage at the VREF pin can be used to bias external op amps used to filter the output signals. For applications in which the VREF is required to drive external op amps, which might draw more than 50 μ A or have dynamic load changes, extra buffering should be used to preserve the quality of the ADAV801 reference.

The digital input data source for the DAC can be selected from a number of available sources by programming the appropriate bits in the datapath control register. Figure 27 shows how the digital data source and the MCLK source for the DAC are selected. Each DAC has an independent volume register giving 256 steps of control, with each step giving approximately 0.375 dB of attenuation. Note that the DACs are muted by default to prevent unwanted pops, clicks, and other noises from appearing on the outputs while the ADAV801 is being configured. Each DAC also has a peak-level register that records the peak value of the digital audio data. Reading the register clears the peak.

Selecting a Sample Rate

Correct operation of the DAC is dependent upon the data rate provided to the DAC, the master clock applied to the DAC, and the selected interpolation rate. By default, the DAC assumes that the MCLK rate is 256 times the sample rate, which requires an 8 \times oversampling rate. This combination is suitable for sample rates of up to 48 kHz.

For a 96 kHz data rate that has a 24.576 MHz MCLK ($256 \times f_s$) associated with it, the DAC MCLK divider should be set to divide the MCLK by 2. This prevents the DAC engine from running too fast. To compensate for the reduced MCLK rate, the interpolator should be selected to operate in $4 \times$ (DAC MCLK = $128 \times f_s$). Similar combinations can be selected for different sample rates.

Figure 27. Clock and Datapath Control on the DAC

Figure 28. DAC Block Diagram

SAMPLE RATE CONVERTER (SRC) FUNCTIONAL OVERVIEW

During asynchronous sample rate conversion, data can be converted at the same sample rate or at different sample rates. The simplest approach to an asynchronous sample rate conversion is to use a zero-order hold between the two samplers, as shown in Figure 29. In an asynchronous system, T_2 is never equal to T_1 , nor is the ratio between T_2 and T_1 rational. As a result, samples at f_{S_OUT} are repeated or dropped, producing an error in the resampling process.

The frequency domain shows the wide side lobes that result from this error when the sampling of f_{S_OUT} is convolved with the attenuated images from the $\sin(x)/x$ nature of the zero-order hold. The images at f_{S_IN} (dc signal images) of the zero-order hold are infinitely attenuated. Because the ratio of T_2 to T_1 is an irrational number, the error resulting from the resampling at f_{S_OUT} can never be eliminated. The error can be significantly reduced, however, through interpolation of the input data at f_{S_IN} . Therefore, the sample rate converter in the ADAV801 is conceptually interpolated by a factor of 2^{20} .

Figure 29. Zero-Order Hold Used by f_{S_OUT} to Resample Data from f_{S_IN}

Conceptual High Interpolation Model

Interpolation of the input data by a factor of 2^{20} involves placing $(2^{20} - 1)$ samples between each f_{S_IN} sample. Figure 30 shows both the time domain and the frequency domain of interpolation by a factor of 2^{20} . Conceptually, interpolation by 2^{20} involves the steps of zero-stuffing $(2^{20} - 1)$ number of samples between each f_{S_IN} sample and convolving this interpolated signal with a digital low-pass filter to suppress the images. In the time domain, it can be seen that f_{S_OUT} selects the closest $f_{S_IN} \times 2^{20}$ sample from the zero-order hold, as opposed to the nearest f_{S_IN} sample in the case of no interpolation. This significantly reduces the resampling error.

Figure 30. SRC Time Domain

In the frequency domain shown in Figure 31, the interpolation expands the frequency axis of the zero-order hold. The images from the interpolation can be sufficiently attenuated by a good low-pass filter. The images from the zero-order hold are now pushed by a factor of 2^{20} closer to the infinite attenuation point of the zero-order hold, which is $f_{S_IN} \times 2^{20}$. The images at the zero-order hold are the determining factor for the fidelity of the output at f_{S_OUT} .

Figure 31. Frequency Domain of the Interpolation and Resampling

The worst-case images can be computed from the zero-order hold frequency response:

$$\text{Maximum Image} = \sin(\pi \times F/f_{S_INTERP}) / (\pi \times F/f_{S_INTERP})$$

where:

F is the frequency of the worst-case image that would be

$$2^{20} \times f_{S_IN} \pm f_{S_IN}/2.$$

$$f_{S_INTERP} = f_{S_IN} \times 2^{20}.$$

The following worst-case images would appear for f_{S_IN} equal to 192 kHz:

$$\text{Image at } f_{S_INTERP} - 96 \text{ kHz} = -125.1 \text{ dB}$$

$$\text{Image at } f_{S_INTERP} + 96 \text{ kHz} = -125.1 \text{ dB}$$

Hardware Model

The output rate of the low-pass filter in Figure 30 is the interpolation rate:

$$2^{20} \times 192,000 \text{ kHz} = 201.3 \text{ GHz}$$

Sampling at a rate of 201.3 GHz is clearly impractical, in addition to the number of taps required to calculate each interpolated sample. However, because interpolation by 2^{20} involves zero-stuffing $2^{20} - 1$ samples between each f_{S_IN} sample, most of the multiplies in the low-pass FIR filter are by zero. A further reduction can be realized because only one interpolated sample is taken at the output at the f_{S_OUT} rate, so only one convolution needs to be performed per f_{S_OUT} period instead of 2^{20} convolutions. A 64-tap FIR filter for each f_{S_OUT} sample is sufficient to suppress the images caused by the interpolation.

One difficulty with the preceding approach is that the correct interpolated sample must be selected upon the arrival of f_{S_OUT} . Because there are 2^{20} possible convolutions per f_{S_OUT} period, the arrival of the f_{S_OUT} clock must be measured with an accuracy of $1/201.3 \text{ GHz} = 4.96 \text{ ps}$. Measuring the f_{S_OUT} period with a clock of 201.3 GHz frequency is clearly impossible; instead, several coarse measurements of the f_{S_OUT} clock period are made and averaged over time.

Another difficulty with the preceding approach is the number of coefficients required. Because there are 2^{20} possible convolutions with a 64-tap FIR filter, there must be 2^{20} polyphase coefficients for each tap, which requires a total of 2^{26} coefficients. To reduce the number of coefficients in ROM, the SRC stores a small subset of coefficients and performs a high order interpolation between the stored coefficients.

The preceding approach works when $f_{S_OUT} > f_{S_IN}$. However, when the output sample rate, f_{S_OUT} , is less than the input sample rate, f_{S_IN} , the ROM starting address, input data, and length of the convolution must be scaled. As the input sample rate rises over the output sample rate, the antialiasing filter's cutoff frequency must be lowered because the Nyquist frequency of the output samples is less than the Nyquist frequency of the input samples. To move the cutoff frequency of the antialiasing filter, the coefficients are dynamically altered and the length of the convolution is increased by a factor of (f_{S_IN}/f_{S_OUT}) .

This technique is supported by the Fourier transform property that, if $f(t)$ is $F(\omega)$, then $f(k \times t)$ is $F(\omega/k)$. Thus, the range of decimation is limited by the size of the RAM.

SRC Architecture

The architecture of the sample rate converter is shown in Figure 32. The sample rate converter's FIFO block adjusts the left and right input samples and stores them for the FIR filter's convolution cycle. The f_{S_IN} counter provides the write address to the FIFO block and the ramp input to the digital servo loop. The ROM stores the coefficients for the FIR filter convolution and performs a high order interpolation between the stored coefficients. The sample rate ratio block measures the sample rate for dynamically altering the ROM coefficients and scaling of the FIR filter length as well as the input data. The digital servo loop automatically tracks the f_{S_IN} and f_{S_OUT} sample rates and provides the RAM and ROM start addresses for the start of the FIR filter convolution.

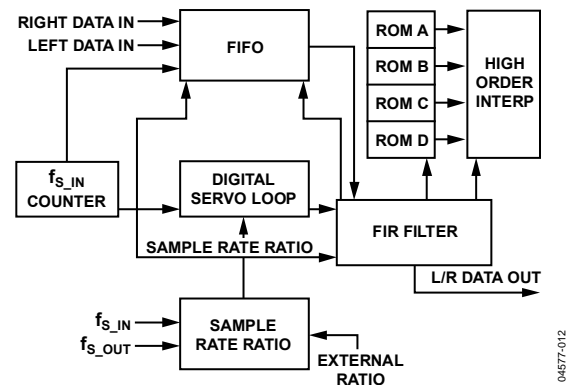

Figure 32. Architecture of the Sample Rate Converter

The FIFO receives the left and right input data and adjusts the amplitude of the data for both the soft muting of the sample rate converter and the scaling of the input data by the sample rate ratio before storing the samples in the RAM. The input data is scaled by the sample rate ratio because, as the FIR filter length of the convolution increases, so does the amplitude of the convolution output. To keep the output of the FIR filter from saturating, the input data is scaled down by multiplying it by (f_{S_OUT}/f_{S_IN}) when $f_{S_OUT} < f_{S_IN}$. The FIFO also scales the input data for muting and unmuting of the SRC.

The RAM in the FIFO is 512 words deep for both left and right channels. An offset to the write address provided by the f_{S_IN} counter is added to prevent the RAM read pointer from overlapping the write address. The minimum offset on the SRC is 16 samples. However, the group delay and mute-in register can be used to increase this offset.

The number of input samples added to the write pointer of the FIFO on the SRC is 16 plus Bit 6 to Bit 0 of the group delay register. This feature is useful in varispeed applications to prevent the read pointer to the FIFO from running ahead of the write pointer. When set, Bit 7 of the group delay and mute-in register soft-mutes the sample rate. Increasing the offset of the

write address pointer is useful for applications in which small changes in the sample rate ratio between f_{S_IN} and f_{S_OUT} are expected. The maximum decimation rate can be calculated from the RAM word depth and the group delay as

$$(512 - 16)/64 \text{ taps} = 7.75$$

for short group delay and

$$(512 - 64)/64 \text{ taps} = 7$$

for long group delay.

The digital servo loop is essentially a ramp filter that provides the initial pointer to the address in RAM and ROM for the start of the FIR convolution. The RAM pointer is the integer output of the ramp filter, and the ROM is the fractional part. The digital servo loop must provide excellent rejection of jitter on the f_{S_IN} and f_{S_OUT} clocks, as well as measure the arrival of the f_{S_OUT} clock within 4.97 ps. The digital servo loop also divides the fractional part of the ramp output by the ratio of f_{S_IN}/f_{S_OUT} to dynamically alter the ROM coefficients when $f_{S_IN} > f_{S_OUT}$.

Figure 33. Clock and Datapath Control on the SRC

The digital servo loop is implemented with a multirate filter. To settle the digital servo loop filter more quickly upon startup or a change in the sample rate, a fast mode has been added to the filter. When the digital servo loop starts up or the sample rate is changed, the digital servo loop enters fast mode to adjust and settle on the new sample rate. Upon sensing that the digital servo loop is settling down to a reasonable value, the digital servo loop returns to normal (or slow) mode.

During fast mode, the MUTE_IND bit in the Sample Rate Converter Error register is asserted to let the user know that clicks or pops might be present in the digital audio data. The output of the SRC can be muted by asserting Bit 7 of the Group

Delay and Mute register until the SRC has changed to slow mode. The MUTE_IND bit can be set to generate an interrupt when the SRC changes to slow mode, indicating that the data is being sample rate converted accurately.

The frequency responses of the digital servo loop for fast mode and slow mode are shown in Figure 34. The FIR filter is a 64-tap filter when $f_{S_OUT} \geq f_{S_IN}$ and is $(f_{S_IN}/f_{S_OUT}) \times 64$ taps when $f_{S_IN} > f_{S_OUT}$. The FIR filter performs its convolution by loading in the starting address of the RAM address pointer and the ROM address pointer from the digital servo loop at the start of the f_{S_OUT} period. The FIR filter then steps through the RAM by decrementing its address by 1 for each tap, and the ROM pointer increments its address by the $(f_{S_OUT}/f_{S_IN}) \times 2^{20}$ ratio for $f_{S_IN} > f_{S_OUT}$ or 2^{20} for $f_{S_OUT} \geq f_{S_IN}$. Once the ROM address rolls over, the convolution is completed.

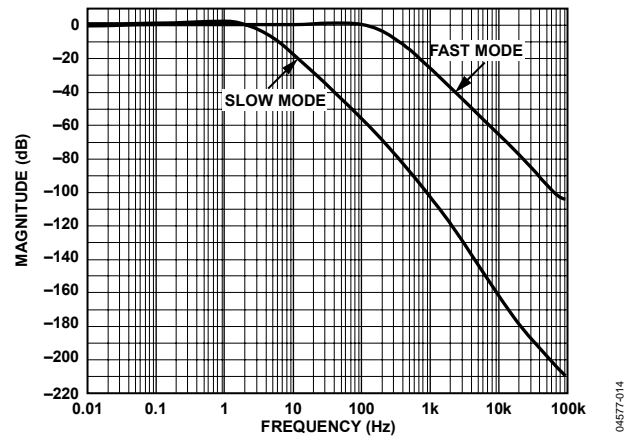

Figure 34. Frequency Response of the Digital Servo Loop; f_{S_IN} is the X-Axis, $f_{S_OUT} = 192 \text{ kHz}$, Master Clock is 30 MHz

The convolution is performed for both the left and right channels, and the multiply accumulate circuit used for the convolution is shared between the channels. The f_{S_IN}/f_{S_OUT} sample rate ratio circuit is used to dynamically alter the coefficients in the ROM when $f_{S_IN} > f_{S_OUT}$. The ratio is calculated by comparing the output of an f_{S_OUT} counter to the output of an f_{S_IN} counter. If $f_{S_OUT} > f_{S_IN}$, the ratio is held at one. If $f_{S_IN} > f_{S_OUT}$, the sample rate ratio is updated, if it is different by more than two f_{S_OUT} periods from the previous f_{S_OUT} to f_{S_IN} comparison. This is done to provide some hysteresis to prevent the filter length from oscillating and causing distortion.

Figure 33 shows the detail of the SRC section. The SRC master clock is expected to be equal to 256 times the output sample rate. This master clock can be provided by four different clock sources. The selection is set by the SRC and Clock Control register (Address 0x00), and the selected clock source can be divided using the same register.

ADAV801

PLL SECTION

The ADAV801 features a dual PLL configuration to generate independent system clocks for asynchronous operation. Figure 37 shows the block diagram of the PLL section. The PLL generates the internal and system clocks from a 27 MHz clock. This clock is generated either by a crystal connected between XIN and XOUT, as shown in Figure 35, or from an external clock source connected directly to XIN. A 54 MHz clock can also be used, if the internal clock divider is used.

Figure 35. Crystal Connection

Both PLLs (PLL1 and PLL2) can be programmed independently and can accommodate a range of sampling rates (32 kHz/44.1 kHz/48 kHz) with selectable system clock oversampling rates of 256 and 384. Higher oversampling rates can also be selected by enabling the doubling of the sampling rate to give 512 or 768 $\times f_s$ ratios. Note that this option also allows oversampling ratios of 256 or 384 at double sample rates of 64 kHz/88.2 kHz/96 kHz.

The PLL outputs can be routed internally to act as clock sources for the other component blocks such as the ADC and DAC. The outputs of the PLLs are also available on the three SYSCLK pins. Figure 38 shows how the PLLs can be configured to provide the sampling clocks.

Table 7. PLL Frequency Selection Options

PLL	Sample Rate, f_s (kHz)	MCLK Selection	
		Normal f_s	Double f_s
1	32/44.1/48	256/384 $\times f_s$	512/768 $\times f_s$
	64/88.2/96	256/384 $\times f_s$	256/384 $\times f_s$
2A	32/44.1/48	256/384 $\times f_s$	512/768 $\times f_s$
	64/88.2/96	256/384 $\times f_s$	256/384 $\times f_s$
2B	Same as f_s selected for PLL2A	256/512 $\times f_s$	

The PLLs require some external components to operate correctly. These components, shown in Figure 36, form a loop filter that integrates the current pulses from a charge pump and produces a voltage that is used to tune the VCO. Good quality capacitors, such as PPS film, are recommended. Figure 37 shows a block diagram of the PLL section, including the master clock selection. Figure 38 shows how the clock frequencies at the clock output pins, SYSCLK1 to SYSCLK3, and the internal PLL clock values, PLL1 and PLL2, are selected.

The clock nodes, PLL1 and PLL2, can be used as master clocks for the other blocks in the ADAV801, such as the DAC or ADC. The PLL has separate supply and ground pins, which should be as clean as possible to prevent electrical noise from being converted into clock jitter by coupling onto the loop filter pins.

Figure 36. PLL Loop Filter

Figure 37. PLL Section Block Diagram

Figure 38. PLL Clocking Scheme

S/PDIF TRANSMITTER AND RECEIVER

The ADAV801 contains an integrated S/PDIF transmitter and receiver. The transmitter consists of a single output pin, DITOUT, on which the biphas encoded data appears. The S/PDIF transmitter source can be selected from the different blocks making up the ADAV801. Additionally, the clock source for the S/PDIF transmitter can be selected from the various clock sources available in the ADAV801.

The receiver uses two pins, DIRIN and DIR_LF. DIRIN accepts the S/PDIF input data stream. The DIRIN pin can be configured to accept a digital input level, as defined in the Specifications section, or an input signal with a peak-to-peak level of 200 mV minimum, as defined by the IEC 60958-3 specification. DIR_LF is a loop filter pin, required by the internal PLL, which is used to recover the clock from the S/PDIF data stream.

The components shown in Figure 42 form a loop filter, which integrates the current pulses from a charge pump and produces a voltage that is used to tune the VCO of the clock recovery PLL. The recovered audio data and audio clock can be routed to the different blocks of the ADAV801, as required. Figure 39 shows a conceptual diagram of the DIRIN block.

ADAV801

Serial Digital Audio Transmission Standards

The ADAV801 can receive and transmit S/PDIF, AES/EBU, and IEC-958 serial streams. S/PDIF is a consumer audio standard, and AES/EBU is a professional audio standard. IEC-958 has both consumer and professional definitions. This data sheet is not intended to fully define or to provide a tutorial for these standards. Contact the international standards-setting bodies for the full specifications.

All these digital audio communication schemes encode audio data and audio control information using the biphase-mark method. This encoding method minimizes the dc content of the transmitted signal. As can be seen from Figure 43, 1s in the original data end up with midcell transitions in the biphase-mark encoded data, while 0s in the original data do not. Note that the biphase-mark encoded data always has a transition between bit boundaries.

Figure 43. Biphase-Mark Encoding

Digital audio-communication schemes use preambles to distinguish among channels (called subframes) and among longer-term control information blocks (called frames). Preambles are particular biphase-mark patterns, which contain encoding violations that allow the receiver to uniquely recognize them. These patterns and their relationship to frames and subframes are shown in Table 8 and Figure 44.

Table 8. Biphase-Mark Encode Preamble

	Biphase Patterns	Channel
X	11100010 or 00011101	Left
Y	11100100 or 00011011	Right
Z	11101000 or 00010111	Left and CS block start

Figure 44. Preambles, Frames, and Subframes

The biphase-mark encoding violations are shown in Figure 45. Note that all three preambles include encoding violations. Ordinarily, the biphase-mark encoding method results in a polarity transition between bit boundaries.

Figure 45. Preambles

The serial digital audio communication scheme is organized using a frame and subframe construction. There are two subframes per frame (ordinarily the left and right channel). Each subframe includes the appropriate 4-bit preamble, up to 24 bits of audio data, a validity (V) bit, a user (U) bit, a channel status (C) bit, and an even parity (P) bit. The channel status bits and the user bits accumulate over many frames to convey control information. The channel status bits accumulate over a 192 frame period (called a channel status block). The user bits accumulate over 1176 frames when the interconnect is implementing the so-called subcode scheme (EIAJ CP-2401). The organization of the channel status block, frames, and subframes is shown in Table 9 and Table 10. Note that the ADAV801 supports the professional audio standard from a software point of view only. The digital interface supports only consumer mode.

¹ N = 0x20 for receiver channel status buffer.
N = 0x38 for transmitter channel status buffer.

The standards allow the channel status bits in each subframe to be independent, but ordinarily the channel status bits in the two subframes of each frame are the same. The channel status bits are defined differently for the consumer audio standards and the professional audio standards. The 192 channel status bits are organized into 24 bytes and have the interpretations shown in Table 9 and Table 10.

The S/PDIF transmitter and receiver have a comprehensive register set. The registers give the user full access to the functions of the S/PDIF block, such as detecting nonaudio and validity bits, Q subcodes, and preambles. The channel status bits as defined by the IEC60958 and AES3 specifications are stored in register buffers for ease of use. An autobuffering function allows channel status bits and user bits read by the receiver to be copied directly to the transmitter block, removing the need for user intervention.

Receiver Section

The ADAV801 uses a double-buffering scheme to handle reading channel status and user bit information. The channel status

bits are available as a memory buffer, taking up 24 consecutive register locations. The user bits are read using an indirect memory addressing scheme, where the receiver user bit indirect-address register is programmed with an offset to the user bit buffer, and the receiver user bit data register can be read to determine the user bits at that location. Reading the receiver user bit data register automatically updates the indirect address register to the next location in the buffer. Typically, the receiver user bit indirect-address register is programmed to zero (the start of the buffer), and the receiver user bit data register is read repeatedly until all the buffer’s data has been read. Figure 46 and Figure 47 show how receiving the channel status bits and user bits is implemented.

Figure 46. Channel Status Buffer

Figure 47. Receiver User Bit Buffer

The S/PDIF receive buffer is updated continuously by the incoming S/PDIF stream. Once all the channel status bits for the block (192 for Channel A and 192 for Channel B) are received, the bits are copied into the receiver channel status buffer. This buffer stores all 384 bits of channel status information, and the RxCSSWITCH bit in the channel status switch buffer register determines whether the Channel A or the Channel B status bits are required to be read. The receive channel status bit buffer is 24 bytes long and spans the address range from 0x20 to 0x37.

Because the channel status bits of an S/PDIF stream rarely change, a software interrupt/flag bit, RxCSBINT, is provided to notify the host control either that a new block of channel status bits is available or that the first five bytes of channel status information have changed from a previous block. The function of the RxCSBINT is controlled by the RxBCONF3 bit in the Receiver Buffer Configuration register.

ADAV801

The size of the user bit buffer can be set by programming the RxBCONF0 bit in the receiver buffer configuration register, as shown in Table 11.

Table 11. RxBCONF3 Functionality

RxBCONF0	Receiver User Bit Buffer Size
0	384 bits with Preamble Z as the start of the block.
1	768 bits with Preamble Z as the start of the block.

The updating of the user bit buffer is controlled by Bits RxBCONF[2:1] and Bit 7 to Bit 4 of the channel status register, as shown in Table 12 and Table 13.

Table 12. RxBCONF[2:1] Functionality

RxBCONF		Receiver User Bit Buffer Configuration
Bit 2	Bit 1	
0	0	User bits are ignored.
0	1	Update second buffer when first buffer is full.
1	0	Format according to Byte 1, Bit 4 to Bit 7, if PRO bit is set. Format according to IEC60958-3, if PRO bit is clear.

Table 13. Automatic User Bit Configuration

Bits				Automatic Receiver User Bit Buffer Configuration
7	6	5	4	
0	0	0	0	User bits are ignored.
0	1	0	0	AES-18 format: the user bit buffer is treated in the same way as when RxBCONF[2:1] = 0b01.
1	0	0	0	User bit buffer is updated in the same way as when RxBCONF[2:1] = 0b01 and RxBCONF0 = 0b00.
1	1	0	0	User-defined format: the user bit buffer is treated in the same way as when RxBCONF[2:1] = 0b01.

When the user bit buffer has been filled, the RxUBINT interrupt bit in the interrupt status register is set, provided that the RxUBINT mask bit is set, to indicate that the buffer has new information and can be read.

For the special case when the user data is formatted according to the IEC 60958-3 standard into messages made of information units, called IUs, the zeros stuffed between each IU and each message are removed and only the IUs are stored. Once the end of the message is sensed by more than eight zeros between IUs, the user bit buffer is updated with the complete message and the first buffer begins looking for the start of the next message.

Each IU is stored as a byte consisting of 1, Q, R, S, T, U, V, and W bits (see the IEC 60958-3 specification for more information). When 96 IUs are received, the Q subcode of the IUs is stored in the Q subcode buffer, consisting of 10 bytes. The Q subcode is the Q bits taken from each of the 96 IUs. The first 10 bytes (80 bits) of the Q subcode contain information sent by CD, MD, and DAT systems. The last 16 bits of the Q subcode are used to perform a CRC check of the Q subcode. If an error occurs in

the CRC check of the Q subcode, the QRCERROR bit is set. This is a sticky bit that remains high until the register is read.

Transmitter Operation

The S/PDIF transmitter has a similar buffer structure to the receive section. The transmitter channel status buffer occupies 24 bytes of the register map. This buffer is long enough to store the 192 bits required for one channel of channel status information. Setting the TxCSSWITCH bit determines if the data loaded to the transmitter channel status buffer is intended for Channel A or Channel B. In most cases, the channel status bits for Channel A and Channel B are the same, in which case setting the Tx_A/B_Same bit reads the data from the transmitter channel status buffer and transmits it on both channels.

Because the channel status information is rarely changed during transmission, the information contained in the buffer is transmitted repeatedly. The Disable_Tx_Copy bit can be used to prevent the channel status bits from being copied from the transmitter CS buffer into the S/PDIF transmitter buffer until the user has finished loading the buffers. This feature is typically used, if the Channel A data and Channel B data are different. Setting the bit prevents the data from being copied. Clearing the bit allows the data to be copied and then transmitted. Figure 48 shows how the buffers are organized.

Figure 48. Transmitter Channel Status Buffer

As with the receiver section, the transmitted user bits are also double-buffered. This is required because, unlike the channel status bits, the user bits do not necessarily repeat themselves. The user bits can be buffered in various configurations, as listed in Table 14. Transmission of the user bits is determined by the state of the BCONF3 bit. If the bit is 0, the user bits begin transmitting right away without alignment to the Z preamble. If this bit is 1, the user bits do not start transmitting until a Z preamble occurs when the TxBCONF[2:1] bits are 01.

Table 14. Transmitter User Bit Buffer Configurations

TxBCONF[2:1]		Transmitter User Bit Buffer Configuration
Bit 2	Bit 1	
0	0	Zeros are transmitted for the user bits.
0	1	Host writes user bits to the buffer until it is full.
1	0	Writes the user bits to the buffer in IUs specified by IEC60958-3 and transmits them according to the standard.
1	1	First 10 bytes of the user-bit buffer are configured to store a Q subcode.

Table 15. Transmitter User Bit Buffer Size

TxBCONF0	Buffer Size
0	384 bits with Preamble Z as the start of the block.
1	768 bits with Preamble Z as the start of the block.

By using sticky bits and interrupts, the transmit buffers can notify the host or microcontroller about their status. The sticky bit, TxUBINT, is set when the transmit user bit buffer has been updated and the second transmit user bit buffer is empty and ready to accept new user bits. This bit is located in the interrupt status register. When the host reads the interrupt status register, this bit is cleared. Interrupts for the TxUBINT sticky bit can be enabled by setting the TxUBINT Mask bit in the interrupt status mask register

Figure 49. Transmitter User Bit Buffer

Autobuffering

The ADAV801 S/PDIF receiver and transmitter sections have an autobuffering mode allowing the channel status and user bits to be copied automatically from the receiver to the transmitter without user intervention. The channel status and user bits can be independently selected for autobuffering using the Auto_CSBits and Auto_UBits bits, respectively, in the Autobuffer register. When the receiver and transmitter are running at the same sample rate, the transmitted channel status and user bits are the same as the received channel-status and user bits.

In many systems, however, it is likely that the receiver and transmitter are not running at the same frequency. When the transmitter sample rate is higher than receiver sample rate, the channel status and user bit blocks are sometimes repeated. When the transmitter sample rate is lower than the receiver sample rate, the channel status and user bit blocks might be dropped. Because the first five bytes of the channel status are typically constant, they can be repeated or dropped with no information loss. However, if the PRO bit in the channel status is set and the local sample address code and time-of-day code bytes contain information, these bytes might be repeated or dropped, in which case information can be lost. It is up to the user to determine how to handle this case.

When the user bits are transmitted according to the IEC 60958-3 format, the messages contained in the user bits can still be sent without dropping or repeating messages. Because zero-stuffing is allowed between IUs and messages, zeros can be added or subtracted to preserve the messages. When the transmitter sample rate is greater than the receiver sample rate, extra zeros are stuffed between the messages. When the sample rate of the transmitter is less than the sample rate of the receiver, the zeros stuffed between the messages are subtracted. If there are not enough zeros between the messages to be subtracted, the zeros between IUs are subtracted as well. The Zero_Stuff_IU bit in the Autobuffer register enables the adding or subtracting of zeros between messages.

Interrupts

The ADAV801 provides interrupt bits to indicate the presence of certain conditions that require attention. Reading the interrupt status register (Register 0x1C) allows the user to determine if any of the interrupts have been asserted. The bits of the Interrupt Status register remain high, if set, until the register is read. Two bits, SRCError and RxError, indicate interrupt conditions in the sample rate converter and an S/PDIF receiver error, respectively. Both these conditions require a read of the appropriate error register (Register 0x1A and Register 0x18, respectively) to determine the exact cause of the interrupt.

Each interrupt in the interrupt status register has an associated mask bit in the interrupt status mask register. The interrupt mask bit must be set for the corresponding interrupt to be generated. This feature allows the user to determine which functions should be responded to.

The dual function pin ZEROL/INT can be set to indicate the presence of no audio data on the left channel or the presence of an interrupt set in the interrupt status register. As shown in Table 16, the function of this pin is selected by the INTRPT bit in DAC Control Register 4.

Table 16. ZEROL/INT Pin Functionality

INTRPT	Pin Functionality
0	Pin functions as a ZEROL flag pin.
1	Pin functions as an interrupt pin.

SERIAL DATA PORTS

The ADAV801 contains four flexible serial ports (SPORTs) to allow data transfer to and from the codec. All four SPORTs are independent and can be configured as master or slave ports. In slave mode, the xLRCLK and xBCLK signals are inputs to the serial ports. In master mode, the serial port generates the xLRCLK and xBCLK signals. The master clock for the SPORT can be selected from a number of sources, as shown in Figure 50.

Figure 50. SPORT Cloning Scheme

Care should be taken to ensure that the clock rate is appropriate for whatever block is connected to the serial port. For example, if the ADC is running from the MCLKI input at $256 \times f_s$, then the master clock for the SPORT should also run from the MCLKI input to ensure that the ADC and serial port are synchronized.

The SPORTs can be set to transmit or receive data in I²S, left-justified or right-justified formats with different word lengths by programming the appropriate bits in the playback register, auxiliary input port register, record register, and auxiliary output port-control register. Figure 51 is a timing diagram of the serial data port formats.

Clocking Scheme

The ADAV801 provides a flexible choice of on-chip and off-chip clocking sources. The on-chip oscillator with dual PLLs is intended to offer complete system clocking requirements for use with available MPEG encoders, decoders, or a combination of codecs. The oscillator function is designed for generation of a 27 MHz video clock from a 27 MHz crystal connected between the XIN and XOUT pins. Capacitors must also be connected between these pins and DGND, as shown in Figure 35. The capacitor values should be specified by the crystal manufacturer. A square wave version of the crystal clock is output on the MCLKO pin. If the system has a 27 MHz clock available, this clock can be connected directly to the XIN pin.

Figure 51. Serial Data Modes

Datapath

The ADAV801 features a digital input/output switching/multiplexing matrix that gives flexibility to the range of possible input and output connections. Digital input ports include playback and auxiliary input (both 3-wire digital), and S/PDIF (single-wire to the on-chip receiver). Output ports include the record and auxiliary output ports (both 3-wire digital) and the S/PDIF port (single-wire from the on-chip transmitter). Internally, the DIR and DIT are interfaced via 3-wire interfaces. The datapath for each input and output port is selected by programming Datapath Control Register 1 and Datapath Control Register 2. Figure 52 shows the internal datapath structure of the ADAV801.

Figure 52. Datapath

04677-032

INTERFACE CONTROL

The ADAV801 has a dedicated control port to allow access to the internal registers of the ADAV801. Each of the internal registers is eight bits wide. Where bits are described as reserved (RES), these bits should be programmed as zero.

SPI INTERFACE

Control of the ADAV801 is via an SPI-compatible serial port. The SPI control port is a 4-wire serial control port with one cycle of data transfer consisting of 16 bits. Figure 53 shows the format of an SPI write/read of the ADAV801. The transfer of data is initiated on the falling edge of CLATCH. The data presented on the first seven CCLKs represents the register address read/write bit. If this bit is low, the following eight bits of data are loaded to the register address provided. If this bit is high, a read operation is indicated. The contents of the register address are clocked out on the COUT pin on the following eight CCLKs. For a read operation, the data bits after the read/write bits are ignored.

BLOCK READS AND WRITES

The ADAV801 provides the user with the ability to write to or read from a block of registers in one continuous operation. In SPI mode, the CLATCH line should be held low for longer than the 16 CCLK periods to use the block read/write mode. For a write operation, once the LSB has been clocked into the ADAV801 on the 16th CCLK, the register address as specified by the first seven bits of the write operation is incremented and the next eight bits are clocked into the next register address.

The read operation is similar. Once the LSB of a read register operation has been clocked out, the register address is incremented and the data from the next register is clocked out on the following eight CCLKs. Figure 55 and Figure 56 show the timing diagrams for the block write and read operations.

Table 60. Preamble-D LSB Register (Read-Only) Bit Descriptions

Bit Name	Description
PRE_D[7:0]	Eight least significant bits of the 16-bit Preamble-D, when nonaudio data is detected according to the IEC60937 standard; otherwise, bits show zeros. When subframe nonaudio is used, this becomes the eight most significant bits of the 16-bit Preamble-C of Channel B.

ADAV801

Receiver Error—Address 0011000 (0x18)

Table 61. Receiver Error Register (Read-Only) Bit Map

7	6	5	4	3	2	1	0
RxValidity	Emphasis	NonAudio	NonAudio Preamble	CRCErrror	NoStream	BiPhase/Parity	Lock

Table 62. Receiver Error Register (Read-Only) Bit Descriptions

Bit Name	Description
RxValidity	This is the VALIDITY bit in the AES3 received stream.
Emphasis	This bit is set if the audio data is pre-emphasized. Once it has been read, it remains high and does not generate an interrupt unless it changes state.
NonAudio	This bit is set when Channel Status Bit 1 (nonaudio) is set. Once it has been read, it does not generate another interrupt unless the data becomes audio or the type of nonaudio data changes.
NonAudio Preamble	This bit is set if the audio data is nonaudio due to the detection of a preamble. The nonaudio preamble type register indicates what type of preamble was detected. Once read, it remains in its state and does not generate an interrupt unless it changes state.
CRCErrror	This bit is the error flag for the channel status CRCErrror check. This bit does not clear until the receiver error register is read.
NoStream	This bit is set if there is no AES3/S/PDIF stream present at the AES3/S/PDIF receiver. Once read, it remains high and does not generate an interrupt unless it changes state.
BiPhase/Parity	This bit is set if a biphasic or parity error occurred in the AES3/S/PDIF stream. This bit is not cleared until the register is read.
Lock	This bit is set if the PLL has locked or cleared when the PLL loses lock. Once read, it remains in its state and does not generate an interrupt unless it changes state.

Receiver Error Mask—Address 0011001 (0x19)

Table 63. Receiver Error Mask Register Bit Map

7	6	5	4	3	2	1	0
RxValidity Mask	Emphasis Mask	NonAudio Mask	NonAudio Preamble Mask	CRCErrror Mask	NoStream Mask	BiPhase/Parity Mask	Lock Mask

Table 64. Receiver Error Mask Register Bit Descriptions

Bit Name	Description
RxValidity Mask	Masks the RxValidity bit from generating an interrupt. 0 = RxValidity bit does not generate an interrupt. 1 = RxValidity bit generates an interrupt.
Emphasis Mask	Masks the Emphasis bit from generating an interrupt. 0 = Emphasis bit does not generate an interrupt. 1 = Emphasis bit generates an interrupt.
NonAudio Mask	Masks the NonAudio bit from generating an interrupt. 0 = NonAudio bit does not generate an interrupt. 1 = NonAudio bit generates an interrupt.
NonAudio Preamble Mask	Masks the NonAudio preamble bit from generating an interrupt. 0 = NonAudio preamble bit does not generate an interrupt. 1 = NonAudio preamble bit generates an interrupt.
CRCErrror Mask	Masks the CRCErrror bit from generating an interrupt. 0 = CRCErrror bit does not generate an interrupt. 1 = CRCErrror bit generates an interrupt.
NoStream Mask	Masks the NoStream bit from generating an interrupt. 0 = NoStream bit does not generate an interrupt. 1 = NoStream bit generates an interrupt.
BiPhase/Parity Mask	Masks the BiPhase/Parity bit from generating an interrupt. 0 = BiPhase/Parity bit does not generate an interrupt. 1 = BiPhase/Parity bit generates an interrupt.
Lock Mask	Masks the Lock bit from generating an interrupt. 0 = Lock bit does not generate an interrupt. 1 = Lock bit generates an interrupt.

Sample Rate Converter Error—Address 0011010 (0x1A)**Table 65. Sample Rate Converter Error Register (Read-Only) Bit Map**

7	6	5	4	3	2	1	0
Reserved	Reserved	Reserved	Reserved	TOO_SLOW	OVRL	OVR	MUTE_IND

Table 66. Sample Rate Converter Error Register (Read-Only) Bit Descriptions

Bit Name	Description
TOO_SLOW	This bit is set when the clock to the SRC is too slow, that is, there are not enough clock cycles to complete the internal convolution.
OVRL	This bit is set when the left output data of the sample rate converter has gone over the full-scale range and has been clipped. This bit is not cleared until the register is read.
OVR	This bit is set when the right output data of the sample rate converter has gone over the full-scale range and has been clipped. This bit is not cleared until the register is read.
MUTE_IND	Mute indicated. This bit is set when the SRC is in fast mode and clicks or pops can be heard in the SRC output data. The output of the SRC can be muted, if required, until the SRC is in slow mode. Once read, this bit remains in its state and does not generate an interrupt until it has changed state.

Sample Rate Converter Error Mask—Address 0011011 (0x1B)**Table 67. Sample Rate Converter Error Mask Register Bit Map**

7	6	5	4	3	2	1	0
Reserved	Reserved	Reserved	Reserved	Reserved	OVRL Mask	OVR Mask	MUTE_IND MASK

Table 68. Sample Rate Converter Error Mask Register Bit Descriptions

Bit Name	Description
OVRL Mask	Masks the OVRL from generating an interrupt. 0 = OVRL bit does not generate an interrupt. 1 = OVRL bit generates an interrupt.
OVR Mask	Masks the OVR from generating an interrupt. 0 = OVR bit does not generate an interrupt. 1 = OVR bit generates an interrupt. Reserved.
MUTE_IND MASK	Masks the MUTE_IND from generating an interrupt. 0 = MUTE_IND bit does not generate an interrupt. 1 = MUTE_IND bit generates an interrupt.

ADAV801

Interrupt Status—Address 0011100 (0x1C)

Table 69. Interrupt Status Register Bit Map

7	6	5	4	3	2	1	0
SRSError	TxCSTINT	TxUBINT	TxCSBINT	RxCSDIFF	RxUBINT	RxCSBINT	RxERROR

Table 70. Interrupt Status Register Bit Descriptions

Bit Name	Description
SRSError	This bit is set if one of the sample rate converter interrupts is asserted, and the host should immediately read the sample rate converter error register. This bit remains high until the interrupt status register is read.
TxCSTINT	This bit is set if a write to the transmitter channel status buffer was made while transmitter channel status bits were being copied from the transmitter CS buffer to the S/PDIF transmit buffer.
TxUBINT	This bit is set if the S/PDIF transmit buffer is empty. This bit remains high until the interrupt status register is read.
TxCSBINT	This bit is set if the transmitter channel status bit buffer has transmitted its block of channel status. This bit remains high until the interrupt status register is read.
RxCSDIFF	This bit is set if the receiver Channel Status A block is different from the receiver Channel Status B clock. This bit remains high until read, but does not generate an interrupt.
RxUBINT	This bit is set if the receiver user bit buffer has a new block or message. This bit remains high until the interrupt status register is read.
RxCSBINT	This bit is set if a new block of channel status is read when RxBCONF3 = 0, or if the channel status has changed when RxBCONF3 = 1. This bit remains high until the interrupt status register is read.
RxERROR	This bit is set if one of the AES3/S/PDIF receiver interrupts is asserted, and the host should immediately read the receiver error register. This bit remains high until the interrupt status register is read.

Interrupt Status Mask—Address 0011101 (0x1D)

Table 71. Interrupt Status Mask Register Bit Map

7	6	5	4	3	2	1	0
SRSError Mask	TxCSTINT Mask	TxUBINT Mask	TxCSBINT Mask	Reserved	RxUBINT Mask	RxCSBINT Mask	RxError Mask

Table 72. Interrupt Status Mask Register Bit Descriptions

Bit Name	Description
SRSError Mask	Masks the SRSError bit from generating an interrupt. 0 = SRSError bit does not generate an interrupt. 1 = SRSError bit generates an interrupt.
TxCSTINT Mask	Masks the TxCSTINT bit from generating an interrupt. 0 = TxCSTINT bit does not generate an interrupt. 1 = TxCSTINT bit generates an interrupt.
TxUBINT Mask	Masks the TxUBINT bit from generating an interrupt. 0 = TxUBINT bit does not generate an interrupt. 1 = TxUBINT bit generates an interrupt.
TxCSBINT Mask	Masks the TxCSBINT bit from generating an interrupt. 0 = TxCSBINT bit does not generate an interrupt. 1 = TxCSBINT bit generates an interrupt.
RxUBINT Mask	Masks the RxUBINT bit from generating an interrupt. 0 = RxUBINT bit does not generate an interrupt. 1 = RxUBINT bit generates an interrupt.
RxCSBINT Mask	Masks the RxCSBINT bit from generating an interrupt. 0 = RxCSBINT bit does not generate an interrupt. 1 = RxCSBINT bit generates an interrupt.
RxError Mask	Masks the RxError bit from generating an interrupt. 0 = RxError bit does not generate an interrupt. 1 = RxError bit generates an interrupt.

Mute and De-Emphasis—Address 0011110 (0x1E)

Table 73. Mute and De-Emphasis Register Bit Map

7	6	5	4	3	2	1	0
Reserved	Reserved	TxMUTE	Reserved	Reserved	SRC_DEEM1	SRC_DEEM0	Reserved

Table 74. Mute and De-Emphasis Register Bit Descriptions

Bit Name	Description
TxMUTE	Mutes the AES3/S/PDIF transmitter. 0 = Transmitter is not muted. 1 = Transmitter is muted.
SRC_DEEM[1:0]	Selects the de-emphasis filter for the input data to the sample rate converter. 00 = No de-emphasis. 01 = 32 kHz de-emphasis. 10 = 44.1 kHz de-emphasis. 11 = 48 kHz de-emphasis.

NonAudio Preamble Type—Address 0011111 (0x1F)

Table 75. NonAudio Preamble Type Register (Read-Only) Bit Map

7	6	5	4	3	2	1	0
Reserved	Reserved	Reserved	Reserved	DTS-CD Preamble	NonAudio Frame	NonAudio Subframe_A	NonAudio Subframe_B

Table 76. NonAudio Preamble Type Register (Read-Only) Bit Descriptions

Bit Name	Description
DTS-CD Preamble	This bit is set if the DTS-CD preamble is detected.
NonAudio Frame	This bit is set if the data received through the AES3/S/PDIF receiver is nonaudio data according to the IEC61937 standard or nonaudio data according to SMPTE337M.
NonAudio Subframe_A	This bit is set if the data received through Channel A of the AES3/S/PDIF receiver is subframe nonaudio data according to SMPTE337M.
NonAudio Subframe_B	This bit is set if the data received through Channel B of the AES3/S/PDIF receiver is subframe nonaudio data according to SMPTE337M.

Receiver Channel Status Buffer—Address 0100000 to Address 0110111 (0x20 to 0x37)

Table 77. Receiver Channel Status Buffer Register Bit Map

7	6	5	4	3	2	1	0
RCSB7	RCSB6	RCSB5	RCSB4	RCSB3	RCSB2	RCSB1	RCSB0

Table 78. Receiver Channel Status Buffer Register Bit Descriptions

Bit Name	Description
RCSB[7:0]	The 24-byte receiver channel status buffer. The PRO bit is stored at address location 0x20, Bit 0. This buffer is read-only if the channel status is not autobuffered between the receiver and transmitter.

Transmitter Channel Status Buffer—Address 0111000 to Address 1001111 (0x38 to 0x4F)

Table 79. Transmitter Channel Status Buffer Register Bit Map

ALC Control Register 1—Address 1111011 (0x7B)

Table 140. ALC Control Register 1 Bit Map

7	6	5	4	3	2	1	0
FSSEL1	FSSEL0	GAINCNTR1	GAINCNTR0	RECMODE1	RECMODE0	LIMDET	ALCEN

Table 141. ALC Control Register 1 Bit Descriptions

Bit Name	Description
FSSEL[1:0]	These bits should equal the sample rate of the ADC. 00 = 96 kHz. 01 = 48 kHz. 10 = 32 kHz. 11 = Reserved.
GAINCNTR[1:0]	These bits determine the limit of the counter used in limited recovery mode. 00 = 3. 01 = 7. 10 = 15. 11 = 31.
RECMODE[1:0]	These bits determine which recovery mode is used by the ALC section. 00 = No recovery. 01 = Normal recovery. 10 = Limited recovery. 11 = Reserved.
LIMDET	These bits limit detect mode. 0 = ALC is used when either channel exceeds the set limit. 1 = ALC is used only when both channels exceed the set limit.
ALCEN	These bits enable ALC. 0 = Disable ALC. 1 = Enable ALC.

ALC Control Register 2— Address = 1111100 (0x7C)

Table 142. ALC Control Register 2 Bit Map

7	6	5	4	3	2	1	0
Reserved	RECTH1	RECTH0	ATKTH1	ATKTH0	RECTIME1	RECTIME0	ATKTIME

Table 143. ALC Control Register 2 Bit Descriptions

Bit Name	Description
RECTH[1:0]	Recovery threshold. 00 = -2 dB. 01 = -3 dB. 10 = -4 dB. 11 = -6 dB.
ATKTH[1:0]	Attack threshold. 00 = 0 dB. 01 = -1 dB. 10 = -2 dB. 11 = -4 dB.
RECTIME[1:0]	Recovery time selection. 00 = 32 ms. 01 = 64 ms. 10 = 128 ms. 11 = 256 ms.
ATKTIME	Attack timer selection. 0 = 1 ms. 1 = 4 ms.

ALC Control Register 3—Address 1111101 (0x7D)

7	6	5	4	3	2	1	0
ALC RESET	ALC RESET	ALC RESET	ALC RESET	ALC RESET	ALC RESET	ALC RESET	ALC RESET

Table 145. ALC Control Register 3 Bit Description

Bit Name	Description
ALC RESET	A write to this register restarts the ALC operation. The value written to this register is irrelevant. A read from this register gives the gain reduction factor.

LAYOUT CONSIDERATIONS

Getting the best performance from the ADAV801 requires a careful layout of the printed circuit board (PCB). Using separate analog and digital ground planes is recommended, because these give the currents a low resistance path back to the power supplies. The ground planes should be connected in only one place, usually under the ADAV801, to prevent ground loops.

The analog and digital supply pins should be decoupled to their respective ground pins with a 10 μF to 47 μF tantalum capacitor and a 0.1 μF ceramic capacitor. These capacitors should be placed as close as possible to the supply pins.

ADC

The ADC uses a switch capacitor input stage and is, therefore, particularly sensitive to digital noise. Sources of noise, such as PLLs or clocks, should not be routed close to the ADC section. The CAPxN and CAPxP pins form a charge reservoir for the switched capacitor section of the ADC, so keeping these nodes electrically quiet is a key factor in ensuring good performance. The capacitors connected to these pins should be of good quality, either NPO or COG, and should be placed as close as possible to CAPxN and CAPxP.

DAC

The DAC requires an analog filter to filter out-of-band noise from the analog output. A third-order Bessel filter is recommended, although the filter to use depends on the requirements of the application.

PLL

The PLL can be used to generate digital clocks, either for use internally or to clock external circuitry. Because every clock is a potential source of noise, care should be taken when using the PLL. The ADAV801's PLL outputs can be enabled or disabled, as required. If the PLL clocks are not required by external circuitry, it is recommended that the outputs be disabled. To reduce cross-coupling between clocks, a digital ground trace can be routed on either side of the PLL clock signal, if required.

The PLL has its own power supply pins. To get the best performance from the PLL and from the rest of the ADAV801, it is recommended that a separate analog supply be used. Where this is not possible, the user must decide whether to connect the PLL supply to the analog (AVDD) or digital (DVDD) supply. Connecting the PLL supply to AVDD gives the best jitter performance, but can degrade the performance of the ADC and DAC sections slightly due to the increased digital noise created on the AVDD by the PLL. Connecting the PLL supply to DVDD keeps digital noise away from the analog supply, but the jitter specifications might be reduced depending on the quality of the digital supply. Using the layout recommendations described in this section helps to reduce these effects.

RESET AND POWER-DOWN CONSIDERATIONS

When the ADAV801 is held in reset by bringing the $\overline{\text{RESET}}$ pin low, a number of circuit blocks remain powered up. For example, the crystal oscillator circuit based around the XIN and XOUT pins is still active, so that a stable clock source is available when the ADAV801 is taken out of reset. In addition, the VCO associated with the S/PDIF receiver is active so that the receiver locks to the incoming S/PDIF stream in the shortest possible time. Where power consumption is a concern, the individual blocks of the ADAV801 can be powered down via the control registers to gain significant power savings. Table 146 shows typical power savings when using the power-down bits in the control registers.

Table 146. Typical Power Requirements

Operating Mode	AV _{DD} (mA)	DV _{DD} (mA)	ODV _{DD} (mA)	DIR_V _{DD} (mA)	Power (mW)
Normal	50	25	5	5	280.5
Reset low	30	4	2.5	1	123.75
Power-down bits	12	0.1	1.3	0.7	46.53
