

# 42V, 4A Synchronous Step-Down Silent Switcher with 2.5μA Quiescent Current

## FEATURES

- **Silent Switcher® Architecture**
  - **Ultralow EMI Emissions**
- **High Efficiency at High Frequency**
  - **Up to 96% Efficiency at 1MHz, 12V<sub>IN</sub> to 5V<sub>OUT</sub>**
  - **Up to 94% Efficiency at 2MHz, 12V<sub>IN</sub> to 5V<sub>OUT</sub>**
- **Wide Input Voltage Range: 3.4V to 42V**
- **Ultralow Quiescent Current Burst Mode® Operation:**
  - **2.5μA I<sub>Q</sub> Regulating 12V<sub>IN</sub> to 3.3V<sub>OUT</sub>**
  - **Output Ripple < 10mV<sub>p-p</sub>**
- **Fast Minimum Switch On-Time: 30ns**
- **Low Dropout Under All Conditions: 125mV at 1A**
- **Safely Tolerates Inductor Saturation in Overload**
- **Adjustable and Synchronizable: 200kHz to 3MHz**
- **Peak Current Mode Operation**
- **Accurate 1V Enable Pin Threshold**
- **Internal Compensation**
- **Output Soft-Start and Tracking**
- **Small 18-Lead 3mm × 4mm QFN**

## APPLICATIONS

- Automotive and Industrial Supplies
- General Purpose Step-Down
- GSM Power Supplies

## DESCRIPTION

The LT®8614 step-down regulator features Silent Switcher architecture designed to minimize EMI emissions while delivering high efficiency at frequencies up to 3MHz. Assembled in a 3mm × 4mm QFN, the monolithic construction with integrated power switches and inclusion of all necessary circuitry yields a solution with a minimal PCB footprint. An ultralow 2.5μA quiescent current—with the output in full regulation—enables applications requiring highest efficiency at very small load currents. Transient response remains excellent and output voltage ripple is below 10mV<sub>p-p</sub> at any load, from zero to full current.

The LT8614 allows high V<sub>IN</sub> to low V<sub>OUT</sub> conversion at high frequency with a fast minimum top switch on-time of 30ns. Operation is safe in overload even with a saturated inductor.

Essential features are included and easy to use: An open-drain PG pin signals when the output is in regulation. The SYNC pin allows clock synchronization and choice of Burst Mode operation or pulse-skipping mode. Soft-start and tracking functionality is accessed via the TR/SS pin. An accurate enable threshold can be set using the EN/UV pin and a resistor at the RT pin programs switch frequency.

All registered trademarks and trademarks are the property of their respective owners. Protected by U.S. patents, including 8823345.

**Note 1:** Stresses beyond those listed under Absolute Maximum Ratings may cause permanent damage to the device. Exposure to any Absolute Maximum Rating condition for extended periods may affect device reliability and lifetime.

**Note 2:** The LT8614E is guaranteed to meet performance specifications from 0°C to 125°C junction temperature. Specifications over the -40°C to 125°C operating junction temperature range are assured by design, characterization, and correlation with statistical process controls. The LT8614I is guaranteed over the full -40°C to 125°C operating junction temperature range. The LT8614H is guaranteed to meet performance specifications from -40°C to 150°C operating junction temperature range.

High junction temperatures degrade operating lifetimes. Operating lifetime is derated at junction temperatures greater than 125°C.

**Note 3:** θ values determined per JEDEC 51-7, 51-12. See the Applications Information section for information on improving the thermal resistance.

**Note 4:** This IC includes overtemperature protection that is intended to protect the device during overload conditions. Junction temperature will exceed 150°C when overtemperature protection is active. Continuous operation above the specified maximum operating junction temperature will reduce lifetime.

## PIN FUNCTIONS

**BIAS (Pin 1):** The internal regulator will draw current from BIAS instead of  $V_{IN}$  when BIAS is tied to a voltage higher than 3.1V. For output voltages of 3.3V to 30V this pin should be tied to  $V_{OUT}$ . If this pin is tied to a supply other than  $V_{OUT}$  use a  $1\mu\text{F}$  local bypass capacitor on this pin. If no supply is available, tie to GND.

**INTV<sub>CC</sub> (Pin 2):** Internal 3.4V Regulator Bypass Pin. The internal power drivers and control circuits are powered from this voltage. INTV<sub>CC</sub> maximum output current is 20mA. Do not load the INTV<sub>CC</sub> pin with external circuitry. INTV<sub>CC</sub> current will be supplied from BIAS if  $\text{BIAS} > 3.1\text{V}$ , otherwise current will be drawn from  $V_{IN}$ . Voltage on INTV<sub>CC</sub> will vary between 2.8V and 3.4V when BIAS is between 3.0V and 3.6V. Decouple this pin to power ground with at least a  $1\mu\text{F}$  low ESR ceramic capacitor placed close to the IC.

**BST (Pin 3):** This pin is used to provide a drive voltage, higher than the input voltage, to the topside power switch. Place a  $0.1\mu\text{F}$  boost capacitor as close as possible to the IC.

**V<sub>IN1</sub> (Pin 4):** The LT8614 requires two  $1\mu\text{F}$  small input bypass capacitors. One  $1\mu\text{F}$  capacitor should be placed between  $V_{IN1}$  and GND1. A second  $1\mu\text{F}$  capacitor should be placed between  $V_{IN2}$  and GND2. These capacitors must be placed as close as possible to the LT8614. A third larger capacitor of  $2.2\mu\text{F}$  or more should be placed close to the LT8614 with the positive terminal connected to  $V_{IN1}$  and  $V_{IN2}$ , and the negative terminal connected to ground. See applications section for sample layout.

**GND1 (6, 7):** Power Switch Ground. These pins are the return path of the internal bottom side power switch and must be tied together. Place the negative terminal of the input capacitor as close to the GND1 pins as possible. Also be sure to tie GND1 to the ground plane. See the Applications Information section for sample layout.

**SW (Pins 8, 9):** The SW pins are the outputs of the internal power switches. Tie these pins together and connect them to the inductor and boost capacitor. This node should be kept small on the PCB for good performance and low EMI.

**GND2 (10, 11):** Power Switch Ground. These pins are the return path of the internal bottom side power switch and must be tied together. Place the negative terminal of the input capacitor as close to the GND2 pins as possible. Also be sure to tie GND2 to the ground plane. See the Applications Information section for sample layout.

**V<sub>IN2</sub> (Pin 13):** The LT8614 requires two  $1\mu\text{F}$  small input bypass capacitors. One  $1\mu\text{F}$  capacitor should be placed between  $V_{IN1}$  and GND1. A second  $1\mu\text{F}$  capacitor should be placed between  $V_{IN2}$  and GND2. These capacitors must be placed as close as possible to the LT8614. A third larger capacitor of  $2.2\mu\text{F}$  or more should be placed close to the LT8614 with the positive terminal connected to  $V_{IN1}$  and  $V_{IN2}$ , and the negative terminal connected to ground. See the Applications Information section for sample layout.

**EN/UV (Pin 14):** The LT8614 is shut down when this pin is low and active when this pin is high. The hysteresis threshold voltage is 1.00V going up and 0.96V going down. Tie to  $V_{IN}$  if the shutdown feature is not used. An external resistor divider from  $V_{IN}$  can be used to program a  $V_{IN}$  threshold below which the LT8614 will shut down.

**RT (Pin 15):** A resistor is tied between RT and ground to set the switching frequency.

**TR/SS (Pin 16):** Output Tracking and Soft-Start Pin. This pin allows user control of output voltage ramp rate during start-up. A TR/SS voltage below 0.97V forces the LT8614 to regulate the FB pin to equal the TR/SS pin voltage. When TR/SS is above 0.97V, the tracking function is disabled and the internal reference resumes control of the error amplifier. An internal  $2.2\mu\text{A}$  pull-up current from INTV<sub>CC</sub> on this pin allows a capacitor to program output voltage slew rate. This pin is pulled to ground with an internal  $230\Omega$  MOSFET during shutdown and fault conditions; use a series resistor if driving from a low impedance output. This pin may be left floating if the tracking function is not needed.

## PIN FUNCTIONS

**SYNC/MODE (Pin 17):** External Clock Synchronization Input. Ground this pin for low ripple Burst Mode operation at low output loads. Tie to a clock source for synchronization to an external frequency. Apply a DC voltage of 3V or higher or tie to  $INTV_{CC}$  for pulse-skipping mode. When in pulse-skipping mode, the  $I_Q$  will increase to several hundred  $\mu A$ . Do not float this pin.

**GND (Pins 18):** LT8614 Ground Pin. Connect this pin to system ground and to the ground plane.

**PG (Pin 19):** The PG pin is the open-drain output of an internal comparator. PG remains low until the FB pin is within  $\pm 9\%$  of the final regulation voltage, and there are no fault conditions. PG is valid when  $V_{IN}$  is above 3.4V, regardless of EN/UV pin state.

**FB (Pin 20):** The LT8614 regulates the FB pin to 0.970V. Connect the feedback resistor divider tap to this pin. Also, connect a phase lead capacitor between FB and  $V_{OUT}$ . Typically, this capacitor is 4.7pF to 22pF.

**SW (Exposed Pad Pins 21, 22):** The exposed pads should be connected and soldered to the SW trace for good thermal performance. If necessary due to manufacturing limitations Pins 21 and 22 may be left disconnected, however thermal performance will be degraded.

## BLOCK DIAGRAM

## OPERATION

The LT8614 is a monolithic, constant frequency, current mode step-down DC/DC converter. An oscillator, with frequency set using a resistor on the RT pin, turns on the internal top power switch at the beginning of each clock cycle. Current in the inductor then increases until the top switch current comparator trips and turns off the top power switch. The peak inductor current at which the top switch turns off is controlled by the voltage on the internal VC node. The error amplifier servos the VC node by comparing the voltage on the  $V_{FB}$  pin with an internal 0.97V reference. When the load current increases it causes a reduction in the feedback voltage relative to the reference leading the error amplifier to raise the VC voltage until the average inductor current matches the new load current. When the top power switch turns off, the synchronous power switch turns on until the next clock cycle begins or inductor current falls to zero. If overload conditions result in more than 6.9A flowing through the bottom switch, the next clock cycle will be delayed until switch current returns to a safe level.

If the EN/UV pin is low, the LT8614 is shut down and draws 1 $\mu$ A from the input. When the EN/UV pin is above 1V, the switching regulator will become active.

To optimize efficiency at light loads, the LT8614 operates in Burst Mode operation in light load situations. Between bursts, all circuitry associated with controlling the output switch is shut down, reducing the input supply current to 1.7 $\mu$ A. In a typical application, 2.5 $\mu$ A will be consumed

from the input supply when regulating with no load. The SYNC pin is tied low to use Burst Mode operation and can be tied to a logic high to use pulse-skipping mode. If a clock is applied to the SYNC pin the part will synchronize to an external clock frequency and operate in pulse-skipping mode. While in pulse-skipping mode the oscillator operates continuously and positive SW transitions are aligned to the clock. During light loads, switch pulses are skipped to regulate the output and the quiescent current will be several hundred  $\mu$ A.

To improve efficiency across all loads, supply current to internal circuitry can be sourced from the BIAS pin when biased at 3.3V or above. Else, the internal circuitry will draw current from  $V_{IN}$ . The BIAS pin should be connected to  $V_{OUT}$  if the LT8614 output is programmed at 3.3V or above.

Comparators monitoring the FB pin voltage will pull the PG pin low if the output voltage varies more than  $\pm 9\%$  (typical) from the set point, or if a fault condition is present.

The oscillator reduces the LT8614's operating frequency when the voltage at the FB pin is low. This frequency foldback helps to control the inductor current when the output voltage is lower than the programmed value which occurs during start-up or overcurrent conditions. When a clock is applied to the SYNC pin or the SYNC pin is held DC high, the frequency foldback is disabled and the switching frequency will slow down only during overcurrent conditions.

## APPLICATIONS INFORMATION

traces will shield them from the SW and BOOST nodes. The exposed pad on the bottom of the package should be soldered to SW to reduce thermal resistance to ambient. To keep thermal resistance low, extend the ground plane from GND1 and GND2 as much as possible, and add thermal vias to additional ground planes within the circuit board and on the bottom side.

### Achieving Ultralow Quiescent Current

To enhance efficiency at light loads, the LT8614 operates in low ripple Burst Mode operation, which keeps the output capacitor charged to the desired output voltage while minimizing the input quiescent current and minimizing output voltage ripple. In Burst Mode operation the LT8614 delivers single small pulses of current to the output capacitor followed by sleep periods where the output power is supplied by the output capacitor. While in sleep mode the LT8614 consumes 1.7 $\mu$ A.

As the output load decreases, the frequency of single current pulses decreases (see Figure 2a) and the percentage of time the LT8614 is in sleep mode increases, resulting in much higher light load efficiency than for typical converters. By maximizing the time between pulses, the converter quiescent current approaches 2.5 $\mu$ A for a typical application when there is no output load. Therefore, to optimize the quiescent current performance at light loads, the current in the feedback resistor divider must be minimized as it appears to the output as load current.

In order to achieve higher light load efficiency, more energy must be delivered to the output during the single small pulses in Burst Mode operation such that the LT8614 can stay in sleep mode longer between each pulse. This can be achieved by using a larger value inductor (i.e., 4.7 $\mu$ H), and should be considered independent of switching frequency when choosing an inductor. For example, while a lower inductor value would typically be used for a high switching frequency application, if high light load efficiency is desired, a higher inductor value should be chosen. See curve in Typical Performance Characteristics.

While in Burst Mode operation the current limit of the top switch is approximately 600mA resulting in output voltage ripple shown in Figure 3. Increasing the output capacitance will decrease the output ripple proportionally. As load ramps upward from zero the switching frequency will increase but only up to the switching frequency programmed by the resistor at the RT pin as shown in Figure 2a. The output load at which the LT8614 reaches the programmed frequency varies based on input voltage, output voltage, and inductor choice.

### Minimum Load to Full Frequency (SYNC DC High)

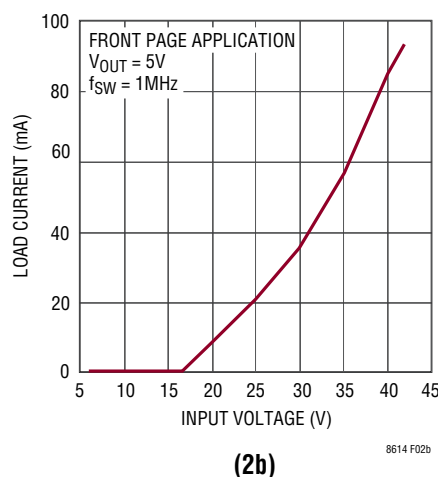

Figure 2. SW Frequency vs Load Information in Burst Mode Operation (2a) and Pulse-Skipping Mode (2b)

## APPLICATIONS INFORMATION

**Figure 3. Burst Mode Operation**

For some applications it is desirable for the LT8614 to operate in pulse-skipping mode, offering two major differences from Burst Mode operation. First is the clock stays awake at all times and all switching cycles are aligned to the clock. In this mode much of the internal circuitry is awake at all times, increasing quiescent current to several hundred  $\mu\text{A}$ . Second is that full switching frequency is reached at lower output load than in Burst Mode operation (see Figure 2b). To enable pulse-skipping mode, the SYNC pin is tied high either to a logic output or to the  $\text{INTV}_{\text{CC}}$  pin. When a clock is applied to the SYNC pin the LT8614 will also operate in pulse-skipping mode.

### FB Resistor Network

The output voltage is programmed with a resistor divider between the output and the FB pin. Choose the resistor values according to:

$$R1 = R2 \left( \frac{V_{\text{OUT}}}{0.970V} - 1 \right) \quad (1)$$

Reference designators refer to the Block Diagram. 1% resistors are recommended to maintain output voltage accuracy.

If low input quiescent current and good light-load efficiency are desired, use large resistor values for the FB resistor divider. The current flowing in the divider acts as a load current, and will increase the no-load input current to the converter, which is approximately:

$$I_Q = 1.7\mu\text{A} + \left( \frac{V_{\text{OUT}}}{R1+R2} \right) \left( \frac{V_{\text{OUT}}}{V_{\text{IN}}} \right) \left( \frac{1}{n} \right) \quad (2)$$

where  $1.7\mu\text{A}$  is the quiescent current of the LT8614 and the second term is the current in the feedback divider reflected to the input of the buck operating at its light load efficiency  $n$ . For a 3.3V application with  $R1 = 1\text{M}$  and  $R2 = 412\text{k}$ , the feedback divider draws  $2.3\mu\text{A}$ . With  $V_{\text{IN}} = 12\text{V}$  and  $n = 80\%$ , this adds  $0.8\mu\text{A}$  to the  $1.7\mu\text{A}$  quiescent current resulting in  $2.5\mu\text{A}$  no-load current from the 12V supply. Note that this equation implies that the no-load current is a function of  $V_{\text{IN}}$ ; this is plotted in the Typical Performance Characteristics section.

When using large FB resistors, a 4.7pF to 22pF phase-lead capacitor should be connected from  $V_{\text{OUT}}$  to FB.

### Setting the Switching Frequency

The LT8614 uses a constant frequency PWM architecture that can be programmed to switch from 200kHz to 3MHz by using a resistor tied from the  $R_T$  pin to ground. A table showing the necessary  $R_T$  value for a desired switching frequency is in Table 1.

The  $R_T$  resistor required for a desired switching frequency can be calculated using:

$$R_T = \frac{46.5}{f_{\text{SW}}} - 5.2 \quad (3)$$

where  $R_T$  is in  $\text{k}\Omega$  and  $f_{\text{SW}}$  is the desired switching frequency in MHz.

## APPLICATIONS INFORMATION

Table 1. SW Frequency vs R<sub>T</sub> Value

f <sub>SW</sub> (MHz)	R <sub>T</sub> (kΩ)
0.2	232
0.3	150
0.4	110
0.5	88.7
0.6	71.5
0.7	60.4

1.0	41.2
1.2	33.2
1.4	28.0
1.6	23.7
1.8	20.5
2.0	18.2
2.2	15.8
3.0	10.7

### Operating Frequency Selection and Trade-Offs

Selection of the operating frequency is a trade-off between efficiency, component size, and input voltage range. The advantage of high frequency operation is that smaller inductor and capacitor values may be used. The disadvantages are lower efficiency and a smaller input voltage range.

The highest switching frequency (f<sub>SW(MAX)</sub>) for a given application can be calculated as follows:

$$f_{SW(MAX)} = \frac{V_{OUT} + V_{SW(BOT)}}{t_{ON(MIN)}(V_{IN} - V_{SW(TOP)} + V_{SW(BOT)})} \quad (4)$$

where V<sub>IN</sub> is the typical input voltage, V<sub>OUT</sub> is the output voltage, V<sub>SW(TOP)</sub> and V<sub>SW(BOT)</sub> are the internal switch drops (~0.45V, ~0.15V, respectively at maximum load) and t<sub>ON(MIN)</sub> is the minimum top switch on-time (see the Electrical Characteristics). This equation shows that a slower switching frequency is necessary to accommodate a high V<sub>IN</sub>/V<sub>OUT</sub> ratio.

For transient operation, V<sub>IN</sub> may go as high as the absolute maximum rating of 42V regardless of the R<sub>T</sub> value, however the LT8614 will reduce switching frequency as necessary to maintain control of inductor current to assure safe operation.

The LT8614 is capable of a maximum duty cycle of greater than 99%, and the V<sub>IN</sub>-to-V<sub>OUT</sub> dropout is limited by the R<sub>DS(ON)</sub> of the top switch. In this mode the LT8614 skips switch cycles, resulting in a lower switching frequency than programmed by R<sub>T</sub>.

For applications that cannot allow deviation from the programmed switching frequency at low V<sub>IN</sub>/V<sub>OUT</sub> ratios use the following formula to set switching frequency:

$$V_{IN(MIN)} = \frac{V_{OUT} + V_{SW(BOT)}}{1 - f_{SW} \cdot t_{OFF(MIN)}} - V_{SW(BOT)} + V_{SW(TOP)} \quad (5)$$

where V<sub>IN(MIN)</sub> is the minimum input voltage without skipped cycles, V<sub>OUT</sub> is the output voltage, V<sub>SW(TOP)</sub> and V<sub>SW(BOT)</sub> are the internal switch drops (~0.45V, ~0.15V, respectively at maximum load), f<sub>SW</sub> is the switching frequency (set by R<sub>T</sub>), and t<sub>OFF(MIN)</sub> is the minimum switch off-time. Note that higher switching frequency will increase the minimum input voltage below which cycles will be dropped to achieve higher duty cycle.

### Inductor Selection and Maximum Output Current

The LT8614 is designed to minimize solution size by allowing the inductor to be chosen based on the output load requirements of the application. During overload or short-circuit conditions the LT8614 safely tolerates operation with a saturated inductor through the use of a high speed peak-current mode architecture.

A good first choice for the inductor value is:

$$L = \frac{V_{OUT} + V_{SW(BOT)}}{f_{SW}} \quad (6)$$

where f<sub>SW</sub> is the switching frequency in MHz, V<sub>OUT</sub> is the output voltage, V<sub>SW(BOT)</sub> is the bottom switch drop (~0.15V) and L is the inductor value in μH.

## APPLICATIONS INFORMATION

To avoid overheating and poor efficiency, an inductor must be chosen with an RMS current rating that is greater than the maximum expected output load of the application. In addition, the saturation current (typically labeled  $I_{SAT}$ ) rating of the inductor must be higher than the load current plus 1/2 of in inductor ripple current:

$$I_{L(PEAK)} = I_{LOAD(MAX)} + \frac{1}{2} \Delta I_L \quad (7)$$

where  $\Delta I_L$  is the inductor ripple current as calculated in Equation 9 and  $I_{LOAD(MAX)}$  is the maximum output load for a given application.

As a quick example, an application requiring 1A output should use an inductor with an RMS rating of greater than 1A and an  $I_{SAT}$  of greater than 1.3A. During long duration overload or short-circuit conditions, the inductor RMS rating requirement is greater to avoid overheating of the inductor. To keep the efficiency high, the series resistance (DCR) should be less than  $0.04\Omega$ , and the core material should be intended for high frequency applications.

The LT8614 limits the peak switch current in order to protect the switches and the system from overload faults. The top switch current limit ( $I_{LIM}$ ) is at least 8.5A at low duty cycles and decreases linearly to 7.2A at  $DC = 0.8$ . The inductor value must then be sufficient to supply the desired maximum output current ( $I_{OUT(MAX)}$ ), which is a function of the switch current limit ( $I_{LIM}$ ) and the ripple current.

$$I_{OUT(MAX)} = I_{LIM} - \frac{\Delta I_L}{2} \quad (8)$$

The peak-to-peak ripple current in the inductor can be calculated as follows:

$$\Delta I_L = \frac{V_{OUT}}{L \cdot f_{SW}} \cdot \left( 1 - \frac{V_{OUT}}{V_{IN(MAX)}} \right) \quad (9)$$

where  $f_{SW}$  is the switching frequency of the LT8614, and  $L$  is the value of the inductor. Therefore, the maximum output current that the LT8614 will deliver depends on the switch current limit, the inductor value, and the input and output voltages. The inductor value may have to be increased if the inductor ripple current does not allow

sufficient maximum output current ( $I_{OUT(MAX)}$ ) given the switching frequency, and maximum input voltage used in the desired application.

In order to achieve higher light load efficiency, more energy must be delivered to the output during the single small pulses in Burst Mode operation such that the LT8614 can stay in sleep mode longer between each pulse. This can be achieved by using a larger value inductor (i.e.,  $4.7\mu H$ ), and should be considered independent of switching frequency when choosing an inductor. For example, while a lower inductor value would typically be used for a high switching frequency application, if high light load efficiency is desired, a higher inductor value should be chosen. See curve in Typical Performance Characteristics.

The optimum inductor for a given application may differ from the one indicated by this design guide. A larger value inductor provides a higher maximum load current and reduces the output voltage ripple. For applications requiring smaller load currents, the value of the inductor may be lower and the LT8614 may operate with higher ripple current. This allows use of a physically smaller inductor, or one with a lower DCR resulting in higher efficiency. Be aware that low inductance may result in discontinuous mode operation, which further reduces maximum load current.

For more information about maximum output current and discontinuous operation, see Linear Technology's Application Note 44.

Finally, for duty cycles greater than 50% ( $V_{OUT}/V_{IN} > 0.5$ ), a minimum inductance is required to avoid sub-harmonic oscillation. See Application Note 19.

### Input Capacitors

The  $V_{IN}$  of the LT8614 should be bypassed with at least three ceramic capacitors for best performance. Two small ceramic capacitors of  $1\mu F$  should be placed close to the part; one at the  $V_{IN1}/GND1$  pins and a second at  $V_{IN2}/GND2$  pins. These capacitors should be 0402 or 0603 in size. For automotive applications requiring 2 series input capacitors, two small 0402 or 0603 may be placed at each side of the LT8614 near the  $V_{IN1}/GND1$  and  $V_{IN2}/GND2$  pins.

## APPLICATIONS INFORMATION

A third, larger ceramic capacitor of 2.2 $\mu$ F or larger should be placed close to  $V_{IN1}$  or  $V_{IN2}$ . See layout section for more detail. X7R or X5R capacitors are recommended for best performance across temperature and input voltage variations.

Note that larger input capacitance is required when a lower switching frequency is used. If the input power source has high impedance, or there is significant inductance due to long wires or cables, additional bulk capacitance may be necessary. This can be provided with a low performance electrolytic capacitor.

A ceramic input capacitor combined with trace or cable inductance forms a high quality (under damped) tank circuit. If the LT8614 circuit is plugged into a live supply, the input voltage can ring to twice its nominal value, possibly exceeding the LT8614's voltage rating. This situation is easily avoided (see [Application Note 88](#)).

### Output Capacitor and Output Ripple

The output capacitor has two essential functions. Along with the inductor, it filters the square wave generated by the LT8614 to produce the DC output. In this role it determines the output ripple, thus low impedance at the switching frequency is important. The second function is to store energy in order to satisfy transient loads and stabilize the LT8614's control loop. Ceramic capacitors have very low equivalent series resistance (ESR) and provide the best ripple performance. For good starting values, see the Typical Applications section.

Use X5R or X7R types. This choice will provide low output ripple and good transient response. Transient performance can be improved with a higher value output capacitor and the addition of a feedforward capacitor placed between  $V_{OUT}$  and FB. Increasing the output capacitance will also decrease the output voltage ripple. A lower value of output capacitor can be used to save space and cost but transient performance will suffer and may cause loop instability. See the Typical Applications in this data sheet for suggested capacitor values.

When choosing a capacitor, special attention should be given to the data sheet to calculate the effective capacitance under the relevant operating conditions of voltage

bias and temperature. A physically larger capacitor or one with a higher voltage rating may be required.

### Ceramic Capacitors

Ceramic capacitors are small, robust and have very low ESR. However, ceramic capacitors can cause problems when used with the LT8614 due to their piezoelectric nature. When in Burst Mode operation, the LT8614's switching frequency depends on the load current, and at very light loads the LT8614 can excite the ceramic capacitor at audio frequencies, generating audible noise. Since the LT8614 operates at a lower current limit during Burst Mode operation, the noise is typically very quiet to a casual ear. If this is unacceptable, use a high performance tantalum or electrolytic capacitor at the output. Low noise ceramic capacitors are also available.

A final precaution regarding ceramic capacitors concerns the maximum input voltage rating of the LT8614. As previously mentioned, a ceramic input capacitor combined with trace or cable inductance forms a high quality (underdamped) tank circuit. If the LT8614 circuit is plugged into a live supply, the input voltage can ring to twice its nominal value, possibly exceeding the LT8614's rating. This situation is easily avoided (see [Application Note 88](#)).

### Enable Pin

The LT8614 is in shutdown when the EN pin is low and active when the pin is high. The rising threshold of the EN comparator is 1.0V, with 40mV of hysteresis. The EN pin can be tied to  $V_{IN}$  if the shutdown feature is not used, or tied to a logic level if shutdown control is required.

Adding a resistor divider from  $V_{IN}$  to EN programs the LT8614 to regulate the output only when  $V_{IN}$  is above a desired voltage (see the Block Diagram). Typically, this threshold,  $V_{IN(EN)}$ , is used in situations where the input supply is current limited, or has a relatively high source resistance. A switching regulator draws constant power from the source, so source current increases as source voltage drops. This looks like a negative resistance load to the source and can cause the source to current limit or latch low under low source voltage conditions. The  $V_{IN(EN)}$  threshold prevents the regulator from operating at source

## APPLICATIONS INFORMATION

voltages where the problems might occur. This threshold can be adjusted by setting the values R3 and R4 such that they satisfy the following equation:

$$V_{IN(EN)} = \left( \frac{R3}{R4} + 1 \right) \cdot 1.0V \quad (10)$$

where the LT8614 will remain off until  $V_{IN}$  is above  $V_{IN(EN)}$ . Due to the comparator's hysteresis, switching will not stop until the input falls slightly below  $V_{IN(EN)}$ .

When operating in Burst Mode operation for light load currents, the current through the  $V_{IN(EN)}$  resistor network can easily be greater than the supply current consumed by the LT8614. Therefore, the  $V_{IN(EN)}$  resistors should be large to minimize their effect on efficiency at low loads.

### INTV<sub>CC</sub> Regulator

An internal low dropout (LDO) regulator produces the 3.4V supply from  $V_{IN}$  that powers the drivers and the internal bias circuitry. The INTV<sub>CC</sub> can supply enough current for the LT8614's circuitry and must be bypassed to ground with a minimum of 1μF ceramic capacitor. Good bypassing is necessary to supply the high transient currents required by the power MOSFET gate drivers. To improve efficiency the internal LDO can also draw current from the BIAS pin when the BIAS pin is at 3.1V or higher. Typically the BIAS pin can be tied to the output of the LT8614, or can be tied to an external supply of 3.3V or above. If BIAS is connected to a supply other than  $V_{OUT}$ , be sure to bypass with a local ceramic capacitor. If the BIAS pin is below 3.0V, the internal LDO will consume current from  $V_{IN}$ . Applications with high input voltage and high switching frequency where the internal LDO pulls current from  $V_{IN}$  will increase die temperature because of the higher power dissipation across the LDO. Do not connect an external load to the INTV<sub>CC</sub> pin.

### Output Voltage Tracking and Soft-Start

The LT8614 allows the user to program its output voltage ramp rate by means of the TR/SS pin. An internal 2.2μA pulls up the TR/SS pin to INTV<sub>CC</sub>. Putting an external capacitor on TR/SS enables soft starting the output to prevent current surge on the input supply. During the soft-start ramp the output voltage will proportionally track the

TR/SS pin voltage. For output tracking applications, TR/SS can be externally driven by another voltage source. From 0V to 0.97V, the TR/SS voltage will override the internal 0.97V reference input to the error amplifier, thus regulating the FB pin voltage to that of TR/SS pin. When TR/SS is above 0.97V, tracking is disabled and the feedback voltage will regulate to the internal reference voltage. The TR/SS pin may be left floating if the function is not needed.

An active pull-down circuit is connected to the TR/SS pin which will discharge the external soft-start capacitor in the case of fault conditions and restart the ramp when the faults are cleared. Fault conditions that clear the soft-start capacitor are the EN/UV pin transitioning low,  $V_{IN}$  voltage falling too low, or thermal shutdown.

### Output Power Good

When the LT8614's output voltage is within the ±9% window of the regulation point, which is a  $V_{FB}$  voltage in the range of 0.883V to 1.057V (typical), the output voltage is considered good and the open-drain PG pin goes high impedance and is typically pulled high with an external resistor. Otherwise, the internal pull-down device will pull the PG pin low. To prevent glitching both the upper and lower thresholds include 1.2% of hysteresis.

The PG pin is also actively pulled low during several fault conditions: EN/UV pin is below 1V, INTV<sub>CC</sub> has fallen too low,  $V_{IN}$  is too low, or thermal shutdown.

### Synchronization

To select low ripple Burst Mode operation, tie the SYNC pin below 0.4V (this can be ground or a logic low output). To synchronize the LT8614 oscillator to an external frequency connect a square wave (with 20% to 80% duty cycle) to the SYNC pin. The square wave amplitude should have valleys that are below 0.4V and peaks above 2.4V (up to 6V).

The LT8614 will not enter Burst Mode operation at low output loads while synchronized to an external clock, but instead will pulse skip to maintain regulation. The LT8614 may be synchronized over a 200kHz to 3MHz range. The  $R_T$  resistor should be chosen to set the LT8614 switching frequency equal to or below the lowest synchronization

## APPLICATIONS INFORMATION

input. For example, if the synchronization signal will be 500kHz and higher, the  $R_T$  should be selected for 500kHz. The slope compensation is set by the  $R_T$  value, while the minimum slope compensation required to avoid subharmonic oscillations is established by the inductor size, input voltage, and output voltage. Since the synchronization frequency will not change the slopes of the inductor current waveform, if the inductor is large enough to avoid subharmonic oscillations at the frequency set by  $R_T$ , then the slope compensation will be sufficient for all synchronization frequencies.

For some applications it is desirable for the LT8614 to operate in pulse-skipping mode, offering two major differences from Burst Mode operation. First is the clock stays awake at all times and all switching cycles are aligned to the clock. Second is that full switching frequency is reached at lower output load than in Burst Mode operation. These two differences come at the expense of increased quiescent current. To enable pulse-skipping mode, the SYNC pin is tied high either to a logic output or to the INTVCC pin.

The LT8614 does not operate in forced continuous mode regardless of SYNC signal. Never leave the SYNC pin floating.

### Shorted and Reversed Input Protection

The LT8614 will tolerate a shorted output. Several features are used for protection during output short-circuit and brownout conditions. The first is the switching frequency will be folded back while the output is lower than the set point to maintain inductor current control. Second, the bottom switch current is monitored such that if inductor current is beyond safe levels switching of the top switch will be delayed until such time as the inductor current falls to safe levels.

Frequency foldback behavior depends on the state of the SYNC pin: If the SYNC pin is low the switching frequency will slow while the output voltage is lower than the programmed level. If the SYNC pin is connected to a clock source or tied high, the LT8614 will stay at the programmed frequency without foldback and only slow switching if the inductor current exceeds safe levels.

There is another situation to consider in systems where the output will be held high when the input to the LT8614 is absent. This may occur in battery charging applications or in battery-backup systems where a battery or some other supply is diode ORed with the LT8614's output. If the  $V_{IN}$  pin is allowed to float and the EN pin is held high (either by a logic signal or because it is tied to  $V_{IN}$ ), then the LT8614's internal circuitry will pull its quiescent current through its SW pin. This is acceptable if the system can tolerate several  $\mu\text{A}$  in this state. If the EN pin is grounded the SW pin current will drop to near  $1\mu\text{A}$ . However, if the  $V_{IN}$  pin is grounded while the output is held high, regardless of EN, parasitic body diodes inside the LT8614 can pull current from the output through the SW pin and the  $V_{IN}$  pin, which may damage the IC. Figure 4 shows a connection of the  $V_{IN}$  and EN/UV pins that will allow the LT8614 to run only when the input voltage is present and that protects against a shorted or reversed input.

Figure 4. Reverse  $V_{IN}$  Protection

### High Temperature Considerations

For higher ambient temperatures, care should be taken in the layout of the PCB to ensure good heat sinking of the LT8614. The ground pins on the bottom of the package should be soldered to a ground plane. This ground should be tied to large copper layers below with thermal vias; these layers will spread heat dissipated by the LT8614. Placing additional vias can reduce thermal resistance further. The maximum load current should be derated as the ambient temperature approaches the maximum junction rating. Power dissipation within the LT8614 can be estimated by calculating the total power loss from an efficiency measurement and subtracting the inductor loss. The die temperature is calculated by multiplying the LT8614 power dissipation by the thermal resistance from junction to ambient. The LT8614 will stop switching and indicate a fault condition if safe junction temperature is exceeded.
