## FEATURES

Small, 16-lead QSOP<br>1000 V rms isolation rating<br>Safety and regulatory approvals<br>UL recognition

UL 1577: 1000 V rms for 1 minute
Low power operation
5 V operation
2.25 mA per channel maximum at 0 Mbps to 1 Mbps
11.5 mA per channel maximum at $\mathbf{2 5}$ Mbps
3.3 V operation
1.5 mA per channel maximum at 0 Mbps to 1 Mbps
8.25 mA per channel maximum at 25 Mbps

Bidirectional communication
Up to $\mathbf{2 5}$ Mbps data rate (NRZ)
3 V/5 V level translation
High temperature operation: $105^{\circ} \mathrm{C}$
High common-mode transient immunity: $\mathbf{> 1 5} \mathbf{k V} / \mu \mathrm{s}$

## APPLICATIONS

General-purpose, multichannel isolation SPI interface/data converter isolation
RS-232/RS-422/RS-485 transceivers
Industrial field bus isolation

## GENERAL DESCRIPTION

The ADuM7440/ADuM7441/ADuM7442 ${ }^{1}$ are 4-channel digital isolators based on the Analog Devices, Inc., iCoupler technology. Combining high speed CMOS and monolithic air core transformer technologies, these isolation components provide outstanding performance characteristics superior to the alternatives, such as optocoupler devices and other integrated couplers.
The ADuM7440/ADuM7441/ADuM7442 family of quad 1 kV digital isolation devices is packaged in a small 16 -lead QSOP. While most 4 -channel isolators come in 16 -lead wide SOIC packages, the ADuM7440/ADuM7441/ADuM7442 free almost $70 \%$ of board space and yet can still withstand high isolation voltage and meet UL regulatory requirements. In addition to the space savings, the ADuM7440/ADuM7441/ADuM7442 offer a lower price than 2.5 kV or 5 kV isolators where only functional isolation is needed.

This family, like many Analog Devices isolators, offers very low power consumption, consuming one-tenth to one-sixth the power of comparable isolators at comparable data rates up to 25 Mbps . Despite the low power consumption, all models of the ADuM7440/ADuM7441/ADuM7442 provide low pulse width distortion ( $<5 \mathrm{~ns}$ for C grade). In addition, every model has an input glitch filter to protect against extraneous noise disturbances.

The ADuM7440/ADuM7441/ADuM7442 isolators provide four independent isolation channels in a variety of channel configurations and two data rates (see the Ordering Guide) up to 25 Mbps . All models operate with the supply voltage on either side ranging from 3.0 V to 5.5 V , providing compatibility with lower voltage systems as well as enabling voltage translation functionality across the isolation barrier. All products also have an output default high logic state in the absence of the input power.
${ }^{1}$ Protected by U.S. Patents $5,952,849,6,873,065$ and $7,075,329$. Other patents pending.

## SPECIFICATIONS

## ELECTRICAL CHARACTERISTICS-5 V OPERATION

All typical specifications are at $\mathrm{T}_{\mathrm{A}}=25^{\circ} \mathrm{C}, \mathrm{V}_{\mathrm{DD} 1}=\mathrm{V}_{\mathrm{DD} 2}=5 \mathrm{~V}$. Minimum/maximum specifications apply over the entire recommended operation range of $4.5 \mathrm{~V} \leq \mathrm{V}_{\mathrm{DD} 1} \leq 5.5 \mathrm{~V}, 4.5 \mathrm{~V} \leq \mathrm{V}_{\mathrm{DD} 2} \leq 5.5 \mathrm{~V}$, and $-40^{\circ} \mathrm{C} \leq \mathrm{T}_{\mathrm{A}} \leq+105^{\circ} \mathrm{C}$, unless otherwise noted. Switching specifications are tested with $\mathrm{C}_{\mathrm{L}}=15 \mathrm{pF}$, and CMOS signal levels, unless otherwise noted.
Table 1.

${ }^{1} \mathrm{t}_{\text {PSK }}$ is the magnitude of the worst-case difference in $\mathrm{t}_{\text {PHL }}$ or $\mathrm{t}_{\text {PLH }}$ that is measured between units at the same operating temperature, supply voltages, and output load within the recommended operating conditions.

${ }^{2}$ Input capacitance is from any input data pin to ground.

## REGULATORY INFORMATION

The ADuM7440/ADuM7441/ADuM7442 are approved by the organization listed in Table 14. See Table 18 and the Insulation Lifetime section for recommended maximum working voltages for specific cross-isolation waveforms and insulation levels.

Table 14.
UL
Recognized under UL 1577 Component Recognition Program ${ }^{1}$
Single Protection, 1000 V rms Isolation Voltage
File E214100
${ }^{1}$ In accordance with UL 1577, each ADuM7440/ADuM7441/ADuM7442 is proof tested by applying an insulation test voltage $\geq 1200 \mathrm{Vrms}$ for 1 sec (current leakage detection limit $=5 \mu \mathrm{~A}$ ).

| Storage Temperature ( $\mathrm{T}_{\text {ST }}$ ) Range | $-65^{\circ} \mathrm{C}$ to $+150^{\circ} \mathrm{C}$ |
| Ambient Operating Temperature ( $\mathrm{T}_{\mathrm{A}}$ ) | $-40^{\circ} \mathrm{C}$ to $+105^{\circ} \mathrm{C}$ |
| Supply Voltages ( $\mathrm{V}_{\mathrm{DD} 1}, \mathrm{~V}_{\mathrm{DD} 2}$ ) | -0.5 V to +7.0 V |
| Input Voltages ( $\left.\mathrm{V}_{1 A}, \mathrm{~V}_{1 B}, \mathrm{~V}_{1 C}, \mathrm{~V}_{\text {II }}\right)^{1,2}$ | -0.5 V to $\mathrm{V}_{\text {DII }}+0.5 \mathrm{~V}$ |
| Output Voltages ( $\left.\mathrm{V}_{\text {OA }}, \mathrm{V}_{\text {OB, }}, \mathrm{V}_{\text {OC, }}, \mathrm{V}_{\text {OD }}\right)^{1,2}$ | -0.5 V to $\mathrm{V}_{\mathrm{DDO}}+0.5 \mathrm{~V}$ |
| Average Output Current per Pin ${ }^{3}$ |  |
| Side 1 (loı) | -10 mA to +10 mA |
| Side 2 (loz) | -10 mA to +10 mA |
| Common-Mode Transients ${ }^{3}$ | $-100 \mathrm{kV} / \mu \mathrm{s}$ to $+100 \mathrm{kV} / \mu \mathrm{s}$ |

${ }^{1} \mathrm{~V}_{\text {DDI }}$ and $\mathrm{V}_{\text {DDO }}$ refer to the supply voltages on the input and output sides of a given channel, respectively. See the Printed Circuit Board (PCB) Layout section.
${ }^{2}$ See Figure 4 for maximum rated current values for various temperatures.
${ }^{3}$ Refers to common-mode transients across the insulation barrier. Commonmode transients exceeding the absolute maximum ratings may cause latch-up or permanent damage.

Stresses at or above those listed under Absolute Maximum Ratings may cause permanent damage to the product. This is a stress rating only; functional operation of the product at these or any other conditions above those indicated in the operational section of this specification is not implied. Operation beyond the maximum operating conditions for extended periods may affect product reliability.

## ESD CAUTION

ESD (electrostatic discharge) sensitive device. Charged devices and circuit boards can discharge without detection. Although this product features patented or proprietary protection circuitry, damage may occur on devices subjected to high energy ESD. Therefore, proper ESD precautions should be taken to avoid performance degradation or loss of functionality.

## APPLICATIONS INFORMATION

## PRINTED CIRCUIT BOARD (PCB) LAYOUT

The ADuM7440/ADuM7441/ADuM7442 digital isolators require no external interface circuitry for the logic interfaces. Power supply bypassing is strongly recommended at the input and output supply pins (see Figure 16). A total of four bypass capacitors should be connected between Pin 1 and Pin 2 for $\mathrm{V}_{\mathrm{DDIA}}$, between Pin 7 and Pin 8 for $\mathrm{V}_{\mathrm{DDI}}$, between Pin 9 and Pin 10 for $V_{\text {dD2B, }}$, and between Pin 15 and Pin 16 for Vdd2A. Supply Vddia $\operatorname{Pin} 1$ and Vddib $\operatorname{Pin} 7$ should be connected together and supply $V_{\text {DD2 }}$ Pin 10 and $V_{\text {DD2A }}$ Pin 16 should be connected together. The capacitor values should be between $0.01 \mu \mathrm{~F}$ and $0.1 \mu \mathrm{~F}$. The total lead length between both ends of the capacitor and the power supply pin should not exceed 20 mm .

Figure 16. Recommended Printed Circuit Board Layout
In applications involving high common-mode transients, it is important to minimize board coupling across the isolation barrier. Furthermore, users should design the board layout so that any coupling that does occur equally affects all pins on a given component side. Failure to ensure this can cause voltage differentials between pins exceeding the absolute maximum ratings of the device, thereby leading to latch-up or permanent damage.
See the AN-1109 Application Note for board layout guidelines.

## PROPAGATION DELAY-RELATED PARAMETERS

Propagation delay is a parameter that describes the time it takes a logic signal to propagate through a component. The input-tooutput propagation delay time for a high-to-low transition may differ from the propagation delay time of a low-to-high transition.

Figure 17. Propagation Delay Parameters
Pulse width distortion is the maximum difference between these two propagation delay values and an indication of how accurately the timing of the input signal is preserved.

Channel-to-channel matching refers to the maximum amount the propagation delay differs between channels within a single ADuM7440/ADuM7441/ADuM7442 component.
Propagation delay skew refers to the maximum amount the propagation delay differs between multiple ADuM7440/ ADuM7441/ADuM7442 components operating under the same conditions.

## DC CORRECTNESS AND MAGNETIC FIELD IMMUNITY

Positive and negative logic transitions at the isolator input cause narrow ( $\sim 1 \mathrm{~ns}$ ) pulses to be sent to the decoder using the transformer. The decoder is bistable and is, therefore, either set or reset by the pulses, indicating input logic transitions. In the absence of logic transitions at the input for more than $\sim 1 \mu \mathrm{~s}$, a periodic set of refresh pulses indicative of the correct input state is sent to ensure dc correctness at the output. If the decoder receives no internal pulses of more than approximately $5 \mu \mathrm{~s}$, the input side is assumed to be unpowered or nonfunctional, in which case the isolator output is forced to a default high state by the watchdog timer circuit.
The magnetic field immunity of the ADuM7440/ADuM7441/ ADuM7442 is determined by the changing magnetic field, which induces a voltage in the transformer's receiving coil large enough to either falsely set or reset the decoder. The following analysis defines the conditions under which this can occur. The 3 V operating condition of the ADuM7440/ADuM7441/ ADuM7442 is examined because it represents the most susceptible mode of operation.

The pulses at the transformer output have an amplitude greater than 1.0 V . The decoder has a sensing threshold at about 0.5 V , thus establishing a 0.5 V margin in which induced voltages can be tolerated. The voltage induced across the receiving coil is given by

$$
V=(-d \beta / d t) \sum \pi r_{n}^{2} ; n=1,2, \ldots, N
$$

where:
$\beta$ is magnetic flux density (gauss).
$r_{n}$ is the radius of the $\mathrm{n}^{\text {th }}$ turn in the receiving coil ( cm ).
$N$ is the number of turns in the receiving coil.
Given the geometry of the receiving coil in the ADuM7440/ ADuM7441/ADuM7442 and an imposed requirement that the induced voltage be, at most, $50 \%$ of the 0.5 V margin at the decoder, a maximum allowable magnetic field at a given frequency can be calculated. The result is shown in Figure 18.

Figure 18. Maximum Allowable External Magnetic Flux Density
For example, at a magnetic field frequency of 1 MHz , the maximum allowable magnetic field of 0.5 kgauss induces a voltage of 0.25 V at the receiving coil. This is about $50 \%$ of the sensing threshold and does not cause a faulty output transition. Similarly, if such an event occurred during a transmitted pulse (and was of the worst-case polarity), it would reduce the received pulse from $>1.0 \mathrm{~V}$ to 0.75 V , still well above the 0.5 V sensing threshold of the decoder.

The preceding magnetic flux density values correspond to specific current magnitudes at given distances from the ADuM7440/ADuM7441/ADuM7442 transformers. Figure 19 shows these allowable current magnitudes as a function of frequency for selected distances. As shown, the ADuM7440/ ADuM7441/ADuM7442 are extremely immune and can be affected only by extremely large currents operated at high frequency very close to the component. For the 1 MHz example noted previously, a 1.2 kA current would have to be placed 5 mm away from the ADuM7440/ADuM7441/ADuM7442 to affect the operation of the component.

Figure 19. Maximum Allowable Current for Various Current-to-ADuM7440/ADuM7441/ADuM7442 Spacings

Note that at combinations of strong magnetic field and high frequency, any loops formed by printed circuit board traces can induce error voltages sufficiently large enough to trigger the thresholds of succeeding circuitry. Take care in the layout of such traces to avoid this possibility.

## POWER CONSUMPTION

The supply current at a given channel of the ADuM7440/ ADuM7441/ADuM7442 isolator is a function of the supply voltage, the data rate of the channel, and the output load of the channel.

For each input channel, the supply current is given by

$$
\begin{array}{ll}
I_{D D I}=I_{D D I(Q)} & f \leq 0.5 f_{r} \\
I_{D D I}=I_{D D I(D)} \times\left(2 f-f_{r}\right)+I_{D D I(Q)} & f>0.5 f_{r}
\end{array}
$$

For each output channel, the supply current is given by

$$
\begin{array}{rl}
I_{D D O}=I_{D D O(Q)} & f \leq 0.5 f_{r} \\
I_{D D O}=\left(I_{D D O(D)}+\left(0.5 \times 10^{-3}\right) \times C_{L} \times V_{D D O}\right) \times\left(2 f-f_{r}\right)+I_{D D O(Q)} \\
f & f 0.5 f_{r}
\end{array}
$$

where:
$I_{D D I(D)}, I_{D D O(D)}$ are the input and output dynamic supply currents per channel (mA/Mbps).
$C_{L}$ is the output load capacitance ( pF ).
$V_{D D O}$ is the output supply voltage ( V ).
$f$ is the input logic signal frequency ( MHz ); it is half the input data rate, expressed in Mbps.
$f_{r}$ is the input stage refresh rate (Mbps).
$I_{D D I(Q)}, I_{D D O}(Q)$ are the specified input and output quiescent supply currents ( mA ).
To calculate the total $V_{\text {DD1 }}$ and $V_{D D 2}$ supply current, the supply currents for each input and output channel corresponding to $V_{D D 1}$ and $V_{D D 2}$ are calculated and totaled. Figure 8 and Figure 9 show per-channel supply currents as a function of data rate for an unloaded output condition. Figure 10 shows the per-channel supply current as a function of data rate for a 15 pF output condition. Figure 11 through Figure 15 show the total VDD1 and $\mathrm{V}_{\mathrm{DD} 2}$ supply current as a function of data rate for ADuM7440/ ADuM7441/ADuM7442 channel configurations.

## INSULATION LIFETIME

All insulation structures eventually break down when subjected to voltage stress over a sufficiently long period. The rate of insulation degradation is dependent on the characteristics of the voltage waveform applied across the insulation. In addition to the testing performed by the regulatory agencies, Analog Devices carries out an extensive set of evaluations to determine the lifetime of the insulation structure within the ADuM7440/ ADuM7441/ADuM7442.
Analog Devices performs accelerated life testing using voltage levels higher than the rated continuous working voltage. Acceleration factors for several operating conditions are determined. These factors allow calculation of the time to failure at the actual working voltage. The values shown in Table 18 summarize the peak voltage for 50 years of service life for a bipolar ac operating condition and the maximum CSA approved working voltages. In many cases, the approved working voltage is higher than 50-year service life voltage. Operation at these high working voltages can lead to shortened insulation life in some cases.

## ADuM7440/ADuM7441/ADuM7442

The insulation lifetime of the ADuM7440/ADuM7441/ ADuM7442 depends on the voltage waveform type imposed across the isolation barrier. The iCoupler insulation structure degrades at different rates depending on whether the waveform is bipolar ac, unipolar ac, or dc. Figure 20, Figure 21, and Figure 22 illustrate these different isolation voltage waveforms.

Bipolar ac voltage is the most stringent environment. The goal of a 50 -year operating lifetime under the ac bipolar condition determines the Analog Devices recommended maximum working voltage.
In the case of unipolar ac or dc voltage, the stress on the insulation is significantly lower. This allows operation at higher working voltages while still achieving a 50 -year service life. The working voltages listed in Table 18 can be applied while maintaining the 50 -year minimum lifetime provided the voltage conforms to either the unipolar ac or dc voltage case. Any cross-insulation voltage waveform that does not conform to Figure 21 or Figure 22 should be treated as a bipolar ac waveform, and its peak voltage should be limited to the 50 -year lifetime voltage value listed in Table 18.

Note that the voltage presented in Figure 21 is shown as sinusoidal for illustration purposes only. It is meant to represent any voltage waveform varying between 0 V and some limiting value. The limiting value can be positive or negative, but the voltage cannot cross 0 V .

[^0]:     common-mode voltage edges.

[^1]:    ${ }^{1}|C M|$ is the maximum common-mode voltage slew rate that can be sustained while maintaining $\mathrm{V}_{\mathrm{O}}>0.8 \mathrm{~V}_{\mathrm{DD}}$. The common-mode voltage slew rates apply to both rising and falling common-mode voltage edges.

[^2]:    ${ }^{1}|C M|$ is the maximum common-mode voltage slew rate that can be sustained while maintaining $\mathrm{V}_{\mathrm{O}}>0.8 \mathrm{~V}_{\mathrm{DD}}$. The common-mode voltage slew rates apply to both

[^3]:    ${ }^{1}|C M|$ is the maximum common-mode voltage slew rate that can be sustained while maintaining $\mathrm{V}_{\mathrm{O}}>0.8 \mathrm{~V}_{\mathrm{DD}}$. The common-mode voltage slew rates apply to both rising and falling common-mode voltage edges.

[^4]:    ${ }^{1} V_{1 x}$ and $V_{0 x}$ refer to the input and output signals of a given channel ( $A, B, C$, or $D$ ).
    ${ }^{2} V_{\text {DDI }}$ refers to the power supply on the input side of a given channel ( $A, B, C$, or $D$ ).
    ${ }^{3} V_{D D O}$ refers to the power supply on the output side of a given channel ( $A, B, C$, or $D$ ).

[^5]:    ${ }^{1} \mathrm{Z}=$ RoHS Compliant Part.
