## Isolated, Half Bridge Gate Drivers with Adjustable Dead Time, 4 A Output

## FEATURES

4 A peak current ( $<2 \Omega$ RDson_x)
2.5 V to 6.5 V logic input voltage
4.5 V to 35 V output supply voltage

UVLO V ${ }_{\text {DD } 1}$ positive going threshold: 2.5 V maximum
Multiple UVLO options for $V_{\text {DDA }}$ and $V_{\text {DDB }}$ positive going threshold
Grade A: 4.5 V maximum
Grade B: 7.5 V maximum
Grade C: 11.6 V maximum
Precise timing characteristics
44 ns maximum propagation delay
Adjustable dead time and dual input (ADuM4221)
Adjustable dead time and single input (ADuM4221-1)
No dead time control and dual input (ADuM4221-2)
CMOS input logic levels
High common-mode transient immunity: 150 kV/ $\mu \mathrm{s}$
High junction temperature operation: $\mathbf{1 2 5}^{\circ} \mathrm{C}$
Default low output
Safety and regulatory approvals (pending)
UL recognition per UL 1577
5700 V rms for 1 minute duration
CSA Component Acceptance Notice 5A
VDE certificate of conformity
DIN V VDE V 0884-11: VIorm = 849 V peak
Increased creepage wide body, 16-lead SOIC_IC

## APPLICATIONS

Switching power supplies
Isolated IGBT/MOSFET gate drives
Industrial inverters
Gallium nitride (GaN)/silicon carbide (SiC) compatible

## GENERAL DESCRIPTION

The ADuM4221/ADuM4221-1/ADuM4221-2 are 4 A isolated, half bridge gate drivers that employ the Analog Devices, Inc., iCoupler technology to provide independent and isolated high-side and low-side outputs. The ADuM4221/ADuM4221-1/ ADuM4221-2 provide 5700 V rms isolation in an increased creepage wide body, 16-lead SOIC_IC. Combining high speed CMOS and monolithic transformer technology, these isolation components provide outstanding performance characteristics superior to the alternatives, such as the combination of pulse transformers and gate drivers.

The isolators operate with a logic input voltage ranging from 2.5 V to 6.5 V , providing compatibility with lower voltage systems. In comparison to gate drivers employing high voltage level translation methodologies, the ADuM4221/ADuM4221-1/ ADuM4221-2 offer the benefit of true, galvanic isolation between the input and each output.

The ADuM4221/ADuM4221-1 each have built in overlap protection and allow dead time adjustment. A single resistor between the dead time pin (DT) and the $\mathrm{GND}_{1}$ pin sets the dead time on the secondary side between the high-side and the low-side outputs. The ADuM4221-2 does not have overlap protection nor dead time control.

An internal thermal shutdown (TSD) sets outputs low if the internal temperature on the ADuM4221/ADuM4221-1/ ADuM4221-2 exceeds the TSD temperature. As a result, the ADuM4221/ADuM4221-1/ADuM4221-2 provide reliable control over the switching characteristics of the insulated gate bipolar transistor (IGBT)/metal-oxide semiconductor field effect transistor (MOSFET) configurations over a wide range of positive or negative switching voltages.

| Peak Current | $\mathrm{I}_{\text {Peak }}$ |  | 4 |  | A | $V_{\text {DDA }}, \mathrm{V}_{\text {DDB }}=15 \mathrm{~V}, 2 \Omega$ gate resistance |

 measured from the input falling logic low threshold, $\mathrm{V}_{\mathrm{L}}$, to the output falling $90 \%$ threshold of the Vox signal. See Figure 33 for the waveforms of the propagation delay parameters.
${ }^{2}$ tpSK is the magnitude of the worst case difference in $t_{\text {DLH }}$ and/or $t_{\text {DHL }}$ that is measured between units at the same operating temperature, supply voltages, and output load within the recommended operating conditions. See Figure 33 for the waveforms of the propagation delay parameters.
${ }^{3}$ Channel to channel matching is the absolute value of the difference in propagation delays between two channels on a single device.

| File E214100 | File 205078 | File 2471900-4880-0003 | File (pending) |

${ }^{1}$ In accordance with UL 1577, each ADuM4221/ADuM4221-1/ADuM4221-2 is proof tested by applying an insulation test voltage $\geq 6840 \mathrm{Vrms}$ for 1 sec.
${ }^{2}$ In accordance with DIN VDE $V$ 0884-11, each ADuM4221/ADuM4221-1/ADuM4221-2 is proof tested by applying an insulation test voltage $\geq 1592 \mathrm{~V}$ peak for 1 sec (partial discharge detection limit $=5 \mathrm{pC}$ ). The * marking branded on the component designates DIN VDE V 0884-11 approval.

## INSULATION AND SAFETY RELATED SPECIFICATIONS

Table 4.

| Parameter | Symbol | Value | Unit | Test Conditions/Comments |
| :---: | :---: | :---: | :---: | :---: |
| Rated Dielectric Insulation Voltage |  | 5700 | V rms | 1-minute duration |
| Minimum External Air Gap (Clearance) | L (101) | 8.3 | mm | Measured from input terminals to output terminals, shortest distance through air |
| Minimum External Tracking (Creepage) | L (102) | 8.3 | mm | Measured from input terminals to output terminals, shortest distance path along body |
| Minimum Clearance in the Plane of the Printed Circuit Board, PCB (PCB Clearance) | L (PCB) | 8.3 | mm | Measured from input terminals to output terminals, shortest distance through air, line of sight, in the PCB mounting plane |
| Minimum Internal Gap (Internal Clearance) |  | 25.5 | $\mu \mathrm{m}$ | Insulation distance through insulation |
| Tracking Resistance (Comparative Tracking Index) | CTI | >600 | V | DIN IEC 112/VDE 0303 Part 1 |
| Material Group |  | I |  | Material Group (DIN VDE 0110, 1/89, Table 1) |

## DIN V VDE V 0884-11 (VDE V 0884-11) INSULATION CHARACTERISTICS

This isolator is suitable for reinforced isolation only within the safety limit data. Protective circuits ensure maintenance of the safety data.
Table 5. VDE Characteristics

| Description | Test Conditions/Comments | Symbol | Characteristic | Unit |
| :---: | :---: | :---: | :---: | :---: |
| Installation Classification per DIN VDE 0110 |  |  |  |  |
| For Rated Mains Voltage $\leq 150 \mathrm{~V}$ rms |  |  | Ito IV |  |
| For Rated Mains Voltage $\leq 300 \mathrm{~V}$ rms |  |  | I to IV |  |
| For Rated Mains Voltage $\leq 600 \mathrm{~V}$ rms |  |  | I to IV |  |
| Climatic Classification |  |  | 40/105/21 |  |

Figure 4. Thermal Derating Curve, Dependence of Safety Limiting Values on Case Temperature, per DIN V VDE V 0884-11

## RECOMMENDED OPERATING CONDITIONS

Table 6.

| Parameter | Value |
| :---: | :---: |
| TJ | $-40^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$ |
| Supply Voltages |  |
| $\mathrm{V}_{\text {DD1 }}{ }^{1}$ | 2.5 V to 6.5 V |
| $V_{\text {DDA }}$ and $\mathrm{V}_{\text {DDB }}{ }^{2}$ | 4.5 V to 35 V |
| Common-Mode Transient Immunity |  |
| Static ${ }^{3}$ | $-150 \mathrm{kV} / \mu \mathrm{s}$ to $+150 \mathrm{kV} / \mu \mathrm{s}$ |
| Dynamic ${ }^{4}$ | $-150 \mathrm{kV} / \mu \mathrm{s}$ to $+150 \mathrm{kV} / \mu \mathrm{s}$ |
| Dead Time Resistor Range | $10 \mathrm{k} \Omega$ to $500 \mathrm{k} \Omega$ |

${ }^{1}$ Referenced to GND ${ }_{1}$.
${ }^{2}$ Referenced to $\mathrm{GND}_{\mathrm{A}}$ and $\mathrm{GND}_{\mathrm{B}}$.
${ }^{3}$ Static common-mode transient immunity is defined as the largest $\mathrm{dv} / \mathrm{dt}$ between $\mathrm{GND}_{1}$ and $\mathrm{GND}_{\mathrm{A}}$ and $\mathrm{GND}_{\mathrm{B}}$ with the inputs held either high or low such that the output voltage remains either above $0.8 \times V_{D D A}$ and $V_{D D B}$ for output high or 0.8 V for output low. Operation with transients above recommended levels can cause momentary data upsets.
${ }^{4}$ Dynamic common-mode transient immunity is defined as the largest dv/dt between $\mathrm{GND}_{1}$ and $\mathrm{GND}_{\mathrm{A}}$ and $\mathrm{GND}_{\mathrm{B}}$ with the switching edge coincident with the transient test pulse. Operation with transients above recommended levels can cause momentary data upsets.

## ABSOLUTE MAXIMUM RATINGS

$\mathrm{T}_{\mathrm{A}}=25^{\circ} \mathrm{C}$, unless otherwise noted.
Table 7.

| Parameter | Rating |
| :---: | :---: |
| Voltage Ranges |  |
| Supply |  |
| VDD1 | -0.2 V to +7 V |
| $V_{\text {DDA }}$ and $V_{\text {DDB }}$ | -0.3 V to +40 V |
| Input ${ }^{1}\left(\mathrm{~V}^{\text {A }}\right.$, $\mathrm{V}^{1 B}$, PWM, and DISABLE) | -0.3 V to +7 V |
| Output ${ }^{2}$ |  |
| $V_{\text {OA }}$ | -0.3 V to $\mathrm{V}_{\text {DDA }}+0.3 \mathrm{~V}$ |
| $V_{\text {ob }}$ | -0.3 V to $\mathrm{V}_{\text {DDB }}+0.3 \mathrm{~V}$ |
| VoA Transient for 200 ns | -2 V to $\mathrm{V}_{\mathrm{DDA}}+0.3 \mathrm{~V}$ |
| Vов Transient for 200 ns | -2 V to $\mathrm{V}_{\text {DDB }}+0.3 \mathrm{~V}$ |
| Temperature Range |  |
| Storage ( $\mathrm{T}_{\text {ST }}$ ) | $-55^{\circ} \mathrm{C}$ to $+150^{\circ} \mathrm{C}$ |
| TJ | $-40^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$ |
| Common-Mode Transients ${ }^{3}$ ( $\mathrm{CM}_{\mathrm{H},}$ CML) | $\begin{aligned} & -200 \mathrm{kV} / \mathrm{\mu s} \text { to } \\ & +200 \mathrm{kV} / \mu \mathrm{s} \end{aligned}$ |

${ }^{1}$ Rating assumes $\mathrm{V}_{\mathrm{DDI}}$ is above $2.5 \mathrm{~V} . \mathrm{V}_{1 \mathrm{~A}}, \mathrm{~V}_{1 B}$, and PWM are rated up to 6.5 V when $V_{D D 1}$ is unpowered.
${ }^{2}$ Referenced to $\mathrm{GND}_{\mathrm{A}}$ or $\mathrm{GND}_{\mathrm{B}}$, maximum of 40 V .
${ }^{3}$ Refers to the common-mode transients across the insulation barrier. Common-mode transients exceeding the absolute maximum rating can cause latch-up or permanent damage.

Stresses at or above those listed under Absolute Maximum Ratings may cause permanent damage to the product. This is a stress rating only; functional operation of the product at these or any other conditions above those indicated in the operational section of this specification is not implied. Operation beyond the maximum operating conditions for extended periods may affect product reliability.

## THERMAL RESISTANCE

Thermal performance is directly linked to the PCB design and operating environment. Careful attention to PCB thermal design is required.
$\theta_{\mathrm{JA}}$ is the junction to ambient thermal resistance, and $\Psi_{\text {JT }}$ is the junction to top characterization parameter.

Table 8. Thermal Resistance

| Package Type $^{1}$ | $\boldsymbol{\theta}_{\mathrm{JA}}$ | $\boldsymbol{\Psi}_{\text {JT }}$ | Unit |
| :--- | :--- | :--- | :--- |
| RI-16-2 | 45 | 16.67 | ${ }^{\circ} \mathrm{C} / \mathrm{W}$ |
| ${ }^{1}$ 4-layer PCB. |  |  |  |

## ESD CAUTION

|  | ESD (electrostatic discharge) sensitive device. <br> Charged devices and circuit boards can discharge <br> without detection. Although this product features <br> patented or proprietary protection circuitry, damage <br> may occur on devices subjected to high energy ESD. <br> Therefore, proper ESD precautions should be taken to <br> avoid performance degradation or loss of functionality. |
| :--- | :--- |

Table 9. Maximum Continuous Working Voltage ${ }^{1}$

| Parameter | Rating | Unit | Constraint |
| :--- | :--- | :--- | :--- |
| AC Voltage |  |  |  |
| $\quad$ Bipolar Waveform | 900 | V peak | 20 year minimum insulation lifetime per VDE-0884-11 |
| $\quad$ Basic Insulation | Reinforced Insulation | 849 | V peak |
| 20 year minimum insulation lifetime per VDE-0884-11 |  |  |  |
| DC Voltage | 1660 | V peak | Lifetime limited by package creepage maximum approved working voltage per IEC 60664-1, <br> Basic Insulation |
| Reilution Degree 2, Material Group I |  |  |  |
| Reinforced Insulation | 830 | V peak | Lifetime limited by package creepage maximum approved working voltage per IEC 60664-1, <br> Pollution Degree 2, Material Group I |

[^2]
## PIN CONFIGURATIONS AND FUNCTION DESCRIPTIONS

Table 10. ADuM4221 Pin Function Descriptions

| Pin No. ${ }^{1}$ | Mnemonic | Description |
| :---: | :---: | :---: |
| 1 | $V_{\text {IA }}$ | Logic Input A. |
| 2 | $V_{\text {IB }}$ | Logic Input B. |
| 3,8 | $V_{\text {DD1 }}$ | Input Supply Voltage. |
| 4 | $\mathrm{GND}_{1}$ | Ground Reference for Input Logic Signals. |
| 5 | DISABLE | Input Disable. The DISABLE pin disables the isolator inputs and refresh circuits. |
| 6 | DT | Dead Time Control Input. The resistor connected from the DT pin to ground sets the dead time between the output transitions. |
| 7,12,13 | NC | No Connect. Do not connect to these pins. |
| 9 | $\mathrm{GND}_{\text {B }}$ | Ground Reference for Output B. |
| 10 | $\mathrm{V}_{\text {ов }}$ | Output B. |
| 11 | $V_{\text {DDB }}$ | Output B Supply Voltage. |
| 14 | $\mathrm{GND}_{\text {A }}$ | Ground Reference for Output A. |
| 15 | $V_{O A}$ | Output A. |
| 16 | VDDA | Output A Supply Voltage. |

${ }^{1}$ Pin 3 and Pin 8 are internally connected. Connecting both the $V_{D D 1}$ pins to the $V_{D D 1}$ input supply is recommended.

Table 11. ADuM4221 Truth Table (Positive Logic with Dead Time)

## THEORY OF OPERATION

Gate drivers are required where fast rise times of switching device gates are desired. The gate signal for most enhancement type power devices is referred to a source or emitter node. The gate driver must have the ability to follow this source or emitter node, necessitating isolation between the controlling signal and the output of the gate driver in topologies where the source or emitter nodes swing, such as a half bridge. Gate switching times are a function of the drive strength of the gate driver. Buffer stages before a CMOS output reduce the total delay time and increase the final drive strength of the driver.
The ADuM4221/ADuM4221-1/ADuM4221-2 each achieve isolation between the control side and output side of the gate driver by means of a high frequency carrier that transmits data across the isolation barrier using $i$ Coupler chip scale transformer coils separated by layers of polyimide isolation. The encoding
scheme used by the ADuM4221/ADuM4221-1/ADuM4221-2 is a positive logic on/off keying (OOK), a high signal transmitted by the presence of the carrier frequency across the iCoupler chip scale transformer coils. Positive logic encoding ensures that a low signal is seen on the output when the input side of the gate driver is unpowered. A low state is the most common safe state in enhancement mode power devices, driving in situations where shoot through conditions can exist. The architecture is designed for high common-mode transient immunity and high immunity to electrical noise and magnetic interference. Radiated emissions are minimized with a spread spectrum OOK carrier and other techniques such as differential coil layout. Figure 31 illustrates the OOK encoding used by the ADuM4221/ADuM4221-1/ADuM4221-2.

Figure 31. Operational Block Diagram of OOK Encoding (VIN Is the Input Voltage, $G N D_{2}$ is $G N D_{A}$ or $G N D_{B,}$ and Vout Is the Output Voltage.)

## APPLICATIONS INFORMATION

## PCB LAYOUT

The ADuM4221/ADuM4221-1/ADuM4221-2 require no external interface circuitry for the logic interfaces. Power supply bypassing is required at the input and output supply pins (see Figure 32). Use a small ceramic capacitor with a value between $0.01 \mu \mathrm{~F}$ and $0.1 \mu \mathrm{~F}$ to provide a good high frequency bypass. On the output power supply pin, $V_{\text {DDA }}$ or $V_{D D B}$, it is also recommended to add a $10 \mu \mathrm{~F}$ capacitor to provide the charge required to drive the gate capacitance at the ADuM4221/ ADuM4221-1/ADuM4221-2 outputs. On the output supply pin, avoid the use of vias with a bypass capacitor or use multiple vias to reduce the inductance in the bypassing. The total lead length between both ends of the smaller capacitor and the input or output power supply pin must be as short as possible.

Figure 32. ADuM4221/ADum4221-1/ADuM4221-2 Recommended PCB Layout (Note Pin 6 Is NC for the ADuM4221-2)

## PROPAGATION DELAY-RELATED PARAMETERS

The propagation delay parameter describes the time it takes a logic signal to propagate through a component. The propagation delay to a logic low output can differ from the propagation delay to a logic high output. The ADuM4221/ADuM4221-1/ ADuM4221-2 specify the rising edge propagation delay ( $\mathrm{t}_{\text {DLH }}$ ) as the time between the rising input high logic threshold $\left(\mathrm{V}_{\text {IH }}\right)$ to the output rising ( $\mathrm{t}_{\mathrm{R}}$ ) $10 \%$ threshold (see Figure 33). Likewise, the falling edge propagation delay ( $\mathrm{t}_{\mathrm{DHL}}$ ) is the time between the input falling logic low threshold $\left(\mathrm{V}_{\text {II }}\right)$ and the output falling $\left(\mathrm{t}_{\mathrm{F}}\right)$ $90 \%$ threshold. The rise and fall times are dependent on the loading conditions and are not included in the propagation delay, which is the industry standard for gate drivers.

Figure 33. Propagation Delay Parameters
Channel to channel matching is the maximum amount that the propagation delay differs between channels within a single component.
Propagation delay skew is the maximum amount that the propagation delay differs between multiple components operating under the same conditions.

## PEAK CURRENT RATING

The ADuM4221/ADuM4221-1/ADuM4221-2 each have two output channels, and each channel connects to the gate of the power device through an external series gate resistor. The output driver MOSFETs of the gate driver IC can source or sink more than 6 A (per $\mathrm{V}_{\mathrm{OA}}$ and $\mathrm{V}_{\mathrm{OB}}$ ). In a practical application, to control the drive strength and to spread the power dissipation of driving the gate to outside of the gate driver IC, standard external series gate resistors are used. The output current of the gate driver is shown in Figure 28 of the Typical Performance Characteristics section.

## PROTECTION FEATURES

## TSD

If the internal temperature of the ADuM4221/ADuM4221-1/ ADuM4221-2 exceeds $155^{\circ} \mathrm{C}$ (typical), these devices enter TSD. During the TSD time, the gate drive is disabled and the outputs, $V_{\mathrm{OA}}$ and $\mathrm{V}_{\mathrm{OB}}$, are driven low. When TSD occurs, the devices do not leave TSD until the internal temperature drops below $125^{\circ} \mathrm{C}$ (typical), at which time, the devices exit shutdown.

## UVLO

The ADuM4221/ADuM4221-1/ADuM4221-2 each have UVLO protections for both the primary and secondary side of the devices. If either the primary or secondary side voltages are below the falling edge UVLO, the devices output a low signal. After the ADuM4221/ADuM4221-1/ADuM4221-2 are powered above the rising edge UVLO threshold, the devices output the signal found at the input. To account for small voltage source ripple, hysteresis is built into the UVLO. The primary side UVLO thresholds are common among all models.

## OUTPUT LOAD CHARACTERISTICS

The output signals depend on the characteristics of the output load, which is typically an N channel MOSFET. The driver output response to an N channel MOSFET load with a gate voltage ( $\mathrm{V}_{\mathrm{GATE}}$ ) can be modeled with a switch output resistance ( $\mathrm{R}_{\mathrm{sw}}$ ), an inductance due to the PCB trace ( $\mathrm{L}_{\text {TRACE }}$ ), a series gate resistor ( $\mathrm{R}_{\mathrm{GATE}}$ ), and a gate to source capacitance $\left(\mathrm{C}_{G S}\right)$, as shown in Figure 34.

Figure 34. Resistor, Inductor, and Capacitor (RLC) Model of the Gate of an N Channel MOSFET
$\mathrm{R}_{\mathrm{sw}}$ is the switch resistance of the internal driver output, which is approximately $2 \Omega$. R Rate is the intrinsic gate resistance of the MOSFET and any external series resistance. A MOSFET that requires a 4 A gate driver has a typical intrinsic gate resistance of approximately $1 \Omega$ and a $C_{G S}$ of between 2 nF and 10 nF . $L_{\text {trace }}$ is the inductance of the PCB trace, typically a value of 5 nH or less for a well designed layout with a short and wide connection from the ADuM4221/ADuM4221-1/ADuM4221-2 output to the gate of the MOSFET. The following equation defines the Q factor of the RLC circuit, which indicates how the output responds to a step change. For a well damped output, Q is less than 1.

$$
Q=\frac{1}{\left(R_{S W}+R_{G A T E}\right)} \times \sqrt{\frac{L_{T R A C E}}{C_{G S}}}
$$

Output ringing is reduced by adding a series gate resistance to dampen the response. The waveforms in Figure 8 show a correctly damped example with a 2 nF load and a $3.9 \Omega$ external series gate resistor. The waveforms in Figure 9 show an underdamped example with a 2 nF load and a $0 \Omega$ external series gate resistor.

## ADJUSTABLE DEAD TIME CONTROL

The ADuM4221/ADuM4221-1 include overlap protection such that the gate driver outputs ( $\mathrm{V}_{\mathrm{OA}}$ and $\mathrm{V}_{\mathrm{OB}}$ ) cannot simultaneously go high even if both inputs are high. Additionally, the ADuM4221/ ADuM4221-1 also have a dead time control pin (DT) that can adjust the delay between the output high-side and low-side transitions by using a single resistor between the DT pin and ground (see Figure 38). The relationship between the dead time resistor $\left(\mathrm{R}_{\mathrm{DT}}\right)$ and the obtained dead time is shown in Figure 35.

Figure 35. Dead Time vs. $R_{D T}$
Use the following equation to calculate the required amount of dead time:

$$
D T(\mathrm{~ns}) \approx 5 \times R_{D T}(\mathrm{k} \Omega)
$$

The $V_{O A}$ and $V_{\text {OB }}$ pins react to the $V_{\text {IA }}$ and $V_{\text {IB }}$ pins for the ADuM4221 only or the PWM pin for the ADuM4221-1 only depending on the dead time value set by the $\mathrm{R}_{\mathrm{DT}}$ resistor. The DT pin controls the edge transitions between $\mathrm{V}_{\mathrm{OA}}$ and $\mathrm{V}_{\mathrm{OB}}$. Dead time only affects the rising edge transition of the gate drive signal, and the dead time operation is shown in Figure 36 for the ADuM4221 and in Figure 37 for the ADuM4221-1.

Figure 36. Dead Time Operation for the Different Input Transitions for the ADuM4221

Figure 37. Dead Time Operation for the Different Input Transitions for the ADuM4221-1

## BOOTSTRAPPED, HALF BRIDGE OPERATION

The ADuM4221/ADuM4221-1/ADuM4221-2 are well suited for operating two output gate signals referenced to separate grounds, as in the case for a half bridge configuration. Because isolated auxiliary supplies are often expensive, it is beneficial to reduce the amount of supplies.

One method to reduce power supplies is to use a bootstrapped configuration for the high-side supply of the ADuM4221 (see Figure 38). A similar setup can also be obtained for the ADuM4221-1/ADuM4221-2. In this topology, the decoupling
capacitor $\left(\mathrm{C}_{\mathrm{A}}\right)$ acts as the energy storage for the high-side supply and is filled whenever the low-side switch is closed, bringing $\mathrm{GND}_{\mathrm{A}}$ to $\mathrm{GND}_{\mathrm{B}}$. During the $\mathrm{C}_{\mathrm{A}}$ charging time, control the dv/dt of the V $\mathrm{V}_{\text {DA }}$ voltage to reduce the possibility of glitches on the output. To control the dv/dt of the VDDA voltage, introduce a series resistance ( $\mathrm{R}_{\text {воот }}$ ) into the $\mathrm{C}_{\mathrm{A}}$ charging path.

Note that in Figure 38, $\mathrm{D}_{\text {Boot }}$ is the bootstrapped diode, $\mathrm{C}_{\mathrm{DDI}}$ is the decoupling capacitor on the input side, and $\mathrm{C}_{в}$ is the decoupling capacitor for the driver low-side supply.

Figure 38. Bootstrapped, Half Bridge Operation Circuit for the ADuM4221

## POWER DISSIPATION

When driving a MOSFET or IGBT gate, the driver must dissipate power. This power is not insignificant and can lead to TSD if considerations are not made. The gate of an IGBT can be approximately simulated as a capacitive load. Due to Miller capacitance and other nonlinearities, it is common practice to take the stated input capacitance of a given MOSFET or IGBT, $\mathrm{C}_{\text {ISS }}$, and multiply this capacitance by a factor of 3 to 5 to arrive at a conservative estimate of the approximate load being driven. With this value, the estimated total power dissipation in the system due to the switching action is given by

$$
P_{D I S S}=C_{E S T} \times\left(V_{D D 2}-G N D_{2}\right)^{2} \times f_{S W}
$$

where:
$C_{\text {ESt }}=C_{\text {ISS }} \times 5$.
$V_{D D 2}$ is $V_{D D A}$ or $V_{\text {DDB }}$
$\mathrm{GND}_{2}$ is $\mathrm{GND}_{\mathrm{A}}$ or $\mathrm{GND}_{\mathrm{B}}$.
$\mathrm{f}_{\text {sw }}$ is the switching frequency of the IGBT.
Alternately, use the gate charge as follows:

$$
P_{D I S S}=Q_{G} \times\left(V_{D D 2}-G N D_{2}\right) \times f_{S W}
$$

where $\mathrm{Q}_{\mathrm{G}}$ is the total gate charge of the devices being driven. This power dissipation is shared between the internal on resistances of the internal gate driver switches and the external gate resistances, $\mathrm{R}_{\text {GON }}$ and $\mathrm{R}_{\text {Goff. }}$. The ratio of the internal gate resistances to the total series resistance allows the calculation of losses seen within the ADuM4221/ADuM4221-1/ADuM4221-2 devices.

$$
\begin{aligned}
& P_{\text {DISS_ADuM422I }} / P_{\text {DISS_ADuM422I-1 } /} / P_{\text {DISS_ADuM422I-2 }}=P_{\text {DISS }} \times \\
& 0.5\left(R_{\text {DSON_P }} /\left(R_{\text {GON }}+R_{\text {DSON_P }}\right)+0.5\left(R_{\text {DSON_N }} /\left(R_{\text {GOFF }}+R_{\text {DSON_N }}\right)\right)\right.
\end{aligned}
$$

Take the power dissipation found inside the chip and multiply it by $\theta_{J A}$ to see the rise above ambient temperature that the ADuM4221/ADuM4221-1/ADuM4221-2 experience, then multiply this value by two because there are two channels.

$$
\begin{aligned}
& T_{A D u M 421 /} / T_{\text {ADuM422l-1 }} / T_{\text {ADuM4221-2 }}=\theta_{\text {IA }} \times 2 \times \\
& P_{\text {DISS_ADuM421/ }} / P_{\text {DISS_ADuM4221-1 }} / P_{\text {DISS_ADUM421-2 }}+T_{A}
\end{aligned}
$$

For the devices to remain within specification, $T_{\text {ADuM422II }} / T_{\text {ADuM4221--1 }} /$ $T_{A D u M 4221-2}$ must not exceed $125^{\circ} \mathrm{C}$. If $T_{A D u M 422 I} / T_{\text {ADuM422I-1/ }} / T_{\text {ADuM422I-2 }}$ exceeds the TSD rising edge, the devices enter TSD, and the output remains low until the TSD falling edge is crossed.

## DC CORRECTNESS AND MAGNETIC FIELD IMMUNITY

The ADuM4221/ADuM4221-1/ADuM4221-2 are resistant to external magnetic fields. The limitation on the ADuM4221/ ADuM4221-1/ADuM4221-2 magnetic field immunity is set by the condition in which the induced voltage in the transformer receiving coil is sufficiently large to either falsely set or reset the decoder. The following analysis defines the conditions under which falsely set or reset of the decoder can occur (see Figure 39 and Figure 40).

Figure 39. Maximum Allowable External Magnetic Flux Density

Figure 40. Maximum Allowable Current for Various Current to ADuM4221/ADuM4221-1/ADuM4221-2 Spacings

## INSULATION LIFETIME

All insulation structures eventually break down when subjected to voltage stress over a sufficiently long period. The rate of insulation degradation is dependent on the characteristics of the voltage waveform applied across the insulation. In addition to the testing performed by regulatory agencies, Analog Devices carries out an extensive set of evaluations to determine the lifetime of the insulation structure within the ADuM4221/ ADuM4221-1/ADuM4221-2.

Analog Devices performs accelerated life testing using voltage levels higher than the rated continuous working voltage. Acceleration factors for several operating conditions are determined. These factors allow calculation of the time to failure at the actual working voltage.

The values detailed in Table 9 summarize the peak voltage for 20 years of service life for a bipolar ac operating condition, and the maximum CSA and VDE approved working voltages. In many cases, the approved working voltage is higher than the 20 year service life voltage. Operation at these high working voltages can lead to shortened insulation life in some cases.
The insulation lifetime of the ADuM4221/ADuM4221-1/
ADuM4221-2 depends on the voltage waveform type imposed across the isolation barrier. The $i$ Coupler insulation structure degrades at different rates depending on whether the waveform is bipolar ac, unipolar ac, or dc. Figure 41, Figure 42, and Figure 43 illustrate these different isolation voltage waveforms.

A bipolar ac voltage environment is the worst condition for $i$ Coupler products and is the 20 year operating lifetime that Analog Devices recommends for the maximum working voltage. In the case of unipolar ac or dc voltage, the stress on the insulation is significantly lower. Unipolar ac or dc voltage operation allows operation at higher working voltages while still achieving a 20 year service life. Any cross insulation voltage waveform that does not conform to Figure 42 or Figure 43 must be treated as a bipolar ac waveform, and its peak voltage must be limited to the 20 year lifetime voltage value listed in Table 9.

The voltage presented in Figure 42 is shown as sinusoidal for illustration purposes only. This voltage is meant to represent any voltage waveform varying between 0 V and some limiting value. The limiting value can be positive or negative, but the voltage cannot cross 0 V .

[^0]:    ${ }^{1}$ Protected by U.S. Patents 5,952,849; 6,873,065; 7,075,239. Other patents pending.

[^1]:    ${ }^{1}$ The device is considered a 2-terminal device: Pin 1 through Pin 8 are shorted together, and Pin 9 through Pin 16 are shorted together.
    ${ }^{2}$ Input capacitance is from any input data pin to ground.

[^2]:    ${ }^{1}$ Refers to the continuous voltage magnitude imposed across the isolation barrier. See the Insulation Lifetime section for more details.

[^3]:    ${ }^{1} \mathrm{X}$ means don't care.

[^4]:    ${ }^{1} \mathrm{X}$ means don't care.

[^5]:    ${ }^{1} \mathrm{X}$ means don't care.

[^6]:    ${ }^{1} Z=$ RoHS Compliant Part.
