## FEATURES

Power input voltage range: $\mathbf{2 . 9 5} \mathrm{V}$ to $\mathbf{2 0 ~ V}$
On-board bias regulator
Minimum output voltage: 0.6 V
0.6 V reference voltage with $\pm 1.0 \%$ accuracy

Supports all N-channel MOSFET power stages
Available in $\mathbf{3 0 0}$ kHz, 600 kHz, and 1.0 MHz options
No current sense resistor required
Power saving mode (PSM) for light loads (ADP1879 only)
Resistor programmable current limit
Power good with internal pull-up resistor
Externally programmable soft start
Thermal overload protection
Short-circuit protection
Standalone precision enable input
Integrated bootstrap diode for high-side drive
Starts into a precharged output
Available in a 14-lead LFCSP_WD package

## APPLICATIONS

Telecommunications and networking systems Mid-to-high end servers
Set-top boxes
DSP core power supplies

## GENERAL DESCRIPTION

The ADP1878/ADP1879 are versatile current-mode, synchronous step-down controllers. They provide superior transient response, optimal stability, and current-limit protection by using a constant on time, pseudo fixed frequency with a programmable current-limit, current control scheme. These devices offer optimum performance at low duty cycles by using a valley, current-mode control architecture allowing the ADP1878/ADP1879 to drive all N-channel power stages to regulate output voltages to as low as 0.6 V .

The ADP1879 is the power saving mode (PSM) version of the device and is capable of pulse skipping to maintain output regulation while achieving improved system efficiency at light loads (see the ADP1879 Power Saving Mode (PSM) section for more information).

Available in three frequency options ( $300 \mathrm{kHz}, 600 \mathrm{kHz}$, and 1.0 MHz ) plus the PSM option, the ADP1878/ADP1879 are well suited for a wide range of applications that require a single input power supply range from 2.95 V to 20 V . Low voltage biasing is supplied via a 5 V internal low dropout regulator (LDO). In addition, soft start programmability is included to limit input inrush current from the input supply during startup and to provide reverse current protection during precharged output

## TYPICAL APPLICATIONS CIRCUIT

conditions. The low-side current sense, current gain scheme and integration of a boost diode, together with the PSM/forced pulse-width modulation (PWM) option, reduce the external device count and improve efficiency.
The ADP1878/ADP1879 operate over the $-40^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$ junction temperature range and are available in a 14-lead LFCSP_WD package.

Figure 2. ADP1878/ADP1879 Efficiency vs. Load Current (Vout $=1.8 \mathrm{~V}, 300 \mathrm{kHz}$ )

## SPECIFICATIONS

All limits at temperature extremes are guaranteed via correlation using standard statistical quality control (SQC). VREG = 5 V , BST - SW $=$ VREG $-V_{\text {Rect_Drop }}$ (see Figure 40 to Figure 42). VIN $=12 \mathrm{~V}$. The specifications are valid for $\mathrm{T}_{\mathrm{J}}=-40^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$, unless otherwise specified.

## ADP1878/ADP1879

## ABSOLUTE MAXIMUM RATINGS

Table 2.

| Parameter | Rating |
| :--- | :--- |
| VREG to PGND, GND | -0.3 V to +6 V |
| VIN, EN, PGOOD to PGND | -0.3 V to +28 V |
| FB, COMP, RES, SS to GND | -0.3 V to (VREG +0.3 V ) |
| DRVL to PGND | -0.3 V to (VREG +0.3 V ) |
| SW to PGND | -2.0 V to +28 V |
| BST to SW | -0.6 V to (VREG +0.3 V ) |
| BST to PGND | -0.3 V to +28 V |
| DRVH to SW | -0.3 V to VREG |
| PGND to GND | $\pm 0.3 \mathrm{~V}$ |
| PGOOD Input Current | 35 mA |
| ӨJA (14-Lead LFCSP_WD) |  |
| $\quad 4-$ Layer Board | $30^{\circ} \mathrm{C} / \mathrm{W}$ |
| Operating Junction Temperature Range | $-40^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$ |
| Storage Temperature Range | $-65^{\circ} \mathrm{C}$ to $+150^{\circ} \mathrm{C}$ |
| Soldering Conditions | $\mathrm{JEDEC} \mathrm{J-STD-020}$ |
| Maximum Soldering Lead Temperature | $300^{\circ} \mathrm{C}$ |
| $\quad$ (10 sec) |  |

Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only; functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.
Absolute maximum ratings apply individually only, not in combination. Unless otherwise specified, all other voltages are referenced to PGND.

## THERMAL RESISTANCE

$\theta_{\mathrm{IA}}$ is specified for the worst-case conditions, that is, a device soldered in a circuit board for surface-mount packages.

## Boundary Condition

In determining the values given in Table 2 and Table 3, natural convection is used to transfer heat to a 4-layer evaluation board.

Table 3. Thermal Resistance

| Package Type | $\boldsymbol{\theta}_{\mathrm{JA}}$ | Unit |
| :--- | :--- | :--- |
| JA <br> (14-Lead LFCSP_WD) <br> 4-Layer Board | 30 | ${ }^{\circ} \mathrm{C} / \mathrm{W}$ |

## ESD CAUTION

ESD (electrostatic discharge) sensitive device. Charged devices and circuit boards can discharge without detection. Although this product features patented or proprietary protection circuitry, damage may occur on devices subjected to high energy ESD. Therefore, proper ESD precautions should be taken to avoid performance degradation or loss of functionality.

## PIN CONFIGURATION AND FUNCTION DESCRIPTIONS

| NOTES | o |
| :--- | ---: |
| 1. CONNECT THE EXPOSED PAD TO THE | $\vdots$ |
| ANALOG GROUND PIN (GND). | $\frac{\ddagger}{\circ}$ |

Figure 3. Pin Configuration
Table 4. Pin Function Descriptions

| Pin No. | Mnemonic | Description |
| :---: | :---: | :---: |
| 1 | VIN | High-Side Input Voltage. Connect VIN to the drain of the high-side MOSFET. |
| 2 | COMP | Output of the Error Amplifier. Connect compensation network between this pin and AGND to achieve stability (see the Compensation Network section). |
| 3 | EN | IC Enable. Connect EN to VREG to enable the IC. When pulled down to AGND externally, EN disables the IC. |
| 4 | FB | Noninverting Input of the Internal Error Amplifier. This is the node where the feedback resistor is connected. |
| 5 | GND | Analog Ground Reference Pin of the IC. Connect all sensitive analog components to this ground plane (see the Layout Considerations section). |
| 6 | RES | Current Sense Gain Resistor (External). Connect a resistor between the RES pin and GND (Pin 5). |
| 7 | VREG | Internal Regulator Supply Bias Voltage for the ADP1878/ADP1879 Controller (Includes the Output Gate Drivers). Connecting a bypass capacitor of $1 \mu \mathrm{~F}$ directly from this pin to PGND and a $0.1 \mu \mathrm{~F}$ capacitor across VREG and GND are recommended. |
| 8 | SS | Soft Start Input. Connect an external capacitor to GND to program the soft start period. There is a capacitance value of 10 nF for every 1 ms of soft start delay. |
| 9 | PGOOD | Open-Drain Power-Good Output. PGOOD sinks current when FB is out of regulation or during thermal shutdown. Connect a $3 \mathrm{k} \Omega$ resistor between PGOOD and VREG. Leave PGOOD unconnected if it is not used. |
| 10 | DRVL | Drive Output for the External Low-Side, N-Channel MOSFET. This pin also serves as the current sense gain setting pin (see Figure 69). |
| 11 | PGND | Power Ground. Ground for the low-side gate driver and low-side N-channel MOSFET. |
| 12 | DRVH | Drive Output for the External High-Side N-Channel MOSFET. |
| 13 | SW | Switch Node Connection. |
| 14 | BST | Bootstrap for the High-Side N-Channel MOSFET Gate Drive Circuitry. An internal boot rectifier (diode) is connected between VREG and BST. A capacitor from BST to SW is required. An external Schottky diode can also be connected between VREG and BST for increased gate drive capability. |
|  | EP | Exposed Pad. Connect the exposed pad to the analog ground pin (GND). |

## THEORY OF OPERATION

## BLOCK DIAGRAM

Figure 64. ADP1878/ADP1879 Block Diagram

The ADP1878/ADP1879 are versatile current-mode, synchronous step-down controllers that provide superior transient response, optimal stability, and current-limit protection by using a constant on time, pseudo fixed frequency with a programmable current sense gain, current control scheme. In addition, these devices offer
optimum performance at low duty cycles by using a valley, currentmode control architecture. This allows the ADP1878/ADP1879 to drive all N -channel power stages to regulate output voltages to as low as 0.6 V .

## STARTUP

Each ADP1878/ADP1879 has an internal regulator (VREG) for biasing and supplying power for the integrated N -channel MOSFET drivers. Place a bypass capacitor directly across the VREG (Pin 7) and PGND (Pin 13) pins. Included in the powerup sequence is the biasing of the current sense amplifier, the current sense gain circuit (see the Programming Resistor (RES) Detect Circuit section), the soft start circuit, and the error amplifier.
The current sense blocks provide valley current information (see the Programming Resistor (RES) Detect Circuit section) and they are a variable of the compensation equation for loop stability (see the Compensation Network section). In a process performed by the RES detect circuit, the valley current information is extracted by forcing 0.4 V across the RES and PGND pins generating current. The current through the RES resistor is used to set the current sense amplifier gain (see the Programming Resistor (RES) Detect Circuit section). This process takes approximately $800 \mu \mathrm{~s}$, after which time the drive signal pulses appear at the DRVL and DRVH pins synchronously, and the output voltage begins to rise in a controlled manner through the soft start sequence.
The soft start and error amplifier blocks determine the rise time of the output voltage (see the Soft Start section). At the beginning of a soft start, the error amplifier charges the external compensation capacitor, causing the COMP pin to rise (see Figure 65). Tying the VREG pin to the EN pin via a pull-up resistor causes the voltage at the EN pin to rise above the enable threshold of 630 mV , thereby enabling the ADP1878/ADP1879.

Figure 65. COMP Voltage Range

## SOFT START

The ADP1878 employs externally programmable, soft start circuitry that charges up a capacitor tied to the SS pin to GND. This prevents input inrush current through the external MOSFET from the input supply $\left(\mathrm{V}_{\mathrm{IN}}\right)$. The output tracks the ramping voltage by producing PWM output pulses to the high-side MOSFET. The purpose is to limit the inrush current from the high voltage input supply $\left(\mathrm{V}_{\text {IN }}\right)$ to the output $\left(\mathrm{V}_{\text {OUT }}\right)$.

## PRECISION ENABLE CIRCUITRY

The ADP1878/ADP1879 have precision enable circuitry. The precision enable threshold is 630 mV including 30 mV of hysteresis (see Figure 66). Connecting the EN pin to GND disables the ADP1878/ADP1879, reducing the supply current of the device to approximately $140 \mu \mathrm{~A}$.

Figure 66. Connecting EN Pin to VREG via a Pull-Up Resistor to Enable the ADP1878/ADP1879

## UNDERVOLTAGE LOCKOUT

The undervoltage lockout (UVLO) feature prevents the device from operating both the high- and low-side N-channel MOSFETs at extremely low or undefined input voltage $\left(\mathrm{V}_{\text {IN }}\right)$ ranges. Operation at an undefined bias voltage can result in the incorrect propagation of signals to the high-side power switches. This, in turn, results in invalid output behavior that can cause damage to the output devices, ultimately destroying the device tied at the output. The UVLO level is set at 2.65 V (nominal).

## ON-BOARD LOW DROPOUT (LDO) REGULATOR

The ADP1878/ADP1879 use an on-board LDO to bias the internal digital and analog circuitry. With proper bypass capacitors connected to the VREG pin (output of the internal LDO), this pin also provides power for the internal MOSFET drivers. It is recommended to float VREG if VIN is used for greater than 5.5 V operation. The minimum voltage at which bias is guaranteed to operate is 2.75 V at VREG (see Figure 67).

Figure 67. On-Board Regulator
For applications where VIN is decoupled from VREG, the minimum voltage at VIN must be 2.9 V . It is recommended to tie VIN and VREG together if the VIN pin is subjected to a 2.75 V rail.

Table 5. Power Input and LDO Output Configurations

| VIN | VREG | Comments |
| :--- | :--- | :--- |
| $>5.5 \mathrm{~V}$ | Float | Must use the LDO |
| $<5.5 \mathrm{~V}$ | Connect to VIN | LDO drop voltage is not <br> realized (that is, if VIN $=2.75 \mathrm{~V}$, <br> then VREG $=2.75 \mathrm{~V}$ ) |
| $<5.5 \mathrm{~V}$ | Float | LDO drop is realized |
| VIN ranging <br> above and <br> below 5.5 V | Float | LDO drop is realized, minimum |

## THERMAL SHUTDOWN

Thermal shutdown is a protection feature that prevents the IC from damage caused by a very high operating junction temperature. If the junction temperature of the device exceeds $155^{\circ} \mathrm{C}$, the device enters the thermal shutdown state. In this state, the device shuts off both the high- and low-side MOSFETs and disables the entire controller immediately, thus reducing the power consumption of the IC. The device resumes operation after the junction temperature of the device cools to less than $140^{\circ} \mathrm{C}$.

## PROGRAMMING RESISTOR (RES) DETECT CIRCUIT

Upon startup, one of the first blocks to become active is the RES detect circuit. This block powers up before soft start begins. It forces a 0.4 V reference value at the RES pin (see Figure 68) and is programmed to identify four possible resistor values: $47 \mathrm{k} \Omega, 22 \mathrm{k} \Omega$, open, and $100 \mathrm{k} \Omega$.

The RES detect circuit digitizes the value of the resistor at the RES pin (Pin 6). An internal ADC outputs a 2-bit digital code that is used to program four separate gain configurations in the current sense amplifier (see Figure 69). Each configuration corresponds to a current sense gain ( $\mathrm{A}_{C s}$ ) of $3 \mathrm{~V} / \mathrm{V}, 6 \mathrm{~V} / \mathrm{V}, 12 \mathrm{~V} / \mathrm{V}$, or $24 \mathrm{~V} / \mathrm{V}$, respectively (see Table 6 and Table 7). This variable is used for the valley current-limit setting, which sets up the appropriate current sense gain for a given application and sets the compensation necessary to achieve loop stability (see the Valley Current-Limit Setting section and the Compensation Network section).

Figure 68. Programming Resistor Location

| Resistor | Acs |
| :--- | :--- |
| $47 \mathrm{k} \Omega$ | $3 \mathrm{~V} / \mathrm{V}$ |
| $22 \mathrm{k} \Omega$ | $6 \mathrm{~V} / \mathrm{V}$ |
| Open | $12 \mathrm{~V} / \mathrm{V}$ |
| $100 \mathrm{k} \Omega$ | $24 \mathrm{~V} / \mathrm{V}$ |

## VALLEY CURRENT-LIMIT SETTING

The architecture of the ADP1878/ADP1879 is based on valley current-mode control. The current limit is determined by three components: the RoN of the low-side MOSFET, the output voltage swing of the current sense amplifier, and the current sense gain. The output range of the current sense amplifier is internally fixed at 1.4 V . The current sense gain is programmable via an external resistor at the RES pin (see the Programming Resistor (RES) Detect Circuit section). The RoN of the low-side MOSFET can vary over temperature and usually has a positive $\mathrm{T}_{\mathrm{C}}$ (meaning that it increases with temperature); therefore, it is recommended to program the current sense, gain resistor based on the rated Ron of the MOSFET at $125^{\circ} \mathrm{C}$.

Because the ADP1878/ADP1879 are based on valley current control, the relationship between ICLIM and ILOAD is

$$
I_{C L I M}=I_{L O A D} \times\left(1-\frac{K_{I}}{2}\right)
$$

where:
$K_{I}$ is the ratio between the inductor ripple current and the desired average load current (see Figure 70).
$I_{\text {CLIM }}$ is the desired valley current limit.
$I_{L O A D}$ is the current load.
Establishing $K_{I}$ helps to determine the inductor value (see the Inductor Selection section), but in most cases, $\mathrm{K}_{\mathrm{I}}=0.33$.

Figure 70. Valley Current Limit to Average Current Relation

When the desired valley current limit (I $\mathrm{I}_{\text {сıм }}$ ) has been determined, the current sense gain can be calculated as follows:

$$
I_{\text {CLIM }}=\frac{1.4 \mathrm{~V}}{A_{C S} \times R_{O N}}
$$

where:
$R_{\text {ON }}$ is the channel impedance of the low-side MOSFET.
$A_{C S}$ is the current sense gain multiplier (see Table 6 and Table 7).
Although the ADP1878/ADP1879 have only four discrete current sense gain settings for a given Ron variable, Table 7 and Figure 71 outline several available options for the valley current setpoint based on various Ron values.

Table 7. Valley Current Limit Program (See Figure 71)

| $\begin{aligned} & \text { Ron } \\ & (\mathrm{m} \Omega) \end{aligned}$ | Valley Current Level (A) ${ }^{1}$ |  |  |  |

[^1]

Figure 71. Valley Current-Limit Value vs. Ron of the Low-Side MOSFET for Each Programming Resistor (RES)

The valley current limit is programmed as listed in Table 7 and shown in Figure 71. The inductor that is chosen must be rated to handle the peak current, which is equal to the valley current from Table 7 plus the peak-to-peak inductor ripple current (see the Inductor Selection section). In addition, the peak current value must be used to compute the worst-case power dissipation in the MOSFETs (see Figure 72).

Figure 72. Valley Current-Limit Threshold in Relation to Inductor Ripple Current

Figure 73. Idle Mode Entry Sequence Due to Current-Limit Violation

## HICCUP MODE DURING SHORT CIRCUIT

A current-limit violation occurs when the current across the source and drain of the low-side MOSFET exceeds the currentlimit setpoint. When 32 current-limit violations are detected, the controller enters idle mode and turns off the MOSFETs for 6 ms , allowing the converter to cool down. Then, the controller reestablishes soft start and begins to cause the output to ramp up again (see Figure 73). While the output ramps up, the current sense amplifier output is monitored to determine if the violation is still present. If it is still present, the idle event occurs again, followed by the full chip, power-down sequence. This cycle continues until the violation no longer exists. If the violation disappears, the converter is allowed to switch normally, maintaining regulation.

## SYNCHRONOUS RECTIFIER

The ADP1878/ADP1879 employ internal MOSFET drivers for the external high- and low-side MOSFETs. The low-side synchronous rectifier not only improves overall conduction efficiency, but it also ensures proper charging of the bootstrap capacitor located at the high-side driver input. This is beneficial during startup to provide sufficient drive signal to the external high-side MOSFET and to attain fast turn-on response, which is essential for minimizing switching losses. The integrated highand low-side MOSFET drivers operate in complementary fashion with built-in anti cross conduction circuitry to prevent unwanted shoot through current that may potentially damage the MOSFETs or reduce efficiency because of excessive power loss.

## ADP1879 POWER SAVING MODE (PSM)

A power saving mode is provided in the ADP1879. The ADP1879 operates in the discontinuous conduction mode (DCM) and pulse skips at light to medium load currents. The controller outputs pulses as necessary to maintain output regulation. Unlike the continuous conduction mode (CCM), DCM operation prevents negative current, thus allowing improved system efficiency at light loads. Current in the reverse direction through this pathway, however, results in power dissipation and, therefore, a decrease in efficiency.

Figure 74. Discontinuous Mode of Operation (DCM)
To minimize the chance of negative inductor current buildup, an on-board zero-cross comparator turns off all high- and lowside switching activities when the inductor current approaches the zero current line, causing the system to enter idle mode, where the high- and low-side MOSFETs are turned off. To ensure idle mode entry, a 10 mV offset, connected in series at the SW node, is implemented (see Figure 75).

Figure 75. Zero-Cross Comparator with 10 mV of Offset
As soon as the forward current through the low-side MOSFET decreases to a level where
$10 \mathrm{mV}=I_{Q_{2}} \times R_{\text {ON(Q2) }}$
the zero-cross comparator (or $\mathrm{I}_{\mathrm{Rev}}$ comparator) emits a signal to turn off the low-side MOSFET. From this point, the slope of the inductor current ramping down becomes steeper (see Figure 76) as the body diode of the low-side MOSFET begins to conduct current and continues conducting current until the remaining energy stored in the inductor has been depleted.

Figure 76.10 mV Offset to Ensure Prevention of Negative Inductor Current The system remains in idle mode until the output voltage drops below regulation. Next, a PWM pulse is produced, turning on the high-side MOSFET to maintain system regulation. The ADP1879 does not have an internal clock; it switches purely as a hysteretic controller, as described in this section.

## TIMER OPERATION

The ADP1878/ADP1879 employ a constant on-time architecture, which provides a variety of benefits, including improved load and line transient response when compared with a constant (fixed) frequency current-mode control loop of comparable loop design. The constant on-time timer, or tos timer, senses the high-side input voltage ( $\mathrm{V}_{\text {IN }}$ ) and the output voltage ( $\mathrm{V}_{\text {out }}$ ) using SW waveform information to produce an adjustable one shot PWM pulse. The pulse varies the on-time of the high-side MOSFET in response to dynamic changes in input voltage, output voltage, and load current conditions to maintain output regulation. The timer generates an on-time (tos) pulse that is inversely proportional to $\mathrm{V}_{\mathrm{IN}}$.

$$
t_{O N}=K \times \frac{V_{O U T}}{V_{I N}}
$$

where $K$ is a constant that is trimmed using an RC timer product for the $300 \mathrm{kHz}, 600 \mathrm{kHz}$, and 1.0 MHz frequency options.

Figure 77. Constant On-Time Time
The constant on-time (ton) is not strictly constant because it varies with $V_{\text {IN }}$ and Vout. However, this variation occurs in such a way as to keep the switching frequency virtually independent of $V_{\text {IN }}$ and Vout.

The ton timer uses a feedforward technique that, when applied to the constant on-time control loop, makes it a pseudo fixed frequency to a first-order approximation.
Second-order effects, such as dc losses in the external power MOSFETs (see the Efficiency Consideration section), cause some variation in frequency vs. load current and line voltage. These effects are shown in Figure 23 to Figure 34. The variations in frequency are much reduced compared with the variations generated if the feedforward technique is not used.
The feedforward technique establishes the following relationship:

$$
f_{S W}=\frac{1}{K}
$$

where $f_{s w}$ is the controller switching frequency ( 300 kHz , 600 kHz , and 1.0 MHz ).
The ton timer senses $V_{\text {IN }}$ and Vout to minimize frequency variation as previously explained. This provides pseudo fixed frequency as explained in the Pseudo Fixed Frequency section. To allow headroom for $\mathrm{V}_{\text {IN }}$ and $V_{\text {out }}$ sensing, adhere to the following equations:

$$
\begin{aligned}
& V_{\text {REG }} \geq V_{I N} / 8+1.5 \\
& V_{\text {REG }} \geq V_{\text {OUTT }} / 4
\end{aligned}
$$

For typical applications where $V_{\text {reg }}$ is 5 V , these equations are not relevant; however, for lower $V_{\text {Reg }}$ inputs, care may be required.

## PSEUDO FIXED FREQUENCY

The ADP1878/ADP1879 employ a constant on-time control scheme. During steady state operation, the switching frequency stays relatively constant, or pseudo fixed. This is due to the one shot ton timer that produces a high-side PWM pulse with a fixed duration, given that external conditions such as input voltage, output voltage, and load current are also at steady state. During load transients, the frequency momentarily changes for the duration of the transient event so that the output comes back within regulation quicker than if the frequency were fixed, or if it were to remain unchanged. After the transient event is complete, the frequency returns to a pseudo fixed value.
To illustrate this feature more clearly, this section describes one such load transient event-a positive load step-in detail. During load transient events, the high-side driver output pulse width stays relatively consistent from cycle to cycle; however, the off time (DRVL on time) dynamically adjusts according to the instantaneous changes in the external conditions mentioned.
When a positive load step occurs, the error amplifier (out of phase with the output, $\mathrm{V}_{\text {out }}$ ) produces new voltage information at its output (COMP). In addition, the current sense amplifier senses new inductor current information during this positive load transient event. The output voltage reaction of the error amplifier is compared with the new inductor current information that sets the start of the next switching cycle. Because current information is produced from valley current sensing, it is sensed at the down ramp of the inductor current, whereas the voltage loop information
is sensed through the counter action upswing of the output (COMP) of the error amplifier.
The result is a convergence of these two signals (see Figure 78), which allows an instantaneous increase in switching frequency during the positive load transient event. In summary, a positive load step causes Vout to transient down, which causes COMP to transient up and, therefore, shortens the off time. This resulting increase in frequency during a positive load transient helps to quickly bring Vout back up in value and within the regulation window.
Similarly, a negative load step causes the off time to lengthen in response to Vout rising. This effectively increases the inductor demagnetizing phase, helping to bring $V_{\text {out }}$ within regulation. In this case, the switching frequency decreases, or experiences a foldback, to help facilitate output voltage recovery.

Because the ADP1878/ADP1879 have the ability to respond rapidly to sudden changes in load demand, the recovery period in which the output voltage settles back to its original steady state operating point is much quicker than it would be for a fixed frequency equivalent. Therefore, using a pseudo fixed frequency results in significantly better load transient performance compared to using a fixed frequency.

## POWER-GOOD MONITORING

The ADP1878/ADP1879 power-good circuitry monitors the output voltage via the FB pin. The PGOOD pin is an opendrain output that can be pulled up by an external resistor to a voltage rail that does not necessarily have to be VREG. When the internal NMOS switch is in high impedance (off state), this means that the PGOOD pin is logic high and the output voltage via the FB pin is within the specified regulation window. When
the internal switch is turned on, PGOOD is internally pulled low when the output voltage via the FB pin is outside this regulation window.

The power-good window is defined with a typical upper specification of +90 mV and a lower specification of -70 mV below the FB voltage of 600 mV . When an overvoltage event occurs at the output, there is a typical propagation delay of $12 \mu$ s prior to the deassertion (logic low) of the PGOOD pin. When the output voltage reenters the regulation window, there is a propagation delay of $12 \mu \mathrm{~s}$ prior to PGOOD reasserting back to a logic high state. When the output is outside the regulation window, the PGOOD open-drain switch is capable of sinking 1 mA of current and providing 140 mV of drop across this switch. The user is free to tie the external pull-up resistor ( $\mathrm{R}_{\text {RES }}$ ) to any voltage rail up to 20 V . The following equation provides the proper external pull-up resistor value:

$$
R_{P G D}=\frac{V_{E X T}-140 \mathrm{mV}}{1 \mathrm{~mA}}
$$

where:
$R_{P G D}$ is the PGOOD external resistor.
$V_{E X T}$ is a user chosen voltage rail.

Figure 79. Power Good, Output Voltage Monitoring Circuit

Figure 80. Power-Good Timing Diagram, $t_{P G D}=12 \mu \mathrm{~s}$ (Diagram May Look Disproportionate For Illustration Purposes)

## APPLICATIONS INFORMATION <br> FEEDBACK RESISTOR DIVIDER

The required resistor divider network can be determined for a given $\mathrm{V}_{\text {OUT }}$ value because the internal band gap reference $\left(\mathrm{V}_{\text {REF }}\right)$ is fixed at 0.6 V . Selecting values for $R_{T}$ and $R_{B}$ determine the minimum output load current of the converter. Therefore, for a given value of $R_{B}$, the $R_{T}$ value can be determined through the following expression:

$$
R_{T}=R_{B} \times \frac{\left(V_{\text {OUT }}-0.6 \mathrm{~V}\right)}{0.6 \mathrm{~V}}
$$

## INDUCTOR SELECTION

The inductor value is inversely proportional to the inductor ripple current. The peak-to-peak ripple current is given by

$$
\Delta I_{L}=K_{I} \times I_{L O A D} \approx \frac{I_{L O A D}}{3}
$$

where $K_{I}$ is typically 0.33 .
The equation for the inductor value is given by

$$
L=\frac{\left(V_{I N}-V_{\text {OUT }}\right)}{\Delta I_{L} \times f_{S W}} \times \frac{V_{\text {OUT }}}{V_{I N}}
$$

where:
$V_{I N}$ is the high voltage input.
$V_{\text {OUT }}$ is the desired output voltage.
$f_{S W}$ is the controller switching frequency ( $300 \mathrm{kHz}, 600 \mathrm{kHz}$, and 1.0 MHz).

When selecting the inductor, choose an inductor saturation rating that is above the peak current level, and then calculate the inductor current ripple (see the Valley Current-Limit Setting section and Figure 81).

## OUTPUT RIPPLE VOLTAGE ( $\Delta \mathrm{V}_{\text {RR }}$ )

The output ripple voltage is the ac component of the dc output voltage during steady state. For a ripple error of $1.0 \%$, the output capacitor value needed to achieve this tolerance can be determined using the following equation. (Note that an accuracy of $1.0 \%$ is possible during steady state conditions only, not during load transients.)

$$
\Delta V_{R R}=(0.01) \times V_{\text {OUT }}
$$

## OUTPUT CAPACITOR SELECTION

The primary objective of the output capacitor is to facilitate the reduction of the output voltage ripple; however, the output capacitor also assists in the output voltage recovery during load transient events. For a given load current step, the output voltage ripple generated during this step event is inversely proportional to the value chosen for the output capacitor. The speed at which the output voltage settles during this recovery period depends on where the crossover frequency (loop bandwidth) is set. This crossover frequency is determined by the output capacitor, the equivalent series resistance (ESR) of the capacitor, and the compensation network.
To calculate the small signal voltage ripple (output ripple voltage) at the steady state operating point, use the following equation:

$$
C_{O U T}=\Delta I_{L} \times\left(\frac{1}{8 \times f_{S W} \times\left[\Delta V_{R I P P L E}-\left(\Delta I_{L} \times E S R\right)\right]}\right)
$$

where $E S R$ is the equivalent series resistance of the output capacitors.
To calculate the output load step, use the following equation:

$$
C_{O U T}=2 \times \frac{\Delta I_{L O A D}}{f_{S W} \times\left(\Delta V_{D R O O P}-\left(\Delta I_{L O A D} \times E S R\right)\right)}
$$

where $\Delta V_{D R O O P}$ is the amount that $\mathrm{V}_{\text {OUT }}$ is allowed to deviate for a given positive load current step ( $\Delta I_{L O A D}$ ).

Ceramic capacitors are known to have low ESR. However, there is a trade-off in using the popular X5R capacitor technology because as much as $80 \%$ of its capacitance may be lost due to derating as the voltage applied across the capacitor is increased (see Figure 82). Although X7R series capacitors can also be used, the available selection is limited to $22 \mu \mathrm{~F}$ maximum.

Figure 82. Capacitance vs. DC Voltage Characteristics for Ceramic Capacitors
Electrolytic capacitors satisfy the bulk capacitance requirements for most high current applications. However, because the ESR of electrolytic capacitors is much higher than that of ceramic capacitors, mount several MLCCs in parallel with the electrolytic capacitors to reduce the overall series resistance.

## COMPENSATION NETWORK

Due to its current-mode architecture, the ADP1878/ADP1879 require Type II compensation. To determine the component values needed for compensation (resistance and capacitance values), it is necessary to examine the overall loop gain (H) of the converter at the unity-gain frequency $\left(\mathrm{f}_{\mathrm{sw}} / 10\right)$ when $\mathrm{H}=1 \mathrm{~V} / \mathrm{V}$ :

$$
H=1 \mathrm{~V} / \mathrm{V}=G_{M} \times G_{C S} \times \frac{V_{R E F}}{V_{O U T}} \times Z_{C O M P} \times Z_{F I L T}
$$

Examining each variable at high frequency enables the unitygain transfer function to be simplified to provide expressions for the $\mathrm{R}_{\text {COMP }}$ and $\mathrm{C}_{\text {СОMP }}$ component values.

## Output Filter Impedance ( $Z_{\text {FLLT }}$ )

Examining the transfer function of the filter at high frequencies simplifies to

$$
Z_{F I L T E R}=R_{L} \times \frac{1+s \times E S R \times C_{\text {OUT }}}{1+s\left(R_{L}+E S R\right) C_{O U T}}
$$

at the crossover frequency ( $s=2 \pi \mathrm{f}_{\text {CROSS }}$ ). ESR is the equivalent series resistance of the output capacitors.

## Error Amplifier Output Impedance ( $Z_{\text {cомр }}$ )

Assuming $\mathrm{C}_{\mathrm{C} 2}$ is significantly smaller than $\mathrm{C}_{\mathrm{COMP}}, \mathrm{C}_{\mathrm{C} 2}$ can be omitted from the output impedance equation of the error amplifier. The transfer function simplifies to

$$
Z_{\text {COMP }}=\frac{R_{\text {COMP }}}{f_{\text {CROSS }}} \times \sqrt{f_{\text {CROSS }^{2}}+f_{\text {ZERO }}{ }^{2}}
$$

and

$$
f_{\text {CROSS }}=\frac{1}{12} \times f_{S W}
$$

where $f_{\text {ZERO }}$, the zero frequency, is set to be $1 / 4^{\text {th }}$ of the crossover frequency for the ADP1878.

## Error Amplifier Gain ( $\mathbf{G}_{\boldsymbol{m}}$ )

The error amplifier gain (transconductance) is

$$
\mathrm{G}_{\mathrm{m}}=500 \mu \mathrm{~A} / \mathrm{V}(\mu \mathrm{~s})
$$

## Current-Sense Loop Gain ( $\boldsymbol{G}_{\text {cs }}$ )

The current-sense loop gain is

$$
G_{C S}=\frac{1}{A_{C S} \times R_{O N}}(A / V)
$$

where:
$A_{C S}(\mathrm{~V} / \mathrm{V})$ is programmable for $3 \mathrm{~V} / \mathrm{V}, 6 \mathrm{~V} / \mathrm{V}, 12 \mathrm{~V} / \mathrm{V}$, and $24 \mathrm{~V} / \mathrm{V}$ (see the Programming Resistor (RES) Detect Circuit and Valley Current-Limit Setting sections).
$R_{\text {ON }}$ is the channel impedance of the low-side MOSFET.

## Crossover Frequency

The crossover frequency is the frequency at which the overall loop (system) gain is $0 \mathrm{~dB}(\mathrm{H}=1 \mathrm{~V} / \mathrm{V})$. It is recommended for current-mode converters, such as the ADP1878, that the user set the crossover frequency between $1 / 10^{\text {th }}$ and $1 / 15^{\text {th }}$ of the switching frequency.

$$
f_{\text {CROSS }}=\frac{1}{12} f_{S W}
$$

The relationship between $\mathrm{C}_{\text {COMP }}$ and $\mathrm{f}_{\text {ZERO }}$ (zero frequency) is as follows:

$$
f_{\text {ZERO }}=\frac{1}{2 \pi \times R_{\text {COMP }} \times C_{\text {COMP }}}
$$

The zero frequency is set to $1 / 4^{\text {th }}$ of the crossover frequency.
Combining all of the above parameters results in

$$
\begin{aligned}
& R_{\text {COMP }}= \\
& \quad \frac{f_{\text {CROSS }}}{\sqrt{f_{\text {CROSS }}{ }^{2}+f_{\text {ZERO }}{ }^{2}}} \times \frac{\sqrt{1^{2}+\left(s\left(R_{L}+E S R\right) C_{\text {OUT }}\right)^{2}}}{\sqrt{1^{2}+\left(s \times E S R \times C_{\text {OUT }}\right)^{2}}} \times \frac{1}{R_{L}} \times \\
& \frac{V_{\text {OUT }}}{V_{R E F}} \times \frac{1}{G_{M} G_{C S}}
\end{aligned}
$$

where ESR is the equivalent series resistance of the output capacitors.

$$
C_{\text {COMP }}=\frac{1}{2 \times \pi \times R_{\text {COMP }} \times f_{\text {ZERO }}}
$$

## EFFICIENCY CONSIDERATION

An important criteria to consider in constructing a dc-to-dc converter is efficiency. By definition, efficiency is the ratio of the output power to the input power. For high power applications at load currents of up to 20 A , the following are important MOSFET parameters that aid in the selection process:

- $\quad \mathrm{V}_{\mathrm{GS}}(\mathrm{TH})$ is the MOSFET voltage applied between the gate and the source that starts channel conduction.
- $\mathrm{R}_{\mathrm{DS} \text { (ON) }}$ is the on resistance of the MOSFET during channel conduction.
- $\mathrm{Q}_{\mathrm{G}}$ is the total gate charge.
- $\mathrm{C}_{\mathrm{N} 1}$ is the input capacitance of the high-side switch.
- $\mathrm{C}_{\mathrm{N}_{2}}$ is the input capacitance of the low-side switch.

The following are the losses experienced through the external component during normal switching operation:

- Channel conduction loss (both of the MOSFETs).
- MOSFET driver loss.
- MOSFET switching loss.
- Body diode conduction loss (low-side MOSFET).
- Inductor loss (copper and core loss).

## Channel Conduction Loss

During normal operation, the bulk of the loss in efficiency is due to the power dissipated through MOSFET channel conduction. Power loss through the high-side MOSFET is directly proportional to the duty cycle (D) for each switching period, and the power loss through the low-side MOSFET is directly proportional to $1-\mathrm{D}$ for each switching period. The selection of MOSFETs is governed by the maximum dc load current that the converter is expected to deliver. In particular, the selection of the low-side MOSFET is dictated by the maximum load current because a typical high current application employs duty cycles of less than $50 \%$. Therefore, the low-side MOSFET is in the on state for most of the switching period.

$$
P_{N 1, N 2(C L)}=\left[D \times R_{N 1(O N)}+(1-D) \times R_{N 2(O N)}\right] \times I_{L O A D}^{2}
$$

## MOSFET Driver Loss

Other dissipative elements are the MOSFET drivers. The contributing factors are the dc current flowing through the driver during operation and the $\mathrm{Q}_{\mathrm{GATE}}$ parameter of the external MOSFETs.

$$
\begin{aligned}
& P_{D R(L O S S)}=\left[V_{D R} \times\left(f_{\text {SW }} C_{\text {upperFET }} V_{D R}+I_{B I A S}\right)\right]+\left[V_{R E G} \times\right. \\
& \left.\left(f_{S W} \times \text { lowerFET } V_{R E G}+I_{B I A S}\right)\right]
\end{aligned}
$$

where:
$C_{\text {upperfet }}$ is the input gate capacitance of the high-side MOSFET. $C_{\text {lowerfet }}$ is the input gate capacitance of the low-side MOSFET. $I_{B A A}$ is the dc current flowing into the high- and low-side drivers. $V_{D R}$ is the driver bias voltage (that is, the low input voltage ( $V_{R E G}$ ) minus the rectifier drop (see Figure 83)).
$V_{\text {REG }}$ is the bias voltage.

Figure 83. Internal Rectifier Voltage Drop vs. Switching Frequency

## MOSFET Switching Loss

The SW node transitions due to the switching activities of the high- and low-side MOSFETs. This causes removal and replenishing of charge to and from the gate oxide layer of the MOSFET, as well as to and from the parasitic capacitance associated with the gate oxide edge overlap and the drain and source terminals. The current that enters and exits these charge paths presents additional loss during these transition times. This can be approximately quantified by using the following equation, which represents the time in which charge enters and exits these capacitive regions:

$$
t_{S W-T R A N S}=R_{G A T E} \times C_{T O T A L}
$$

where:
$C_{\text {Total }}$ is the $\mathrm{C}_{\mathrm{GD}}+\mathrm{C}_{\mathrm{GS}}$ of the external MOSFET.
$R_{G A T E}$ is the gate input resistance of the external MOSFET.
The ratio of this time constant to the period of one switching cycle is the multiplying factor to be used in the following expression:

$$
P_{S W(L O S S)}=\frac{t_{S W-\mathrm{TRANS}}}{t_{S W}} \times I_{L O A D} \times V_{I N} \times 2
$$

or

$$
P_{S W(L O S S)}=f_{S W} \times R_{G A T E} \times C_{T O T A L} \times I_{L O A D} \times V_{I N} \times 2
$$

## Body Diode Conduction Loss

The ADP1878/ADP1879 employ anti cross conduction circuitry that prevents the high- and low-side MOSFETs from conducting current simultaneously. This overlap control is beneficial, avoiding large current flow that may lead to irreparable damage to the external components of the power stage. However, this blanking period comes with the trade-off of a diode conduction loss occurring immediately after the MOSFETs change states and continuing well into idle mode.

The amount of loss through the body diode of the low-side MOSFET during the anti overlap state is given by the following expression:

$$
P_{B O D Y(L O S S)}=\frac{t_{B O D Y(L O S S)}}{t_{S W}} \times I_{L O A D} \times V_{F} \times 2
$$

where:
$t_{\text {BODY(LOSS) }}$ is the body conduction time (refer to Figure 84 for dead time periods).
$t_{S W}$ is the period per switching cycle.
$V_{F}$ is the forward drop of the body diode during conduction. (Refer to the selected external MOSFET data sheet for more information about the $\mathrm{V}_{\mathrm{F}}$ parameter.)

Figure 84. Body Diode Conduction Time vs. Low Voltage Input ( $V_{\text {REG }}$ )

## Inductor Loss

During normal conduction mode, further power loss is caused by the conduction of current through the inductor windings, which have dc resistance (DCR). Typically, larger sized inductors have smaller DCR values.
The inductor core loss is a result of the eddy currents generated within the core material. These eddy currents are induced by the changing flux, which is produced by the current flowing through the windings. The amount of inductor core loss depends on the core material, the flux swing, the frequency, and the core volume. Ferrite inductors have the lowest core losses, whereas powdered iron inductors have higher core losses. It is recommended to use shielded ferrite core material type inductors with the ADP1878/ADP1879 for a high current, dc-to-dc switching application to achieve minimal loss and negligible electromagnetic interference (EMI).

$$
P_{D C R(L O S S)}=D C R \times I_{L O A D}^{2}+\text { Core Loss }
$$

## INPUT CAPACITOR SELECTION

The goal in selecting an input capacitor is to reduce or minimize input voltage ripple and to reduce the high frequency source impedance, which is essential for achieving predictable loop stability and transient performance.
The problem with using bulk capacitors, other than their physical geometries, is their large equivalent series resistance (ESR) and large equivalent series inductance (ESL). Aluminum electrolytic
capacitors have such high ESR that they cause undesired input voltage ripple magnitudes and are generally not effective at high switching frequencies.
If bulk electrolytic capacitors are used, it is recommended to use multilayered ceramic capacitors (MLCC) in parallel due to their low ESR values. This dramatically reduces the input voltage ripple amplitude as long as the MLCCs are mounted directly across the drain of the high-side MOSFET and the source terminal of the low-side MOSFET (see the Layout Considerations section). Improper placement and mounting of these MLCCs may cancel their effectiveness due to stray inductance and an increase in trace impedance.

$$
I_{C I N, R M S}=I_{L O A D, M A X} \times \frac{\sqrt{V_{\text {OUT }} \times\left(V_{I N}-V_{\text {OUT }}\right)}}{V_{\text {OUT }}}
$$

The maximum input voltage ripple and maximum input capacitor rms current occur at the end of the duration of $1-\mathrm{D}$ while the high-side MOSFET is in the off state. The input capacitor rms current reaches its maximum at time D . When calculating the maximum input voltage ripple, account for the ESR of the input capacitor as follows:

$$
V_{M A X, R I P P L E}=V_{R I P P}+\left(I_{L O A D, M A X} \times E S R\right)
$$

where:
$V_{\text {RIPP }}$ is usually $1 \%$ of the minimum voltage input. $I_{\text {LOAD,MAX }}$ is the maximum load current.
$E S R$ is the equivalent series resistance rating of the input capacitor.
Inserting $\mathrm{V}_{\mathrm{MAX}, \text { RIPPLE }}$ into the charge balance equation to calculate the minimum input capacitor requirement gives

$$
C_{I N, M I N}=\frac{I_{L O A D, M A X}}{V_{M A X, R I P P L E}} \times \frac{D(1-D)}{f_{S W}}
$$

or

$$
C_{I N, M I N}=\frac{I_{L O A D, M A X}}{4 f_{S W} V_{M A X, R I P P L E}}
$$

where $D=50 \%$.

## THERMAL CONSIDERATIONS

The ADP1878/ADP1879 are used for dc-to-dc, step down, high current applications that have an on-board controller, an on-board LDO, and on-board MOSFET drivers. Because applications may require up to 20 A of load current and be subjected to high ambient temperature, the selection of external high- and low-side MOSFETs must be associated with careful thermal consideration to not exceed the maximum allowable junction temperature of $125^{\circ} \mathrm{C}$. To avoid permanent or irreparable damage, if the junction temperature reaches or exceeds $155^{\circ} \mathrm{C}$, the part enters thermal shutdown, turning off both external MOSFETs, and is not reenabled until the junction temperature cools to $140^{\circ} \mathrm{C}$ (see the On-Board Low Dropout (LDO) Regulator section).
In addition, it is important to consider the thermal impedance of the package. Because the ADP1878/ADP1879 employ an on-board LDO, the ac current ( fxCxV ) consumed by the internal drivers to drive the external MOSFETs, adds another element of
power dissipation across the internal LDO. Equation 3 shows the power dissipation calculations for the integrated drivers and for the internal LDO. Table 9 lists the thermal impedance for the ADP1878/ADP1879, which are available in a 14-lead LFCSP_WD.

Table 9. Thermal Impedance for 14-Lead LFCSP_WD

| Package | Thermal Impedance |
| :--- | :--- |
| 14-Lead LFCSP_WD $\theta_{\mathrm{JA}}$ <br> 4-Layer Board | $30^{\circ} \mathrm{C} / \mathrm{W}$ |

Figure 85 specifies the maximum allowable ambient temperature that can surround the ADP1878/ADP1879 IC for a specified high input voltage ( $\mathrm{V}_{\text {IN }}$ ). Figure 85 illustrates the temperature derating conditions for each available switching frequency for low, typical, and high output setpoints for the 14-lead LFCSP_WD package. All temperature derating criteria are based on a maximum IC junction temperature of $125^{\circ} \mathrm{C}$.

Figure 85. Ambient Temperature vs. $V_{I N}$, 4-Layer Evaluation Board, CIN $=4.3 \mathrm{nF}$ (High-/Low-Side MOSFET)

The maximum junction temperature allowed for the ADP1878/ ADP1879 IC is $125^{\circ} \mathrm{C}$. This means that the sum of the ambient temperature $\left(T_{A}\right)$ and the rise in package temperature $\left(T_{R}\right)$, which is caused by the thermal impedance of the package and the internal power dissipation, should not exceed $125^{\circ} \mathrm{C}$, as dictated by the following expression:

$$
\begin{equation*}
T_{J}=T_{R} \times T_{A} \tag{1}
\end{equation*}
$$

where:
$T_{J}$ is the maximum junction temperature.
$T_{R}$ is the rise in package temperature due to the power
dissipated from within.
$T_{A}$ is the ambient temperature.

The rise in package temperature is directly proportional to its thermal impedance characteristics. The following equation represents this proportionality relationship:

$$
\begin{equation*}
T_{R}=\theta_{I A} \times P_{D R(L O S S)} \tag{2}
\end{equation*}
$$

where:
$\theta_{J A}$ is the thermal resistance of the package from the junction to the outside surface of the die, where it meets the surrounding air. $P_{\text {DR(Loss) }}$ is the overall power dissipated by the IC.
The bulk of the power dissipated is due to the gate capacitance of the external MOSFETs and current running through the on-board LDO. The power loss equations for the MOSFET drivers and internal low dropout regulator (see the MOSFET Driver Loss section and the Efficiency Consideration section) are:

$$
\begin{align*}
& P_{D R(L O S S)}=\left[V_{D R} \times\left(f_{S W} C_{\text {upperFET }} V_{D R}+I_{B I A S}\right)\right]+ \\
& {\left[V_{R E G} \times\left(f_{S W} C_{\text {lowerFET }} V_{\text {REG }}+I_{B I A S}\right)\right]} \tag{3}
\end{align*}
$$

where:
$C_{\text {upperfet }}$ is the input gate capacitance of the high-side MOSFET. $C_{\text {lowerFET }}$ is the input gate capacitance of the low-side MOSFET. $I_{B I A S}$ is the dc current ( 2 mA ) flowing into the high- and lowside drivers.
$V_{D R}$ is the driver bias voltage (the low input voltage ( $\mathrm{V}_{\mathrm{REG}}$ ) minus the rectifier drop (see Figure 83)).
$V_{R E G}$ is the LDO output/bias voltage.

$$
\begin{align*}
& P_{D I S S(L D O)}=P_{D R(L O S S)}+\left(V_{I N}-V_{R E G}\right) \times\left(f_{S W} \times C_{T O T A L} \times\right. \\
& V_{R E G}+I_{B I A S} \tag{4}
\end{align*}
$$

where $P_{D I S S(L D O)}$ is the power dissipated through the pass device in the LDO block across $V_{I N}$ and $V_{\text {REG }}$.
$P_{D R(L O S S)}$ is the MOSFET driver loss.
$V_{I N}$ is the high voltage input.
$V_{\text {REG }}$ is the LDO output voltage and bias voltage.
$C_{\text {Total }}$ is the $\mathrm{C}_{\mathrm{GD}}+\mathrm{C}_{\mathrm{GS}}$ of the external MOSFET.
$I_{B I A S}$ is the dc input bias current.
For example, if the external MOSFET characteristics are $\theta_{\text {JA }}$ (14-lead LFCSP_WD) $=30^{\circ} \mathrm{C} / \mathrm{W}, \mathrm{f}_{\text {sw }}=300 \mathrm{kHz}, \mathrm{I}_{\text {BIAS }}=2 \mathrm{~mA}$, $\mathrm{C}_{\text {upperfET }}=3.3 \mathrm{nF}, \mathrm{C}_{\text {lowerfet }}=3.3 \mathrm{nF}, \mathrm{V}_{\mathrm{DR}}=4.62 \mathrm{~V}$, and $\mathrm{V}_{\text {REG }}=5.0 \mathrm{~V}$, then the power loss is

$$
\begin{aligned}
& P_{\text {DR(LOSS) }}=\left[V_{D R} \times\left(f_{S W C \text { UpperFET }} V_{D R}+I_{\text {BIAS }}\right)\right]+ \\
& {\left[V_{R E G} \times\left(f_{\text {SWClowerFET }} V_{R E G}+I_{\text {BIAS }}\right)\right]} \\
& =\left(4.62 \times\left(300 \times 10^{3} \times 3.3 \times 10^{-9} \times 4.62+0.002\right)\right)+ \\
& \left(5.0 \times\left(300 \times 10^{3} \times 3.3 \times 10^{-9} \times 5.0+0.002\right)\right) \\
& =57.12 \mathrm{~mW} \\
& P_{\text {DISS(LDO) }}=\left(V_{I N}-V_{R E G}\right) \times\left(f_{S W} \times C_{\text {TOTAL }} \times V_{\text {REG }}+I_{\text {BIAS }}\right)= \\
& (13 \mathrm{~V}-5 \mathrm{~V}) \times\left(300 \times 10^{3} \times 3.3 \times 10^{-9} \times 5+0.002\right) \\
& =55.6 \mathrm{~mW} \\
& P_{\text {DISS(TOTAL) }}=P_{\text {DISS(LDO) }}+P_{\text {DR(LOSS })} \\
& =77.13 \mathrm{~mW}+55.6 \mathrm{~mW} \\
& =132.73 \mathrm{~mW}
\end{aligned}
$$

The rise in package temperature (for a 14-lead LFCSP_WD) is

$$
\begin{aligned}
& T_{R}=\theta_{I A} \times P_{D R(L L O S S)} \\
& =30^{\circ} \mathrm{C} \times 132.05 \mathrm{~mW} \\
& =4.0^{\circ} \mathrm{C}
\end{aligned}
$$

Assuming a maximum ambient temperature environment of $85^{\circ} \mathrm{C}$,

$$
T_{J}=T_{R} \times T_{A}=4.0^{\circ} \mathrm{C}+85^{\circ} \mathrm{C}=89.0^{\circ} \mathrm{C}
$$

which is below the maximum junction temperature of $125^{\circ} \mathrm{C}$.

## DESIGN EXAMPLE

The ADP1878/ADP1879 are easy to use, requiring only a few design criteria. For example, the example outlined in this section uses only four design criteria: $\mathrm{V}_{\text {OUT }}=1.8 \mathrm{~V}, \mathrm{I}_{\text {LOAD }}=15 \mathrm{~A}$ (pulsing), $\mathrm{V}_{\text {IN }}=12 \mathrm{~V}$ (typical), and $\mathrm{f}_{\mathrm{SW}}=300 \mathrm{kHz}$.

## Input Capacitor

The maximum input voltage ripple is usually $1 \%$ of the minimum input voltage ( $11.8 \mathrm{~V} \times 0.01=120 \mathrm{mV}$ ).
$V_{\text {RIPP }}=120 \mathrm{mV}$
$V_{M A X, \text { RPPPLE }}=V_{\text {RIPP }}-\left(I_{\text {LOAD,MAX }} \times E S R\right)$
$=120 \mathrm{mV}-(15 \mathrm{~A} \times 0.001)=45 \mathrm{mV}$
$C_{I N, M I N}=\frac{I_{L O A D, M A X}}{4 f_{S W} V_{M A X, R I P P L E}}=\frac{15 \mathrm{~A}}{4 \times 300 \times 10^{3} \times 105 \mathrm{mV}}$
$=120 \mu \mathrm{~F}$
Choose five $22 \mu \mathrm{~F}$ ceramic capacitors. The overall ESR of five $22 \mu \mathrm{~F}$ ceramic capacitors is less than $1 \mathrm{~m} \Omega$.

$$
\begin{aligned}
& I_{R M S}=I_{L O A D} / 2=7.5 \mathrm{~A} \\
& P_{C I N}=\left(I_{R M S}\right)^{2} \times E S R=(7.5 \mathrm{~A})^{2} \times 1 \mathrm{~m} \Omega=56.25 \mathrm{~mW}
\end{aligned}
$$

## Inductor

Determining inductor ripple current amplitude:

$$
\Delta I_{L} \approx \frac{I_{L O A D}}{3}=5 \mathrm{~A}
$$

Then, calculating for the inductor value

$$
\begin{aligned}
& L=\frac{\left(V_{\text {IN,MAX }}-V_{\text {OUT }}\right)}{\Delta I_{L}} \times \frac{V_{\text {OUT }}}{V_{\text {IN,MAX }}} \\
& =\frac{13.2 \mathrm{~V}-1.8 \mathrm{~V}}{5 \mathrm{~V} \times 300 \times 10^{3}} \times \frac{1.8 \mathrm{~V}}{13.2 \mathrm{~V}} \\
& =1.03 \mu \mathrm{H}
\end{aligned}
$$

The inductor peak current is approximately

$$
15 \mathrm{~A}+(5 \mathrm{~A} \times 0.5)=17.5 \mathrm{~A}
$$

Therefore, an appropriate inductor selection is $1.0 \mu \mathrm{H}$ with $\mathrm{DCR}=3.3 \mathrm{~m} \Omega$ (Würth Elektronik 7443552100) with a peak current handling of 20 A .

$$
\begin{aligned}
& P_{D C R(\text { LOSS })}=D C R \times I_{L}^{2} \\
& =0.003 \times(15 \mathrm{~A})^{2}=675 \mathrm{~mW}
\end{aligned}
$$

## Current-Limit Programming

The valley current is approximately

$$
15 \mathrm{~A}-(5 \mathrm{~A} \times 0.5)=12.5 \mathrm{~A}
$$

Assuming a low-side MOSFET $\mathrm{R}_{\mathrm{ON}}$ of $4.5 \mathrm{~m} \Omega$ and 13 A , as the valley current limit from Table 7 and Figure 71 indicate, a programming resistor (RES) of $100 \mathrm{k} \Omega$ corresponds to an $\mathrm{A}_{\mathrm{CS}}$ of $24 \mathrm{~V} / \mathrm{V}$.

Choose a programmable resistor of $\mathrm{R}_{\text {RES }}=100 \mathrm{k} \Omega$ for a current sense gain of $24 \mathrm{~V} / \mathrm{V}$.

## Output Capacitor

Assume that a load step of 15 A occurs at the output and no more than $5 \%$ output deviation is allowed from the steady state operating point. In this case, the advantage of the ADP1878 is that because the frequency is pseudo fixed, the converter is able to respond quickly because of the immediate, though temporary, increase in switching frequency.

$$
\Delta V_{\text {DROOP }}=0.05 \times 1.8 \mathrm{~V}=90 \mathrm{mV}
$$

Assuming the overall ESR of the output capacitor ranges from $5 \mathrm{~m} \Omega$ to $10 \mathrm{~m} \Omega$,

$$
\begin{aligned}
& C_{\text {OUT }}=2 \times \frac{\Delta I_{\text {LOAD }}}{f_{S W} \times\left(\Delta V_{\text {DROOP }}\right)} \\
& =2 \times \frac{15 \mathrm{~A}}{300 \times 10^{3} \times(90 \mathrm{mV})} \\
& =1.11 \mathrm{mF}
\end{aligned}
$$

Therefore, an appropriate inductor selection is five $270 \mu \mathrm{~F}$ polymer capacitors with a combined ESR of $3.5 \mathrm{~m} \Omega$.
Assuming an overshoot of 45 mV , determine if the output capacitor that was calculated previously is adequate

$$
\begin{aligned}
& C_{\text {OUT }}=\frac{\left(L \times I_{\text {LOAD }}^{2}\right)}{\left(\left(V_{\text {OUT }}-\Delta V_{\text {OVSHT }}\right)^{2}-\left(V_{\text {OUT }}\right)^{2}\right)} \\
& =\frac{1 \times 10^{-6} \times(15 \mathrm{~A})^{2}}{(1.8-45 \mathrm{mV})^{2}-(1.8)^{2}} \\
& =1.4 \mathrm{mF}
\end{aligned}
$$

Choose five $270 \mu \mathrm{~F}$ polymer capacitors.
The rms current through the output capacitor is

$$
\begin{aligned}
& I_{R M S}=\frac{1}{2} \times \frac{1}{\sqrt{3}} \frac{\left(V_{I N, M A X}-V_{\text {OUT }}\right)}{L \times f_{S W}} \times \frac{V_{\text {OUT }}}{V_{I N, M A X}} \\
& =\frac{1}{2} \times \frac{1}{\sqrt{3}} \frac{(13.2 \mathrm{~V}-1.8 \mathrm{~V})}{1 \mu \mathrm{~F} \times 300 \times 10^{3}} \times \frac{1.8 \mathrm{~V}}{13.2 \mathrm{~V}}=1.49 \mathrm{~A}
\end{aligned}
$$

The power loss dissipated through the ESR of the output capacitor is

$$
P_{\text {COUT }}=\left(I_{\text {RMS }}\right)^{2} \times E S R=(1.5 \mathrm{~A})^{2} \times 1.4 \mathrm{~m} \Omega=3.15 \mathrm{~mW}
$$

## ADP1878/ADP1879

## Feedback Resistor Network Setup

Choosing $R_{B}=1 \mathrm{k} \Omega$ as an example. Calculate $R_{T}$ as follows:

$$
R_{T}=1 \mathrm{k} \Omega \times \frac{(1.8 \mathrm{~V}-0.6 \mathrm{~V})}{0.6 \mathrm{~V}}=2 \mathrm{k} \Omega
$$

## Compensation Network

To calculate $\mathrm{R}_{\text {COMP }}, \mathrm{C}_{\text {СОMP }}$, and $\mathrm{C}_{\text {PAR }}$, the transconductance parameter and the current sense gain variable are required. The transconductance parameter $\left(\mathrm{G}_{\mathrm{m}}\right)$ is $500 \mu \mathrm{~A} / \mathrm{V}$, and the current sense loop gain is

$$
G_{C S}=\frac{1}{A_{C S} R_{O N}}=\frac{1}{24 \times 0.005}=8.33 \mathrm{~A} / \mathrm{V}
$$

where $A_{C S}$ and $R_{O N}$ are taken from setting up the current limit (see the Programming Resistor (RES) Detect Circuit section and the Valley Current-Limit Setting section).
The crossover frequency is $1 / 12^{\text {th }}$ of the switching frequency:

$$
300 \mathrm{kHz} / 12=25 \mathrm{kHz}
$$

The zero frequency is $1 / 4^{\text {th }}$ of the crossover frequency:

$$
\begin{aligned}
& 25 \mathrm{kHz} / 4=6.25 \mathrm{kHz} \\
& \begin{array}{l}
R_{\text {COMP }}= \\
\frac{1}{\sqrt{R_{L}}} \times \frac{f_{\text {CROSOSS }}}{V_{\text {OUT }}} \times \frac{1}{V_{\text {REF }}} \times \frac{\sqrt{1_{\text {ZERO }}^{2}}+\left(s\left(R_{L}+E S R\right) C_{\text {OUT }}\right)^{2}}{G_{\text {CS }}} \\
R_{\text {COMP }}=\frac{25 \mathrm{k} \Omega}{\sqrt{25 \mathrm{k} \Omega^{2}+6.25 \mathrm{k} \Omega^{2}}} \times \\
\frac{\sqrt{1^{2}+(2 \pi \times 25 \mathrm{k} \Omega \times((1.8 / 15)+0.0035) \times 0.0011)^{2}}}{\sqrt{1^{2}+(2 \pi \times 25 \mathrm{k} \Omega \times 0.0035 \times 0.0011)^{2}}} \times \\
\frac{1.8}{0.6} \times \frac{1}{500 \times 10^{-6} \times 8.3} \times \frac{15}{1.8} \\
=60.25 \mathrm{k} \Omega \\
C_{\text {COMP }}=\frac{1}{2 \pi R_{\text {COMP }} f_{\text {ZERO }}} \\
=\frac{1}{2 \times 3.14 \times 60.25 \times 10^{3} \times 6.25 \times 10^{3}} \\
=423 \mathrm{pF}
\end{array} .
\end{aligned}
$$

## Loss Calculations

Duty cycle $=1.8 / 12 \mathrm{~V}=0.15$
$\mathrm{R}_{\mathrm{ON}(\mathrm{N} 2)}=5.4 \mathrm{~m} \Omega$
$t_{\text {BODY(LOSS) }}=20 \mathrm{~ns}$ (body conduction time)
$\mathrm{V}_{\mathrm{F}}=0.84 \mathrm{~V}$ (MOSFET forward voltage)

## LAYOUT CONSIDERATIONS

The performance of a dc-to-dc converter depends highly on how the voltage and current paths are configured on the printed circuit board (PCB). Optimizing the placement of sensitive analog and power components are essential to minimize output ripple, maintain tight regulation specifications, and reduce PWM jitter and electromagnetic interference.

Figure 86 shows the schematic of a typical ADP1878/ADP1879 used for a high current application. Blue traces denote high current pathways. VIN, PGND, and $\mathrm{V}_{\text {Out }}$ traces should be wide and possibly replicated, descending down into the multiple layers. Vias should populate, mainly around the positive and negative terminals of the input and output capacitors, alongside the source of Q1/Q2, the drain of Q3/Q4, and the inductor.

Figure 86. ADP1878 High Current Evaluation Board Schematic (Blue Traces Indicate High Current Paths)

Figure 87. Overall Layout of the ADP1878/ADP1879 High Current Evaluation Board

Figure 88. Layer 2 of Evaluation Board

Figure 89. Layer 3 of Evaluation Board

Figure 90. Layer 4 (Bottom Layer) of Evaluation Board

## IC SECTION (LEFT SIDE OF EVALUATION BOARD)

A dedicated plane for the analog ground plane (GND) should be separate from the main power ground plane (PGND). With the shortest path possible, connect the analog ground plane to the GND pin (Pin 5). Place this plane on the top layer only of the evaluation board. To avoid crosstalk interference, do not allow any other voltage or current pathway directly below this plane on Layer 2, Layer 3, or Layer 4. Connect the negative terminals of all sensitive analog components to the analog ground plane. Examples of such sensitive analog components include the bottom resistor of the resistor divider, the high frequency bypass capacitor for biasing ( $0.1 \mu \mathrm{~F}$ ), and the compensation network.

Mount a $1 \mu \mathrm{~F}$ bypass capacitor directly across the VREG pin (Pin 7) and the PGND pin (Pin 11). In addition, tie a $0.1 \mu \mathrm{~F}$ across the VREG pin (Pin 7) and the GND pin (Pin 5).

## POWER SECTION

As shown in Figure 87, an appropriate configuration to localize large current transfer from the high voltage input $\left(\mathrm{V}_{\mathrm{IN}}\right)$ to the output ( $\mathrm{V}_{\text {OUT }}$ ) and then back to the power ground is to put the $\mathrm{V}_{\mathrm{IN}}$ plane on the left, the output plane on the right, and the main power ground plane in between the two. Current transfers from the input capacitors to the output capacitors, through Q1/Q2, during the on state (see Figure 91). The direction of this current
(yellow arrow) is maintained as Q1/Q2 turns off and Q3/Q4 turns on. When Q3/Q4 turns on, the current direction continues to be maintained (red arrow) as it circles from the power ground terminal of the bulk capacitor to the output capacitors, through the Q3/Q4. Arranging the power planes in this manner minimizes the area in which changes in flux occur if the current through Q1/Q2 stops abruptly. Sudden changes in flux, usually at the source terminals of Q1/Q2 and the drain terminal of Q3/Q4, cause large $\mathrm{dV} / \mathrm{dt}$ at the SW node.

The SW node is near the top of the evaluation board. The SW node should use the least amount of area possible and be away from any sensitive analog circuitry and components. This is because the SW node is where most sudden changes in flux density occur. When possible, replicate this pad onto Layer 2 and Layer 3 for thermal relief and eliminate any other voltage and current pathways directly beneath the SW node plane. Populate the SW node plane with vias, mainly around the exposed pad of the inductor terminal and around the perimeter of the source of Q1/Q2 and the drain of Q3/Q4.

The output voltage power plane $\left(\mathrm{V}_{\text {oUT }}\right)$ is at the rightmost end of the evaluation board. This plane should be replicated, descending down to multiple layers with vias surrounding the inductor terminal and the positive terminals of the output bulk capacitors. Ensure that the negative terminals of the output capacitors are placed close to the main power ground (PGND), as previously mentioned. All of these points form a tight circle (component geometry permitting) that minimizes the area of flux change as the event switches between D and 1-D.

Figure 91. Primary Current Pathways During the On State of the High-Side MOSFET (Left Arrow) and the On State of the Low-Side MOSFET (Right Arrow)

## DIFFERENTIAL SENSING

Because the ADP1878/ADP1879 operate in valley current-mode control, a differential voltage reading is taken across the drain and source of the low-side MOSFET. Connect the drain of the low-side MOSFET s as close as possible to the SW pin (Pin 13) of the IC. Likewise, connect the source as close as possible to the PGND pin (Pin 11) of the IC. When possible, keep both of these track lines narrow and away from any other active device or voltage/current path.

Figure 92. Drain/Source Tracking Tapping of the Low-Side MOSFET for CS Amp Differential Sensing (Yellow Sense Line on Layer 2)

In addition, employ differential sensing between the outermost output capacitor and the feedback resistor divider (see Figure 89 and Figure 90). Connect the positive terminal of the output capacitor to the top resistor $\left(\mathrm{R}_{\mathrm{T}}\right)$. Connect the negative terminal of the output capacitor to the negative terminal of the bottom resistor, which connects to the analog ground plane as well. Keep both of these track lines, as previously mentioned, narrow and away from any other active device or voltage/ current path.

## TYPICAL APPLICATION CIRCUITS

Figure 93. Application Circuit for 12 V Input, 1.8 V Output, 12 A, 300 kHz (Q2/Q4 No Connect)

### 5.5 V INPUT, 600 kHz CURRENT APPLICATION CIRCUIT

Figure 94. Application Circuit for 5.5 V Input, 2.5 V Output, 12 A, 600 kHz (Q2/Q4 No Connect)

## 300 kHz HIGH CURRENT APPLICATION CIRCUIT

Figure 95. Application Circuit for 13 V Input, 1.8 V Output, 12 A, 300 kHz (Q2/Q4 No Connect)

## PACKAGING AND ORDERING INFORMATION

## OUTLINE DIMENSIONS

Figure 96. 14-Lead Lead Frame Chip Scale Package [LFCSP_WD]
$4 \mathrm{~mm} \times 3 \mathrm{~mm}$ Body, Very Very Thin Dual (CP-14-2)
Dimensions shown in millimeters

## ORDERING GUIDE

| Model $^{1}$ | Temperature Range | Package Description | Package Option |
| :--- | :--- | :--- | :--- |
| ADP1878ACPZ-0.3-R7 $_{\text {ADP1878ACPZ-0.6-R7 }}$ | $-40^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$ | 14-Lead Frame Chip Scale Package [LFCSP_WD] | CP-14-2 |
| ADP1878ACPZ-1.0-R7 | $-40^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$ | 14-Lead Frame Chip Scale Package [LFCSP_WD] | CP-14-2 |
| ADP1878-0.3-EVALZ | $-40^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$ | 14-Lead Frame Chip Scale Package [LFCSP_WD] | CP-14-2 |
| ADP1878-0.6-EVALZ |  | Evaluation Board |  |
| ADP1878-1.0-EVALZ |  | Evaluation Board |  |
| ADP1879ACPZ-0.3-R7 | $-40^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$ | Evaluation Board |  |
| ADP14-Lead Frame Chip Scale Package [LFCSP_WD] | CP-14-2 |  |  |
| ADP1879ACPZ-1.0-R7 | $-40^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$ | $-40^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$ | 14-Lead Frame Chip Scale Package [LFCSP_WD] |
| ADP1879-0.3-EVALZ |  | 14-Lead Frame Chip Scale Package [LFCSP_WD] | CP-14-2 |
| ADP1879-0.6-EVALZ |  | Evaluation Board | CP-14-2 |
| ADP1879-1.0-EVALZ |  | Evaluation Board |  |
| Evaluation Board |  |  |  |

${ }^{1} Z=$ RoHS Compliant Part.
