## features

- Three Independent LED Driver Channels
- Wide Input Voltage Range: 2.5V to 40V
- VIN Transient Ride-Through Up to 60V
- Rail-to-Rail LED Current Sense: OV to 100V
- 3000:1 PWM Dimming
- TG Drivers for PMOS LED Disconnection
- Operates in Boost, Buck Mode, Buck-Boost Mode, SEPIC or Flyback Topology
- Open-LED Protection
- Short-Circuit Protected Boost Capable
- Fault Flags for Independent Channels
- Programmable $\mathrm{V}_{\text {IN }}$ Undervoltage and Overvoltage Lockout
- Adjustable Switching Frequency: 100 kHz to 1 MHz
- Synchronizeable to an External Clock
- CTRL Pins Provide Analog Dimming
- Programmable Soft-Start
- Low Profile 52-Lead 7mm x 8mm QFN and 48-Lead Exposed Pad LQFP

## applications

- Automotive and Industrial Lighting
- RGB Lighting
- Billboards and Large Displays

## Triple Output LED Driver Controller <br> \section*{DESCRIPTIOn}

The LT®3797 is a triple output DC/DC controller designed to drive three strings of LEDs. The fixed frequency, current mode architecture results in stable operation over a wide range of supply and output voltages. The LT3797 includes an integrated DC/DC converter to produce a regulated 7.5 V supply for the N-channel MOSFET gate drivers of the three channels. This high efficiency converter enables the part to operate from a wide input voltage range from 2.5 V to 40 V .

The LT3797 is designed so that each converter can use the most suitable configuration to drive its LED load, whether step-up, step-down or a combination. Two key features enable this flexibility: first the LT3797 can sense output current at the high side of the LED string; and second, the voltage feedback pin, FBH, is referred to the ISP current sensing input. The CTRL inputs provide output current analog dimming capability. The TG drivers level shift the PWM signals to drive the gates of external LED-disconnect P-channel MOSFETs, allowing high PWM dimming range, and providing LED overcurrent protection and short-circuit protected boost capability.

## NMOS Gate Drivers

## PMOS Gate Drivers

| TG1, TG2, TG3 Turn-On Time | CTG $=1000 \mathrm{pF}$, ISP1, ISP2, ISP3, FBH1, FBH2, <br> FBH3 $=48 \mathrm{~V}$ (Note 6) | 200 | ns |
| :--- | :--- | :---: | :---: |
| TG1, TG2, TG3 Turn-Off Time | CTG $=1000 \mathrm{pF}$, ISP1, ISP2, ISP3, FBH1, FBH2, <br> FBH3 $=48 \mathrm{~V}$ (Note 6) | 70 | ns |
| PMOS Gate On Voltage <br> (ISP1-TG1, ISP2-TG2, ISP3-TG3) | ISP1, ISP2, ISP3, FBH1, FBH2, FBH3 = 48V | 6.5 | V |
| PMOS Gate Off Voltage <br> (ISP1-TG1, ISP2-TG2, ISP3-TG3) | ISP1, ISP2, ISP3, FBH1, FBH2, FBH3 = 48V | 0.3 | V |

Note 1: Stresses beyond those listed under Absolute Maximum Ratings may cause permanent damage to the device. Exposure to any Absolute Maximum Rating condition for extended periods may affect device reliability and lifetime.
Note 2: Do not apply a positive or negative voltage or current source to SW1, SW2, GATE1, GATE2, GATE3, TG1, TG2, TG3 pins, otherwise permanent damage may occur.
Note 3: The LT3797E is guaranteed to meet performance specifications from the $0^{\circ} \mathrm{C}$ to $125^{\circ} \mathrm{C}$ junction temperature. Specifications over the $-40^{\circ} \mathrm{C}$ to $125^{\circ} \mathrm{C}$ operating junction temperature range are assured by
design, characterization and correlation with statistical process controls. The LT3797I is guaranteed over the full $-40^{\circ} \mathrm{C}$ to $125^{\circ} \mathrm{C}$ operating junction temperature range.
Note 4: $\operatorname{FBH}($ REG $)$ denotes the regulation voltage ( $||\mathrm{ISP}-\mathrm{FBH}|$ ) of the corresponding FBH pin.
Note 5: Rise and fall times are measured at $10 \%$ and $90 \%$ levels.
Note 6: Gate turn-on/turn-off time is measured from $50 \%$ level of PWM voltage to $90 \%$ level of gate on/off voltage.
Note 7: The INTV ${ }_{\text {CC }}$ regulation voltage is tested in an open loop. Closed loop operation is guaranteed by design and process controls.

TYPICAL PGRFORMAOCE CHARACT $\in$ RISTICS $T_{A}=25^{\circ} \mathrm{C}$ unless otherwise noted.

TYPICAL PGRFORMAOCE CHARACT $\in$ RISTICS $\mathrm{T}_{\mathrm{A}}=25^{\circ} \mathrm{C}$ unless otherwise noted.

TYPICAL PGRFORMAOCG CHARACT $\in$ RISTICS $\mathrm{I}_{\mathrm{A}}=25^{\circ} \mathrm{C}$ unless otherwise noted.

## PIn functions

FIT1, $\overline{\text { FLT2, }} \overline{\text { FLT3 }}$ (Pins 1, 2, 3): Open-Collector PullDowns on FLT Pins Report The Fault Conditions:

1. $V_{\text {IN }}>41 \mathrm{~V}$ (typical)
2. Overtemperature $\left(T_{j}>165^{\circ} \mathrm{C}\right)$
3. INTV $\mathrm{CC}<5.2 \mathrm{~V}$ (typical)
4. OVLO > 1.25 V (typical)
5. LED Overcurrent
6. Open LED

## 7. Output Overvoltage

PWM1, PWM2, PWM3 (Pins 4, 5, 6): Pulse Width Modulated Input Pins. Signal low causes the respective converter to go into idle mode which means it stops switching, the TG pin transitions high, the quiescent currents are reduced, and the VC becomes high impedance. If not used, connect to the REF pin.
$\mathbf{V}_{\text {REF }}$ (Pin 7): Reference Output Pin. Can supply up to $450 \mu \mathrm{~A}$. This pin drives a resistor divider for the CTRL1, CTRL2, CTRL3 pins, either for analog dimming or for temperature limit/compensation of LED loads. The normal output voltage is 2 V .

CTRL1, CTRL2, CTRL3 (Pins 8, 9, 10): Current Sense Threshold Adjustment Pins. Sets voltage across external sense resistor between ISP and ISN pins of the respective converter:
$V_{\text {ISP-ISN }}=0 \mathrm{~V}$, when $\mathrm{V}_{\text {CTRL }}<0.2 \mathrm{~V}$
$V_{\text {ISP-ISN }}=\left(V_{\text {CTRL }}-0.2 \mathrm{~V}\right) / 4$, when $0.2 \mathrm{~V}<\mathrm{V}_{\text {CTRL }}<1.2 \mathrm{~V}$
$V_{\text {ISP-ISN }}=250 \mathrm{mV}$, when $V_{\text {CTRL }}>1.2 \mathrm{~V}$
Connect CTRL pins to $\mathrm{V}_{\text {REF }}$ for the 250 mV default threshold. When $\mathrm{V}_{\text {CTRL }}<150 \mathrm{mV}$ (typical), the respective converter goes into idle mode, which is the same as PWM pin being pulled low. Do not leave these pins open.
RT (Pin 11): Switching Frequency Adjustment Pin. Set the frequency using a resistor to GND. Do not leave the RT pin open.
SYNC (Pin 12): The SYNC pin is used to synchronize the internal oscillator to an external logic-level signal. The $R_{T}$ resistor should be chosen to program an internal switching frequency $20 \%$ slower than the SYNC pulse frequency. Gate turn-on occurs at a $0.2 \mu \mathrm{~s}$ (typical) delay after the rising edge of SYNC. Tie SYNC to GND if not used.

## PIN FUNCTIONS (afM/Lofp)

TG1, TG2, TG3 (Pins 14, 33, 35/Pins 13, 30, 32): Top Gate Driver Output Pins for Driving LED Loads Disconnect P-Channel MOSFETs (PMOSs). One for each channel. An inverted PWM signal drives an external PMOS gate of the respective converter between $\mathrm{V}_{I S P}$ and $\left(\mathrm{V}_{I S P}-6.5 \mathrm{~V}\right)$. Leave TG pins unconnected if not used.
ISN1, ISN2, ISN3 (Pins 15, 32, 36/Pins 14, 29, 33): Connection Points for the Negative Terminals of the Current Feedback Resistors.

ISP1, ISP2, ISP3 (Pins 16, 31, 37/Pins 15, 28, 34): Connection Points for the Positive Terminals of the Current Feedback Resistors. Also serves as positive rails for TG pin drivers and the reference point for FBH.
FBH1, FBH2, FBH3 (Pins 17, 30, 38/Pins 16, 27, 35): Voltage Loop Feedback Pins. The output feedback voltage $V_{F B}$ is measured between the ISP pin and the FBH pin (absolute value): $V_{F B}=|I S P-F B H|$. The FBH pin is intended for constantvoltage regulation or for LED protection/open-LED detection for each channel. In an open-LED event, the internal amplifier with output VC regulates $\mathrm{V}_{\mathrm{FB}}$ to 1.25 V (typical) through the respective converter. If $\mathrm{V}_{\mathrm{FB}}$ is above the overvoltage threshold (typical 1.3V), the TG pin of the same channel is driven high to disconnect the external PMOS to protect the LEDs from an overvoltage event. Either openLED or overvoltage event signals a fault condition. Do not leave the FBH pins open. It requires ISP to be no less than 4.5 V to maintain an accurate $\mathrm{V}_{\text {FB } 1}$ voltage sense. If ISP falls below 4.5 V , the voltage regulation is deactivated and the ISP-ISN current regulation dominates regardless of the |ISP-FBH| value. If not used, connect the FBH pin to the ISP pin of the same channel.

VC1, VC2, VC3 (Pins 19, 28, 40/Pins 17, 26, 36): Error Amplifier Compensation Pins. Connect a series RC from each VC pin to GND. In each channel, the VC pin is high impedance when the PWM pin is low, or the CTRL pin is below 150 mV . This feature allows the VC pin to store the demand current state variable for the next PWM or CTRL high transition.

SS1, SS2, SS3 (Pins 20, 27, 41/Pins 18, 25, 37): SoftStart Pins. Each SS pin modulates compensation VC pin voltage of the respective channel. Each of the soft-start intervals is set with an external capacitor.

SENSEN1, SENSEN2, SENSEN3 (Pins 21, 26, 42/Pins 19, 24, 38): The Negative Current Sense Inputs for the Control Loops. Kelvin connect the SENSEN pin to the negative terminal of the switch current sense resistor (which connects to the GND plane) of the respective converter.

SENSEP1, SENSEP2, SENSEP3 (Pins 22, 25, 43/Pins 20, 23, 39): The Positive Current Sense Inputs for the Control Loops. Kelvin connect the SENSEP pin to the positive terminal of the switch current sense resistor in the source of the external N -channel MOSFET (NMOS) switch of the respective converter.

GATE1, GATE2, GATE3 (Pins 23, 24, 44/Pins 21, 22, 40): N-Channel MOSFET Gate Driver Outputs. Switch between INTV ${ }_{C C}$ and GND. Driven to GND during shutdown, fault or idle states.

INTV $_{\text {CC }}$ (Pins 45, 46/Pins 41, 42): INTV ${ }_{\text {CC }}$ pins are the integrated power supply output voltage nodes that provide supply for control circuits and NMOS gate drivers. The two INTV $C$ pins are internally shorted. Must be bypassed with a $10 \mu \mathrm{~F}$ ceramic capacitor placed close to the pins.

SW2 (Pin 47/Pin 43): Integrated Power Supply Switch Node. Connect this pin to one side of the integrated power supply inductor.
BOOST (Pin 48/Pin 44): Connect this pin to SW1 pin through a $0.1 \mu \mathrm{~F}$ ceramic capacitor.

SW1 (Pin 49/Pin 45): Integrated Power Supply Switch Node. Connect this pin to the other side of the integrated power supply inductor, and to the BOOST pin with a $0.1 \mu \mathrm{~F}$ ceramic capacitor.
$\mathbf{V}_{\text {IN }}$ (Pin 50/Pin 46): Input Supply Pin. If $\mathrm{V}_{\text {IN }}$ is over 41V (typical), the integrated INTV ${ }_{\text {CC }}$ power supply is turned off. All three channels are also turned off (including pulling the GATE pins to GND and TG pins to ISP) and the soft-starts are reset. Must be locally bypassed with low ESR capacitors placed close to the pin.

## PIn functions (afNLafp)

EN/UVLO (Pin 51/Pin 47): Enable and Undervoltage Lockout Pin. An accurate 1.22V falling threshold with externally programmable hysteresis detects when power is OK to enable the integrated INTV ${ }_{\text {CC }}$ power supply and each channel switching. Rising hysteresis is generated by the external resistor divider and an accurate internal $2 \mu \mathrm{~A}$ pull-down current. Above the 1.24 V (typical) rising threshold (but below 2.5V), EN/UVLO input bias current is sub- $\mu \mathrm{A}$. Below the 1.22 V (typical) falling threshold, a $2 \mu \mathrm{~A}$ pull-down current is enabled so the user can define the hysteresis with the external resistor selection. An undervoltage condition turns off the integrated INTV ${ }_{C C}$ power supply and all the three channels and resets the soft-starts. Tie to 0.4 V , or less, to disable the device and reduce $\mathrm{V}_{\text {IN }}$ quiescent current below $1 \mu \mathrm{~A}$.

OVLO (Pin 52/Pin 48): Overvoltage Lockout Pin. An accurate 1.25 V rising threshold with 125 mV hysteresis detects an overvoltage condition. An overvoltage condition turns off all three channels (including pulling the GATE pins to GND and TG pins to ISP) and resets the soft-starts. Tie OVLO to GND if not used.

GND (Exposed Pad Pin 53/Exposed Pad Pin 49): Ground. Solder the exposed pad directly to ground plane.

## BLOCK DIAGRAM

Figure 1. LT3797 Block Diagram Working in Boost Configuration (for Simplicity, Only Channel 1 Is Shown)

## OPERATION

The LT3797 uses a fixed frequency, current mode control scheme to provide excellent line and load regulation. It contains three independent switching regulators. Operation can be best understood by referring to the Block Diagram in Figure 1. The oscillator, internal power supply etc., are shared among the three converters. The LED current control circuitry, gate drivers etc., are replicated for each of the three converters. For simplicity, Figure 1 shows the shared circuits and the channel specific circuits for converter 1.

The LED current regulation can be understood by following the operation of converter 1 . The start of each oscillator cycle sets the SR latch SR1 and turns on the external power MOSFET switch M1 through gate driver G2 (the three converters share the same oscillator, which means if all the three channels are enabled the GATE pins of all the three channels transition high at the same instant). The switch current flows through the external current sensing resistor R SW_SEN1 and generates a voltage proportional to the switch current. This current sense voltage (amplified by A14) is added to a stabilizing slope compensation ramp and the resulting sum $V_{\text {ISENSE1 }}$ is fed into the negative terminal of the PWM comparator A12. The current in the external inductor L1 increases steadily during the time the switch is on. When $V_{\text {ISENSE1 }}$ exceeds the level at the negative input of A12 (VC1), SR1 is reset, turning off the power switch. During the switch-off phase, L1 current decreases.

Through this repetitive action, the PWM control algorithm establishes a switch duty cycle to regulate a current in the LED string. The VC1 voltage is set by the error amplifier A8 and is an amplified version of the difference between the LED current sense voltage, measured between ISP1 and ISN1, and the target difference voltage set by the CTRL1 pin. In this manner, the error amplifier sets the correct switch peak current level to keep the LED current in regulation.

The LT3797 has a switch current limit function. The switch current sense signal is input to the current limit comparator A13. If the current sense voltage is higher than
the sense current limit threshold, $\mathrm{V}_{\text {SENSE(MAX) }}$ (typical 110 mV ), A13 will reset SR1 and turn off M1 immediately.

The LT3797 provides the constant voltage regulation mode to allow the users to accurately program the output regulation voltage in an open-LED event. In voltage regulation mode, the operation is similar to that described above, except the VC1 voltage is set by A9 and is an amplified version of the difference between the internal reference of 1.25 V (typical) and the output feedback voltage, $\mathrm{V}_{\mathrm{FB} 1}$, which is measured between ISP1 and FBH1 (the absolute value):

$$
V_{F B 1}=|I S P 1-F B H 1|
$$

The LED current sense feedback interacts with the FBH1 voltage feedback so that the sense voltage between ISP1 and ISN1 does not exceed the threshold set by the CTRL1 pin, and $\mathrm{V}_{\text {FB1 }}$ does not exceed 1.25 V (typical).

For accurate current or voltage regulation, it is necessary to be sure that under normal operating conditions, the appropriate loop is dominant. To deactivate the voltage loop entirely, FBH1 can be connected to ISP1. To deactivate the LED current loop entirely, the ISP1 and ISN1 should be tied together and the CTRL1 input tied to $\mathrm{V}_{\text {REF }}$.

It requires ISP to be no less than 4.5 V to maintain an accurate $\mathrm{V}_{\text {FB1 }}$ voltage sense. If ISP falls below 4.5 V , the voltage regulation is deactivated and the current regulation dominates regardless of the |ISP1-FBH1| value.

Two LED driver specific functions featured on the LT3797 are controlled by the voltage feedback pin FBH1. First, when the $\mathrm{V}_{\mathrm{FB} 1}$ exceeds a voltage 50 mV lower ( $-4 \%$ ) than the $\mathrm{V}_{\mathrm{FB} 1}$ regulation voltage (typical 1.25 V ), it indicates that the LED may be disconnected and the constantvoltage feedback loop is taking control of the switching regulator. $\overline{\mathrm{FLT}} 1$ is pulled low to report a fault condition. Second, when $\mathrm{V}_{\mathrm{FB} 1}$ exceeds the $\mathrm{V}_{\mathrm{FB} 1}$ regulation voltage by 60 mV ( $5 \%$ typical), it indicates an output overvoltage fault. In this condition, TG1 pin is driven high by G3 and G4, turning off the external PMOS M2. This action disconnects the LED load from the power path, preventing excessive current from damaging the LEDs. FLT1 is kept low to report the fault condition.

## APPLICATIONS INFORMATION

## Switching Frequency and Synchronization

The RT frequency adjust pin allows the user to program the switching frequency ( $\mathrm{f}_{s}$ ) from 100 kHz to 1 MHz to optimize efficiency/performance or external component size. Higher frequency operation yields smaller component size but increases switching losses and gate driving current, and may not allow sufficiently high or low duty cycle operation. Lower frequency operation gives higher efficiency, achieves higher maximum duty cycle or lower minimum duty cycle at the cost of larger external component size. An external resistor from the RT pin to GND is required-do not leave this pin open. For an appropriate $\mathrm{R}_{\mathrm{T}}$ resistor value see Table 1.

Table 1. Switching Frequency ( $\mathbf{f}_{\mathbf{S W}}$ ) vs $\mathbf{R}_{\mathbf{T}}$ Value

| $\mathbf{f}_{\mathbf{S W}}(\mathbf{k H z})$ | $\mathbf{R}_{\mathbf{T}} \mathbf{( k \boldsymbol { \Omega } )}$ | $\mathbf{f}_{\mathbf{S W}}(\mathbf{k H z})$ | $\mathbf{R}_{\mathbf{T}} \mathbf{( k \boldsymbol { \Omega } )}$ |
| :---: | :---: | :---: | :---: |
| 100 | 154 | 600 | 22.6 |
| 150 | 102 | 650 | 20.5 |
| 200 | 75.0 | 700 | 17.4 |
| 250 | 59.0 | 750 | 19.1 |
| 300 | 48.7 | 800 | 16.2 |
| 350 | 41.2 | 850 | 15.0 |
| 400 | 35.7 | 900 | 14.0 |
| 450 | 31.6 | 950 | 13.3 |
| 500 | 28.0 | 1000 | 12.4 |
| 550 | 24.9 |  |  |

The operating frequency of the LT3797 can be synchronized to an external clock source. By providing a digital clock signal into the SYNC pin, the LT3797 will operate at the SYNC clock frequency. If this feature is used, an $\mathrm{R}_{\top}$ resistor should be chosen to program a switching frequency $20 \%$ slower than SYNC pulse frequency. Tie the SYNC pin to GND if this feature is not used.

## Duty Cycle Considerations

Switching duty cycle is a key variable defining converter operation, therefore, its limits must be considered when programming the switching frequency for a particular application. The minimum duty cycle of the switch is limited by the fixed minimum on-time (200ns maximum) and the switching frequency (fsw). The maximum duty cycle of the switch is limited by the fixed minimum off-time
(200ns maximum) and $\mathrm{f}_{\mathrm{SW}}$. The following equations express the minimum/maximum duty cycle:

$$
\begin{aligned}
& \text { Minimum Duty Cycle }=200 \mathrm{~ns} \bullet \mathrm{f}_{\mathrm{SW}} \\
& \text { Maximum Duty Cycle }=1-200 \mathrm{~ns} \bullet \mathrm{f}_{\mathrm{SW}}
\end{aligned}
$$

Besides the limitation by the minimum off-time, it is also recommended to choose the maximum duty cycle below 95\%.

## PWM Dimming Control

The LED of each channel can be dimmed with pulse width modulation using the PWM pin. Figure 1 shows the channel 1 driver. If the PWM1 pin is pulled high, M2 is turned on by G3 and G4. Converter 1 operates normally. G4 limits ISP1-TG1 to 6.5 V to protect the gate of M2. If the PWM1 pin is pulled low, the external NMOS M1 is turned off through G1 etc, and converter 1 stops operating. M 2 is turned off through the TG1 pin, disconnecting LED1 and stopping current drawing from output capacitor, $\mathrm{C}_{0}$. The VC1 pin is also disconnected from the internal circuitry through S 1 . The capacitors $\mathrm{C}_{\mathrm{C}}$ and $\mathrm{C}_{0 \text { UT }}$ store the state of the LED string current until PWM1 is pulled up again. This leads to a highly linear relationship between PWM duty cycle and output light (brightness), and allows for a large and accurate dimming range. The PWM dimming range can be maximized by using the PWM pin for dimming and the CTRL pin for linearly adjusting the current sense threshold.

In the applications where the operation frequency of the LT3797 is synchronized to an external clock source applied to the SYNC pin, it is recommended to synchronize the rising edge of the external clock and the rising edge of the PWM signal of each of the three channels, as shown in Figure 2.

Figure 2. Synchronize the SYNC Pin Input Signal and the PWM Pin Input Signal

## APPLICATIONS INFORMATION

Besides analog dimming, the CTRL pin can also be used for PWM dimming control. Refer to Figure 1 for channel 1 operation. If CTRL1 falls below 150mV, the CTRL_ON signal is pulled low by comparator A11. Since CTRL_ON is connected to one of G3's inputs, channel 1 has the same operation as PWM1 being pulled low (such as disconnecting LED1 from $\mathrm{C}_{0}$ 位 and disconnecting $\mathrm{C}_{\mathrm{C}}$ from VC1, etc). Therefore, the CTRL pin can be used for a combination of linear and PWM dimming control if it is connected to a PWM signal whose low level is below 150 mV and high level is between 0.2 V and 1.3 V . Connect the PWM pins to the $\mathrm{V}_{\text {REF }}$ pin if the CTRL pins are used for PWM dimming or no PWM dimming is used.

Do not use a low $\mathrm{V}_{\text {TH }}$ PMOS for LED disconnection. The PMOS with a minimum $\mathrm{V}_{\text {TH }}$ of -1 V to -2 V is recommended. In the applications where accurate PWM dimming is not required, the P-channel MOSFETs can be omitted to reduce cost. In these conditions, the TG pins should be left open.

## Programming the LED Current

The LED current of each channel is programmed by connecting an external sense resistor, R RED_SEN, in series with the LED Ioad, and setting the voltage regulation threshold across R RED_SEN using CTRL input. The ISP and ISN sense node traces should run parallel to each other to a Kelvin connection on the positive and negative terminals of REED_SEN. Typically, sensing of the current should be done at the top of the LED string. If this option is not available, then the current may be sensed at the bottom of the LED string. The CTRL pin should be tied to a voltage higher than 1.3 V to get the full-scale 250 mV (typical) threshold across the sense resistor. The CTRL pin can also be used to dim the LED current from full scale to zero, although relative accuracy decreases with the decreasing voltage sense threshold. When the CTRL pin voltage is less than 1.1 V and higher than 0.2 V , the LED current is:

$$
\mathrm{I}_{\text {LED }}=\frac{\mathrm{V}_{\text {CTRL }}-200 \mathrm{mV}}{\mathrm{R}_{\text {LED_SEN }} \bullet 4}
$$

When the CTRL pin voltage is between 1.1 V and 1.3 V the LED current varies with CTRL, but departs from the equation above by an increasing amount as CTRL voltage increases. Ultimately, above CTRL $=1.3 \mathrm{~V}$ the LED current no longer varies with CTRL. The typical (ISP-ISN) threshold vs CTRL voltage when CTRL is close to 1.2 V is listed in Table 2.

Table 2. (ISP-ISN) Threshold vs CTRL
When CTRL Is Close to 1.2 V

| $\mathbf{V}_{\text {CRTL }}(\mathbf{V})$ | (ISP-ISN) THRESHOLD (mV) |
| :---: | :---: |
| 1.1 | 225 |
| 1.15 | 236 |
| 1.2 | 244.5 |
| 1.25 | 248.5 |
| 1.3 | 250 |

When CTRL is higher than 1.3 V , the LED current is regulated to:

$$
\mathrm{I}_{\mathrm{LED}}=\frac{250 \mathrm{mV}}{\mathrm{R}_{\text {LED_SEN }}}
$$

The LED current is regulated to OA when CTRL is lower than 200 mV (typical).
The CTRL pin should not be left open (tie to $\mathrm{V}_{\text {REF }}$ if not used). The CTRL pin can also be used in conjunction with a thermistor to provide overtemperature protection for the LED Ioad, or with a resistor divider to $\mathrm{V}_{\text {IN }}$ to reduce output power and limit peak switching current when $V_{\text {IN }}$ is low. The presence of a time varying differential voltage signal (ripple) across ISP and ISN at the switching frequency is expected. The amplitude of this signal is increased by high LED load current, low switching frequency and/ or a smaller value output filter capacitor. Some level of ripple signal is acceptable: the compensation capacitor on the VC pin filters the signal so the average difference between ISP and ISN is regulated to the user-programmed value. Ripple voltage amplitude (peak-to-peak) in excess of 50 mV should not cause misoperation, but may lead to noticeable offset between the average value and the user-programmed value.

## APPLICATIONS INFORMATION

## Programming Output Regulation Voltage for the Open-LED Event

The output voltage of each channel in the open-LED event can be programmed by selecting two external sense resistors. Figure 3 shows the sense resistor connection of channel 1. In the open-LED event, $\mathrm{V}_{\mathrm{FB} 1}$ is regulated to 1.25 V , therefore the output regulation voltage can be set according to the following equation:

$$
V_{\text {OUT }}=1.25 \mathrm{~V} \cdot \frac{\mathrm{R} 5+\mathrm{R} 6}{\mathrm{R} 5}
$$

Since the output voltage is directly measured between ISP1 and LED1 ${ }^{-}$, the Figure 3 approach works well for the converter topologies where LED1- is connected to GND (such as boost, SEPIC, flyback), as well as the topologies where LED1 ${ }^{-}$is connected to an inductor (such as buck mode, buck-boost mode LED drivers).
Typically, the current sense resistor R RED_SEN1 and disconnect PMOS M2 are connected to the top of the LED string (LED1 ${ }^{+}$), as shown in Figure 3. If this option is not available (for example some multi-string LED modules are built with a common anode configuration), then the current may be sensed at the bottom of the LED string as shown in Figure 4. In this configuration, the FBH pin draws $2 \mu \mathrm{~A}$ (typical) current. Therefore, the output regulation voltage in the open-LED event can be set according to the following equation:

$$
V_{\text {OUT }}=1.25 \mathrm{~V} \cdot \frac{\mathrm{R} 5+\mathrm{R} 6}{\mathrm{R} 5}+2 \mu \mathrm{~A} \cdot \mathrm{R} 6
$$

Under normal operating conditions, the LED current regulation loop is dominant. Therefore, the output regulation voltage $\left(\mathrm{V}_{\text {OUT }}\right)$ in the open-LED event should be programmed so that $\mathrm{V}_{\mathrm{FB} 1}\left(\mathrm{~V}_{\mathrm{FB} 1}=|\mathrm{ISP} 1-\mathrm{FBH} 1|\right)$ should never exceed 1.1 V when LED1 is connected. The only way for $\mathrm{V}_{\mathrm{FB} 1}$ to be within 50 mV of the regulation voltage $(1.25 \mathrm{~V})$ is for an open-LED event to occur.

Figure 3. Output Voltage Sense Resistor Connection

Figure 4. Output Voltage Sense Resistor Connection When Red_sen1 $^{\text {and }}$ M2 Are Connected to the Bottom of the LED String

## Programming Enable and Undervoltage Lockout with the EN/UVLO Pin

EN/UVLO pin controls whether the LT3797 is enabled or is in shutdown state. As shown in Figure 1, a 1.22V reference, a comparator, A1, and a controllable current source, IS1, allow the user to accurately program the supply voltage at which the IC turns on and off. The falling value can be accurately set by the resistor divider R1 and R2. When $\mathrm{EN} / \mathrm{UVLO}$ is above 0.4 V and below the 1.22 V threshold, the small pull-down current source, IS1 (typical $2 \mu \mathrm{~A}$ ), is active. The purpose of this current is to allow the user to program the rising hysteresis. The falling threshold voltage and rising threshold voltage can be calculated by the following equations:

$$
\begin{aligned}
& V_{\operatorname{IN}(\text { FALLING })}=1.22 \mathrm{~V} \cdot \frac{\mathrm{R} 1+\mathrm{R} 2}{\mathrm{R} 2} \\
& \mathrm{~V}_{\operatorname{IN}(\mathrm{RISING})}=\mathrm{V}_{\operatorname{IN}(\text { (FALLING })}+2 \mu \mathrm{~A} \cdot \mathrm{R} 1
\end{aligned}
$$

## APPLICATIONS INFORMATION

For applications where the EN/UVLO pin is to be used only as a logic input, the EN/UVLO pin can be connected directly to the input voltage, $\mathrm{V}_{\mathbf{I N}}$, for "always on" operation.

## Programming Overvoltage Lockout Threshold with the OVLO Pin

The LT3797 provides an OVLO pin that allows user-programmable overvoltage lockout. A 1.25 V (typical) rising threshold with 125 mV hysteresis detects the overvoltage condition. The OVLO pin can be used to monitor $\mathrm{V}_{\mathrm{IN}}$ or other voltages against overvoltage conditions.
Figure 1 shows OVLO connecting to $\mathrm{V}_{\text {IN }}$ through a voltage divider to protect against $\mathrm{V}_{\text {IN }}$ overvoltage. The rising threshold voltage and falling threshold voltage can be calculated by the following equations:

$$
\begin{aligned}
& V_{O V(R I S I N G)}=1.25 \mathrm{~V} \cdot \frac{\mathrm{R} 3+\mathrm{R} 4}{\mathrm{R} 4} \\
& V_{O V(\text { FALLING) })}=1.125 \mathrm{~V} \cdot \frac{\mathrm{R} 3+\mathrm{R} 4}{\mathrm{R} 4}
\end{aligned}
$$

An overvoltage condition turns off all three channels (including pulling the GATE pins to GND and TG pins to ISP) and resets the soft-starts.

## Loop Compensation

Loop compensation determines the stability and transient performance. The LT3797 uses current mode control to regulate the output which simplifies loop compensation. The optimum values depend on the converter topology, the component values and the operating conditions (including the input voltage, LED current switching frequency). To compensate the feedback loop of the LT3797, a series resistor-capacitor network is usually connected from the VC pin to GND. Figure 1 shows the typical VC compensation network. For most applications, the capacitor should be in the range of 2.2 nF to 22 nF , and the resistor should be in the range of 2 k to 25 k . A practical approach to designing the compensation network is to start with one of the circuits in this data sheet that is similar to your application, and tune the compensation network to optimize the performance. Stability should then be checked across all operating conditions, including LED current,
input voltage and temperature. Application Note 76 is a good reference for loop compensation.

## Soft-Start and Fault Protection

The LT3797 has identical soft-start and fault protection functions for each channel. The soft-start feature is designed to limit peak switch currents and output voltage ( $\mathrm{V}_{\text {OUT }}$ ) overshoot during start-up or recovery from a fault condition. Figure 4 shows the state diagram of the softstart and fault protection of channel 1. Also refer to Figure 1for channel 1 operation. In soft-start mode, the softstart capacitor is charged up by the $25 \mu \mathrm{~A}$ current source. The SS1 pin gradually increases the peak switch current allowed in M1 by clamping the VC1 voltage through Q4. In this way the SS1 pin allows the output capacitor, $\mathrm{C}_{0 \text { ut }}$, voltage to be charged gradually toward its final value while limiting M1 current overshoot. The soft-start interval is set by the soft-start capacitor selection according to the following equation:

$$
\mathrm{t}_{\mathrm{SS}}=\frac{1.2 \mathrm{~V}}{25 \mu \mathrm{~A}} \cdot \mathrm{C}_{\mathrm{SS}}
$$

The discharge time of the soft-start capacitor is controlled by a $2.5 \mu \mathrm{~A}$ current source. Therefore, the SS1 pin is also used as an adjustable timer in the FAULT2 protection modes (see Figure 5) to prevent thermal runaway problems on the external components and/or the LEDs. In some fault conditions, the soft-start capacitor is charged and discharged repetitively, referred to as the hiccup mode operation. A typical hiccup mode operation occurs when an LT3797 LED driver has an output short-circuit fault. Figure 5 shows that if an output short-circuit fault causes LT3797 overcurrent (sensed by ISP1-ISN1) in the normal operation mode, the LT3797 moves to FAULT2 protection mode, where TG1 is pulled high, turning off the external PMOS and isolating the output. As a result, the overcurrent condition is cleared. When SS1 is discharged below 200 mV , the LT3797 moves to soft-start mode, where TG1 is pulled low to turn on the external PMOS. If the short-circuit fault still exists, the LT3797 senses an overcurrent fault again and moves to FAULT2 protection mode: SS1 charged up and a new cycle starts. In this manner, the soft-start capacitor is kept charging and discharging between 200 mV and 1.7 V until the short-circuit fault is cleared.

## APPLICATIONS INFORMATION

Figure 5. State Diagram of the Soft-Start and Fault Protection of Channel 1

## APPLICATIONS INFORMATION

The LT3797 fault protection can be configured as the latch-off mode by connecting a 470 k resistor between the SS pin and $V_{\text {REF }}$ pin. The FAULT2 conditions (see Figure 4) cause the LT3797 latch off. The LT3797 does not retry a soft-start even if the fault condition is cleared, since the SS pin is not able to fall below 0.2 V by the $2.5 \mu \mathrm{~A}$ pulldown current to reset the latch, due to the pulling up of the 470 k resistor. The latch-off can only be cleared by toggling the EN/UVLO pin low to high.
The open-LED fault and the output overvoltage fault are not included in FAULT2 in Figure 5. These two faults do not affect the soft-start status. The open-LED fault in channel 1 causes $\overline{\text { FLT1 }}$ low. The output overvoltage fault in channel 1 causes FLT1 low and TG1 high to disconnect the LED Ioad from power path.

## APPLICATION CIRCUIT DESIGN GUIDELINE

The LT3797 contains three independent switching regulators. The following sections describe the LT3797 LED driver design guideline for the key parameters calculation and external components selection. The design guideline applies to each of the switching regulators.

## Switch Duty Cycle

The LT3797 can be configured with different topologies. The boost LED driver is used for the applications where the LED voltage is higher than the input voltage. The LT3797 can be configured as a buck mode LED driver for the applications where the LED voltage is lower than the input voltage. The buck-boost mode and the SEPIC LED driver allow for the input voltage to be higher, equal to or lower than the LED voltage. The switch duty cycles
of different topologies in continuous conduction mode (CCM) are:

$$
\begin{aligned}
& D_{\text {BOOST }}=\frac{V_{\text {LED }}-V_{I N}}{V_{\text {LED }}} \\
& D_{\text {BUCK }}=\frac{V_{\text {LED }}}{V_{I N}} \\
& D_{\text {BUCK-BOOST }}=\frac{V_{\text {LED }}}{V_{\text {LED }}+V_{I N}} \\
& D_{\text {SEPIC }}=\frac{V_{\text {LED }}}{V_{\text {LED }}+V_{I N}}
\end{aligned}
$$

The maximum duty cycle ( $\mathrm{D}_{\mathrm{MAX}}$ ) occurs when the converter has the minimum input voltage ( $\left.\mathrm{V}_{\operatorname{IN}(\mathrm{MIN})}\right)$.

## Inductor Selection

Figure 6 shows a typical inductor current waveform when the LED driver has maximum output current at the minimum input voltage. $\Delta \mathrm{I}_{\mathrm{L}}$ and $\mathrm{I}_{\mathrm{L}_{-} \mathrm{AVG}(\mathrm{MAX})}$ denote the inductor ripple current and the maximum average inductor current respectively.

Figure 6. A Typical Inductor Waveform

## APPLICATIONS INFORMATION

The I ${ }_{\text {L_AVG(MAX) }}$ of boost, buck mode, and buck-boost mode LED drivers in CCM are:

$$
\begin{aligned}
& I_{\text {L_AVG(MAX)_BUCK }}=I_{\text {LED }}(M A X) \\
& \mathrm{L}_{\mathrm{L}_{-} A V G(M A X)_{-} B O O S T}=\mathrm{I}_{\operatorname{LED}(M A X)} \bullet \frac{1}{1-\mathrm{D}_{\text {MAX }}} \\
& L_{L_{-}} A V G(M A X)_{-} B U C K-B O O S T=L_{\operatorname{LED}(M A X)} \cdot \frac{1}{1-D_{\text {MAX }}}
\end{aligned}
$$

The primary and secondary maximum average inductor current of the SEPIC LED driver are:

$$
\begin{aligned}
& \mathrm{I}_{\mathrm{L} 1 \_A V G(M A X) \_S E P I C}=\mathrm{I}_{\mathrm{LED}(\mathrm{MAX})} \cdot \frac{\mathrm{D}_{\text {MAX }}}{1-D_{\text {MAX }}} \\
& \mathrm{I}_{\mathrm{L} 2 \_A V G(M A X) \_S E P I C}=\mathrm{I}_{\mathrm{LED}(\mathrm{MAX})}
\end{aligned}
$$

where $\mathrm{I}_{\text {LED(MAX) }}$ is the maximum LED current.
The inductor ripple current $\Delta l_{L}$ has a direct effect on the choice of the inductor value. Choosing smaller values of $\Delta l_{L}$ requires large inductances and reduces the current loop gain (the converter will approach voltage mode). Accepting larger values of $\Delta l_{\mathrm{L}}$ provides fast transient response and allows the use of low inductances, but results in higher input current ripple and greater core losses.

The inductor ripple percentage of the boost, buck mode, and buck-boost mode LED drivers is:

$$
\frac{\Delta I_{L}}{l_{\mathrm{L}(\operatorname{MAX})}}
$$

For the SEPIC converter, $\Delta l_{L}$ of the primary inductor is equal to $\Delta l_{\mathrm{L}}$ of the secondary inductor. The inductor ripple percentage can be calculated as:

$$
\frac{2 \cdot \Delta \mathrm{I}_{\mathrm{L}}}{\mathrm{~L}_{\mathrm{L}(\mathrm{MAX})}+\mathrm{I}_{\mathrm{L} 2(\mathrm{MAX})}}
$$

The user should choose an appropriate $\Delta I_{\mathrm{L}}$ based on the trade-offs to optimize the LED driver performance. It is recommended that the ripple current percentage fall within the range of $20 \%$ to $60 \%$ at $D_{\text {MAX }}$.

Given an operating input voltage range, and having chosen the operating frequency, f , and ripple current $\Delta \mathrm{I}_{\mathrm{L}}$ in the inductor, the inductor values of the boost, buck mode, and buck-boost mode LED drivers can be determined using the following equations:

$$
\begin{aligned}
& \mathrm{L}_{\text {BUCK }}=\frac{V_{\mathrm{LED}}}{\Delta \mathrm{I}_{\mathrm{L}} \cdot f} \cdot\left(1-\mathrm{D}_{\mathrm{MAX})}\right) \\
& \mathrm{L}_{\text {BOOST }}=\frac{V_{\text {IN(MIN })}}{\Delta \mathrm{I}_{\mathrm{L}} \bullet f} \cdot \mathrm{D}_{\mathrm{MAX}} \\
& \mathrm{~L}_{\text {BUCK-BOOST }}=\frac{V_{\text {IN(MIN })}}{\Delta \mathrm{I}_{\mathrm{L}} \cdot f} \cdot \mathrm{D}_{\mathrm{MAX}}
\end{aligned}
$$

The primary and secondary inductor values of the SEPIC LED driver are:

$$
\mathrm{L} 1=\mathrm{L} 2=\frac{\mathrm{V}_{\mathrm{IN}(\mathrm{MIN})}}{\Delta \mathrm{I}_{\mathrm{L}} \cdot f} \cdot \mathrm{D}_{\mathrm{MAX}}
$$

By making $\mathrm{L} 1=\mathrm{L} 2$, and winding them on the same core, the value of inductance in the preceding equation is replaced by 2L, due to mutual inductance:

$$
\mathrm{L}=\frac{\mathrm{V}_{\mathrm{IN}(\mathrm{MIN})}}{2 \cdot \Delta \mathrm{I}_{\mathrm{L}} \cdot f} \cdot \mathrm{D}_{\mathrm{MAX}}
$$

The inductor peak current and RMS current in continuous mode operation can be calculated based on $I_{\text {L(MAX) }}$ and $\Delta I_{L}$.

$$
\begin{aligned}
& \mathrm{I}_{\mathrm{L}(\mathrm{PEAK})}=\mathrm{I}_{\mathrm{L}(\mathrm{MAX})}+0.5 \cdot \Delta \mathrm{I}_{\mathrm{L}} \\
& \mathrm{I}_{\mathrm{L}(\mathrm{RMS})} \approx \mathrm{I}_{\mathrm{L}(\mathrm{MAX})}
\end{aligned}
$$

Based on the preceding equations, the user should choose the inductors having sufficient saturation and RMS current ratings.

## APPLICATIONS INFORMATION

## Switch Current Sense Resistors Selection

The LT3797 measures each channel's power N-channel MOSFET current by using a sense resistor (see RSw_SEN in Figure 1) between GND and the MOSFET source. Figure 7 shows a typical waveform of the sense voltage $\left(\mathrm{V}_{\mathrm{SW}}\right.$ SENSE) across the sense resistor in CCM. The placement of the sense resistor $\mathrm{R}_{\text {Sw _ SEN }}$ should be close to the source of the MOSFET and GND. The SENSEP and SENSEN sense node traces should run parallel to each other to a Kelvin connection on the positive and negative terminals of $\mathrm{R}_{\text {sw_sen }}$.
Due to the current limit function of the power switch current control, RSW_SEN should be selected to guarantee that the peak current sense voltage $\mathrm{V}_{\text {SW_SENSE(PEAK) }}$ during steady-state normal operation is lower than the SENSE current limit threshold ( 100 mV minimum). It is recommended to give a $20 \%$ margin and set $V_{\text {SW_SENSE(PEAK) }}$ to be 80 mV . Then, the switch current sense resistor value can be calculated as:

$$
\mathrm{R}_{\text {SW_SEN }}=\frac{80 \mathrm{mV}}{I_{\text {SW (PEAK })}}
$$

where $I_{\text {SW(PEAK) }}$ is the peak switch current. $I_{\text {SW(PEAK })}$ of the boost, buck mode and buck-boost mode LED driver is:
$I_{\text {SW (PEAK })}=I_{\text {L(PEAK })}$
$I_{\text {SW(PEAK) }}$ of the SEPIC LED driver is:

$$
I_{\text {SW(PEAK })}=I_{\text {L1(PEAK) }}+\mathrm{I}_{\text {L2(PEAK) }}
$$

Figure 7. The Sense Voltage Across the Sense Resistor in CCM

## Sense Voltage Ripple Verification

After the inductor ripple current and the switch current sense resistor value have been selected according to the previous sections, the sense voltage ripple $\Delta \mathrm{V}_{\text {SW }}$ sense (refer to Figure 7) of the boost, buck, and buck-boost LED drivers can be determined using the following equation:

$$
\Delta V_{\text {SW_SENSE }}=\Delta I_{L} \bullet R_{S W \_S E N}
$$

$\Delta V_{\text {SW_SENSE }}$ of the SEPIC LED driver can be determined using the following equation:

$$
\Delta V_{\text {SW_SENSE }}=2 \cdot \Delta I_{L} \bullet R_{S W} \text { SEN }
$$

The LT3797 has internal slope compensation to stabilize the control loop against sub-harmonic oscillation. When the LT3797 operates at a duty cycle greater than 0.66 in CCM, the sense voltage ripple, $\Delta V_{\text {Sw_SENSE }}$ (refer to Figure 7), needs to be limited to ensure the internal slope compensation is sufficient to stabilize the control loop. Figure 8 shows the maximum $\Delta V_{\text {SW_SENSE }}$ over the duty cycle. It is recommended to check and ensure $\Delta \mathrm{V}_{\text {SW }}$ SENSE is below this curve at the highest duty cycle. If $\Delta V_{\text {SW_SENSE }}$ is above the maximum $\Delta V_{\text {SW_SENSE }}$ curve at the highest duty cycle, the $\Delta l_{L}$ needs to be reduced and the parameters in the previous two sections need to be recalculated until the optimized values are obtained.

Figure 8. The Maximum Sense Voltage Ripple vs Duty Cycle for CCM

## APPLICATIONS INFORMATION

## Power MOSFET Selection

The selection criteria for the power MOSFET includes the drain-source breakdown voltage ( $\mathrm{BV}_{\mathrm{DSS}}$ ), the threshold voltage $\left(\mathrm{V}_{\mathrm{GS}(\mathrm{TH})}\right)$, the on-resistance $\left(\mathrm{R}_{\mathrm{DS}(\mathrm{ON})}\right)$, the total gate charge $\left(Q_{G}\right)$, the maximum drain current ( $\left.I_{D(M A X)}\right)$ and the MOSFET's thermal resistances ( $\mathrm{R}_{\theta \mathrm{JC}}$ and $\mathrm{R}_{\theta \mathrm{JA}}$ ), etc.
The required power MOSFET BV ${ }_{\text {DSS }}$ rating of different topologies can be estimated using the following equations. Add a diode forward voltage, and any additional ringing across its drain-to-source during its off-time.

$$
\begin{aligned}
& \text { BV }_{\text {DSS_BOOST }}>V_{\text {LED }} \\
& \text { BV }_{\text {DSS_BUCK }}>V_{\text {IN(MAX) }} \\
& \mathrm{BV}_{\text {DSS_BUCK-BOOST }}>V_{\text {IN(MAX })}+V_{\text {LED }} \\
& \text { BV }_{\text {DSS_SEPIC }}>V_{\text {IN(MAX })}+V_{\text {LED }}
\end{aligned}
$$

The power dissipated by the MOSFET in a boost, buck mode, or buck-boost mode LED driver is:

$$
\begin{aligned}
& P_{\text {FET }}=\mathrm{I}_{\mathrm{L}(\mathrm{MAX})^{2}} \cdot \mathrm{R}_{\mathrm{DS}(\mathrm{ON})} \bullet \mathrm{D}_{\mathrm{MAX}}+2 \bullet \mathrm{~V}_{\mathrm{SW}(\text { PEAK })} \bullet \\
& \mathrm{I}_{\mathrm{L}(\mathrm{MAX})} \cdot \mathrm{C}_{\text {RSS }} \cdot \boldsymbol{f} / 1.5 \mathrm{~A}
\end{aligned}
$$

The power dissipated by the MOSFET in a SEPIC LED driver is:

$$
\begin{aligned}
& \mathrm{P}_{\mathrm{FET}}=\left(\mathrm{l}_{\mathrm{L} 1(\mathrm{MAX})}+\mathrm{I}_{\mathrm{L} 2(\mathrm{MAX})}\right)^{2} \bullet \mathrm{R}_{\mathrm{DS}(\mathrm{ON})} \bullet \mathrm{D}_{\mathrm{MAX}}+2 \bullet \\
& \mathrm{~V}_{\mathrm{SW}(\mathrm{PEAK})} \bullet\left(\mathrm{I}_{\mathrm{L} 1(\mathrm{MAX})}+\mathrm{I}_{\mathrm{L} 2(\mathrm{MAX})}\right) \bullet \mathrm{C}_{\mathrm{RSS}} \bullet \mathrm{f} / 1.5 \mathrm{~A}
\end{aligned}
$$

The first terms in the preceding equations represent the conduction losses in the devices, and the second terms, the switching losses. $\mathrm{C}_{\mathrm{RSS}}$ is the reverse transfer capacitance, which is usually specified in the MOSFET characteristics. For maximum efficiency, $R_{D S(O N)}$ and $Q_{G}$ should be minimized. From a known power dissipated in the power

MOSFET, its junction temperature can be obtained using the following equation:

$$
\mathrm{T}_{\mathrm{J}}=\mathrm{T}_{\mathrm{A}}+\mathrm{P}_{\mathrm{FET}} \bullet \theta_{\mathrm{JA}}=\mathrm{T}_{\mathrm{A}}+\mathrm{P}_{\mathrm{FET}} \bullet\left(\theta_{\mathrm{JC}}+\theta_{\mathrm{CA}}\right)
$$

$\mathrm{T}_{\mathrm{J}}$ must not exceed the MOSFET maximum junction temperature rating. It is recommended to measure the MOSFET temperature in steady state to ensure that absolute maximum ratings are not exceeded.

## Schottky Rectifier Selection

The power Schottky diode conducts current during the interval when the switch is turned off. In an LT3797 LED driver, the Schottky diode should have the same voltage rating as the power N -channel MOSFET in the same channel. Refer to the power MOSFET $\mathrm{BV}_{\text {DSS }}$ rating in the previous section for the peak reverse voltage rating selection. If using the PWM feature for dimming, it is important to consider diode leakage, which increases with the temperature, from the output during the PWM Iow interval. Choose a Schottky diode with sufficiently low leakage current.

The power dissipated by the diode in a boost, buck, or buck-boost converter in CCM is:

$$
P_{D}=I_{L \_A V G(M A X)} \bullet V_{D} \bullet(1-D M A X)
$$

where $V_{D}$ is the diode forward voltage drop.
The power dissipated by the diode in a SEPIC converter is:

$$
P_{D}=\left(I_{L 1 \_A V G(M A X)}+l_{L 2 \_A V G(M A X)}\right) \bullet V_{D} \bullet\left(1-D_{M A X}\right)
$$

and the diode junction temperature is:

$$
T_{J}=T_{A}+P_{D} \bullet\left(\theta_{J C}+\theta_{C A}\right)
$$

$T_{J}$ must not exceed the diode maximum junction temperature rating.

## APPLICATIONS INFORMATION

## High Side PMOS Disconnect Switch Selection

A PMOS with a minimum $V_{G S(T H)}$ of -1 V to -2 V is recommended for the high side disconnect switch in most LT3797 applications to improve the PWM dimming ratio and protect the LED array from excessive heating during fault conditions. The PMOS BV ${ }_{\text {DSS }}$ rating must be higher than the open-LED regulation voltage set by the FBH pin. The maximum continuous drain current $I_{D(M A X)}$ rating should be higher than the maximum LED current.

## Input Capacitor Selection

The input capacitor $\mathrm{C}_{\text {IN }}$ supplies the AC ripple current to the power inductor of the converter and must be placed and sized according to the transient current requirements. The switching frequency, output current and tolerable input voltage ripple are key inputs to estimating the required capacitor value. The X5R or X7R type ceramic capacitors are usually good choices since they have small variation with temperature and DC bias. Typically, the boost or SEPIC converter requires a lower value input capacitor than the buck mode or buck-boost mode converter, due to the fact that its inductor is in series with the input, and the input current waveform is continuous. The input capacitor value can be estimated based on the inductor ripple $\Delta \mathrm{I}_{\mathrm{L}}$ (refer to Inductor Selection section), the switching frequency, and the acceptable input voltage ripple $\Delta \mathrm{V}_{\text {IN }}$ on $\mathrm{C}_{\text {IN }}$. $\mathrm{C}_{\text {IN }}$ value of the boost and SEPIC converter can be calculated by:

$$
\mathrm{C}_{\mathrm{IN}}=0.125 \cdot \frac{\Delta \mathrm{I}_{\mathrm{L}}}{\Delta \mathrm{~V}_{\mathrm{IN}} \bullet f}
$$

$\mathrm{C}_{\text {IN }}$ value of the buck mode and buck-boost mode LED driver can be calculated by:

$$
\mathrm{C}_{\mathrm{IN}}=\mathrm{I}_{\mathrm{LED}} \cdot \frac{\mathrm{~V}_{\mathrm{LED}} \bullet\left(\mathrm{~V}_{\mathrm{IN}(\mathrm{MIN})}-\mathrm{V}_{\mathrm{LED}}\right)}{\mathrm{V}_{\mathrm{IN}(\mathrm{MIN})^{2}} \bullet \Delta \mathrm{~V}_{\text {IN }} \bullet \mathrm{f}}
$$

## Output Capacitor Selection

The output filter capacitors should be sized to attenuate the LED current ripple. Use of X5R or X7R type ceramic capacitors is recommended. To achieve the same LED ripple current, the required filter capacitor is smaller in the buck mode applications than that in the boost, buck-boost mode and SEPIC applications. This is due to the fact that, in the buck converter, the inductor is in series with the output and the ripple current flowing through the output capacitor is continuous. Lower operating frequencies will require proportionately higher capacitor values.

## The DC Coupling Capacitor Selection for SEPIC LED Driver

The DC voltage rating of the DC coupling capacitor, $C_{D C}$, connected between the primary and secondary inductors should be larger than the maximum input voltage:

$$
V_{C D C}>V_{\operatorname{IN}(\operatorname{MAX})}
$$

$\mathrm{C}_{\mathrm{DC}}$ has nearly a rectangular current waveform in CCM. During the switch off-time, the current through $\mathrm{C}_{\mathrm{DC}}$ is $\mathrm{I}_{\mathrm{VIN}}$, while approximately $-_{\text {LED }}$ flows during the on-time. The $C_{D C}$ voltage ripple causes distortions on the primary and secondary inductor current waveforms. The $C_{D C}$ should be sized to limit its voltage ripple. The power loss on the $C_{D C}$ ESR reduces the LED driver efficiency. Therefore, the sufficient low ESR ceramic capacitors should be selected. The X5R or X7R ceramic capacitor is recommended for $C_{D C}$.

## Integrated INTV CC Power Supply

The LT3797 includes an internal switch mode DC/DC converter to generate a regulated 7.5 V INTV ${ }_{\text {CC }}$ power supply to power the NMOS gate drivers of the three channels ( $l_{\text {DRIVE }}$ ). This INTV $C C$ power supply can also be used to drive external circuits ( $\mathrm{l}_{\mathrm{EXT}}$ ). This INTV ${ }_{\text {CC }}$ power supply

## APPLICATIONS INFORMATION

has two major advantages over the traditional internal LDO regulators. It is able to generate 7.5 V INTV $C C$ voltage from a $\mathrm{V}_{\text {IN }}$ voltage as low as 2.5 V , allowing the LT3797 to drive high threshold MOSFETs in the low $\mathrm{V}_{\text {IN }}$ applications. It is also able to deliver large current from a $\mathrm{V}_{\text {IN }}$ voltage as high as 40 V without overheating the package, due to its high efficiency (over 70\% at full load). This integrated DC/DC converter requires three external components (CVCC, $\mathrm{C}_{\text {bOost }}$ and LpWR) for operation, as shown in Figure 1. Select these three components based on the following guidelines:

- $\mathrm{C}_{\text {Vcc }}$ is a $10 \mu \mathrm{~F} / 10 \mathrm{~V}$ ceramic capacitor used to bypass INTV ${ }_{\text {CC }}$ to GND immediately adjacent to the pins.
- $\mathrm{C}_{\text {BOOST }}$ is a $0.1 \mu \mathrm{~F} / 10 \mathrm{~V}$ ceramic capacitor connected between the BOOST pin and the SW1 pin.
- Select a $47 \mu \mathrm{H}$ inductor with the saturation current rating of 0.6 A or greater and RMS current rating of 0.4 A or greater for LPWR.
The INTV ${ }_{\text {CC }}$ power supply has an output current limit function to protect itself from excessive electrical and thermal stress. Figure 9 shows the INTV ${ }_{C C}$ output limit (linTVCC LMT) vs $V_{I N}$ and switching frequency. Make sure the sum of the $I_{\text {DRIVE }}$ and $I_{\text {EXT }}$ is always lower than the $I_{\text {INTVCC_LMT }}$ across the whole $\mathrm{V}_{\text {IN }}$ range of the application circuit:

$$
I_{\text {DRIVE }}+\mathrm{I}_{\text {EXT }}<\mathrm{I}_{\text {INTVCC_LMT }}
$$

where:

$$
I_{\text {DRIVE }}=\left(Q_{G_{-} C H 1}+Q_{G_{-} C H 2}+Q_{G_{-} C H 3}\right) \bullet f_{S W}
$$

$Q_{G_{C}} \mathrm{CH1-3}^{2}$ is the total gate charge of the NMOS of the three channels at $\mathrm{V}_{\mathrm{GS}}=0 \mathrm{~V}$ to 7.5 V .

Figure 9. INTV $_{\text {CC }}$ Current Limit vs $\mathrm{V}_{\mathbb{I N}}, \mathrm{f}_{\text {SW }}$

## Board Layout

The high speed operation of the LT3797 demands careful attention to board layout and component placement. The exposed pad of the package is the only GND terminal of the IC, and is important for thermal management of the IC. Therefore, it is crucial to achieve a good electrical and thermal contact between the exposed pad and the ground planes of the board. For the LT3797 to deliver its full output power, it is imperative that a good thermal path be provided to dissipate the heat generated within the package. It is recommended that multiple vias in the printed circuit board be used to conduct heat away from the IC and into copper planes with as much area as possible.

## APPLICATIONS INFORMATION

Due to the highly compact integration of the three switching channels within the LT3797, careful consideration must be given to possible noise coupling between channels. To reduce noise coupling, the compensation network components connected to the VC1-3 pins and the DC control signal components connected to the SS1-3, RT, EN/UVLO, and CTRL1-3 pins must be connected to signal ground (SGND). The signal ground (SGND) and power ground (PGND) connection should only occur at the LT3797 exposed GND pad. Further, board traces for high impedance signals such as FBH1-3 and VC1-3 should be kept to the shortest length possible to avoid unwanted noise pick up. Also, the decoupling capacitors that connect $V_{\text {IN }}$ to PGND and INTV ${ }_{\text {CC }}$ to PGND should be physically located close to their respective pins. Finally, for high voltage and/or high current applications, an effective approach to attenuate possible switch noise coupling into each channel's control loop is to add a small footprint size
$0.1 \mu \mathrm{~F}$ ceramic capacitor between each SENSEP pin and the corresponding SENSEN pin. When used, these noise filtering capacitors should be physically located near their respective pins. Figure 10 provides an example of a PCB layout of the LT3797 (QFN), decoupling capacitors, compensation networks and ground separation.
To reduce electromagnetic interference (EMI) and high frequency resonance problems, proper layout of the LT3797 LED driver power stage is essential, especially the power paths with high di/dt. Figure 11-14 show the simplified power stage circuits of boost, buck mode, buck-boost mode and SEPIC topologies with the high di/dt loops highlighted. The high di/dt loops of different topologies should be kept as tight as possible to reduce inductive ringing. Figure $15-16$ shows the examples of the high di/dt loop layout of the different topologies shown in Figure 11-14.

Figure 16. A Layout Example of the High di/dt Loop of the SEPIC Drivers

## APPLICATIONS INFORMATION

Check the stress on the power MOSFETs by measuring the drain-to-source voltage directly across the terminals of each device (reference the ground of a single scope probe directly to the source pad on the PC board). Beware of inductive ringing, which can exceed the maximum specified voltage rating of the MOSFET. If this ringing cannot be avoided, and exceeds the maximum rating of the device, either choose a higher voltage device or specify an avalanche rated power MOSFET.

The LT3797 LED driver circuit can be implemented in a 2-layer PCB board. However, a well designed 4-layer or 6 -layer PCB board provides extra ground plane shielding and larger area of electrical and thermal conduction path, therefore provides better electrical and thermal performance.

## Recommended Component Manufacturers

Some of the recommended component manufacturers are listed in Table 3.

| LT3596 | 60V Step-Down LED Driver | $\mathrm{V}_{\mathrm{IN}}: 6 \mathrm{~V}$ to 60 V, PWM Dimming $=10000: 1, \mathrm{I}_{\text {SD }}<1 \mu \mathrm{~A}$, $5 \mathrm{~mm} \times 8 \mathrm{~mm}$ QFN-52 Package |
| LT3598 | 44V, 1.5A, 2.5MHz Boost 6-Channel LED Driver | $\mathrm{V}_{\text {IN: }}: 3 \mathrm{~V}$ to $30 \mathrm{~V}\left(40 \mathrm{~V}_{\text {MAX }}\right), \mathrm{V}_{\text {OUt(max }}=44 \mathrm{~V}$, PWM Dimming $=1000: 1$, $I_{\mathrm{SD}}<1 \mu \mathrm{~A}, 4 \mathrm{~mm} \times 4 \mathrm{~mm}$ QFN-24 Package |
| LT3599 | 2A Boost Converter with Internal 4-String 150mA LED Ballaster | $V_{\text {IN: }}: 3 V$ to $30 \mathrm{~V}, \mathrm{~V}_{\text {OUT (MAX) }}=44 \mathrm{~V}$, PWM Dimming $=1000: 1, \mathrm{I}_{\text {SD }}<1 \mu \mathrm{~A}$, $5 \mathrm{~mm} \times 5 \mathrm{~mm}$ QFN-32 and TSSOP-28 Packages |
| LT3754 | 16 -Channel $\times 50 \mathrm{~mA}$ LED Driver with 60V Boost Controller and PWM Dimming | $\mathrm{V}_{\text {IN: }}: 6 \mathrm{~V}$ to $40 \mathrm{~V}, \mathrm{~V}_{\text {OUt }}$ (MAX) $=45 \mathrm{~V}$, PWM Dimming $=3000: 1, \mathrm{I}_{\text {SD }}<1 \mu \mathrm{~A}$, $5 \mathrm{~mm} \times 5 \mathrm{~mm}$ QFN-32 Package |

## X-ON Electronics

Largest Supplier of Electrical and Electronic Components
