## FEATURES

## Easy Drive <br> Greatly reduced input kickback

Input current reduced to $0.5 \mu \mathrm{~A} / \mathrm{MSPS}$
Enhanced acquisition phase, $\geq \mathbf{7 9 \%}$ of cycle time at 1 MSPS
First conversion accurate, no latency or pipeline delay
Input span compression for single-supply operation
Fast conversion allows low SPI clock rates
Input overvoltage clamp protection sinks up to $\mathbf{5 0} \mathbf{~ m A}$
SPI-/QSPI-/MICROWIRE-/DSP-compatible serial interface

## High performance

Differential analog input range: $\pm \mathrm{V}_{\text {REF }}, \mathrm{V}_{\text {Ref }}$ from 2.4 V to 5.1 V
Throughput: 2 MSPS/1 MSPS options
INL: $\pm 0.4$ LSB maximum
Guaranteed 16-bit, no missing codes
SNR: 96.2 dB at $\mathrm{f}_{\mathrm{IN}}=\mathbf{1 k H z}, \mathrm{V}_{\text {REF }}=5 \mathrm{~V}$
THD: -123 dB at $\mathrm{f}_{\mathrm{IN}}=1 \mathrm{kHz},-99 \mathrm{~dB}$ at $\mathrm{f}_{\mathrm{in}}=100 \mathrm{kHz}$
SINAD: 88.5 dB at $\mathrm{f}_{\mathrm{IN}}=1 \mathrm{MHz}$ (see Figure 17)
Oversampled dynamic range
99.3 dB for OSR $=2$

126 dB for OSR = 1024
Low power
Single 1.8 V supply operation with 1.71 V to 5.5 V logic interface
4.9 mW at 1 MSPS (VDD only)
$80 \mu \mathrm{~W}$ at $10 \mathrm{kSPS}, 16 \mathrm{~mW}$ at 2 MSPS (total power)
10-lead packages: $3 \mathrm{~mm} \times 3 \mathrm{~mm}$ LFCSP, $3 \mathrm{~mm} \times 4.90 \mathrm{~mm}$ MSOP
Pin compatible with AD4003/AD4007/AD4011 family
Guaranteed operation: $-40^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$
APPLICATIONS
Automated test equipment
Machine automation
Medical equipment
Battery-powered equipment
Precision data acquisition systems
Instrumentation and control systems

Figure 1.

## GENERAL DESCRIPTION

The AD4001/AD4005 are high accuracy, high speed, low power, 16-bit, Easy Drive, precision successive approximation register (SAR) analog-to-digital converters (ADCs) that operate from a single power supply, VDD. The reference voltage, $\mathrm{V}_{\text {ref }}$, is applied externally and can be set independent of the supply voltage. The AD4001/AD4005 power scales linearly with throughput.
Easy Drive features reduce both signal chain complexity and power consumption while enabling higher channel density. The reduced input current, particularly in high- Z mode, coupled with a long signal acquisition phase, eliminates the need for a dedicated ADC driver. Easy Drive broadens the range of companion circuitry that is capable of driving these ADCs (see Figure 2).
Input span compression eliminates the need to provide a negative supply to the ADC driver amplifier while preserving access to the full ADC code range. The input overvoltage clamp protects the ADC inputs against overvoltage events, minimizing disturbances on the reference pin and eliminating the need for external protection diodes.
Fast device throughput up to 2 MSPS allows users to accurately capture high frequency signals and to implement oversampling techniques to alleviate the challenges associated with antialias filter designs. Decreased serial peripheral interface (SPI) clock rate requirements reduce digital input and output power consumption, broadens digital host options, and simplifies the task of sending data across digital isolation. The SPI-compatible serial user interface is compatible with $1.8 \mathrm{~V}, 2.5 \mathrm{~V}, 3 \mathrm{~V}$, and 5 V logic by using the separate VIO logic supply.

\section*{PIN CONFIGURATIONS AND FUNCTION DESCRIPTIONS}

Figure 3. 10-Lead MSOP Pin Configuration

Table 7. Pin Function Descriptions
\begin{tabular}{|c|c|c|c|}
\hline Pin No. & Mnemonic & Type \({ }^{1}\) & Description \\
\hline 1 & REF & AI & Reference Input Voltage. The \(\mathrm{V}_{\text {REF }}\) range is 2.4 V to 5.1 V . This pin is referred to the GND pin and must be decoupled closely to the GND pin with a \(10 \mu \mathrm{~F}, \mathrm{X} 7 \mathrm{R}\) ceramic capacitor. \\
\hline 2 & VDD & P & 1.8 V Power Supply. The VDD range is 1.71 V to 1.89 V . Bypass VDD to GND with a \(0.1 \mu \mathrm{~F}\) ceramic capacitor. \\
\hline 3 & IN+ & AI & Differential Positive Analog Input. See the Differential Input Considerations section. \\
\hline 4 & IN- & AI & Differential Negative Analog Input. See the Differential Input Considerations section. \\
\hline 5 & GND & P & Power Supply Ground. Connect to the ground plane of the board. \\
\hline 6 & CNV & DI & Convert Input. This input has multiple functions. On its leading edge, the input initiates the conversions and selects the interface mode of the device, which is either daisy-chain mode or \(\overline{C S}\) mode. In \(\overline{C S}\) mode, the SDO pin is enabled when CNV is low. In daisy-chain mode, the data is read when CNV is high. \\
\hline 7 & SDO & DO & Serial Data Output. The conversion result is output on this pin. The SDO pin is synchronized to the SCK signal on the SCK pin. \\
\hline 8 & SCK & DI & Serial Data Clock Input. When the device is selected, the conversion result is shifted out by this clock. \\
\hline 9 & SDI & DI & \begin{tabular}{l}
Serial Data Input. This input provides multiple features and selects the interface mode of the ADC as follows: Daisy-chain mode is selected if SDI is low during the CNV rising edge. In this mode, SDI is used as a data input to daisy-chain the conversion results of two or more ADCs onto a single SDO line. The digital data level on SDI is output on SDO with a delay of 16 SCK cycles. \\
\(\overline{\mathrm{CS}}\) mode is selected if SDI is high during the CNV rising edge. In this mode, either SDI or CNV can enable the serial output signals when low. If SDI or CNV is low when the conversion is complete, the busy indicator feature is enabled. With CNV low, program the device by clocking in a 16-bit word on SDI on the rising edge of SCK.
\end{tabular} \\
\hline 10 & VIO & P & Input/Output Interface Digital Power. Nominally, this pin is at the same supply as the host interface ( \(1.8 \mathrm{~V}, 2.5 \mathrm{~V}, 3 \mathrm{~V}\), or 5 V ). Bypass VIO to GND with a \(0.1 \mu \mathrm{~F}\) ceramic capacitor. \\
\hline \(\mathrm{N} / \mathrm{A}^{2}\) & EPAD & P & Exposed Pad. Connect the exposed pad to GND. This connection is not required to meet the specified performance. Note that the exposed pad only applies to the LFCSP. \\
\hline
\end{tabular}

\footnotetext{
\({ }^{1} \mathrm{Al}\) is analog input, P is power, DI is digital input, and DO is digital output.

\section*{TERMINOLOGY}

\section*{Integral Nonlinearity Error (INL)}

INL is the deviation of each individual code from a line drawn from negative full scale through positive full scale. The point used as negative full scale occurs \(1 / 2\) LSB before the first code transition. Positive full scale is defined as a level \(11 / 2\) LSB beyond the last code transition. The deviation is measured from the middle of each code to the true straight line (see Figure 38).

\section*{Differential Nonlinearity Error (DNL)}

In an ideal ADC, code transitions are 1 LSB apart. DNL is the maximum deviation from this ideal value. It is often specified in terms of resolution for which no missing codes are guaranteed.

\section*{Zero Error}

Zero error is the difference between the ideal voltage that results in the first code transition ( \(1 / 2\) LSB above analog ground) and the actual voltage producing that code.

\section*{Gain Error}

The first transition (from \(100 \ldots 00\) to 100 ... 01 ) occurs at a level \(1 / 2\) LSB above nominal negative full scale ( -4.999981 V for the \(\pm 5 \mathrm{~V}\) range). The last transition (from \(011 \ldots 10\) to \(011 \ldots 11\) ) occurs for an analog voltage \(11 / 2\) LSB below the nominal full scale ( +4.999943 V for the \(\pm 5 \mathrm{~V}\) range). The gain error is the deviation of the difference between the actual level of the last transition and the actual level of the first transition from the difference between the ideal levels.

\section*{Spurious-Free Dynamic Range (SFDR)}

SFDR is the difference, in decibels (dB), between the rms amplitude of the input signal and the peak spurious signal.

\section*{Effective Number of Bits (ENOB)}

ENOB is a measurement of the resolution with a sine wave input. It is related to SINAD as follows:
\[
E N O B=(S I N A D-1.76) / 6.02
\]

ENOB is expressed in bits, and SINAD is expressed in dB.
Total Harmonic Distortion (THD)
THD is the ratio of the rms sum of the first five harmonic components to the rms value of a full-scale input signal and is expressed in decibels.

\section*{Dynamic Range}

Dynamic range is the ratio of the rms value of the full scale to the total rms noise measured. The value for dynamic range is expressed in decibels. It is measured with a signal at -60 dBFS so that it includes all noise sources and DNL artifacts.

\section*{Signal-to-Noise Ratio (SNR)}

SNR is the ratio of the rms value of the actual input signal to the rms sum of all other spectral components below the Nyquist frequency, excluding harmonics and dc. The value for SNR is expressed in decibels.

\section*{Signal-to-Noise-and-Distortion Ratio (SINAD)}

SINAD is the ratio of the rms value of the actual input signal to the rms sum of all other spectral components that are less than the Nyquist frequency, including harmonics but excluding dc. The value of SINAD is expressed in decibels.

\section*{Aperture Delay}

Aperture delay is the measure of the acquisition performance and is the time between the rising edge of the CNV input and when the input signal is held for a conversion.

\section*{Transient Response}

Transient response is the time required for the ADC to acquire a full-scale input step to \(\pm 1\) LSB accuracy.

\section*{Common-Mode Rejection Ratio (CMRR)}

CMRR is the ratio of the power in the ADC output at the frequency, f , to the power of a 200 mV p-p sine wave applied to the common-mode voltage of \(\mathrm{IN}+\) and \(\mathrm{IN}-\) of frequency, f .
\[
C M R R(\mathrm{~dB})=10 \log \left(P_{A D C \_I N} / P_{A D C \_O U T}\right)
\]
where:
\(P_{A D C_{-} I N}\) is the common-mode power at the frequency, f , applied to the \(\mathrm{IN}+\) and IN - inputs.
\(P_{A D C \_ \text {out }}\) is the power at the frequency, f , in the ADC output.

\section*{Power Supply Rejection Ratio (PSRR)}

PSRR is the ratio of the power in the ADC output at the frequency, f , to the power of a 200 mV p-p sine wave applied to the ADC VDD supply of frequency, \(f\).
\[
\operatorname{PSRR}(\mathrm{dB})=10 \log \left(P_{V D D_{-} I N} / P_{A D C_{-} \text {OUT }}\right)
\]
where:
\(P_{V D D_{-} I N}\) is the power at the frequency, f , at the VDD pin.
\(P_{A D C \_o u t ~ i s ~ t h e ~ p o w e r ~ a t ~ t h e ~ f r e q u e n c y, ~} \mathrm{f}\), in the ADC output.

\section*{AD4001/AD4005}

\section*{THEORY OF OPERATION}

Figure 37. ADC Simplified Schematic

\section*{CIRCUIT INFORMATION}

The AD4001/AD4005 are high speed, low power, single-supply, precise, 16-bit differential ADCs based on a SAR architecture.

The AD4001 is capable of converting 2,000,000 samples per second ( 2 MSPS), the AD4005 is capable of converting 1,000,000 samples per second ( 1 MSPS). The power consumption of the AD4001/AD4005 scales with throughput because they power down in between conversions. For example, when operating at 10 kSPS , the devices typically consume \(80 \mu \mathrm{~W}\), making them ideal for battery-powered applications. The AD4001/AD4005 also have a valid first conversion after being powered down for long periods, which can further reduce power consumed in applications in which the ADC does not need to be constantly converting.

The AD4001/AD4005 provide the user with an on-chip track-and-hold and do not exhibit any pipeline delay or latency, making them ideal for multiplexed applications.

The AD4001/AD4005 incorporate a multitude of unique, easy to use features that result in a lower system power and smaller footprint.
The AD4001/AD4005 each have an internal voltage clamp that protects the device from overvoltage damage on the analog inputs.
The analog input incorporates circuitry that reduces the nonlinear charge kickback seen from a typical switched capacitor SAR input. This reduction in kickback, combined with a longer acquisition phase, allows the use of lower bandwidth and lower power amplifiers as drivers. This combination has the additional benefit of allowing a larger resistor value in the input RC filter and a corresponding smaller capacitor, which results in a smaller RC load for the amplifier, improving stability and power dissipation.
High-Z mode can be enabled via the SPI interface by programming a register bit (see Table 12). When high- Z mode is enabled, the ADC input has a low input charging current at low input signal frequencies, as well as improved distortion over a wide frequency range up to 100 kHz . For frequencies greater than 100 kHz and multiplexing functionality, disable high-Z mode.

For single-supply applications, a span compression feature creates additional headroom and footroom for the driving amplifier to access the full range of the ADC.

The fast conversion time of the AD4001/AD4005, along with turbo mode, allows low clock rates to read back conversions, even when running at their respective maximum throughput rates of 2 MSPS/ 1 MSPS. Note that, for the AD4001, the full throughput rate of 2 MSPS can be achieved only with turbo mode enabled.

The AD4001/AD4005 can interface with any 1.8 V to 5 V digital logic family. These devices are available in a 10 -lead MSOP or a tiny 10-lead LFCSP that allows space savings and flexible configurations.

The AD4001/AD4005 are pin for pin compatible with some of the 14-/16-/18-/20-bit precision SAR ADCs listed in Table 8.

\section*{CONVERTER OPERATION}

The AD4001/AD4005 are SAR-based ADCs using a charge redistribution sampling digital-to-analog converter (DAC). Figure 37 shows the simplified schematic of the ADC. The capacitive DAC consists of two identical arrays of 16 binary weighted capacitors, which are connected to the comparator inputs.

During the acquisition phase, terminals of the array tied to the input of the comparator are connected to ground via the \(\mathrm{SW}+\) and SW- switches (see Figure 37). All independent switches connect the other terminal of each capacitor to the analog inputs. The capacitor arrays are used as sampling capacitors and acquire the analog signal on the \(\mathrm{IN}+\) and IN - inputs.
When the acquisition phase is complete and the CNV input goes high, a conversion phase initiates. When the conversion phase begins, SW+ and SW- are opened first. The two capacitor arrays are then disconnected from the inputs and connected to the GND input. The differential voltage between the IN+ and IN - inputs captured at the end of the acquisition phase is applied to the comparator inputs, causing the comparator to become unbalanced. By switching each element of the capacitor array between GND and \(V_{\text {ReF }}\), the comparator input varies by binary weighted voltage steps ( \(\mathrm{V}_{\text {ReF }} / 2, \mathrm{~V}_{\text {ReF }} / 4, \ldots, \mathrm{~V}_{\text {REF }} / 65,536\) ). The control logic toggles these switches, starting with the MSB, to bring the comparator back into a balanced condition. After
the process completes, the control logic generates the ADC output code and a busy signal indicator.
Because the AD4001 and the AD4005 have on-board conversion clocks, the serial clock, SCK, is not required for the conversion process.

\section*{TRANSFER FUNCTIONS}

The ideal transfer characteristics for the AD4001/AD4005 are shown in Figure 38 and Table 9.

Figure 38. ADC Ideal Transfer Function (FSR Is Full-Scale Range)

Table 9. Output Codes and Ideal Input Voltages
\begin{tabular}{l|l|l|l}
\hline Description & Analog Input, V \(_{\text {REF }}=\mathbf{5} \mathrm{V}\) & V \(_{\text {REF }}=\mathbf{5} \mathrm{V}\) with Span Compression Enabled & Digital Output Code (Hex) \\
\hline+ FSR -1 LSB & +4.999847 V & +3.999878 V & \(0 \times 7 \mathrm{FFF}^{1}\) \\

\({ }^{1}\) This output code is also the code for an overranged analog input ( \(\mathrm{V}_{\mathbb{I N}+}-\mathrm{V}_{\mathbb{I N}-}\) above \(\mathrm{V}_{\text {REF }}\) with span compression disabled and above \(0.8 \times \mathrm{V}_{\mathrm{REF}}\) with span compression enabled).
\({ }^{2}\) This output code is also the code for an underranged analog input ( \(\mathrm{V}_{\mathbb{I N}+}-\mathrm{V}_{\mathbb{I N}-}\) below \(-\mathrm{V}_{\mathrm{REF}}\) with span compression disabled and below \(-0.8 \times \mathrm{V}_{\mathrm{REF}}\) with span compression enabled).
}

\section*{APPLICATIONS INFORMATION \\ TYPICAL APPLICATION DIAGRAMS}

Figure 39 shows an example of the recommended connection diagram for the AD4001/AD4005 when multiple supplies, V+ and \(\mathrm{V}-\), are available. This configuration is used for optimal performance because the amplifier supplies can be selected to allow the maximum signal range (see Figure 39 for the range).

Figure 40 shows a recommended connection diagram when using a single-supply system. This setup is preferable when only a limited number of rails are available in the system and power dissipation is of critical importance.

Figure 41 shows a typical application diagram when using a fully differential amplifier (FDA).

Figure 39. Typical Application Diagram with Multiple Supplies

\({ }^{1}\) SEE THE VOLTAGE REFERENCE INPUT SECTION FOR REFERENCE SELECTION. C \(_{\text {REF }}\) IS USUALLY A 10 \(\mu\) F CERAMIC CAPACITOR (X7R). \({ }^{2}\) SPAN COMPRESSION MODE ENABLED.
\({ }^{3}\) SEE TABLE 10 FOR RC FILTER AND AMPLIFIER SELECTION.

Figure 41. Typical Application Diagram with a Fully Differential Amplifier

\section*{ANALOG INPUTS}

Figure 42 shows an equivalent circuit of the analog input structure, including the overvoltage clamp of the AD4001/AD4005.

Figure 42. Equivalent Analog Input Circuit

\section*{Input Overvoltage Clamp Circuit}

Most ADC analog inputs, IN+ and IN-, have no overvoltage protection circuitry apart from ESD protection diodes. During an overvoltage event, an ESD protection diode from an analog input pin (IN+ or IN-) to REF forward biases and shorts the input pin to REF, potentially overloading the reference or damaging the device. The AD4001/AD4005 internal overvoltage clamp circuit with a larger external resistor \((\mathrm{Rexx}=200 \Omega)\) eliminates the need for external protection diodes and protects the ADC inputs against dc overvoltages.
In applications where the amplifier rails are greater than \(V_{\text {REF }}\) and less than ground, it is possible for the output to exceed the input voltage range (specified in Table 1) of the device. In this case, the AD4001/AD4005 internal overvoltage clamp circuit ensures that the voltage on the input pin does not exceed \(V_{\text {ReF }}+0.4 \mathrm{~V}\) and prevents damage to the device by clamping the input voltage in a safe operating range and avoiding disturbance of the
reference, which is particularly important for systems that share the reference among multiple ADCs.
If the analog input exceeds the reference voltage by 0.4 V , the internal clamp circuit turns on and the current flows through the clamp into ground, preventing the input from rising further and potentially causing damage to the device. The clamp turns on before D1 (see Figure 42) and can sink up to 50 mA of current. When the clamp is active, it sets the overvoltage \((\overline{\mathrm{OV}})\) clamp flag bit in the configuration register that is accessed with a 16 bit SPI read command or via the \(\overline{\mathrm{OV}}\) in the status bits. The \(\overline{\mathrm{OV}}\) clamp flag gives an indication of overvoltage condition when it is set to 0 . The \(\overline{\mathrm{OV}}\) clamp flag is a read only sticky bit, and is cleared only if the register is read while the overvoltage condition is no longer present.
The clamp circuit does not dissipate static power in the off state. Note that the clamp cannot sustain the overvoltage condition for an indefinite amount of time.
The external RC filter, formed by the \(\mathrm{R}_{\mathrm{EXT}}\) resistor and the CEXT capacitor (see Figure 42), is usually present at the ADC input to band limit the input signal. During an overvoltage event, excessive voltage is dropped across \(\mathrm{R}_{\mathrm{EXT}}\), and \(\mathrm{R}_{\mathrm{ExT}}\) becomes part of a protection circuit. The \(\mathrm{R}_{\mathrm{EXT}}\) value can vary from \(200 \Omega\) to \(20 \mathrm{k} \Omega\) for 15 V protection. The \(\mathrm{C}_{\mathrm{ExT}}\) value can be as low as 100 pF for correct operation of the clamp. See Table 1 for input overvoltage clamp specifications.

\section*{Differential Input Considerations}

The analog input structure allows the sampling of the true differential signal between \(\mathrm{IN}+\) and \(\mathrm{IN}-\). By using these differential inputs, signals common to both inputs are rejected. Figure 32 shows the common-mode rejection capability of the AD4001/AD4005 over frequency. It is important to note that the differential input signals must be truly antiphase in nature, \(180^{\circ}\) out of phase, which is required to keep the common-mode voltage of the input signal within the specified range around \(\mathrm{V}_{\text {ref }} / 2\) as shown in Table 1.

\section*{Switched Capacitor Input}

During the acquisition phase, the impedance of the analog inputs (IN+ or IN-) can be modeled as a parallel combination of Capacitor Cpin and the network formed by the series connection of \(\mathrm{R}_{\mathbb{N}}\) and \(\mathrm{C}_{\mathrm{IN}}\). CPIN is primarily the pin capacitance. \(\mathrm{R}_{\mathbb{N}}\) is typically \(400 \Omega\) and is a lumped component composed of serial resistors and the on resistance of the switches. CIN is typically 40 pF and is mainly the ADC sampling capacitor.
During the conversion phase, where the switches are open, the input impedance is limited to \(\mathrm{C}_{\text {pin }} \mathrm{R}_{\text {IN }}\) and \(\mathrm{C}_{\text {IN }}\) make a singlepole, low-pass filter that reduces undesirable aliasing effects and limits noise.

\section*{RC Filter Values}

The RC filter value (represented by R and C in Figure 39 to Figure 43) and driving amplifier can be selected depending on the input signal bandwidth of interest at the full throughput. Lower input signal bandwidth means that the RC cutoff can be lower, thereby reducing noise into the converter. For optimum performance at various throughputs, use the recommended RC values ( \(200 \Omega, 180 \mathrm{pF}\) ) and the ADA4807-1.

The RC values shown in Table 10 are chosen for ease of drive considerations and greater ADC input protection. The combination of a large R value ( \(200 \Omega\) ) and small C value results in a reduced dynamic load for the amplifier to drive. The smaller value of C means fewer stability and phase margin concerns with the amplifier. The large value of R limits the current into the ADC input when the amplifier output exceeds the ADC input range.

\section*{DRIVER AMPLIFIER CHOICE}

Although the AD4001/AD4005 are easy to drive, the driver amplifier must meet the following requirements:
- The noise generated by the driver amplifier must be kept low enough to preserve the SNR and transition noise performance of the AD4001/AD4005. The noise from the driver is filtered by the single-pole, low-pass filter of the AD4001/AD4005 analog input circuit made by \(\mathrm{R}_{\mathrm{IN}}\) and \(\mathrm{C}_{\mathrm{IN}}\), or by the external filter, if one is used. Because the typical noise of the AD4001/AD4005 is \(54 \mu \mathrm{~V} \mathrm{rms}\), the SNR degradation due to the amplifier is the following:
\(S N R_{\text {LOSS }}=20 \log \left(\frac{54 \mu \mathrm{~V}}{\sqrt{54 \mu V^{2}+\frac{\pi}{2} f_{-3 d B}\left(N e_{N}\right)^{2}}}\right)\)
where:
\(f_{-3 d B}\) is the input bandwidth, in megahertz, of the AD4001/ AD4005 ( 10 MHz ) or the cutoff frequency of the input filter, if one is used.
\(N\) is the noise gain of the amplifier (for example, 1 in buffer configuration).
\(e_{N}\) is the equivalent input noise voltage of the operational amplifier in \(\mathrm{nV} / \sqrt{ } \mathrm{Hz}\).
- For ac applications, the driver must have a THD performance commensurate with the AD4001/AD4005.
- For multichannel multiplexed applications, the driver amplifier and the analog input circuit of the AD4001/AD4005 must settle for a full-scale step onto the capacitor array at a 16-bit level ( \(0.0001525 \%, 15.25 \mathrm{ppm}\) ). In amplifier data sheets, settling at \(0.1 \%\) to \(0.01 \%\) is more commonly specified. Settling at \(0.1 \%\) to \(0.01 \%\) may differ significantly from the settling time at a 16 -bit level and must be verified prior to driver selection.

The Precision ADC Driver Tool can be used to model the settling behavior and estimate ac performance of the AD4001/AD4005 with a selected driver amplifier and RC filter. Once the Precision ADC Driver Tool has modelled a specific circuit, the circuit can be exported for simulation in LTspice.

Table 10. RC Filter and Amplifier Selection for Various Input Bandwidths
\begin{tabular}{l|l|l|l|l|l}

\end{tabular}

Figure 43. Typical Application Diagram for Single-Ended to Differential Conversion with a Fully Differential Amplifier

\section*{Single to Differential Driver}

The AD4001/AD4005 requires a differential input signal for proper operation. For applications using a single-ended analog signal, either bipolar or unipolar, a fully differential amplifier, such as the ADA4940-1 or ADA4945-1, can be used to convert the singleended signal to a differential signal, as shown in Figure 43.
High Frequency Input Signals
The AD4001/AD4005 ac performance over a wide input frequency range is shown in Figure 17 and Figure 20. Unlike other traditional SAR ADCs, the AD4001/AD4005 maintain exceptional ac performance for input frequencies up to the Nyquist frequency with minimal performance degradation. Note that the input frequency is limited to the Nyquist frequency of the sample rate in use.

\section*{Multiplexed Applications}

The AD4001/AD4005 significantly reduce system complexity for multiplexed applications that require superior performance in terms of noise, power, and throughput. Figure 44 shows a simplified block diagram of a multiplexed data acquisition system including a multiplexer, an ADC driver, and the precision SAR ADC.

Figure 44. Multiplexed Data Acquisition Signal Chain Using the AD4001/AD4005
Switching multiplexer channels typically results in large voltage steps at the ADC inputs. To ensure an accurate conversion result, the step must be given adequate time to settle before the ADC samples its inputs (on the rising edge of CNV). The settling time error is dependent on the drive circuitry (multiplexer and ADC driver), RC filter values, and the time when the multiplexer channels are switched. Switch the multiplexer channels immediately after \(\mathrm{t}_{\text {QUетı }}\) has elapsed from the start of the conversion to maximize settling time and to prevent corruption of the conversion result. To avoid conversion corruption, do not switch the channels during the tQuieti time. If the analog inputs are multiplexed during the quiet conversion time ( \(\mathrm{t}_{\text {QUieti }}\) ), the current conversion is possibly corrupted.

\section*{EASE OF DRIVE FEATURES}

\section*{Input Span Compression}

In single-supply applications, it is recommended to use the full range of the ADC. However, the amplifier can have some headroom and footroom requirements, which can be a problem, even if it is a rail-to-rail input and output amplifier. The AD4001/ AD4005 include a span compression feature, which increases the headroom and footroom available to the amplifier by reducing the input range by \(10 \%\) from the top and bottom of the range while still accessing all available ADC codes (see Figure 45). The SNR decreases by approximately \(1.9 \mathrm{~dB}(20 \times \log (8 / 10))\) for the reduced input range when span compression is enabled. Span compression is disabled by default but is enabled by writing to the relevant register bit (see the Digital Interface section).

Figure 45. Span Compression

\section*{High-Z Mode}

The AD4001/AD4005 incorporate high-Z mode, which reduces the nonlinear charge kickback when the capacitor DAC switches back to the input at the start of acquisition. Figure 28 shows the analog input current of the AD4001/AD4005 with high-Z mode enabled and disabled. The low input current makes the ADC easier to drive than the traditional SAR ADCs, even with highZ mode disabled. The input current reduces further to submicroampere range when high- Z mode is enabled. High-Z mode is disabled by default but can be enabled by writing to the configuration register (see Table 12). Disable high-Z mode for input frequencies above 100 kHz or when multiplexing.

To achieve the optimal data sheet performance from traditional high resolution precision SAR ADCs, system designers must often use a dedicated high power, high speed amplifier to drive the switched capacitor SAR ADC inputs. High-Z mode allows a choice of lower power and lower bandwidth precision amplifiers with a lower RC filter cutoff to drive the ADC, removing the need for dedicated high speed ADC drivers, which saves system power, size, and cost in precision, low bandwidth applications. High-Z mode allows the amplifier and RC filter in front of the ADC to be chosen based on the signal bandwidth of interest, rather than the settling requirements of the switched capacitor SAR ADC inputs. High-Z mode also improves THD performance and reduces analog input current for input signals up to 100 kHz .

Additionally, the AD4001/AD4005 can be driven with a much higher source impedance than traditional SARs, which means the resistor in the RC filter can have a value 10 times larger than previous SAR designs and with high-Z mode enabled, can tolerate
even greater impedance. Figure 26 shows the THD performance for various source impedances with high-Z mode disabled and enabled.

Figure 46 and Figure 47 show the AD4001 SNR and THD performance using the ADA4077-1 (supply current per amplifier \(\left.\left(\mathrm{I}_{\mathrm{sY}}\right)=400 \mu \mathrm{~A}\right)\) and ADA4610-1 \(\left(\mathrm{I}_{\mathrm{sY}}=1.50 \mathrm{~mA}\right)\) precision amplifiers when driving the AD4001 at full throughput for highZ mode both enabled and disabled with various RC filter values. These amplifiers achieve 93 dB to 96 dB typical SNR and close to -110 dB typical THD with high-Z mode enabled for a 2.27 MHz RC bandwidth. The THD is improved by approximately 10 dB with high- Z mode enabled, even for large R values greater than \(200 \Omega\). SNR maintains close to 96 dB , even with a low RC filter cutoff. The ADA4077-1 and ADA4610-1 data sheets of the selected precision amplifiers (see Figure 46 and Figure 47) show that their own noise and distortion performance dominates the SNR and THD specification at a certain input frequency.

Figure 46. SNR vs. RC Filter Bandwidths for Various Precision ADC Drivers for the AD4001, \(f_{i N}=1\) kHz (See the Typical Performance Characteristics Section for Operating Conditions)

Figure 47. THD vs. RC Filter Bandwidths for Various Precision ADC Drivers for the AD4001, \(f_{I N}=1\) kHz (See the Typical Performance Characteristics Section for Operating Conditions)

For applications that require a programmable gain instrumentation amplifier (PGIA), the LTC6373 can directly drive the AD4001/AD4005 without the need for a dedicated ADC driver. The LTC6373 data sheet shows ac performance results of an example circuit of the LTC6373 directly interfacing with the AD4020.

When high-Z mode is enabled, the ADC consumes approximately 2 mW per MSPS of extra power. However, this additional power is still significantly lower than using dedicated ADC drivers like the ADA4807-1.

\section*{Long Acquisition Phase}

The AD4001/AD4005 also feature a fast conversion time of 290 ns , which results in a long acquisition phase. The acquisition is further extended by a key feature of the AD4001/AD4005. The ADC returns to the acquisition phase typically 100 ns before the end of the conversion. This feature provides an even longer time for the ADC to acquire the new input voltage. A longer acquisition phase reduces the settling requirement on the driving amplifier, and a lower power and lower bandwidth amplifier can be chosen. The longer acquisition phase means that a lower RC filter (represented by R and C in Figure 39 to Figure 41 and Figure 43) cutoff can be used, which means a noisier amplifier can also be tolerated. A larger value of R can be used in the RC filter with a corresponding smaller value of C , reducing amplifier stability concerns without affecting distortion performance significantly. A larger value of R also results in reduced dynamic power dissipation in the amplifier.

See Table 10 for details on setting the RC filter bandwidth and choosing a suitable amplifier.

\section*{VOLTAGE REFERENCE INPUT}

A \(10 \mu \mathrm{~F}\) ( \(\mathrm{X} 7 \mathrm{R}, 0805\) size) ceramic chip capacitor is appropriate for the optimum performance of the reference input.

For higher performance and lower drift, use a reference such as the ADR4550. Using a low power reference such as the ADR3450 can result in a slight decrease in the noise performance. It is recommended to use a reference buffer, such as the ADA4807-1, between the reference and the ADC reference input. It is important to consider the optimum capacitance necessary to keep the reference buffer stable as well as to meet the minimum ADC requirement stated previously in this section (that is, a \(10 \mu \mathrm{~F}\) ceramic chip capacitor, Cref).

\section*{POWER SUPPLY}

The AD4001/AD4005 use two power supply pins: a core supply (VDD) and a digital input/output interface supply (VIO). VIO allows direct interface with any logic between 1.8 V and 5.5 V . To reduce the number of supplies needed, VIO and VDD can be tied together for 1.8 V operation. The ADP7118 low noise, CMOS, low dropout (LDO) linear regulator is recommended to power
the VDD and VIO pins. The AD4001/AD4005 are independent of power supply sequencing between VIO and VDD.

Additionally, the AD4001/AD4005 are insensitive to power supply variations over a wide frequency range, as shown in Figure 33.
The AD4001/AD4005 power down automatically at the end of each conversion phase. Therefore, the power scales linearly with the sampling rate. This feature makes the device ideal for low sampling rates (even a few samples per second) and batterypowered applications. Figure 31 shows the AD4001/AD4005 total power dissipation and individual power dissipation for each rail.

\section*{DIGITAL INTERFACE}

The AD4001/AD4005 digital interface is used to perform analog to digital conversions and to enable and disable various features. The AD4001/AD4005 are compatible with SPI, QSPI'", and MICROWIRE \({ }^{\bullet}\) digital hosts and DSPs. SCK must be set with clock polarity \((\mathrm{CPOL})=\) clock phase \((\mathrm{CPHA})=0\). A 3-wire interface using the CNV, SCK, and SDO signals minimizes wiring connections, which is useful in applications with digital isolation. A 4-wire interface using the SDI, CNV, SCK, and SDO signals allows CNV, which initiates the conversions, to be independent of the readback timing (SDI). This interface is useful in low jitter sampling or simultaneous sampling applications. In either 3-wire or 4-wire \(\overline{\mathrm{CS}}\) mode, a busy signal can be enabled to indicate when the conversion result is ready. The busy signal acts as an interrupt to the digital host to initiate data readback.

The AD4001/AD4005 digital interface also supports daisychaining multiple devices to read back results from multiple ADCs over a single SPI bus.

Timing diagrams and explanations for each digital interface mode are given in the digital modes of operation sections (see the \(\overline{\mathrm{CS}}\) Mode, 3-Wire Turbo Mode section through the DaisyChain Mode section).

Turbo mode allows the use of slower SPI clock rates by extending the amount of time available to clock out conversion results. Turbo mode is enabled by setting the Turbo Mode Enable field to 1 in the configuration register and replaces the busy indicator feature when enabled. The maximum throughput of 2 MSPS for the AD4001 can be achieved only with turbo mode enabled and a minimum SCK frequency of 70 MHz (see the \(\overline{\mathrm{CS}}\) Mode, 3-Wire Turbo Mode section). See the \(\overline{\mathrm{CS}}\) Mode, 4-Wire Turbo Mode for descriptions of turbo mode operation.

Status bits can also be clocked out at the end of the conversion data if the status bits are enabled in the configuration register (see the Status Bits section).

For isolated systems, the ADuM141D is recommended, which can support the 70 MHz SCK frequency required to run the AD4001 at its full throughput of 2 MSPS.

The state of SDO on power-up is either low or high-Z, depending on the states of CNV and SDI, as shown in Table 11.
Table 11. State of SDO on Power-Up
\begin{tabular}{l|l|l}
\hline CNV & SDI & SDO \\
\hline 0 & 0 & Low \\
0 & 1 & Low \\
1 & 0 & Low \\
1 & 1 & High-Z \\
\hline
\end{tabular}

\section*{Configuration Register Details}

The AD4001/AD4005 features are controlled via the configuration register. The configuration register is eight bits wide and contains enable bits for the status bits, span compression, high-Z mode, and turbo mode, as well as an overvoltage detection flag. The 16-bit SPI instructions are used to read from and write to the contents in the configuration register. Table 12 shows the locations and descriptions of each field in the configuration register.

\section*{Serial Clock Frequency Requirements}

The AD4001/AD4005 digital interface minimizes the SCK frequency required for reading back conversion results, even when operating at a high throughput. The minimum SCK frequency required for a given application depends on the number of bits
being read on SDO, whether turbo mode is enabled or disabled, and the throughput in use.
See Table 13 for several examples of SCK frequency requirements for different throughputs.
Note that the SCK frequency must obey the minimum SCK period specification for the given VIO level and interface mode (see \(\mathrm{t}_{\mathrm{sck}}\) in Table 2).
The minimum SCK frequency ( \(\mathrm{f}_{\mathrm{SCK}}\) ) required to access the conversion result plus status bits when turbo mode is enabled is calculated with the following equation:
\[
f_{\text {SCK }}>\frac{N_{D}+N_{S}}{t_{\text {CYC }}-t_{\text {QUIET } 1}-t_{E N}-t_{\text {QUIET } 2}}
\]
where:
\(\mathrm{N}_{\mathrm{D}}\) is the ADC resolution (16 bits).
\(\mathrm{N}_{\mathrm{s}}\) is the number of status bits being accessed.
\(\mathrm{t}_{\text {CYC }}\), \(\mathrm{t}_{\mathrm{QUIET}} \mathrm{t}_{\text {EN }}\) and \(\mathrm{t}_{\text {QUIET2 }}\) correspond to timing specifications described in Table 2.

The minimum SCK frequency required to access the conversion result plus status bits when turbo mode is not enabled is calculated with the following equation:
\[
f_{S C K}>\frac{N_{D}+N_{S}}{t_{\text {CYC }}-t_{\text {CONV }}-t_{E N}-t_{\text {QUIET } 2}}
\]

Where tconv corresponds to the conversion time, and is described in Table 2.

\section*{REGISTER READ/WRITE FUNCTIONALITY}

The AD4001/AD4005 configuration register is read from and written to with a 16 -bit SPI instruction. The state of the fields in the configuration register determine which of the device features are enabled or disabled (see the Configuration Register Details section).

The 16-bit SPI instructions consist of the 8-bit register access command (see Table 14) followed by the register data. When performing register read and write operations, CNV is analogous to a chip select signal, and CNV must be brought low to access the configuration register contents. Data on SDI is latched in on each SCK rising edge. Data is shifted out on SDO on each SCK falling edge. SDO returns to a high impedance state when CNV is brought high.

The first bit read on SDI after a CNV falling edge (represented by \(\overline{\mathrm{WEN}}\) in Table 14) must be a 0 to initiate the register access command. The next bit \((\mathrm{R} / \overline{\mathrm{W}})\) determines whether the instruction is a write or a read. The following six bits must match the values for Bit 5 through Bit 0 shown in Table 14 to perform the SPI read/write.

When performing a write operation, the new register contents are written over SDI, MSB-first, and the writeable bits in the configuration register are updated after the device receives the full byte. When performing a read operation, the current register contents are shifted out on SDO MSB-first. Figure 48 and Figure 49 show timing diagrams for register read and write operations when using any of the \(\overline{\mathrm{CS}}\) modes. Figure 50 shows the timing diagram for performing a register write operation to multiple devices connected in daisy-chain mode. Register reads are not supported when daisy-chaining multiple devices (see the Daisy-Chain Mode section). To verify the contents of the configuration register, enable and read the status bits.

The LSB of the configuration register (Bit 0 ) is a read only bit that allows digital hosts to ensure the desired digital interface mode is selected in the frame immediately following a register write operation. For digital hosts that are limited to 16 -bit SPI frames (such as some microcontrollers), set this bit accordingly to ensure SDI is at the desired level on the rising edge of CNV. For example, set this bit to 1 and/or set the idle state of SDI to 1 when using any of the \(\overline{\mathrm{CS}}\) modes.

SPI write instructions can be performed in the same frame as reading a conversion result. To ensure the conversion is executed correctly, the CNV signal must obey the timing requirements for the selected interface mode.

\({ }^{1}{ }^{1}\) HE CNV HIGH TIME MUST FOLLOW THEt \({ }_{\text {coNV }}\) SPECIFICATION TO GENERATE A VALID CONVERSION RESULT

Figure 49. Register Write Timing Diagram

Figure 50. Register Write Timing Diagram, Daisy-Chain Mode

\section*{STATUS BITS}

A set of six optional status bits can be appended to the end of each conversion result. The status bits allow the digital host to check the state of the input overvoltage protection circuit and verify that the ADC features are configured correctly without interrupting conversions. The status bits are enabled when the status bits enable bit in the configuration register is set to 1 (see the Configuration Register Details section). Table 15 shows a description of each status bit.
When enabled, the status bits are clocked out MSB first starting on the SCK falling edge immediately following the LSB of the conversion result. The SDO line returns to high impedance after the sixth status bit is clocked out (except in daisy-chain mode). The user is not required to clock out all status bits to start the next conversion. For example, if the digital host must monitor the \(\overline{\mathrm{OV}}\) clamp flag but also must minimize the SCK frequency, the remaining status bits can be ignored to limit the number of SCK pulses required per conversion period. When using multiple AD4001/AD4005 devices in daisy-chain mode, however, all six status bits must be clocked out for each connected device.

Figure 51 shows the serial interface timing for \(\overline{\mathrm{CS}}\) mode, 3-wire without busy indicator with all six status bits clocked out.

Figure 51. \(\overline{C S}\) Mode, 3-Wire Without Busy Indicator Serial Interface Timing Diagram, Including Status Bits

\section*{CS MODE, 3-WIRE TURBO MODE}

This mode is typically used when a single AD4001/AD4005 device is connected to an SPI-compatible digital host. Turbo mode allows lower SCK frequencies by increasing the time that the ADC conversion result can be clocked out. The AD4001 can achieve a throughput rate of 2 MSPS only when turbo mode is enabled and using a minimum SCK frequency of 70 MHz (see the Serial Clock Frequency Requirements). The connection diagram is shown in Figure 52, and the corresponding timing diagram is shown in Figure 53.
To enable turbo mode, set the turbo mode enable bit in the configuration register to 1 (see Table 12). This mode replaces the 3-wire with busy indicator mode when turbo mode is enabled. Writing to the user configuration register requires SDI to be connected to the digital host (see the Register Read/Write Functionality section). When turbo mode is enabled, the conversion result read on SDO corresponds to the result of the previous conversion. When performing conversions in this mode, SDI must be held high. A CNV rising edge initiates a
conversion and forces SDO to high impedance. The user must wait teuieti time after the CNV rising edge before bringing CNV low to clock out the previous conversion result. When the conversion is complete (after tconv), the AD4001/AD4005 enter the acquisition phase and power-down.

When CNV goes low, the MSB is output to SDO. The remaining data bits are clocked by subsequent SCK falling edges. The data is valid on both SCK edges. Although the rising edge can capture the data, a digital host using the SCK falling edge allows a faster reading rate, provided it has an acceptable hold time, as dictated by \(\mathrm{t}_{\text {HSDO }}\) (see Table 2). If the status bits are not enabled, SDO returns to high impedance after the \(16^{\text {th }}\) SCK falling edge. If the status bits are enabled, they are shifted out on SDO on the \(17^{\text {th }}\) through the \(22^{\text {nd }}\) SCK falling edges (see the Status Bits section). SDO returns to high impedance after the final SCK falling edge, or when CNV goes high (whichever occurs first). The user must also provide a delay of \(\mathrm{t}_{\text {Quietr }}\) between the final SCK falling edge and the next CNV rising edge to ensure specified performance.

Figure 53. \(\overline{C S}\) Mode, 3-Wire Turbo Mode Serial Interface Timing Diagram (Status Bits Not Shown)

\section*{CS MODE, 3-WIRE WITHOUT BUSY INDICATOR}

This mode is typically used when a single AD4001/AD4005 is connected to an SPI-compatible digital host. The connection diagram is shown in Figure 54, and the corresponding timing diagram is shown in Figure 55.

Turbo mode must be disabled to use this mode. To disable turbo mode, set the turbo mode enable bit in the configuration register to 0 (see Table 12). Turbo mode is disabled by default.
When performing conversions in this mode, SDI must be held high. SDI can be connected to VIO if register reading and writing is not required. A rising edge on CNV initiates a conversion and forces SDO to high impedance. After a conversion is initiated, it continues until completion irrespective of the state of CNV. This feature can be useful when bringing CNV low to select other SPI devices, such as analog multiplexers. However, CNV must be returned high before the minimum conversion time (tconv) elapses and then held high for the maximum possible
conversion time to avoid the generation of the busy signal indicator. When the conversion is complete, the AD4001/AD4005 enter the acquisition phase and power-down. There must not be any digital activity on SCK during the conversion.
When CNV goes low, the MSB is output onto SDO. The remaining data bits are clocked out on SDO by subsequent SCK falling edges. The data is valid on both SCK edges. Although the rising edge can capture the data, a digital host using the SCK falling edge allows a faster reading rate, provided it has an acceptable hold time, as dictated by thsDo (see Table 2). If the status bits are not enabled, SDO returns to high impedance after the \(16^{\text {th }}\) SCK falling edge. If the status bits are enabled, they are shifted out on SDO on the \(17^{\text {th }}\) through the \(22^{\text {nd }}\) SCK falling edges (see the Status Bits section). SDO returns to high impedance after the final SCK falling edge, or when CNV goes high (whichever occurs first).

Figure 55. \(\overline{C S}\) Mode, 3-Wire Without Busy Indicator Serial Interface Timing Diagram (Status Bits Not Shown)

\section*{CS MODE, 3-WIRE WITH BUSY INDICATOR}

This mode is typically used when a single AD4001/AD4005 is connected to an SPI-compatible digital host with an interrupt input (IRQ). The connection diagram is shown in Figure 56, and the corresponding timing diagram is shown in Figure 57.

Turbo mode must be disabled to use this mode. To disable turbo mode, set the turbo mode enable bit in the configuration register to 0 (see Table 12). Turbo mode is disabled by default.

When performing conversions in this mode, SDI must be held high. SDI can be connected to VIO if register reading and writing is not required. A rising edge on CNV initiates a conversion and forces SDO to high impedance. SDO remains high impedance until the completion of the conversion, irrespective of the state of CNV. Prior to the minimum conversion time, CNV can select other SPI devices, such as analog multiplexers. However, CNV must be returned low before the minimum conversion time ( \(\mathrm{t}_{\text {conv }}\) ) elapses and then held low for the maximum possible conversion time to guarantee the generation of the busy signal indicator. When the conversion is complete, the AD4001/AD4005 then enter the acquisition phase and power down. There must not be any digital activity on the SCK during the conversion.

When the conversion is complete, SDO is driven low. With a pull-up resistor (for example, \(1 \mathrm{k} \Omega\) ) on the SDO line, this transition can be used as an interrupt signal to initiate the data reading controlled by the digital host. The data bits are then clocked out MSB first on SDO by subsequent SCK falling edges. The data is valid on both SCK edges. Although the rising edge can capture the data, a digital host using the SCK falling edge allows a faster reading rate, provided it has an acceptable hold time, as dictated by \(\mathrm{t}_{\text {HSDO }}\) (see Table 2). The conversion result is clocked out on SDO on the first 16 SCK falling edges. If the status bits are enabled, they are clocked out on SDO on the \(17^{\text {th }}\) through the \(22^{\text {nd }}\) SCK falling edges (see the Status Bits section). SDO returns to high impedance after an optional additional SCK falling edge or the next CNV rising edge (whichever occurs first).
If multiple AD4001/AD4005 devices are selected at the same time, the SDO output pin handles this contention without damage or induced latch-up. It is recommended to keep this contention as short as possible to limit extra power dissipation.

\section*{CS MODE, 4-WIRE TURBO MODE}

This mode is typically used when a single AD4001/AD4005 device is connected to an SPI-compatible digital host. Turbo mode allows lower SCK frequencies by increasing the time that the ADC conversion result can be clocked out. The AD4001 can achieve a throughput rate of 2 MSPS only when turbo mode is enabled and using a minimum SCK frequency of 70 MHz (see the Serial Clock Frequency Requirements section). The connection diagram is shown in Figure 58, and the corresponding timing diagram is shown in Figure 59.
To enable turbo mode, set the turbo mode enable bit in the configuration register to 1 (see Table 12). This mode replaces the 4 -wire with busy indicator mode when turbo mode is enabled. The digital host must be able to write data over SDI to perform register reads and writes (see the Register Read/Write Functionality section). When turbo mode is enabled, the conversion result read on SDO corresponds to the result of the previous conversion.

A rising edge on CNV initiates a conversion and forces SDO to high impedance. CNV must be held high throughout the conversion and data readback phase. When performing
conversions in this mode, SDI must be high during the CNV rising edge. The user must wait touieti time after the CNV rising edge before bringing SDI low to clock out the previous conversion result. When the conversion is complete (after tconv), the AD4001/AD4005 enter the acquisition phase and power-down.
SDI is analogous to a chip select input, and bringing SDI low outputs the MSB of the conversion result on SDO. The remaining data bits are clocked out on SDO by subsequent SCK falling edges. The data is valid on both SCK edges. Although the rising edge can capture the data, a digital host using the SCK falling edge allows a faster reading rate, provided it has an acceptable hold time, as dictated by thsio (see Table 2). The conversion result is clocked out on SDO on the first 16 SCK falling edges. If the status bits are enabled, they are shifted out on SDO on the \(17^{\text {th }}\) through the \(22^{\text {nd }}\) SCK falling edges (see the Status Bits section). SDO returns to high impedance after the final SCK falling edge, or when CNV goes high (whichever occurs first). The user must also provide a delay of tquiet between the final \(^{\text {a }}\) SCK falling edge and the next CNV rising edge to ensure specified performance.

Figure 58. \(\overline{C S}\) Mode, 4-Wire Turbo Mode Connection Diagram

Figure 59. \(\overline{C S}\) Mode, 4-Wire Turbo Mode Timing Diagram (Status Bits Not Shown)

\section*{CS MODE, 4-WIRE WITHOUT BUSY INDICATOR}

This mode is typically used when multiple AD4001/AD4005 devices are connected to an SPI-compatible digital host. A connection diagram example using two AD4001/AD4005 devices is shown in Figure 60, and the corresponding timing diagram is shown in Figure 61.

Turbo mode must be disabled to use this mode. To disable turbo mode, set the turbo mode enable bit in the configuration register to 0 (see Table 12). Turbo mode is disabled by default.
A rising edge on CNV initiates a conversion and forces SDO to high impedance. When performing conversions in this mode, SDI must be high during the CNV rising edge. CNV must be held high throughout the conversion and data readback phase. When performing conversions in this mode, SDI must be high during the CNV rising edge. Prior to the minimum conversion time (tconv), SDI can select other SPI devices, such as analog multiplexers. However, SDI must be returned high before the minimum conversion time elapses and then held high for the maximum possible conversion time to avoid the generation of
the busy signal indicator. When the conversion is complete, the AD4001/AD4005 enter the acquisition phase and power down. There must not be any digital activity on SCK during the conversion.

SDI is analogous to a chip select input, and each ADC result can be read by bringing the corresponding SDI input low. Bringing SDI low on each device outputs the MSB of the conversion result on the corresponding SDO pin. The remaining data bits are clocked out on SDO by subsequent SCK falling edges. The data is valid on both SCK edges. The conversion result is clocked out on SDO on the first 16 SCK falling edges. If the status bits are enabled, they are shifted out on SDO on the \(17^{\text {th }}\) through the \(22^{\text {nd }}\) SCK falling edges (see the Status Bits section). SDO returns to high impedance after the final SCK falling edge, or when SDI goes high (whichever occurs first). If the SDO of each device is tied together, ensure SDI is only low for one device at a time. The user must also provide a delay of tQuietz between the final SCK falling edge and the next CNV rising edge to ensure specified performance.

Figure 61. \(\overline{C S}\) Mode, 4-Wire Without Busy Indicator Serial Interface Timing Diagram (Status Bits Not Shown)

\section*{CS MODE, 4-WIRE WITH BUSY INDICATOR}

This mode is typically used when a single AD4001/AD4005 device is connected to an SPI-compatible digital host with an interrupt input (IRQ), and when CNV, which samples the analog input, is required to be independent of the signal used to select the data reading. This independence is particularly important in applications where low jitter on CNV is desired. The connection diagram is shown in Figure 62, and the corresponding timing diagram is shown in Figure 63.
Turbo mode must be disabled to use this mode. To disable turbo mode, set the turbo mode enable bit in the configuration register to 0 (see Table 12). Turbo mode is disabled by default.

A rising edge on CNV initiates a conversion and forces SDO to high impedance. When performing conversions in this mode, SDI must be high during the CNV rising edge. CNV must be held high throughout the conversion and data readback phase. When performing conversions in this mode, SDI must be high during the CNV rising edge. Prior to the minimum conversion time (tconv), SDI can select other SPI devices, such as analog
multiplexers. However, SDI must be returned low before the minimum conversion time elapses and then held low for the maximum possible conversion time to guarantee the generation of the busy signal indicator. When the conversion is complete, the AD4001/AD4005 enter the acquisition phase and power down. There must not be any digital activity on SCK during the conversion.
When the conversion is complete, SDO is driven low. With a pullup resistor (for example, \(1 \mathrm{k} \Omega\) ) on the SDO line, this transition can be used as an interrupt signal to initiate the data reading controlled by the digital host. The data bits are then clocked out MSB first on SDO by subsequent SCK falling edges. The data is valid on both SCK edges. Although the rising edge can capture the data, a digital host using the SCK falling edge allows a faster reading rate, provided it has an acceptable hold time, as dictated by \(\mathrm{t}_{\text {HSDO }}\) (see Table 2). The conversion result is clocked out on SDO on the first 16 SCK falling edges. If the status bits are enabled, they are clocked out on SDO on the \(17^{\text {th }}\) through the \(22^{\text {nd }}\) SCK falling edges (see the Status Bits section). SDO returns to high impedance after an optional additional SCK falling edge or the next CNV rising edge (whichever occurs first).

Figure 62. \(\overline{C S}\) Mode, 4-Wire with Busy Indicator Connection Diagram

Figure 63. \(\overline{C S}\) Mode, 4-Wire with Busy Indicator Serial Interface Timing Diagram (Status Bits Not Shown

\section*{DAISY-CHAIN MODE}

Use this mode to daisy-chain multiple AD4001/AD4005 devices on a 3-wire or 4-wire serial interface. This feature is useful for reducing component count and wiring connections such as cases with isolated multiconverter applications or for systems with a limited interfacing capacity. Data readback is analogous to clocking a shift register. A connection diagram example using two AD4001/AD4005 devices is shown in Figure 64, and the corresponding timing diagram is shown in Figure 65.
Turbo mode must be disabled to use this mode. To disable turbo mode, set the turbo mode enable bit in the configuration register to 0 (see Table 12). Writing to the user configuration register requires SDI to be connected to the digital host (see the Register Read/Write Functionality section). Turbo mode is disabled by default.

When SDI and CNV are low, SDO is driven low. A rising edge on CNV initiates a conversion and SDO remains low. When performing conversions in this mode, SDI and SCK must be low during the CNV rising edge. CNV must be held high throughout the conversion and data readback phase.
When the conversion is complete, the MSB is output onto the SDO of each device, and the AD4001/AD4005 enter the acquisition phase and power down. The remaining data bits are clocked out on SDO by subsequent SCK falling edges.

For each ADC, SDI feeds the input of the internal shift register and is clocked in on each SCK rising edge. Results are therefore passed through each device until they are all received by the digital host. When the status bits are disabled, \(16 \times \mathrm{N}\) clocks are required to read back N ADCs. When the status bits are enabled, \(22 \times \mathrm{N}\) clocks are required to read back the conversion data and status bits for N ADCs. The data is valid on both SCK edges.

The maximum achievable conversion rate when using daisy-chain mode is typically less than when reading a single device because the number of bits to clock out is larger (see the Serial Clock Frequency Requirements section).

It is possible to write to each ADC register in daisy-chain mode. The timing diagram is shown in Figure 50. This mode requires 4 -wire operation because data is clocked in on the SDI line with CNV held low. The same command byte and register data can be shifted through the entire chain to program all ADCs in the chain with the same register contents, which requires \(8 \times(\mathrm{N}+1)\) clocks for N ADCs. It is possible to write different register contents to each ADC in the chain by first writing to the furthest ADC in the chain first, using \(8 \times(\mathrm{N}+1)\) clocks, and then the second furthest ADC with \(8 \times \mathrm{N}\) clocks, and so forth until reaching the nearest ADC in the chain, which requires 16 clocks for the command and register data. It is not possible to read register contents in daisy-chain mode.

\({ }^{1}\) SDI MUST be CONNECTED TO the digital host data out to write to the configuration register
Figure 64. Daisy-Chain Mode Connection Diagram

Figure 65. Daisy-Chain Mode Serial Interface Timing Diagram (Status Bits Not Shown)

\section*{LAYOUT GUIDELINES}

The PCB that houses the AD4001/AD4005 must be designed so that the analog and digital sections are physically separated, such as on opposite sides of the device as shown in Figure 66. The pinout of the AD4001/AD4005, with the analog signals on the left side and the digital signals on the right side, helps to separate the analog and digital signals.

Avoid running digital lines under the device because they couple noise onto the die, unless a ground plane under the AD4001/ AD4005 is used as a shield. Fast switching signals, such as CNV or clocks, must not run near analog signal paths. Avoid crossover of digital and analog signals.
At least one ground plane must be used. The ground plane can be common or split between the digital and analog sections. In the latter case, join the planes underneath the AD4001/AD4005 devices.

The AD4001/AD4005 voltage reference input (REF) has a dynamic input impedance. Decouple the REF pin with minimal parasitic inductances by placing the reference decoupling ceramic capacitor close to (ideally right up against) the REF and GND pins and connect them with wide, low impedance traces.
Finally, decouple the VDD and VIO power supplies of the AD4001/AD4005 with ceramic capacitors, typically \(0.1 \mu \mathrm{~F}\), placed close to the AD4001/AD4005 and connected using short, wide traces to provide low impedance paths and to reduce the effect of glitches on the power supply lines.
An example of the AD4001 layout following these rules is shown in Figure 66 and Figure 67. Note that the AD4005 layout is equivalent to the AD4001 layout.

\section*{EVALUATING THE AD4001/AD4005 PERFORMANCE}

Other recommended layouts for the AD4001/AD4005 are outlined in the user guide of the evaluation board for the AD4001 (EVAL-AD4001FMCZ). The evaluation board package includes a fully assembled and tested evaluation board with the AD4001, the UG-1042 user guide, and software for controlling the board from a PC via the EVAL-SDP-CH1Z. The EVAL-AD4001FMCZ can also be used to evaluate the AD4005 by limiting the throughput to 1 MSPS in the software (see UG-1042).
