

## FEATURES

### Maximum temperature coefficient (TCV<sub>OUT</sub>):

- 0.8 ppm/°C (D grade 0°C to 70°C)
- 1 ppm/°C (C grade 0°C to 70°C)
- 2 ppm/°C (B grade –40°C to +125°C)
- 4 ppm/°C (A grade –40°C to +125°C)

### Output noise (0.1 Hz to 10 Hz):

- 1 μV p-p at V<sub>OUT</sub> of 2.048 V typical

### Initial output voltage error:

- B, C, D grade: ±0.02% (maximum)

### Input voltage range: 3 V to 15 V

### Operating temperature:

- A grade and B grade: –40°C to +125°C
- C grade and D grade: 0°C to +70°C

### Output current: +10 mA source/–10 mA sink

### Low quiescent current: 950 μA (maximum)

### Low dropout voltage: 300 mV at 2 mA (V<sub>OUT</sub> ≥ 3 V)

### 8-lead SOIC and LCC package

### AEC-Q100 qualified for automotive applications

### Long-term drift: 8 ppm typical at 4500 hours

## APPLICATIONS

### Precision data acquisition systems

### High resolution data converters

### High precision measurement devices

### Industrial instrumentation

### Medical devices

### Automotive battery monitoring

## GENERAL DESCRIPTION

The ADR4520/ADR4525/ADR4530/ADR4533/ADR4540/ADR4550 devices are high precision, low power, low noise voltage references featuring ±0.02% B, C, and D grade maximum initial error, excellent temperature stability, and low output noise.

This family of voltage references uses an innovative core topology to achieve high accuracy while offering industry-leading temperature stability and noise performance. The low, thermally induced output voltage hysteresis and low long-term output voltage drift of the devices also improve system accuracy over time and temperature variations.

A maximum operating current of 950 μA and a maximum low dropout voltage of 300 mV allow the devices to function very well in portable equipment.

The ADR4520/ADR4525/ADR4530/ADR4533/ADR4540/ADR4550 series of references are each provided in an 8-lead SOIC and are available in a wide range of output voltages, all of which are specified over the extended industrial temperature range of –40°C to +125°C.

### Rev. D

### Document Feedback

Information furnished by Analog Devices is believed to be accurate and reliable. However, no responsibility is assumed by Analog Devices for its use, nor for any infringements of patents or other rights of third parties that may result from its use. ## ABSOLUTE MAXIMUM RATINGS

T<sub>A</sub> = 25°C, unless otherwise noted.

Table 9.

Parameter	Rating
Supply Voltage	16 V
Operating Temperature Range	-40°C to +125°C
ADR4525, ADR4540, ADR4550	0°C to 70°C
C and D Grade Only	
Storage Temperature Range	-65°C to +150°C
Junction Temperature Range	-65°C to +150°C
Electrostatic Discharge (ESD) Human Body Model (HBM)	6 kV
Moisture Sensitivity Level Rating	MSL-1

Stresses at or above those listed under Absolute Maximum Ratings may cause permanent damage to the product. This is a stress rating only; functional operation of the product at these or any other conditions above those indicated in the operational section of this specification is not implied. Operation beyond the maximum operating conditions for extended periods may affect product reliability.

## THERMAL RESISTANCE

Thermal performance is directly linked to printed circuit board (PCB) design and operating environment. Close attention to PCB thermal design is required.

Table 10. Thermal Resistance

Package Type	$\theta_{JA}$	$\theta_{JC}^1$	Unit
8-Lead SOIC <sup>2</sup>			
1-Layer JEDEC Board	N/A <sup>3</sup>	63	°C/W
2-Layer JEDEC Board	120	N/A <sup>3</sup>	°C/W
8- Lead LCC	120	N/A <sup>3</sup>	°C/W

<sup>1</sup> For the  $\theta_{JC}$  test, 100  $\mu$ m thermal interface material (TIM) is used. TIM is assumed to have 3.6 W/mK.

<sup>2</sup> Thermal impedance simulated values are based on a JEDEC thermal test board. See JEDEC JESD51.

<sup>3</sup> N/A means not applicable.

## ESD CAUTION

**ESD (electrostatic discharge) sensitive device.** Charged devices and circuit boards can discharge without detection. Although this product features patented or proprietary protection circuitry, damage may occur on devices subjected to high energy ESD. Therefore, proper ESD precautions should be taken to avoid performance degradation or loss of functionality.

## PIN CONFIGURATIONS AND FUNCTION DESCRIPTIONS

- NOTES
1. NIC = NOT INTERNALLY CONNECTED. THIS PIN IS NOT CONNECTED INTERNALLY.
  2. DNC = DO NOT CONNECT. DO NOT CONNECT TO THIS PIN.

Figure 3. 8-Lead SOIC Pin Configuration

Table 11. 8-Lead SOIC Pin Function Descriptions

Pin No.	Mnemonic	Description
1	NIC	Not Internally Connected. This pin is not connected internally.
2	V <sub>IN</sub>	Input Voltage Connection.
3	NIC	Not Internally Connected. This pin is not connected internally.
4	GND	Ground.
5	NIC	Not Internally Connected. This pin is not connected internally.
6	V <sub>OUT</sub>	Output Voltage.
7	NIC	Not Internally Connected. This pin is not connected internally.
8	DNC	Do Not Connect. Do not connect to this pin.

- NOTES
1. NIC = NOT INTERNALLY CONNECTED. THIS PIN IS NOT CONNECTED INTERNALLY.
  2. DNC = DO NOT CONNECT. DO NOT CONNECT TO THIS PIN.

Figure 4. 8-Lead LCC Pin Configuration

Table 12. 8-Lead LCC Pin Function Descriptions

Pin No.	Mnemonic	Description
1	NIC	Not Internally Connected. This pin is not connected internally.
2	V <sub>IN</sub>	Input Voltage Connection.
3	GND <sub>FORCE</sub>	Ground connection
4	GND <sub>SENSE</sub>	Ground sensing connection. Connect directly to the ground connection of the load device
5	NIC	Not Internally Connected. This pin is not connected internally.
6	V <sub>OUT</sub> <sub>SENSE</sub>	Reference Voltage Output.
7	V <sub>OUT</sub> <sub>FORCE</sub>	Reference Voltage Output sensing connection. Connect directly to the voltage input of the load device
8	DNC	Do Not Connect. Do not connect to this pin.

# TYPICAL PERFORMANCE CHARACTERISTICS

T<sub>A</sub> = 25°C, unless otherwise noted.

## TERMINOLOGY

### Dropout Voltage ( $V_{DO}$ )

Dropout voltage, sometimes referred to as supply voltage headroom or supply output voltage differential, is defined as the minimum voltage differential between the input and output such that the output voltage is maintained to within 0.1% accuracy.

$$V_{DO} = (V_{IN} - V_{OUT})_{min}|_{L = constant}$$

Because the dropout voltage depends on the current passing through the device, it is always specified for a given load current. In series mode devices, the dropout voltage typically increases proportionally to the load current (see Figure 7, Figure 22, Figure 41, Figure 54, Figure 69, and Figure 90).

### Line Regulation

Line regulation refers to the change in output voltage in response to a given change in input voltage and is expressed in percent per volt, ppm per volt, or  $\mu\text{V}$  per volt change in input voltage. This parameter accounts for the effects of self heating.

### Load Regulation

Load regulation refers to the change in output voltage in response to a given change in load current and is expressed in  $\mu\text{V}$  per mA, ppm per mA, or ohms of dc output resistance. This parameter accounts for the effects of self heating.

### Solder Heat Resistance (SHR) Shift

SHR shift refers to the permanent shift in output voltage that is induced by exposure to reflow soldering and is expressed as a percentage of the output voltage. This shift is caused by changes in the stress exhibited on the die by the package materials when these materials are exposed to high temperatures. This effect is more pronounced in lead-free soldering processes due to higher reflow temperatures. SHR is calculated after three solder reflow cycles to simulate the worst case conditions when assembling a two-sided PCB with surface mount components with one additional rework cycle. The reflow cycles use the JEDEC standard reflow temperature profile.

### Temperature Coefficient ( $TCV_{OUT}$ )

The temperature coefficient relates the change in the output voltage to the change in the ambient temperature of the device, as normalized by the output voltage at 25°C. The  $TCV_{OUT}$  for the ADR4520/ADR4525/ADR4530/ADR4533/ADR4540/ADR4550 A grade and B grade is fully tested over three temperatures: -40°C, +25°C, and +125°C. The  $TCV_{OUT}$  for the C grade and D grade is fully tested over three temperatures: 0°C, +25°C, and +70°C. This parameter is specified using two methods. The box method is the most common method and accounts for the temperature coefficient over the full temperature range, whereas the bowtie method calculates the worst case slope from +25°C and is therefore more useful for systems which are calibrated at +25°C.

### Box Method

The box method is represented by the following equation:

$$TCV_{OUT} = \left| \frac{\max\{V_{OUT}(T_1, T_2, T_3)\} - \min\{V_{OUT}(T_1, T_2, T_3)\}}{V_{OUT}(T_2) \times (T_3 - T_1)} \right| \times 10^6$$

where:

$TCV_{OUT}$  is expressed in ppm/°C.

$V_{OUT}(T_x)$  is the output voltage at Temperature  $T_x$ .

$T_1 = -40^\circ\text{C}$ .

$T_2 = +25^\circ\text{C}$ .

$T_3 = +125^\circ\text{C}$ .

This box method ensures that  $TCV_{OUT}$  accurately portrays the maximum difference between any of the three temperatures at which the output voltage of the device is measured.

### Bowtie Method

The bowtie method is represented by the following equation:

$$TCV_{OUT} = |\max\{TCV_{OUT1}, TCV_{OUT2}\}|$$

where:

$$TCV_{OUT1} = \left| \frac{\max\{V_{OUT}(T_1, T_2)\} - \min\{V_{OUT}(T_1, T_2)\}}{V_{OUT}(T_2) \times (T_2 - T_1)} \right| \times 10^6$$

$$TCV_{OUT2} = \left| \frac{\max\{V_{OUT}(T_2, T_3)\} - \min\{V_{OUT}(T_2, T_3)\}}{V_{OUT}(T_2) \times (T_3 - T_2)} \right| \times 10^6$$

$TCV_{OUT}$  is expressed in ppm/°C.

$V_{OUT}(T_x)$  is the output voltage at Temperature  $T_x$ .

$T_1 = 0^\circ\text{C}$ .

$T_2 = +25^\circ\text{C}$ .

$T_3 = +70^\circ\text{C}$ .

### Thermally Induced Output Voltage Hysteresis ( $\Delta V_{OUT\_HYS}$ )

Thermally induced output voltage hysteresis represents the change in the output voltage after the device is exposed to a specified temperature cycle. This is expressed as a difference in ppm from the nominal output.

$$\Delta V_{OUT\_HYS} = \frac{V_{OUT1,25^\circ\text{C}} - V_{OUT2,25^\circ\text{C}}}{V_{OUT,25^\circ\text{C}}} \times 10^6 [\text{ppm}]$$

where:

$V_{OUT1,25^\circ\text{C}}$  is the output voltage at 25°C.

$V_{OUT2,25^\circ\text{C}}$  is the output voltage after temperature cycling.

### Long-Term Stability ( $\Delta V_{OUT\_LTD}$ )

Long-term stability refers to the shift in the output voltage versus time. This is expressed as a difference in ppm from the nominal output.

$$\Delta V_{OUT\_LTD} = \left| \frac{V_{OUT}(t_1) - V_{OUT}(t_0)}{V_{OUT}(t_0)} \right| \times 10^6 [\text{ppm}]$$

where:

$V_{OUT}(t_0)$  is the  $V_{OUT}$  at the starting time of the measurement.

$V_{OUT}(t_1)$  is the  $V_{OUT}$  at the end time of the measurement.

## APPLICATIONS INFORMATION

### BASIC VOLTAGE REFERENCE CONNECTION

The circuit shown in Figure 107 shows the basic configuration for the ADR4520/ADR4525/ADR4530/ADR4533/ADR4540/ADR4550 family of voltage references.

Figure 107. ADR4520/ADR4525/ADR4530/ADR4533/ADR4540/ADR4550 Simplified Schematic

### INPUT AND OUTPUT CAPACITORS

#### Input Capacitors

A 1  $\mu\text{F}$  to 10  $\mu\text{F}$  electrolytic or ceramic capacitor can be connected to the input to improve transient response in applications where the supply voltage may fluctuate. It is recommended to connect an additional 0.1  $\mu\text{F}$  ceramic capacitor in parallel to reduce supply noise.

#### Output Capacitors

An output capacitor is required for stability and to filter out low level voltage noise. The minimum value of the output capacitor ( $C_{\text{OUT}}$ ) is shown in Table 13.

Table 13. Minimum  $C_{\text{OUT}}$  Value

Part Number	Minimum $C_{\text{OUT}}$ Value
ADR4520, ADR4525	1.0 $\mu\text{F}$
ADR4530, ADR4533, ADR4540, ADR4550	0.1 $\mu\text{F}$

An additional 1  $\mu\text{F}$  to 10  $\mu\text{F}$  electrolytic or ceramic capacitor can be added in parallel to improve transient performance in response to sudden changes in load current; however, doing so increases the turn-on time of the device.

### LOCATION OF REFERENCE IN SYSTEM

It is recommended to place the ADR4520/ADR4525/ADR4530/ADR4533/ADR4540/ADR4550 reference as close to the load as possible to minimize the length of the output traces and, therefore, the error introduced by the voltage drop. Current flowing through a PCB trace produces a voltage drop; with longer traces, this drop can reach several millivolts or more, introducing considerable error into the output voltage of the reference. A 1-inch long, 5 mm wide trace of 1-ounce copper has a resistance of approximately 100 m $\Omega$  at room temperature; at a load current of 10 mA, this resistance can introduce a full millivolt of error.

### POWER DISSIPATION

The ADR4520/ADR4525/ADR4530/ADR4533/ADR4540/ADR4550 voltage references are capable of sourcing and sinking up to 10 mA of load current at room temperature across the rated input voltage range. However, when used in applications subject to high ambient temperatures, the input voltage and load current must be monitored carefully to ensure that the device does not exceed its maximum power dissipation rating. The maximum power dissipation of the device can be calculated using the following equation:

$$P_D = \frac{T_J - T_A}{\theta_{JA}}$$

where:

$P_D$  is the device power dissipation.

$T_J$  is the device junction temperature.

$T_A$  is the ambient temperature.

$\theta_{JA}$  is the package (junction to air) thermal resistance.

This relationship can cause acceptable load current in high temperature conditions to be less than the maximum current sourcing capability of the device. Do not operate the device outside of its maximum power rating, because doing so can result in premature failure or permanent damage to the device.

### SAMPLE APPLICATIONS

#### Bipolar Output Reference

Figure 108 shows a bipolar reference configuration. By connecting the output of the ADR4550 to the inverting terminal of an operational amplifier, it is possible to obtain both positive and negative reference voltages. R1 and R2 must be matched as closely as possible to ensure minimal difference between the negative and positive outputs. Resistors with low temperature coefficients must also be used if the circuit is deployed in environments with large temperature swings; otherwise, a voltage difference develops between the two outputs as the ambient temperature changes.

Figure 108. ADR4550 Bipolar Output Reference

**Boosted Output Current Reference**

Figure 109 shows a configuration for obtaining higher current drive capability from the ADR4520/ADR4525/ADR4530/ADR4533/ADR4540/ADR4550 references without sacrificing accuracy. The op amp regulates the current flow through the metal-oxide semiconductor field effect transistor (MOSFET) until  $V_{OUT}$  equals the output voltage of the reference; current is then drawn directly from  $V_{IN}$  instead of from the reference itself, allowing increased current drive capability.

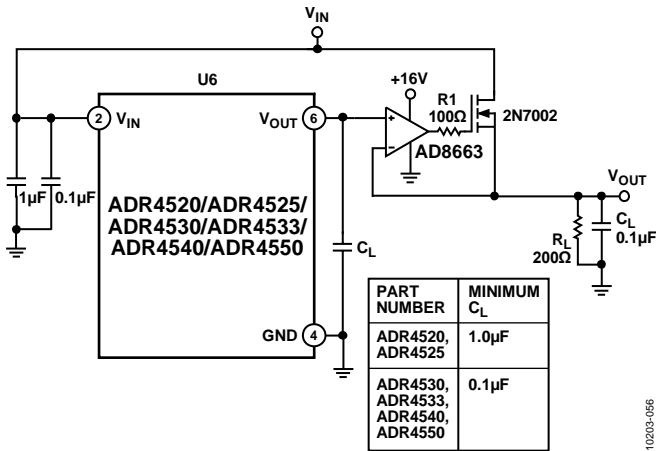

Figure 109. Boosted Output Current Reference

Because the current sourcing capability of this circuit depends only on the current rating of the MOSFET, the output drive capability can be adjusted to the application simply by choosing an appropriate MOSFET. In all cases, tie the  $V_{OUT}$  pin directly to the load device to maintain maximum output voltage accuracy.

**LONG-TERM DRIFT**

The stability of a precision signal path over its lifetime or between calibration procedures is dependent on the long-term stability of the analog components in the path, such as op amps, references, and data converters. To help system designers predict the long-term drift of circuits that use the ADR4520/ADR4525/ADR4530/ADR4533/ADR4540/ADR4550, Analog Devices measured the output voltage of multiple units for more than 4500 hours (more than 6 months) using a high precision measurement system, including an ultrastable oil bath. To replicate real-world system performance, the devices under test (DUTs) were soldered onto an FR4 PCB using a standard reflow profile (as defined in the JEDEC J-STD-020D standard), rather than testing them in sockets. This manner of testing is important because expansion and contraction of the PCB can apply stress to the integrated circuit (IC) package and contribute to shifts in the offset voltage.

Figure 110 shows the long-term drift of the ADR4520/ADR4525/ADR4530/ADR4533/ADR4540/ADR4550. Sample 1, Sample 2, and Sample 3 plot traces show sample units. The mean drift after 4500 hours is 51 ppm. Note that the early life drift (0 hours to 250 hours) accounts for 40% of the total drift observed over 4500 hours, as shown in Figure 111. The first 1000 hours account for 50% of the total drift, and the remaining

3500 hours account for the remaining 50% of the drift. Thus, the early life drift is the dominant contributor, whereas the drift after 1000 hours is significantly lower.

Figure 110. Measured Long-Term Drift of the ADR4520/ADR4525/ADR4530/ADR4533/ADR4540/ADR4550 over 4,500 Hours

Figure 111. Measured Early Life Drift of the ADR4520/ADR4525/ADR4530/ADR4533/ADR4540/ADR4550

Figure 112. Measured Long-Term Drift of the ADR4525D/ADR4540D/ADR4550D over 4,500 Hours

**THERMAL HYSTERESIS**

In addition to stability over time, as described in the Long-Term Drift section, it is useful to know the thermal hysteresis, that is, the stability vs. cycling of temperature. Thermal hysteresis is an important parameter because it tells the system designer how closely the signal returns to its starting amplitude after the ambient temperature changes and the subsequent return to room temperature. Figure 113 shows the change in output voltage as the temperature cycles three times from room temperature to +125°C to -40°C and back to room temperature.

In the three full cycles, the output hysteresis is typically -13 ppm. The histogram in Figure 114 shows that the hysteresis is larger when the device is cycled through only a half cycle, from room temperature to 125°C and back to room temperature, typically -97 ppm.

Figure 113. Change in Output Voltage over Three Full Temperature Cycles (-40°C to +125°C)

Figure 114. Histogram Showing the Temperature Hysteresis of the Output Voltage (-40°C to +125°C)

Figure 115 shows the change in input offset voltage as the temperature cycles three times from room temperature to +70°C to 0°C and back to room temperature. In the three full cycles, the output hysteresis is typically -8 ppm. The histogram in Figure 116 shows that the hysteresis is larger when the device is cycled through only a half cycle, from room temperature to +70°C and back to room temperature, typically -17 ppm.

Figure 115. Change in Output Voltage over Three Full Temperature Cycles (0°C to 70°C)

Figure 116. Histogram Showing the Temperature Hysteresis of the Output Voltage (0°C to 70°C)

Figure 117. D Grade Change in Output Voltage over Three Full Temperature Cycles (0°C to 70°C)

Figure 118. D Grade Histogram Showing the Temperature Hysteresis of the Output Voltage (0°C to 70°C)

Measuring thermal hysteresis over the full operating temperature range is not reflective of a typical operating environment in most applications. Instead, smaller temperature variations are more normal. The ADR4520/ADR4525/ADR4530/ADR4533/ADR4540/ADR4550 were tested over 20 different temperature cycles of increasing magnitude, centered at +25°C, starting with +25°C ± 5°C and going up to the full operating temperature range of -40°C to +125°C. The results are shown in Figure 119.

For a temperature delta of 100°C (that is, +25°C ± 50°C) the thermal hysteresis is less than 20 ppm for both the full cycle and the half cycle. Above this range, the thermal hysteresis increases significantly. These results show that the standard specification, which covers the full operating temperature range, is close to the worst case performance.

Figure 119. Thermal Hysteresis for Increasing Temperature Range

### HUMIDITY SENSITIVITY

The ADR4520/ADR4525/ADR4530/ADR4533/ADR4540/ADR4550 is packaged in a SOIC plastic package and has a moisture sensitivity level of MSL-1, per the JEDEC standard. However, moisture absorption from the air into the package changes the internal mechanical stresses on the die causing shifts in the output voltage. Figure 120 shows the effects of a step change in relative humidity on the output voltage over time.

The humidity chamber is maintained at an ambient temperature of +25°C, while the relative humidity undergoes a step change from 20% to 80% at time zero. The relative humidity is maintained at 80% for the duration of the testing. Note that the output voltage shifts quickly compared to the overall settling time, following the step change in relative humidity.

Figure 121 shows the effects of 10% increases in relative humidity from 30% to 70% and back to 30%. Note that after the relative humidity returns to 30%, the output voltage is settling back to its starting point.

Figure 120. Change in Output Voltage vs. Time After Humidity Step Change (20% to 80% Relative Humidity)

Figure 121. Change in Output Voltage vs. Time for 10% Humidity Steps (30% to 70% to 30% Relative Humidity in 10% Steps)

**POWER CYCLE HYSTERESIS**

By power cycling large numbers of samples, the power cycle hysteresis can be determined. To keep this measurement independent of other variables and environmental effects, the power cycle testing was performed using a high precision measurement system, including an ultrastable oil bath.

Figure 122 shows the power cycle hysteresis. The units were powered down for approximately four hours and then powered up. The ADR4520/ADR4525/ADR4530/ADR4533/ADR4540/ADR4550 do not have any power cycle hysteresis even after a long power-down period, making these devices very suitable for equipment which must maintain its calibration accuracy between power cycles.

<sup>1</sup> Z = RoHS Compliant Part.

<sup>2</sup> W = Qualified for Automotive Applications. See the Automotive Products section.

**AUTOMOTIVE PRODUCTS**

The ADR4525W model is available with controlled manufacturing to support the quality and reliability requirements of automotive applications. Note that this automotive model may have specifications that differ from the commercial models; therefore, designers should review the Specifications section of this data sheet carefully. Only the automotive grade product shown is available for use in automotive applications. Contact your local Analog Devices account representative for specific product ordering information and to obtain the specific Automotive Reliability reports for this model.
