## FEATURES

Output frequency range: $\mathbf{5 0} \mathbf{~ M H z}$ to $\mathbf{2 2 0 0} \mathbf{~ M H z}$
1 dB output compression: $11 \mathrm{dBm} @ 350 \mathrm{MHz}$
Noise floor: - $\mathbf{1 6 0} \mathbf{~ d B m} / \mathrm{Hz}$ @ $\mathbf{3 5 0} \mathbf{~ M H z}$
Sideband suppression: - $\mathbf{4 6} \mathbf{d B c} @ 350 \mathrm{MHz}$
Carrier feedthrough: - $\mathbf{3 8} \mathbf{~ d B m}$ @ $350 \mathbf{~ M H z}$
30 dB of linear AGC dynamic range @ 350 MHz
Single supply: 4.75 V to 5.5 V
40-lead, Pb-free LFCSP_VQ with exposed paddle

## APPLICATIONS

## Radio-link infrastructures

Cable modem termination systems
Wireless/cellular infrastructure systems
Wireless local loops
WiMAX/broadband wireless access systems

## GENERAL DESCRIPTION

The ADL5386 is a quadrature modulator with unmatched integration levels for low intermediate frequency (IF) and radio frequency (RF) transmitters within broadband wireless access systems, microwave radio links, cable modem termination systems, and cellular infrastructure equipment. The ADL5386 operates over a frequency range of 50 MHz to 2200 MHz . Its excellent phase accuracy and amplitude balance supports high data rate, complex modulation for next-generation communication infrastructure equipment.

In addition, the ADL5386 incorporates a standalone logarithmic power detector, as well as a voltage variable attenuator (VVA). The attenuator has its own separate input and output pins for easy cascading with filters and buffer amplifiers. The wide dynamic range of the power detector and VVA provides flexibility in the choice of the signal monitoring point in the transmitter system.

The wide baseband input bandwidth of 700 MHz allows for either baseband drive or a drive from a complex IF signal. Typical applications are in IF or direct-to-RF radio-link transmitters, cable modem termination systems, broadband wireless access systems, and cellular infrastructure equipment.
The ADL5386 takes signals from two differential baseband inputs and modulates them onto two carriers in quadrature with each other. The two internal carriers are derived from a single-ended, external local oscillator (LO) input signal at twice the frequency as the desired output. The output amplifier is designed to drive a $50 \Omega$ load.

The ADL5386 consists of two die, one fabricated using the Analog Devices, Inc., advanced SiGe bipolar process, and the other using an external GaAs process. The ADL5386 is packaged in a 40 -lead, Pb -free LFCSP_VQ with an exposed paddle. Performance is specified over the $-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$ range. A Pb -free evaluation board is also available.

## REVISION HISTORY

1/09—Revision 0: Initial Version

## SPECIFICATIONS

Unless otherwise noted, $\mathrm{V}_{\mathrm{s}}=5 \mathrm{~V}, \mathrm{~T}_{\mathrm{A}}=25^{\circ} \mathrm{C}, \mathrm{LO}=-7 \mathrm{dBm}, \mathrm{I} / \mathrm{Q}$ inputs $=1.4 \mathrm{~V}$ p-p differential sine waves in quadrature on a 500 mV dc bias, baseband frequency $=1 \mathrm{MHz}$, LO source and RF output load impedances are $50 \Omega$.

Table 1.

| Parameter | Conditions | Min | Typ | Max | Unit |
| :---: | :---: | :---: | :---: | :---: | :---: |
| MODULATOR DYNAMIC CHARACTERISTICS |  |  |  |  |  |
| Operating Frequency Range |  | 50 |  | 2200 | MHz |
| External LO Frequency Range | External LO frequency is twice output frequency | 100 |  | 4400 | MHz |
| Output Frequency $=50 \mathrm{MHz}$ |  |  |  |  |  |
| Output Power | Single (lower) sideband output |  | 5.6 |  | dBm |
| Modulator Voltage Gain |  |  | -1.3 |  | dB |
| Output P1dB |  |  | 10.8 |  | dBm |
| Output Return Loss |  |  | -21 |  | dB |
| Carrier Leakage | Unadjusted (nominal drive level) |  | -43 |  | dBm |
|  | At $85^{\circ} \mathrm{C}$ after optimization at $25^{\circ} \mathrm{C}$ |  | -63 |  | dBm |
|  | At $-40^{\circ} \mathrm{C}$ after optimization at $+25^{\circ} \mathrm{C}$ |  | -63 |  | dBm |
| Sideband Suppression | Unadjusted (nominal drive level) |  | -48 |  | dBc |
|  | At $85^{\circ} \mathrm{C}$ after optimization at $25^{\circ} \mathrm{C}$ |  | -60 |  | dBc |
|  | At $-40^{\circ} \mathrm{C}$ after optimization at $+25^{\circ} \mathrm{C}$ |  | -60 |  | dBc |
| Quadrature Error |  |  | -0.2 |  | Degrees |
| I/Q Amplitude Balance |  |  | 0.05 |  | dB |
| Second Harmonic | $\left(f_{\text {LO }}-\left(2 \times \mathrm{f}_{\text {BB }}\right)\right.$ ), Pout $=5 \mathrm{dBm}$ |  | -80 |  | dBC |
| Third Harmonic | $\left(f_{\text {LO }}+\left(3 \times f_{\text {BB }}\right)\right.$ ), Pout $=5 \mathrm{dBm}$ |  | -58 |  | dBC |
| Output IP2 | $\mathrm{F} 1=3.5 \mathrm{MHz}, \mathrm{F} 2=4.5 \mathrm{MHz}$, Pout $=-3 \mathrm{dBm}$ per tone |  | 76 |  | dBm |
| Output IP3 | $\mathrm{F} 1=3.5 \mathrm{MHz}, \mathrm{F} 2=4.5 \mathrm{MHz}$, Pout $=-3 \mathrm{dBm}$ per tone |  | 26 |  | dBm |
| Noise Floor | 20 MHz offset from LO, all BB inputs at a bias of 500 mV |  | -159 |  | $\mathrm{dBm} / \mathrm{Hz}$ |
| Output Frequency $=140 \mathrm{MHz}$ |  |  |  |  |  |
| Output Power | Single (lower) sideband output |  | 5.7 |  | dBm |
| Modulator Voltage Gain |  |  | -1.2 |  | dB |
| Output P1dB |  |  | 11.1 |  | dBm |
| Output Return Loss |  |  | -21 |  | dB |
| Carrier Leakage | Unadjusted (nominal drive level) |  | -42 |  | dBm |
|  | At $85^{\circ} \mathrm{C}$ after optimization at $25^{\circ} \mathrm{C}$ |  | -62 |  | dBm |
|  | At $-40^{\circ} \mathrm{C}$ after optimization at $+25^{\circ} \mathrm{C}$ |  | -62 |  | dBm |
| Sideband Suppression | Unadjusted (nominal drive level) |  | -57 |  | dBC |
|  | At $85^{\circ} \mathrm{C}$ after optimization at $25^{\circ} \mathrm{C}$ |  | -60 |  | dBC |
|  | At $-40^{\circ} \mathrm{C}$ after optimization at $+25^{\circ} \mathrm{C}$ |  | -60 |  | dBc |
| Quadrature Error |  |  | -0.2 |  | Degrees |
| I/Q Amplitude Balance |  |  | 0.05 |  | dB |
| Second Harmonic | $\left(f_{\text {LO }}-\left(2 \times \mathrm{f}_{\text {BB }}\right)\right.$ ), Pout $=5 \mathrm{dBm}$ |  | -79 |  | dBc |
| Third Harmonic | $\left(\mathrm{f}_{\mathrm{LO}}+\left(3 \times \mathrm{f}_{\text {BB }}\right)\right.$ ), Pout $=5 \mathrm{dBm}$ |  | -56 |  | dBc |
| Output IP2 | $\mathrm{F} 1=3.5 \mathrm{MHz}, \mathrm{F} 2=4.5 \mathrm{MHz}$, Pout $=-3 \mathrm{dBm}$ per tone |  | 75 |  | dBm |
| Output IP3 | $\mathrm{F} 1=3.5 \mathrm{MHz}, \mathrm{F} 2=4.5 \mathrm{MHz}$, Pout $=-3 \mathrm{dBm}$ per tone |  | 25 |  | dBm |
| Noise Floor | 20 MHz offset from LO, all BB inputs at a bias of 500 mV |  | -160 |  | $\mathrm{dBm} / \mathrm{Hz}$ |
| Output Frequency $=350 \mathrm{MHz}$ |  |  |  |  |  |
| Output Power | Single (lower) sideband output | 4 | 5.5 | 7 | dBm |
| Modulator Voltage Gain |  |  | -1.4 |  | dB |
| Output P1dB |  |  | 11.1 |  | dBm |
| Output Return Loss |  |  | -19 |  | dB |
| Carrier Leakage | Unadjusted (nominal drive level) |  | -38 |  | dBm |
|  | At $85^{\circ} \mathrm{C}$ after optimization at $25^{\circ} \mathrm{C}$ |  | -58 |  | dBm |
|  | At $-40^{\circ} \mathrm{C}$ after optimization at $+25^{\circ} \mathrm{C}$ |  | -58 |  | dBm |

## ABSOLUTE MAXIMUM RATINGS

Table 3.

| Parameter | Rating |
| :--- | :--- |
| Supply Voltage, VPOS | 5.5 V |
| IBBP, IBBN, QBBP, QBBN Range | 0 V to 2.0 V |
| LOIP and LOIN | 13 dBm |
| Internal Power Dissipation | 1.4 W |
| $\theta_{\mathrm{A}}$ (Exposed Paddle Soldered Down) | $38^{\circ} \mathrm{C} / \mathrm{W}$ |
| Maximum Junction Temperature | $150^{\circ} \mathrm{C}$ |
| Operating Temperature Range | $-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$ |
| Storage Temperature Range | $-65^{\circ} \mathrm{C}$ to $+150^{\circ} \mathrm{C}$ |

Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only; functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

## ESD CAUTION

|  | ESD (electrostatic discharge) sensitive device. <br> Charged devices and circuit boards can discharge <br> without detection. Although this product features <br> patented or proprietary protection circuitry, damage <br> may occur on devices subjected to high energy ESD. <br> Therefore, proper ESD precautions should be taken to <br> avoid performance degradation or loss of functionality. |

## PIN CONFIGURATION AND FUNCTION DESCRIPTIONS

NOTES

1. $\mathrm{NC}=\mathrm{NO}$ CONNECT.
2. CONNECT THE EXPOSED PAD TO GROUND VIA A LOW IMPEDANCE PATH.

Figure 2. Pin Configuration

Table 4. Pin Function Descriptions

| Pin No. | Mnemonic | Description |
| :---: | :---: | :---: |
| 1 | INLO | Detector Common. This pin should be ac-coupled to ground. |
| 2 | INHI | Detector Input. When operating in AGC mode, a portion of the signal at the output of the VVA (or at the output of a subsequent stage) is coupled back to this input. The signal should be ac-coupled into INHI. To provide a $50 \Omega$ match at INHI, a $50 \Omega$ resistor should be connected between INHI and ground (with the ac-coupling capacitor placed between the resistor and the INHI pin). |
| 3 | VSET | Setpoint Input. Setpoint input for controller mode or feedback input for measurement mode. |
| 4 | CLPF | AGC Loop Filter Capacitor. The ground-referenced capacitor that is connected to this pin sets the loop bandwidth of the AGC circuit. |
| $\begin{aligned} & 5,11,13,15, \\ & 16,18,19,27, \\ & 28,31,32,40 \end{aligned}$ | COMM | Device Common. Connect these pins to the same low impedance ground plane. |
| 6 | VREF | Attenuator Control Voltage Reference. In AGC mode, this pin should be left open. In open-loop mode, when the VVA is being controlled externally, a 2 V reference voltage should be applied to this pin. |
| 7 | VDET/VCTL | Detector Output/VVA Control Voltage Input. When the VVA is being controlled externally (open-loop mode), the attenuation is controlled by the external voltage applied to this pin. The VVA control range is from 0 V (maximum attenuation) to 2 V (minimum attenuation). In this mode, VREF (Pin 6) should be tied to approximately 2 V . When the VVA is being operated in AGC mode, this pin is left open with the voltage on the pin representing the AGC drive voltage to the VVA. If the VVA is not being used, the AGC log amp can be used as a standalone detector by connecting this pin to VSET. In this mode, the log amp output voltage is available at this pin. |
| 8 | TEMP | Temperature Sensor Output. This pin provides a standalone temperature sensor output voltage. At room temperature, the nominal output voltage is equal to 1.45 V . The slope of the output voltage is equal to $4.6 \mathrm{mV} /{ }^{\circ} \mathrm{C}$. |
| 9 | NC | No Connect. Do not connect this pin. |
| 10 | MODOUT | RF Output of IQ Modulator. Single-ended, $50 \Omega$ internally biased RF output. MODOUT is generally ac-coupled to the input of the VVA (either ATTI or ATTO). |
| 12, 20 | ATTI, ATTO | VVA RF Input/Output. ATTI is normally ac-coupled to MODOUT. However, because the VVA is completely reversible, MODOUT can also drive ATTO with ATTI operating as the VVA output. |
| 14, 17 | ATTCM | VVA Input/Output Common. These pins should be ac-coupled to ground. |
| $\begin{aligned} & 21 \text { to } 23, \\ & 35 \text { to } 38 \end{aligned}$ | VPOS | Power Supply. Positive supply voltage pins. All pins should be connected to the same supply (VS). To ensure adequate external bypassing, connect a $0.1 \mu \mathrm{~F}$ capacitor between each pin and ground. |

| Pin No. | Mnemonic | Description |
| :---: | :---: | :---: |
| 24 | ENBL | IQ Modulator Enable. The IQ modulator is enabled by connecting this pin to VPOS and is disabled by connecting ENBL to ground. |
| 25, 26, 29, 30 | IBBP, IBBN, QBBN, QBBP | Differential In-Phase and Quadrature Baseband Inputs. These high impedance inputs should be dc-biased to 0.5 V . Nominal characterized ac signal swing is 700 mV p-p on each pin, resulting in a differential drive of 1.4 V p-p on each input pair. These inputs are not self-biased and have to be externally biased. |
| 33 | LOIP | Local Oscillator Input. The local oscillator signal, at two times the output frequency, should be ac-coupled into this pin. |
| 34 | LOIN | Local Oscillator Common. This pin should be ac-coupled to ground. |
| 39 | TADJ | Temperature Compensation Adjustment Pin and Detector Enable/Disable. This pin is primarily used to provide temperature compensation to the on-chip log amp based AGC circuit. The correct compensation current is set by connecting a ground-referenced resistor to this pin. A value of $22.1 \mathrm{k} \Omega$ is recommended for the frequencies over which the ADL5386 is specified. The TADJ pin can also be used to power down the detector section of the ADL5386 by connecting it to VPOS. The detector must be disabled when the modulator/VVA is operating in open loop mode. |
| 41 (EPAD) | Exposed <br> Pad (EPAD) | Connect the exposed pad to ground via a low impedance path. |

## CIRCUIT DESCRIPTION

## OVERVIEW

The ADL5386 consists of three sections: a quadrature modulator, a logarithmic detector, and a voltage variable attenuator (VVA). The modulator section contains the circuitry for the following functions:

- Local oscillator (LO) interface
- Baseband voltage-to-current (V-to-I) converter
- Mixers
- Differential-to-single-ended (D-to-S) amplifier
- Temperature sensor and bias circuit

The detector section contains the logarithmic detector and amplifiers interfacing to the VSET input and VDET output. The variable attenuator section consists of a PI network of PHEMTs and resistors implemented on a GaAs die separate from the silicon die where the rest of the circuits reside. A detailed block diagram of the device is shown in Figure 39.

## QUADRATURE MODULATOR SECTION

The LO interface generates two LO signals at $90^{\circ}$ of phase difference to drive two mixers in quadrature. Baseband signals are converted into currents by the V-to-I converters that feed into the two mixers. The outputs of the mixers are combined in the differential-to-single-ended amplifier, which provides a $50 \Omega$ output interface. Reference currents to each section are generated by the bias circuit. A detailed description of each section follows.

## LO Interface

The LO interface consists of a buffer amplifier followed by a pair of frequency dividers that generate two carriers at half the input frequency and in quadrature with each other. Each carrier is then amplified and amplitude-limited to drive the doublebalanced mixers.

## V-to-I Converter

The differential baseband input voltages that are applied to the baseband input pins are fed to a pair of common-emitter, voltage-to-current converters. The output currents then modulate the two half-frequency LO carriers in the mixer stage.

## Mixers

The ADL5386 has two double-balanced mixers: one for the in-phase channel (I channel) and one for the quadrature channel ( Q channel). These mixers are based on the Gilbert cell design of four cross-connected transistors. The output currents from the two mixers are summed together in the resistor-inductor loads in the D-to-S amplifier.

## D-to-S Amplifier

The output D-to-S amplifier consists of two emitter followers driving a totem-pole output stage. Output impedance is established by the emitter resistors in the output transistors. The output of this stage connects to the output (VOUT) pin.

## Bias Circuits

A band gap based bias circuit provides proportional-to-absolute temperature as well as temperature stable reference currents for the different circuits in the modulator section. The ENBL input controls the operation of this bias circuit. When ENBL is pulled to a low level, the bias references are turned off, and the whole modulator section is turned off as a result. A voltage that is proportional to the absolute temperature of the circuit is also available at the TEMP pin.
A separator bias circuit provides the reference currents as well as the reference voltages for the detector and voltage variable attenuator sections. This bias circuit can also be disabled by pulling the TADJ pin high, which in turn shuts down the detector section.

## ADL5386

## LOGARITHMIC DETECTOR

The design of the log detector is similar to that of the AD8317 standalone $\log$ detector device, where the log function is generated by a series of limiting amplifiers and detectors. The output current from this log detector is compared with that from a voltage-to-current converter connected to the VSET input. Any net difference between these two currents is pumped into an on-chip integrating capacitor that is generally augmented by additional off-chip capacitance. The voltage on the integrating capacitor is amplified and produces an output error voltage that is generally used to adjust the attenuation of the voltage variable attenuator until the VSET current and the current from the log detector are balanced.

## VOLTAGE VARIABLE ATTENUATOR (VVA)

The VVA is implemented on a GaAs die separate from the silicon die where the modulator and detector reside. The VVA is formed by PHEMTs and resistors connected in a PI network to provide the attenuator function. The gate source bias on the PHEMTs are controlled by the voltages on the VREF and VDET/ VCTL pins, resulting in different attenuation between ATTI and ATTO as the voltage at VDET/VCTL is varied. The resistance in the shunt paths between ATTI and ATTO to ATTCM vary in the opposite manner as the paths between ATTI and ATTO to maintain good return loss through different attenuation levels.

## BASIC CONNECTIONS

## OPEN-LOOP POWER CONTROL MODE

Figure 41 shows the basic connections for operating the ADL5386 when the voltage variable attenuator (VVA) is driven from an external voltage source and not from the built-in AGC circuit. In this mode, the inputs to the RF detector should be both ac-coupled to ground. The TADJ pin is tied to the supply, disabling the unused detector and reducing the current consumption by approximately 15 mA . The IQ modulator is enabled by pulling the ENBL pin high.

The output of the modulator is ac-coupled to the input of the VVA (Pin ATTI). The VVA is bidirectional; therefore, the modulator can also be configured to drive ATTO and to take the final output at ATTI.
The attenuation of the VVA is controlled by the voltages on Pin VREF and Pin VDET/VCTL. VREF should be tied to a low impedance external voltage of 2 V . This voltage can be conveniently derived from the supply voltage using a pair of resistors, but this voltage must then be buffered with an op amp to prevent bias current related voltage drops.
With VREF set to 2 V , a variable voltage between 0 V and 2 V on VDET/VCTL sets the attenuation. Maximum attenuation is achieved when $\mathrm{V}_{\text {VDet }} / \mathrm{V}_{\mathrm{VCTL}}=0 \mathrm{~V}$, and minimum attenuation is achieved when $\mathrm{V}_{\mathrm{VDET}} / \mathrm{V}_{\mathrm{VCTL}}=2 \mathrm{~V}$.

Figure 40 shows a plot of Pout vs. the control voltage (applied to the VDET/VCTL pin) at 350 MHz when the modulator is driven by 1 V p-p sine and cosine signals on its baseband inputs and a $2 \times \mathrm{LO}$ of 700 MHz .
In this mode, the detector cannot be used in any kind of standalone mode because its output pin (VDET/VCTL) is used as an input.

Figure 41. Basic Connections for Open-Loop Power Control Mode

## ADL5386

## POWER SUPPLY AND GROUNDING

The VPOS supply pins should be connected to a common 5 V supply. This supply can vary from 4.75 to 5.5 V . The power supply pins should be adequately decoupled using $0.1 \mu \mathrm{~F}$ capacitors located close to each pin. Adjacent pins can share decoupling capacitors, as shown in Figure 41.

The COMM ground pins should be connected to a common low impedance ground plane. The exposed paddle on the underside of the package is also soldered to a low thermal and electrical impedance ground plane. If the ground plane spans multiple layers on the circuit board, the layers should be stitched together with nine vias under the exposed paddle. The Analog Devices, AN-772 Application Note, A Design and Manufacturing Guide for the Lead Frame Chip Scale Package (LFCSP), discusses the thermal and electrical grounding of the LFCSP in detail.

## DEVICE ENABLE AND DISABLE

The IQ modulator section can be enabled or disabled by pulling the ENBL pin high or low, respectively. The detector section of the circuit can be disabled by pulling the TADJ pin high.

## BASEBAND INPUTS

The baseband inputs, QBBP, QBBN, IBBP, and IBBN, must be driven from a differential source. The nominal drive level of 1.4 V p-p differential ( 700 mV p-p on each pin) is biased to a common-mode level of 500 mV dc . This drive level generates an output power level (at MODOUT) of between 2 dBm and 6 dBm based on output frequency.

The dc common-mode bias level for the baseband inputs can range from 400 mV to 600 mV . This results in a reduction in the usable input ac swing range. The nominal dc bias of 500 mV allows for the largest ac swing, limited on the bottom end by the ADL5386 input range and on the top end by the output compliance range on most Analog Devices DACs.

## LO INPUT

A single-ended LO signal is applied to the LOIP pin through an ac coupling capacitor. A square wave or a sine wave can be used to drive the LO port. The recommended LO drive power is -7 dBm . An LO power level of -7 dBm is the minimum level that should be used for output frequencies below 140 MHz ( $\mathrm{f}_{\mathrm{LO}} \leq 280 \mathrm{MHz}$ ). At output frequencies above 140 MHz , the LO power can be reduced to -13 dBm . The LO return pin, LOIN, should be ac-coupled to ground though a low impedance path.
The nominal LO drive of -7 dBm can be increased to up to +2 dBm . The effect of LO power on sideband suppression and carrier feedthrough is shown in Figure 15 and Figure 16.

## AGC MODE

The on-board log amp power detector of the ADL5386 can be used to implement an automatic output power control (commonly referred to as AGC) loop that effectively linearizes the transfer function of the VVA. To implement this mode, a number of circuit modifications are necessary.
A portion of the output signal of the VVA is coupled back to the input of the log amp detector. This can be done with a power splitter or with a directional coupler as shown in Figure 42. The coupling factor or power split ratio should be set so that the detector never sees a power level that is greater than about -10 dBm (the transfer function of the detector loses some linearity above this level). In the example shown in Figure 42, a maximum output power from the VVA/modulator of +3 dBm is desired. A directional coupler with a coupling factor of approximately +15 dB drops this level down to -12 dBm at the input of the detector.
The input signal to the detector produces a current that is drawn from the summing node (Pin CLPF) into the detector block. A setpoint voltage that is applied to the VSET pin is converted into a current that is pumped into the summing node. If these two currents are not equal, the net current flows into or out of the CLPF capacitor on Pin 4 . This changes the voltage on the CLPF node that in turn changes the voltage on the VDET/VCTL pin. This pin is internally connected to the attenuation control pin of the VVA. Therefore, the attenuation control voltage on Pin 7 (VDET/VCTL) increases or decreases until the $\mathrm{I}_{\text {SET }}$ and $\mathrm{I}_{\text {DEt }}$ currents match. When this equilibrium is reached, the voltage on CLPF (and thereby on the control voltage node of the VVA) is held steady.

Figure 42. Basic Connections for AGC Mode

## ADL5386

Figure 43 shows the resulting transfer function of the AGC loop, that is, output power (on ATTO) vs. setpoint voltage (on VSET) at 350 MHz . Figure 43 shows a linear-in-dB relationship between Pout and $\mathrm{V}_{\text {vset }}$ over at least 25 dB . It also includes a plot of the linearity of the transfer function in dB . The linearity is calculated by measuring the slope and intercept of the transfer function using the $\mathrm{V}_{\text {vset }}$ and Pout data between $\mathrm{V}_{\text {veet }}$ levels of 0.7 and 1 V . This yields an idealized transfer function of

Figure 43. Pout vs. Vvset Transfer Function in AGC Mode (1 Vp-p Differential Baseband Input Voltage on I and Q)

The error in decibels is given by

$$
E R R O R(\mathrm{~dB})=(\text { PoUt }- \text { PoUt_IDEAL }) / S L O P E
$$

The relationship between the input level of the detector and the voltage on $V_{\text {VSET }}$ follows from the nominal transfer function of the detector when operating in measurement mode (VSET is connected directly to VDET). Figure 44 shows the measurement mode relationship between the detector input level and the output voltage at 350 MHz . Figure 44 shows that an input level of -12 dBm produces an output of 0.6 V . In AGC mode, a setpoint voltage of 0.6 V causes the loop to adjust until the detector input level is -12 dBm . Remembering the coupling factor of the directional coupler, the -12 dBm level at the detector corresponds to a power level of approximately +3 dBm at the output of the VVA. Therefore, with a 15 dB coupling factor, a setpoint voltage of 0.6 produces an output power from the VVA of 3 dBm , as shown in Figure 43.

In general, the loop should be designed with a level of attenuation between ATTO and INHI (detector input) that results in the detector always seeing a power level that is within its linear operating range. Because the power detector has a linear input range that is larger than the attenuation range of the VVA this is generally achievable. In addition, it is desirable to map the desired VVA output power range into the detector's region of maximum linearity. In the example shown, where a maximum output power of +3 dBm is desired, the input range to the detector is -12 dBm to -44 dBm . Notice how the degraded linearity of the detector below -40 dBm (see Figure 44) can also be observed in the closed-loop transfer function at output power levels below -25 dBm (Figure 43).

## SETTING THE TADJ RESISTOR

The primary component of the temperature variation of the $\mathrm{V}_{\text {vout }} / \mathrm{V}_{\text {vset }}$ voltage and the detector RF input is the drift of the intercept. This temperature drift can be compensated by connecting a resistor between TADJ (Pin 39) and ground. The optimum resistance value for the frequencies at which the ADL5386 is characterized has been experimentally determined to be $22.1 \mathrm{k} \Omega$. Note that the accuracy specifications of the detector and performance plots assume that this resistance is in place.

## USING THE DETECTOR IN STANDALONE MEASUREMENT MODE

The on-board log detector of the ADL5386 can be used in measurement mode, that is, where an RF signal is applied to the INHI pin of the detector, and an output voltage, proportional to the $\log$ of this input signal, is provided at the VDET output. In this mode, short VDET to VSET and ac couple the ATTI, ATTO, and ATTCM pins to ground. Note that the VVA cannot be used because the VVA control voltage shares a common pin with the output of the detector.
Table 5 summarizes the required configuration changes for the three operating modes discussed.

## DAC MODULATOR INTERFACING

The ADL5386 is designed to interface with minimal components to members of the Analog Devices family of digital-to-analog converters (DACs). These DACs feature an output current swing from 0 mA to 20 mA , and the interface described in this section can be used with any DAC that has a similar output.

Table 5. Configuring Operating Modes

| Mode | INHI | VSET | VDET/VCTL | VREF | ENBL | MODOUT | ATTI | ATTO |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| AGC | AC couple to ATTO via directional coupler | Externally apply 0.5 V to 1.4 V | Open | Open | High | AC couple to ATTI | AC couple to MODOUT | RF output |
| Open loop ${ }^{1}$ | AC couple to GND | Open | Externally apply 0 V to 2 V | Externally apply 2 V | High | AC couple to ATTI | AC couple to MODOUT | RF output |
| Standalone detector | AC couple to MODOUT or other RF signal | Connect to VDET | Connect to VSET | Open | High | RF output, ac-coupled | AC couple to GND | AC couple to GND |

${ }^{1}$ Tie TADJ to VPOS.

Figure 45. Connections for Operating the Detector in Standalone Mode

## ADL5386

## Driving the ADL5386 with an Analog Devices TxDAC ${ }^{\circledR}$

An example of the interface using the AD9788 TxDAC is shown in Figure 46. The baseband inputs of the ADL5386 require a dc bias of 500 mV . The average output current on each of the outputs of the AD9788 is 10 mA . Therefore, a single $50 \Omega$ resistor to ground from each of the DAC outputs results in an average current of 10 mA flowing through each of the resistors, thus producing the desired 500 mV dc bias for the inputs to the ADL5386.

Figure 46. Interface Between AD9788 and ADL5386 with $50 \Omega$ Resistors to Ground to Establish the 500 mV DC Bias for the ADL5386 Baseband Inputs
The AD9788 output currents source from 0 mA to 20 mA . With the $50 \Omega$ resistors in place, the ac voltage swing going into the ADL5386 baseband inputs ranges from 0 V to 1 V . A full-scale sine wave out of the AD9788 can be described as a 1 V p-p singleended (or 2 V p-p differential) sine wave with a 500 mV dc bias. The AD9788 also has the capability of easily compensating for gain, offset, and phase mismatch in the IQ signal path; therefore, optimizing performance of the ADL5386.

## Limiting the AC Swing

There are situations in which it is desirable to reduce the ac voltage swing for a given DAC output current. To reduce the ac voltage swing, add an additional resistor to the interface. This resistor is placed in shunt between each side of the differential pair, as shown in Figure 47. It has the effect of reducing the ac swing without changing the dc bias already established by the $50 \Omega$ resistors.

Figure 47. AC Voltage Swing Reduction Through Introduction of Shunt Resistor Between Differential Pair
The value of this ac voltage swing-limiting resistor is chosen based on the desired ac voltage swing. Figure 48 shows the relationship between the swing-limiting resistor and the peak-to-peak ac swing that it produces when $50 \Omega$ bias-setting resistors are used.

Figure 48. Relationship Between AC Swing-Limiting Resistor and Peak-to-Peak Voltage Swing with $50 \Omega$ Bias-Setting Resistors

## Filtering

When driving a modulator from a DAC, it is necessary to introduce a low-pass filter between the DAC and the modulator to reduce the DAC images. The interface for setting up the biasing and ac swing lends itself well to the introduction of such a filter. The filter can be inserted between the dc bias setting resistors and the ac swing-limiting resistor, thus establishing the input and output impedances for the filter. A filter example is shown in Figure 49.

Figure 49. 39 MHz, 5-Pole Chebychev Filter with In-Band Ripple of 0.1 dB for a 155 MSPS, 128 QAM Transmitter

## SPECTRAL PRODUCTS FROM HARMONIC MIXING

For broadband applications, such as cable TV head-end modulators, special attention must be paid to harmonics of the LO. Figure 50 shows the level of these harmonics (out to 3 GHz ) as a function of the output frequency from 125 MHz to 1000 MHz , in a single-sideband (SSB) test configuration, with a baseband signal of 1 MHz and a SSB level of approximately 0 dBm . To read this plot correctly, first pick the output frequency of interest on the trace called Pout. The associated harmonics can be read off the harmonic traces at multiples of this frequency. For example, at an output frequency of 500 MHz , the fundamental power is 0 dBm . The power of the second $\left(\mathrm{P}_{2 f \mathrm{c}-\mathrm{BB}}\right)$ and third $\left(\mathrm{P}_{3 \mathrm{ff}+\mathrm{BB}}\right)$ harmonics is -57 dBm (at 1000 MHz ) and -11 dBm (at 1500 MHz ), respectively. Of particular importance are the products from odd harmonics of the LO, generated from the switching operation in the mixers.
For cable TV operation at frequencies above approximately 500 MHz , these harmonics fall out of the band and can be filtered by a fixed filter. However, as the frequency drops below 500 MHz , these harmonics start to fall close to or inside the cable band. This calls for either limitation of the frequency range to above 500 MHz or the use of a switchable filter bank to block in-band harmonics at low frequencies.

Figure 50. Spectral Components for Output Frequencies from 125 MHz to 1000 MHz

## LO GENERATION USING PLLs

Analog Devices has a line of PLLs that can be used for generating the LO signal. Table 6 lists the PLLs together with their maximum frequency and phase noise performance.

Table 6. PLL Selection Table

| Model | Frequency fiN (MHz) | At $\mathbf{1} \mathbf{~ k H z}$ Phase Noise <br> dBc/Hz, 200 kHz PFD |
| :--- | :--- | :--- |
| ADF4002 | 400 | $-103 @ 400 \mathrm{MHz}$ |
| ADF4106 | 6000 | $-93 @ 900 \mathrm{MHz}$ |
| ADF4110 | 550 | $-91 @ 540 \mathrm{MHz}$ |
| ADF4111 | 1200 | $-87 @ 900 \mathrm{MHz}$ |
| ADF4112 | 3000 | $-90 @ 900 \mathrm{MHz}$ |
| ADF4113 | 4000 | $-91 @ 900 \mathrm{MHz}$ |
| ADF4116 | 550 | $-89 @ 540 \mathrm{MHz}$ |
| ADF4117 | 1200 | $-87 @ 900 \mathrm{MHz}$ |
| ADF4118 | 3000 | $-90 @ 900 \mathrm{MHz}$ |

The ADF4360-x comes as a family of chips, with nine operating frequency ranges. One can be chosen depending on the local oscillator frequency required. While the use of the integrated synthesizer may come at the expense of slightly degraded noise performance from the ADL5386, it can be a cheaper alternative to a separate PLL and VCO solution. Table 7 shows the options available. An up-to-date list of available PLLs can be found at www.analog.com/pll.

Table 7. ADF4360-x Family Operating Frequencies

| Model | Output Frequency Range (MHz) |
| :--- | :--- |
| ADF4360-0 | 2400 to 2725 |
| ADF4360-1 | 2050 to 2450 |
| ADF4360-2 | 1850 to 2150 |
| ADF4360-3 | 1600 to 1950 |
| ADF4360-4 | 1450 to 1750 |
| ADF4360-5 | 1200 to 1400 |
| ADF4360-6 | 1050 to 1250 |
| ADF4360-7 | 350 to 1800 |
| ADF4360-8 | 65 to 400 |
| ADF4360-9 | 1.1 to 200 (using auxiliary dividers) |

## ADL5386

## TRANSMIT DAC OPTIONS

The AD9788 recommended in the previous sections is by no means the only DAC that can be interfaced with the ADL5386. There are other appropriate DACs depending on the level of performance required. Table 8 lists the dual TxDACs that Analog Devices offers for use in transmitter applications with the ADL5386.

Table 8. Dual TxDAC Selection Table

| Part No. | Resolution <br> (Bits) | Output <br> Update <br> Rate (MSPS) |
| :--- | :--- | :--- |
| AD9114/AD9115/AD9116/AD9117 | $8,10,12,14$ | 125 |
| AD9741/AD9743/AD9745/AD9746/ | $8,10,12$, | 250 |
| AD9747 | 14,16 |  |
| AD9780/AD9781/AD9783 | $12,14,16$ | 500 |
| AD9776A/AD9778A/AD9779A | $12,14,16$ | 1000 |
| AD9785/AD9787/AD9788 | $12,14,16$ | 800 |

All DACs listed have nominal bias levels of 0.5 V and use the same DAC-modulator interface shown in Figure 46.

## MODULATOR/DEMODULATOR OPTIONS

Table 9 lists other Analog Devices modulators and demodulators.
Table 9. Modulator/Demodulator Options

| Part No. | Modulator/ <br> Demodulator | Frequency <br> Range (MHz) | Comments |
| :--- | :--- | :--- | :--- |
| AD8345 | Modulator | 140 to 1000 |  |
| AD8346 | Modulator | 800 to 2500 |  |
| AD8349 | Modulator | 700 to 2700 |  |
| ADL5390 | Modulator | 20 to 2400 | External <br> quadrature |
| ADL5370 | Modulator | 300 to 1000 |  |
| ADL5371 | Modulator | 500 to 1500 |  |
| ADL5372 | Modulator | 1500 to 2500 |  |
| ADL5373 | Modulator | 2300 to 3000 |  |
| ADL5374 | Modulator | 3000 to 4000 |  |
| ADL5375 | Modulator | 400 to 6000 |  |
| AD8347 | Demodulator | 800 to 2700 |  |
| AD8348 | Demodulator | 50 to 1000 |  |
| ADL5382 | Demodulator | 700 to 2700 |  |
| ADL5387 | Demodulator | 50 to 2000 |  |
| ADL5590 | Modulator | 869 to 960 |  |
| ADL5591 | Modulator | 1805 to 1990 |  |
| AD8340 | Vector modulator | 700 to 1000 |  |
| AD8341 | Vector modulator | 1500 to 2400 |  |

## EVALUATION BOARD

A populated, RoHS-compliant ADL5386 evaluation board is available. The ADL5386 has an exposed paddle underneath the package, which is soldered to the board.

Table 10. Evaluation Board Configuration Options

| Component | Description | Default Condition |
| :---: | :---: | :---: |
| VP, GND | Power Supply and Ground Clip Leads. | $\mathrm{VP}=5 \mathrm{~V}, \mathrm{GND}=0 \mathrm{~V}$ |
| R22 | Device Enable. Apply either 5 V or 0 V to the SMA connector labeled ENBL to enable or disable the IQ modulator section of the circuit. If the ENBL SMA connector is left open, this node is pulled high by R22, enabling the IQ modulator. | $\mathrm{R} 22=10 \mathrm{k} \Omega$ |
| $\begin{aligned} & \text { R2, C9, C12, } \\ & \text { C19 } \end{aligned}$ | Modulator VVA Interconnect. The output of the IQ modulator is available at the VMOD SMA connector. The input and output of the VVA can be accessed through the ATTIN and ATTOUT SMA connectors. The IQ modulator output can be connected to the VVA by installing a $0 \Omega$ resistor at R2 and a 1000 pF capacitor at C19. In this mode, C9 and C12 should be removed. | $\begin{aligned} & \mathrm{C} 9, \mathrm{C} 12=1000 \mathrm{pF}(0402) \\ & \mathrm{R} 2, \mathrm{C} 19=\operatorname{open}(0402) \end{aligned}$ |
| $\begin{aligned} & \text { R17 to R20, } \\ & \text { R24 to R29 } \end{aligned}$ | Baseband Input Filters. These component pads can be used to implement a low-pass filter for the baseband input signals. | $\begin{aligned} & \text { R17 to R20 }=0 \Omega(0402) \\ & \text { R24to R29 }=\text { open }(0402) \end{aligned}$ |

## ADL5386

| Component | Description | Detector Controller Mode vs. Measurement Mode. When P2 is installed, the detector operates <br> in standalone measurement mode, measuring the signal strength on the DTIN SMA connector <br> and providing an output voltage on the VDET and VSET SMA connectors. To operate the <br> device in AGC mode, P2 should be removed, a sample of the output of the VVA is connected <br> to DTIN (using a directional coupler or a power splitter), and a setpoint voltage should be <br> applied to the VSET SMA connector. To operate the VVA in open-loop mode, disable the <br> detector by connecting TADJ to VP. DTIN should be ac-coupled to ground, and P2 should be <br> removed. The VVA control voltage (0 V to 2 V) is applied to VDET, which becomes an input. The <br> VSS1 terminal must be connected to a fixed 2 V source. |
