

# Ultrathin 1.5A $\mu$ Module Thermoelectric Cooler (TEC) Regulator

## FEATURES

- **Built-in Two Zero-Drift, Rail-to-Rail Chopper Amplifiers**
- 2.7V to 5.5V Input Voltage Range
- 1.5A Driving Capability
- **1% Accuracy 2.5V Internal Reference Output**
- TEC Voltage and Current Monitoring
- Independent Programmable Heating and Cooling Current Limit
- Programmable Maximum TEC Voltage
- Default 2MHz Switching Frequency
- Synchronization from 1.85MHz to 3.25MHz
- Capable of NTC, PTC and RTD Thermal Sensors
- **3.5mm  $\times$  4mm  $\times$  1.3mm LGA Package**

## APPLICATIONS

- TEC Temperature Control
- Optical Networking System, Optical Module
- LiDAR System

## DESCRIPTION

The **LTM®4663** is a complete 1.5A  $\mu$ Module® Thermoelectric Cooler (TEC) regulator in a tiny 3.5mm  $\times$  4mm  $\times$  1.3mm LGA package. Included in the package are the TEC controller, linear power stage, switching regulator, inductor and all support components.

Operating over an input voltage range of 2.7V to 5.5V, the LTM4663 supports a 1.5A continuous sink or source current capability. Only input and output capacitors are needed. The LTM4663 has two zero drift, rail-to-rail chopper amplifiers to serve as the thermistor input amplifier and the temperature feedback control loop.

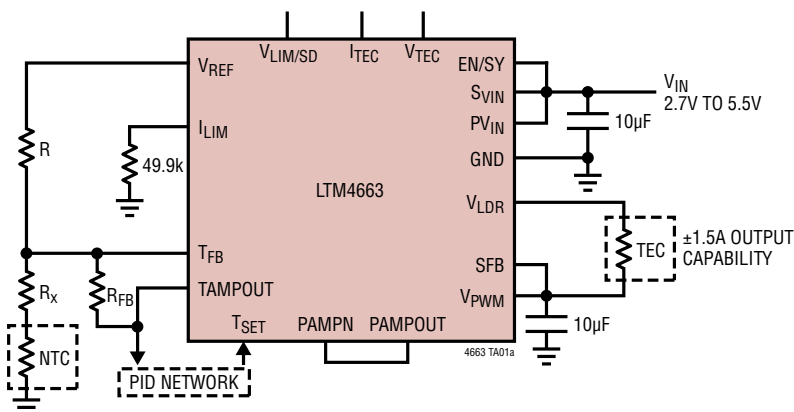

The LTM4663 supports NTC, PTC thermistors and resistive temperature detectors (RTD). The maximum cooling and heating currents can be programmed independently as well as the maximum TEC voltage.

The LTM4663 is available in LGA RoHS compliant terminal finish.

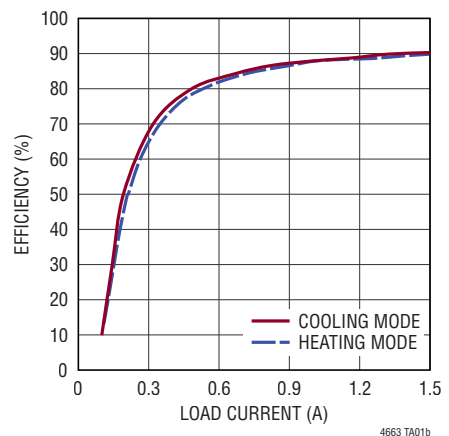

All registered trademarks and trademarks are the property of their respective owners. Protected by U.S. patents, including 6,486,643.

## TYPICAL APPLICATION

**1.5A TEC Supply  $\mu$ Module Regulator**

**Efficiency vs TEC Current at  $V_{IN} = 5V$  in Cooling/Heating Mode with  $2\Omega$  Load**

# LTM4663

**Note 1:** Stresses beyond those listed under Absolute Maximum Ratings may cause permanent damage to the device. Exposure to any Absolute Maximum Rating condition for extended periods may affect device reliability and lifetime.

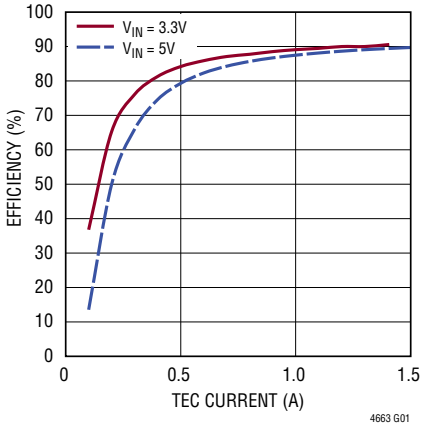

**Note 2:** The LTM4663 is tested under pulsed load conditions such that  $T_J \approx T_A$ . The LTM4663E is guaranteed to meet performance specifications over the  $0^\circ\text{C}$  to  $125^\circ\text{C}$  internal operating temperature range. Specifications over the full  $-40^\circ\text{C}$  to  $125^\circ\text{C}$  internal operating temperature range are assured by design, characterization and correlation with statistical process controls. The LTM4663I is guaranteed to meet specifications over the full  $-40^\circ\text{C}$  to  $125^\circ\text{C}$  internal operating temperature range. Note that the maximum ambient temperature consistent with these specifications is determined by specific operating conditions in conjunction with board layout, the rated package thermal resistance and other environmental factors.

**Note 3:** 100% tested at wafer level.

**Note 4:** This IC includes overtemperature protection that is intended to protect the device during momentary overload conditions. Junction temperature will exceed  $125^\circ\text{C}$  when overtemperature protection is active. Continuous operation above the specified maximum operating junction temperature may impair device reliability.

## TYPICAL PERFORMANCE CHARACTERISTICS $T_A = 25^\circ\text{C}$ , unless otherwise noted.

**Typical Switch and Voltage Ripple Waveforms in Cooling Mode,  $V_{IN} = 3.3\text{V}$ , Load =  $2\Omega$ , TEC Current =  $1\text{A}$**

## PIN FUNCTIONS

**GNDP (A1):** Power Ground Pin for PWM Switching Mode Regulator. Connect to GNDL with large PCB copper area.

**SW (A2, B2):** Switching node of the PWM Switching Mode Regulator that is used for testing purposes. R-C snubber network can be applied to reduce or eliminate switch node ringing, or otherwise leave floating.

**PV<sub>IN</sub> (A3, B3):** Power Input Pins for Both PWM Switching Mode Regulator and Linear Power Stage. Apply input voltage between these pins and GNDP/GNDL pins. Recommend placing input decoupling capacitance directly between PV<sub>IN</sub> pins and GNDP pins.

**V<sub>LDR</sub> (A4, B4):** Linear Power Output Pin. Apply the TEC device between V<sub>PWM</sub> pin and V<sub>LDR</sub> pin.

**GNDL (A5, B5):** Power Ground Pin for Linear Power Stage. Connect to GNDP with large PCB copper area.

**V<sub>PWM</sub> (B1):** PWM Switching Mode Regulator Power Output Pin. Apply the TEC device between V<sub>PWM</sub> pin and V<sub>LDR</sub> pin. Recommend placing output decoupling capacitance directly between V<sub>PWM</sub> pins and GNDP pins.

**SFB (C1):** PWM Switching Mode Regulator Voltage Feedback Pin. Connect this pin close to the TEC device.

**V<sub>TEC</sub> (C2):** Voltage Monitor Pin for the TEC device.

**I<sub>TEC</sub> (C3):** Current Monitor Pin for the TEC device.

**T<sub>FB</sub> (C4):** Temperature Feedback Pin. Connect this pin to the thermistor input. This is connected to the inverting input of the thermistor temperature error amplifier. See the Applications Information section for details.

**TAMPOUT (C5):** Output of the Thermistor Temperature Error Amplifier.

**GND A (D1):** Signal Ground Pin for the Internal Control Circuits. Return ground path of all analog circuitry. Tie a single connection to the GNDP/GNDL in the application. See layout guidelines in Figure 17.

**EN/SY (D2):** Enable and External Synchronization Input of the TEC Driver. Set this pin logic high to enable the device. An external synchronization clock input can be applied to this pin.

**PAMPOUT (D3):** Output of the Compensation Amplifier.

**PAMPN (D4):** Inverting Input of the Compensation Amplifier.

**NC (D5):** Pin used for testing purposes. Leave floating. Do not connect.

**V<sub>REF</sub> (E1):** 2.5V Internal Reference Output Voltage. This pin is internal decoupled with 0.1 $\mu$ F capacitor. No additional decoupling is required.

**SV<sub>IN</sub> (E2):** Signal V<sub>IN</sub>. Filtered Input Voltage to the Internal Control Circuits. Connect to PV<sub>IN</sub> directly in most applications.

**I<sub>LIM</sub> (E3):** Current Limit Set Pin. An external resistor divider R<sub>CT</sub>/R<sub>CB</sub> between V<sub>REF</sub> and GND A sets the TEC driver cooling and heating current limits. See the Applications Information section for details.

**V<sub>LIM/SD</sub> (E4):** Voltage Limit Set Pin. An external resistor between this pin and GND A sets the TEC driver cooling and heating voltage limits. See the Applications Information section for details.

**T<sub>SET</sub> (E5):** Temperature Set Pin for the TEC Driver. This pin is the non-inverting input of the compensation amplifier. The T<sub>SET</sub> voltage controls the target temperature of the thermistor, by either sinking or sourcing current from the TEC device.

## OPERATION

The LTM4663 is a complete Thermoelectric Cooler (TEC)  $\mu$ Module regulator that sets, stabilizes and monitors TEC temperature. It can deliver up to 1.5A of sinking or sourcing current with external input and output capacitors. Operating over 2.7V to 5.5V input voltage range, the LTM4663 controls an internal FET H-bridge whereby the direction of the current fed through the TEC can be either positive (for cooling mode), or negative (for heating mode).

The LTM4663 has two self-correcting, auto-zeroing amplifiers (Chopper 1 and Chopper 2) to linearize the thermal sensor input and to form an analog temperature feedback control loop. With the zero drift chopper amplifiers, extremely good long-term temperature stability is maintained via an autonomous temperature control loop. See Figure 18 for an overview of how to configure the analog PID control, while see Figure 19 for configuring the digital PID control.

The LTM4663 can also be configured for use in a software controlled PID loop. In this scenario, the Chopper 1 amplifier can configure as a thermistor input amplifier

connected to an external temperature measurement analog-to-digital converter (ADC). The Chopper 2 amplifier is used as a buffer for the external digital-to-analog converter (DAC), which controls the temperature setpoint. Connect the DAC to  $T_{SET}$  and short the PAMPN and PAMPOUT pins together. See Figure 19 for an overview of how to configure the LTM4663 external circuitry for digital PID control.

To provide good efficiency and small solution size, the LTM4663 utilizes a PWM switching mode power supply on one side of the H-bridge while a linear power stage on the other side. A default 2MHz switching frequency and a 10 $\mu$ F capacitor maintains less than 1% of the worst-case output voltage ripple across the TEC.

The maximum voltage across the TEC and the current flowing through the TEC are set by using the  $V_{LIM/SD}$  and  $I_{LIM}$  pins. The maximum cooling and heating currents can be set independently to allow asymmetric cooling and heating limits. The real time TEC voltage and current can be monitored using  $V_{TEC}$  and  $I_{TEC}$  pins.

---

## APPLICATIONS INFORMATION

### THEORY OF OPERATION

The LTM4663 has two half-bridge type power stages, a PWM switching mode regulator and a linear power stage, to allow current flow in or out of the TEC device connected in between (see Figure 2).

The object temperature is measured from an external thermal sensor. The sensed temperature (voltage) is fed back to the LTM4663 at  $T_{FB}$  pin to complete a closed thermal control loop. The thermistor input amplifier gains the thermistor sensed voltage, then outputs to the PID compensation amplifier. The PID compensation amplifier then compensates a feedback loop response to drive both the PWM switching mode regulator and the linear power stage to drive the TEC to heat up or cool down the object.

### INPUT AND OUTPUT DECOUPLING CAPACITORS

Benefiting from the unique topology and the 2MHz default switching frequency, only one ceramic capacitor is required at the input and output of the PWM switching regulator to maintain less than 1% of the worst-case output voltage ripple across the TEC. Additional output filtering may be required by the system designer if further reduction of output ripples or dynamic transient spikes is required.

### ENABLE AND SHUTDOWN

To enable the LTM4663, apply a logic high voltage to the EN/SY pin while the voltage at the  $V_{LIM/SD}$  pin is above the maximum shutdown threshold of 0.07V. If either the EN/SY pin voltage is set to logic low or the  $V_{LIM/SD}$  voltage is

## APPLICATIONS INFORMATION

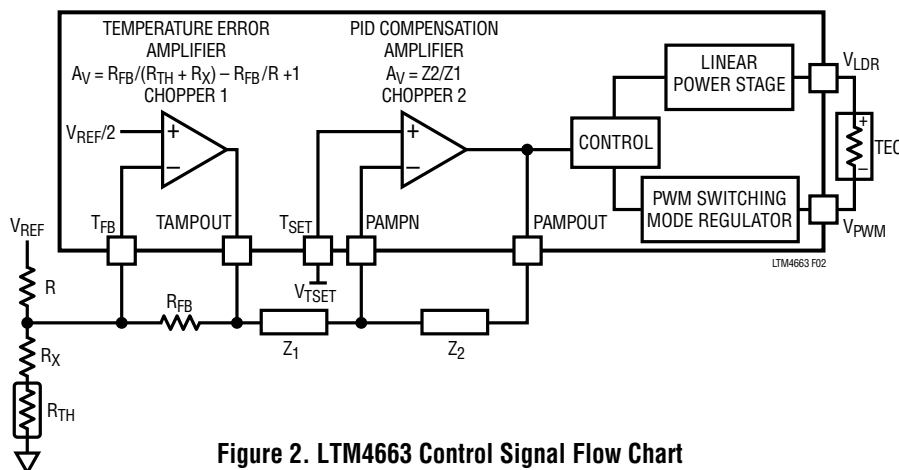

Figure 2. LTM4663 Control Signal Flow Chart

below 0.07V, the controller goes into an ultralow current state. The current drawn in shutdown mode is 480 $\mu$ A typically. Most of the current is consumed by the  $V_{REF}$  circuit block, which is always on even when the device is disabled or shut down. The device can also be enabled when an external synchronization clock signal is applied to the EN/SY pin, and the voltage at  $V_{LIM/SD}$  input is above 0.07V. Table 1 shows the combinations of the two input signals that are required to enable the LTM4663.

Table 1. Enable Pin Combinations

EN/SY PIN	$V_{LIM/SD}$ PIN	STATUS
>2.1V	>0.07V	Enable
Clock	>0.07V	Enable
<0.8V	No Effect*	Shutdown
No Effect*	<0.07V	Shutdown

\*No effect means this signal has no effect in shutting down or in enabling the device.

### OPERATING FREQUENCY

The LTM4663 has a default 2MHz switching frequency for the PWM switching regulator output stage. The oscillator is active when the enabled voltage at the EN/SY pin is set to a logic level higher than 2.1V and the  $V_{LIM/SD}$  pin voltage is greater than the shutdown threshold of 0.07V.

### FREQUENCY SYNCHRONIZATION AND CLOCK IN

The switching frequency of the LTM4663 can be synchronized to an external clock from 1.85MHz to 3.25MHz

applied to the EN/SY input pin. The clock high level must be above 2.1V and the clock low level below 0.8V.

### SOFT-START

The LTM4663 has an internal soft-start circuit that generates a ramp with a typical 150ms profile to minimize inrush current during power-up. The settling time and the final voltage across the TEC depends on the TEC voltage required by the control voltage of voltage loop. The higher the TEC voltage is, the longer it requires to reach the final output voltage.

When the LTM4663 is first powered up, the linear side discharges the output of any prebias voltage. As soon as the prebias is eliminated, the soft-start cycle begins. During the soft-start cycle, both the PWM and linear outputs track the internal soft-start ramp until they reach mid-scale  $V_B$ . From the mid-scale voltage, the PWM and linear outputs are then diverge from each other until the required differential voltage is developed across the TEC or the differential voltage reaches the voltage limit. The voltage developed across the TEC depends on the control point at that moment. Figure 3 shows an example of the soft-start in cooling mode. Note that, as both the  $V_{LDR}$  and  $V_{PWM}$  voltages increase with the soft-start ramp and approach  $V_B$ , the ramp slows down to avoid possible current overshoot at the point where the TEC voltage starts to build up.

## APPLICATIONS INFORMATION

Figure 3. Soft-Start Profile in Cooling Mode

### MAXIMUM TEC VOLTAGE LIMIT

The maximum voltage of the TEC driver in the LTM4663 can be programmed individually by applying a resistor ( $R_V$ ) from  $V_{LIM/SD}$  pin to GNDA. The voltage limiter operates bidirectionally and allows the cooling limit to be different from the heating limit.

As shown in Figure 4, the internal current sink circuitry connected to  $V_{LIM/SD}$  draws a current when the LTM4663 drives the TEC in a heating direction, which lowers the voltage at  $V_{LIM/SD}$ . The current sink is not active when the TEC is driven in a cooling direction; therefore, the TEC heating voltage limit is always lower than the cooling voltage limit.

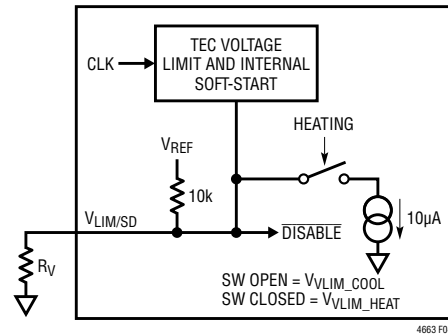

Figure 4. TEC Voltage Limit Setting

The maximum TEC voltage in the cooling mode can be calculated as:

$$V_{LIM\_COOL} = 2 \cdot 2.5V \cdot \frac{R_V}{10k + R_V}$$

The maximum TEC voltage in the heating mode can be calculated as:

$$V_{LIM\_HEAT} = 2 \cdot \left( 2.5V \cdot \frac{R_V}{10k + R_V} - 10\mu A \cdot \frac{10k \cdot R_V}{10k + R_V} \right)$$

See Table 2 for the list of Typical TEC Voltage Limit settings.

Table 2. Example of Typical TEC Voltage Limit Setting

BOTTOM RESISTOR $R_V$ (k $\Omega$ )	MAX TEC VOLTAGE (COOLING MODE) (V)	MAX TEC VOLTAGE (HEATING MODE) (V)

2.49	1	-0.96

## APPLICATIONS INFORMATION

### MAXIMUM TEC CURRENT LIMIT

The maximum current of the TEC driver in the LTM4663 can be programmed individually by applying a resistor divider  $R_{CT}/R_{CB}$  between  $V_{REF}$  and  $GNDA$ .

As shown in Figure 5, the internal current sink circuitry connected to  $I_{LIM}$  draws a  $40\mu A$  current when the LTM4663 drives the TEC in a cooling direction, which allows a high cooling current. The current sink is not active when the TEC is driven in a heating direction.

Figure 5. TEC Current Limit Setting

The maximum TEC current limit in the heating mode can be calculated as:

$$I_{LIM\_HEAT} = \frac{1.25V - 2.5V \cdot \frac{R_{CB}}{R_{CT} // 249k + R_{CB}}}{0.535}$$

The maximum TEC current limit in the cooling mode can be calculated as:

$$I_{LIM\_COOL} = \frac{2.5V \cdot \frac{R_{CB}}{R_{CT} // 249k + R_{CB}} + 40\mu A \cdot \frac{R_{CT} // 249k \cdot R_{CB}}{R_{CT} // 249k + R_{CB}} - 1.25V}{0.535}$$

See Table 3 for the list of Typical TEC Current Limit settings.

Table 3. Example of Typical TEC Current Limit Setting

TOP RESISTOR $R_{CT}$ ( $k\Omega$ )	BOTTOM RESISTOR $R_{CB}$ ( $k\Omega$ )	TEC CURRENT LIMIT (COOLING MODE) (A)	TEC CURRENT LIMIT (HEATING MODE) (A)

63.4	28	0.7	-0.7
38.3	21.5	0.5	-0.5

## APPLICATIONS INFORMATION

### TEC VOLTAGE MONITOR

$V_{TEC}$  is an analog voltage output pin with a voltage proportional to the actual voltage across the TEC. A center  $V_{TEC}$  voltage of 1.25V corresponds to 0V across the TEC. Convert the voltage at  $V_{TEC}$  and the voltage across the TEC using the following equation:

$$V_{V_{TEC}} = 1.25V + 0.25 \cdot (V_{LDR} - V_{PWM})$$

### TEC CURRENT MONITOR

$I_{TEC}$  is an analog voltage output pin with a voltage proportional to the actual current through TEC. A center  $I_{TEC}$  voltage of 1.25V corresponds to 0A through the TEC. Convert the voltage at  $I_{TEC}$  and the current through the TEC using the following equations:

$$V_{ITEC\_COOLING} = 1.25V + I_{LDR} \cdot R_{CS}$$

$$V_{ITEC\_HEATING} = 1.25V - I_{LDR} \cdot R_{CS}$$

where the current sense gain  $R_{CS}$  is 0.535V/A.

### THERMISTOR SETUP

The thermistor has a nonlinear relationship to temperature; near optimal linearity over a specified temperature range can be achieved with the proper value of  $R_X$  placed in series with the thermistor.

First, the thermistor resistances at different temperatures must be known, where:

$$R_{LOW} = R_{TH} \text{ at } T_{LOW}$$

$$R_{MID} = R_{TH} \text{ at } T_{MID}$$

$$R_{HIGH} = R_{TH} \text{ at } T_{HIGH}$$

$T_{LOW}$  and  $T_{HIGH}$  are the endpoints of the temperature range and  $T_{MID}$  is the average. In some cases, with only the thermistor material constant  $\beta$  available, calculate  $R_{TH}$  using the following equation:

$$R_{TH} = R_R \exp \left[ \beta \left( \frac{1}{T} - \frac{1}{T_R} \right) \right]$$

where:

$R_{TH}$  is a thermistor resistance at temperature  $T$  (K).

$R_R$  is a nominal thermistor resistance at standard reference temperature  $T_R$  (K).

Calculate  $R_X$  using the following equation:

$$R_X = \left( \frac{R_{LOW} R_{MID} + R_{MID} R_{HIGH} - 2R_{LOW} R_{HIGH}}{R_{LOW} + R_{HIGH} - 2R_{MID}} \right)$$

### THERMISTOR AMPLIFIER

The Chopper 1 amplifier can be used as a thermistor input amplifier. In Figure 6, the output voltage is a function of the thermistor temperature. The voltage at TAMPOUT is expressed as:

$$V_{TAMPOUT} = \left( \frac{R_{FB}}{R_{TH} + R_X} - \frac{R_{FB}}{R} + 1 \right) \cdot \frac{V_{REF}}{2}$$

where:

$R_{TH}$  is a thermistor resistance at a certain temperature.

$R_X$  is a compensation resistor.

The Chopper 1 amplifier should be optimized according to the temperature range for each application to gain better voltage-to-temperature linearity and temperature setting resolution. To center the  $V_{TAMPOUT}$  vs Temperature curve around  $T_{MID}$ , calculate  $R$  using the following equation:

$$R = R_X + R_{MID}$$

Figure 6 shows a  $V_{TAMPOUT}$  vs Temperature curve, where  $V_{TAMPOUT}$  is centered around  $V_{REF}/2$  at 25°C. The average temperature-to-voltage coefficient is 25mV/°C at a range of 5°C to 45°C.

Figure 6.  $V_{TAMPOUT}$  vs Temperature

4663 F06

## APPLICATIONS INFORMATION

### PID COMPENSATION AMPLIFIER

Use the Chopper 2 amplifier as the PID compensation amplifier. The voltage at TAMPOUT feeds into the PID compensation amplifier. The frequency response is dictated by the compensation network. Apply the temperature set voltage at T<sub>SET</sub>. In Figure 7, the voltage at PAMPOUT is calculated using the following equation:

$$V_{\text{PAMPOUT}} = V_{\text{TSET}} - \frac{Z_2}{Z_1} (V_{\text{TAMPOUT}} - V_{\text{TSET}})$$

where:

V<sub>TSET</sub> is the control voltage input to the T<sub>SET</sub> pin. V<sub>TSET</sub> sets the object target temperature. Take Figure 6 for an example, 1.25V T<sub>SET</sub> voltage setting maintains a 25°C target temperature for the object; 0.75V T<sub>SET</sub> voltage setting cools down the object to 5°C; and 1.75V T<sub>SET</sub> voltage setting heats up the object to 45°C.

Z<sub>1</sub> is the impedance of R<sub>I</sub>, R<sub>D</sub>, and C<sub>D</sub> (see Figure 7).

Z<sub>2</sub> is the impedance of R<sub>P</sub>, C<sub>I</sub>, and C<sub>F</sub> (see Figure 7).

The user sets the exact compensation network. This network varies from a simple integrator to proportional-integral (PI), PID (proportional-integral-derivative), or any other type of network. The user also determines the type of compensation and component values because they are dependent on the thermal response of the object and the TEC. One method to empirically determine these values is to input a step function to T<sub>SET</sub>; thus changing the target temperature, and adjust the compensation network to minimize the settling time of the TEC temperature.

A typical compensation network for temperature control of a laser module is a PID loop consisting of a very low frequency pole and two separate zeros at higher frequencies. Figure 7 shows a simple network for implementing PID compensation. To reduce the noise sensitivity of the control loop, an additional pole is added at a higher frequency than that of the zeros. The bode plot of the magnitude is shown in Figure 8.

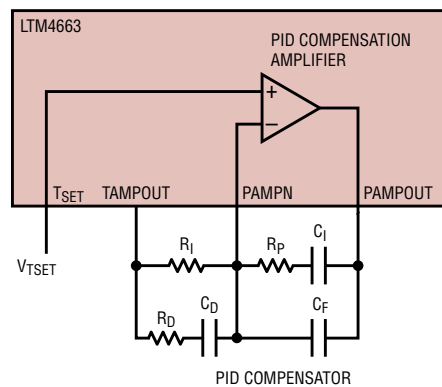

Figure 7. Analog PID Compensation Network

Figure 8. Bode Plot for PID Compensation

To ensure stability, the crossover frequency must be lower than the thermal time constant of the TEC and thermistor. There are many texts written on loop stabilization, and it is beyond the scope of this data sheet to discuss all methods and trade-offs for optimizing compensation networks.

TAMPOUT is a convenient measure to gauge the thermal instability of the system. If the thermal loop is in steady state, the TAMPOUT voltage equals the T<sub>SET</sub> voltage, meaning that the temperature of the controlled object equals the target temperature.

## APPLICATIONS INFORMATION

### Switching Mode and Linear Power Stages

The output of the PID compensation amplifier signal (PAMPOUT) will be used to drive both a switching mode regulator and a linear power stage to form a positive or negative voltage across the TEC device connected in between. Figure 9 shows the relationship between PAMPOUT voltage and the differential voltage of  $V_{LDR} - V_{PWM}$  which is the voltage applied at TEC device.

Figure 9. TEC Voltage vs PAMPOUT Voltage

### Thermal Considerations and Output Current Derating

The thermal resistances reported in the Pin Configuration section of the data sheet are consistent with those parameters defined by JESD51-9 and are intended for use with finite element analysis (FEA) software modeling tools that leverage the outcome of thermal modeling, simulation, and correlation to hardware evaluation performed on a  $\mu$ Module package mounted to a hardware test board—also defined by JESD51-9 (Test Boards for Area Array Surface Mount Package Thermal Measurements). The motivation for providing these thermal coefficients is found in JESD51-12 (Guidelines for Reporting and Using Electronic Package Thermal Information).

Many designers may opt to use laboratory equipment and a test vehicle such as the demo board to anticipate the  $\mu$ Module regulator's thermal performance in their application at various electrical and environmental operating conditions to compliment any FEA activities. Without FEA software, the thermal resistances reported in the Pin Configuration section are in-and-of themselves not

relevant to providing guidance of thermal performance; instead, the derating curves provided in the data sheet can be used in a manner that yields insight and guidance pertaining to one's application-usage, and can be adapted to correlate thermal performance to one's own application.

The Pin Configuration section typically gives four thermal coefficients explicitly defined in JESD 51-12; these coefficients are quoted or paraphrased below:

1.  $\theta_{JA}$ , the thermal resistance from junction to ambient, is the natural convection junction-to-ambient air thermal resistance measured in a one cubic foot sealed enclosure. This environment is sometimes referred to as still air although natural convection causes the air to move. This value is determined with the part mounted to a JESD 51-9 defined test board, which does not reflect an actual application or viable operating condition.
2.  $\theta_{JCbottom}$ , the thermal resistance from junction to the bottom of the product case, is determined with all of the component power dissipation flowing through the bottom of the package. In the typical  $\mu$ Module regulator, the bulk of the heat flows out the bottom of the package, but there is always heat flow out into the ambient environment. As a result, this thermal resistance value may be useful for comparing packages but the test conditions don't generally match the user's application.
3.  $\theta_{JCtop}$ , the thermal resistance from junction to top of the product case, is determined with nearly all of the component power dissipation flowing through the top of the package. As the electrical connections of the typical  $\mu$ Module are on the bottom of the package, it is rare for an application to operate such that most of the heat flows from the junction to the top of the part. As in the case of  $\theta_{JCbottom}$ , this value may be useful for comparing packages but the test conditions don't generally match the user's application.
4.  $\theta_{JB}$ , the thermal resistance from junction to the printed circuit board, is the junction-to-board thermal resistance where almost all of the heat flows through the bottom of the  $\mu$ Module and into the board, and is really the sum of the  $\theta_{JCbottom}$  and the thermal

## APPLICATIONS INFORMATION

resistance of the bottom of the part through the solder joints and through a portion of the board. The board temperature is measured a specified distance from the package, using a two sided, two-layer board. This board is described in JESD 51-9.

A graphical representation of the aforementioned thermal resistances is given in Figure 10; blue resistances are contained within the  $\mu$ Module regulator, whereas green resistances are external to the  $\mu$ Module.

As a practical matter, it should be clear to the reader that no individual or subgroup of the four thermal resistance parameters defined by JESD 51-12 or provided in the Pin Configuration section replicates or conveys normal operating conditions of a  $\mu$ Module regulator. For example, in normal board-mounted applications, never does 100% of the device's total power loss (heat) thermally conduct exclusively through the top or exclusively through bottom of the  $\mu$ Module regulator—as the standard defines for  $\theta_{JCtop}$  and  $\theta_{JCbottom}$ , respectively. In practice, power loss is thermally dissipated in both directions away from the package—granted, in the absence of a heat sink and airflow, a majority of the heat flow is into the board.

Within a SIP (system-in-package) module, be aware there are multiple power devices and components dissipating power, with a consequence that the thermal resistances relative to different junctions of components or die are not exactly linear with respect to total package power loss. To reconcile this complication without sacrificing modeling simplicity—but also, not ignoring practical realities—an approach has been taken using FEA software modeling along with laboratory testing in a controlled-environment

chamber to reasonably define and correlate the thermal resistance values supplied in this data sheet: (1) Initially, FEA software is used to accurately build the mechanical geometry of the  $\mu$ Module and the specified PCB with all of the correct material coefficients along with accurate power loss source definitions; (2) this model simulates a software-defined JEDEC environment consistent with JESD51-9 to predict power loss heat flow and temperature readings at different interfaces that enable the calculation of the JEDEC-defined thermal resistance values; (3) the model and FEA software is used to evaluate the  $\mu$ Module with heat sink and airflow; (4) having solved for and analyzed these thermal resistance values and simulated various operating conditions in the software model, a thorough laboratory evaluation replicates the simulated conditions with thermocouples within a controlled-environment chamber while operating the device at the same power loss as that which was simulated. An outcome of this process and due-diligence yields a set of derating curves provided in other sections of this data sheet. After these laboratory test have been performed and correlated to the  $\mu$ Module model, then the  $\theta_{JB}$  and  $\theta_{BA}$  are summed together to correlate quite well with the  $\mu$ Module model with no airflow or heat sinking in a properly define chamber. This  $\theta_{JB} + \theta_{BA}$  value is shown in the Pin Configuration section and should accurately equal the  $\theta_{JA}$  value because approximately 100% of power loss flows from the junction through the board into ambient with no airflow or top mounted heat sink.

The power loss curves in Figure 11 and Figure 12 can be used in coordination with the load current derating curves in Figure 13 to Figure 16 for calculating an approximate  $\theta_{JA}$  thermal resistance for the LTM4663. The power loss

## APPLICATIONS INFORMATION

curves are taken at room temperature, and are increased with multiplicative factors according to the ambient temperature. These approximate factor is 1.1 assuming at 110°C junction temperature. Maximum load current is achievable while increasing ambient temperature as long as the junction temperature is less than 110°C, which is a 15°C guard band from maximum junction temperature of 125°C. The derating curves are plotted with the output current up to 1.5A and the ambient temperature at 90°C. The resistive load is set to be 2Ω for both cooling and heating modes, and the input voltage is chosen from 3.3V and 5V. These are chosen to include the lower and higher input and load ranges for correlating the thermal resistance. Thermal models are derived from several temperature measurements in a controlled temperature chamber along with thermal modeling analysis. The junction temperatures are monitored while ambient temperature is increased with and without airflow. The power loss increase with ambient temperature change is factored into the derating curves. The junctions are maintained at 110°C maximum while lowering output current or power with increasing ambient temperature. The decreased output current will decrease the internal module loss as ambient temperature is increased. The monitored junction temperature of 110°C minus the ambient operating temperature specifies how much

module temperature rise can be allowed. As an example in Figure 13, the ambient temperature is derated to 90°C at 1.5A of load current with no air to prevent the junction temperature exceeding 110°C. Figure 11 shows that the cooling mode power loss for the 5V<sub>IN</sub> to 1.5A is 0.5W, and the 1.1 multiplying factor would make the total power loss to be 0.55W. If the 90°C ambient temperature is subtracted from the 110°C junction temperature, then the difference of 20°C divided by 0.55W equals a 36.3°C/W for  $\theta_{JA}$  thermal resistance. Table 4 specifies a 36°C/W value which is very close.

Table 4 and Table 5 provide equivalent thermal resistances with and without airflow. The derived thermal resistances for the various conditions can be multiplied by the calculated power loss as a function of ambient temperature to derive temperature rise above ambient, thus maximum junction temperature. Room temperature power loss can be derived from the efficiency curves in the Typical Performance Characteristics section and adjusted with the above ambient temperature multiplicative factors. The printed circuit board is a 1.6mm thick four-layer board with two-ounce copper for the two outer layers and one-ounce copper for the two inner layers. The PCB dimensions are 90mm × 75mm.

## APPLICATIONS INFORMATION

### SAFETY CONSIDERATIONS

The LTM4663 module does not provide galvanic isolation from  $V_{IN}$  to  $V_{OUT}$ . There is no internal fuse. If required, a slow blow fuse with a rating twice the maximum input current needs to be provided to protect each unit from catastrophic failure. The device does support thermal shutdown and over current protection.

### LAYOUT CHECKLIST/EXAMPLE

The high integration of LTM4663 makes the PCB board layout very simple and easy. However, to optimize its electrical and thermal performance, some layout considerations are still necessary.

- Use large PCB copper areas for high current paths, including  $PV_{IN}$ , GND,  $V_{PWM}$  and  $V_{LDR}$ . It helps to minimize the PCB conduction loss and thermal stress.

- Place high frequency ceramic input and output capacitors next to the  $PV_{IN}$ , PGND and  $V_{PWM}$  pins to minimize high frequency noise.
- Place a dedicated power ground layer underneath the unit.
- To minimize the via conduction loss and reduce module thermal stress, use multiple vias for interconnection between top layer and other power layers.
- Use a separated GNDA ground copper area for components connected to signal pins. Connect the GNDA to GNDP and GNDL underneath the unit.

Figure 17 gives a good example of the recommended layout.
