LTC6412

## $800 \mathrm{MHz}, 31 \mathrm{~dB}$ Range Analog-Controlled VGA

## FGATURES

- 800MHz -3dB Small-Signal Bandwidth
- Continuously-Adjustable Gain Control
- -14 dB to +17 dB Linear-in-dB Gain Range
- 35dBm OIP3 at 240MHz Across All Gain Settings
- 10dB Noise Figure at Maximum Gain
- (IIP3 - NF) $=+8 \mathrm{dBm}$ at 240 MHz Across All Gains
- $2.7 \mathrm{nV} / \sqrt{\mathrm{Hz}}$ Input Referred Noise
- Differential Inputs and Outputs
- $50 \Omega$ Input Impedance Across all Gains
- Single Supply Operation from 3 V to 3.6 V
- 110mA Supply Current
- $4 \mathrm{~mm} \times 4 \mathrm{~mm} \times 0.75 \mathrm{~mm} 24$-Pin QFN Package

## APPLICATIONS

- IF Signal Chain Automatic Gain Control (AGC)
- 2.5 G and 3 G Cellular Basestation Transceivers
- WiMAX, WiBro, WLAN Receivers
- Satellite and GPS Receiver IF

## DESCRIPTIOn

The LTC ${ }^{\circledR} 6412$ is a fully differential variable gain amplifier with linear-in-dB analog gain control. It is designed for AC-coupled operation in IF receiver chains from 1 MHz to 500 MHz . The part has a constant OIP3 across a wide output amplitude range and across the 31dB gain control range. The output noise (NF + Gain) is also flat versus gain to provide a uniform spurious-free dynamic range (SFDR) $>120 \mathrm{~dB}$ over the full gain control range at 240 MHz .

The LTC6412 is ideal for interfacing with the LT ${ }^{\circledR} 5527$ and LT5557 downconverting mixers, LTC6410-6 IF amplifier and the LTC6400/LTC6401/LTC6416 ADC drivers for use in 12-, 14-, and 16-bit ADC applications.

The LTC6412 recovers quickly from an overdrive condition, and the $\overline{E N}$ pin allows for a fast output signal disable to protect sensitive downstream components. Asserting the SHDN pin reduces the current consumption below 1 mA for power-down or sleep modes.

## TYPICAL APPLICATION

3.3V Fully Differential 240MHz IF Receiver Chain with 31dB Gain Control

VGA Gain vs Frequency Over Gain Control Range

6412601

## ABSOLUTE MAXIMUM RATIOGS

(Note 1)
Total Supply Voltage (VCC to GND)..........................3.8V
Amplifier Input Current (+IN, -IN)........................ $\pm 20 \mathrm{~mA}$
Amplifier Output Current (+OUT, -OUT) ............... $\pm 70 \mathrm{~mA}$
Input Current ( $\left.+V_{G},-V_{G}, V_{\text {REF }}, \overline{E N}, \overline{S H D N}\right) \ldots . . . . . \pm 10 \mathrm{~mA}$
Input Current (VCM, DECL1, DECL2) .................... $\pm 10 \mathrm{~mA}$
RF Input Power, Continuous, $50 \Omega$...................... +15 dBm
RF Input Power, $100 \mu$ s pulse, $50 \Omega$.................... 20 dBm
Operating Temperature Range (Note 2).... $-40^{\circ} \mathrm{C}$ to $85^{\circ} \mathrm{C}$
Specified Temperature Range (Note 3) .... $-40^{\circ} \mathrm{C}$ to $85^{\circ} \mathrm{C}$
Storage Temperature Range.................. $-65^{\circ} \mathrm{C}$ to $150^{\circ} \mathrm{C}$
Junction Temperature .......................................... $150^{\circ} \mathrm{C}$

## PIn CONFIGURATIOn

AC ELECTRICAL CHARACTERISTICS The e denotes specifications that apply over the tull operating
temperature range, otherwise specifications are at $\mathrm{T}_{\mathrm{A}}=25^{\circ} \mathrm{C}$. Typical AC electrical performance measured in demo board DC1464A
(Figure 3, Test Circuit A) unless otherwise noted. Default operating conditions are $V_{C C}=3.3 V, \overline{E N}=0.8 \mathrm{~V}, \overline{S H D N}=2.2 V,+V_{G}$ tied to $V_{\text {REF }}$ (negative gain slope mode), and $Z_{\text {SOURCE }}=Z_{\text {LOAD }}=50 \Omega$ unless otherwise noted.

| SYMBOL | PARAMETER | CONDITIONS | MIN | TYP | MAX |
| :--- | :--- | :--- | :---: | :---: | :---: | UNITS

Note 1: Stresses beyond those listed under Absolute Maximum Ratings may cause permanent damage to the device. Exposure to any Absolute Maximum Rating condition for extended periods may affect device reliability and lifetime. RF input power rating is guaranteed by design and engineering characterization, but not production tested. The absolute maximum continuous RF input power shall not exceed +15 dBm
Note 2: The LTC6412C/LTC6412I are guaranteed functional over the operating temperature range of $-40^{\circ} \mathrm{C}$ to $85^{\circ} \mathrm{C}$.
Note 3: The LTC6412C is guaranteed to meet specified performance from $0^{\circ} \mathrm{C}$ to $70^{\circ} \mathrm{C}$. It is designed, characterized and expected to meet specified performance from $-40^{\circ} \mathrm{C}$ and $85^{\circ} \mathrm{C}$ but is not tested or QA sampled at these temperatures. The LT6412I is guaranteed to meet specified performance from $-40^{\circ} \mathrm{C}$ to $85^{\circ} \mathrm{C}$.
Note 4: Power gain is defined at $Z_{\text {SOURCE }}=50 \Omega$ and $Z_{\text {LOAD }}=200 \Omega$. Voltage gain for this test condition is 6 dB higher than the stated power gain.

Note 5: $e_{n}$ can be calculated from $50 \Omega$ NF with the formula:

$$
\begin{aligned}
& e_{n}=\sqrt{\left\{4 \mathrm{kT}(50)\left(10^{\mathrm{NF} / 10-1)\}}\right\}\right.} \\
& \text { where } \\
& \quad \mathrm{e}_{\mathrm{n}}=\text { Input referred voltage noise in } \mathrm{V} / \sqrt{\mathrm{Hz}} \\
& \mathrm{NF}=50 \Omega \text { noise figure in dB } \\
& \mathrm{k}=\text { Boltzmann's constant }=1.38 \cdot 10^{-23} \mathrm{~J} /{ }^{\circ} \mathrm{K} \\
& \mathrm{~T}=\text { Absolute temperature in }{ }^{\circ} \mathrm{K}={ }^{\circ} \mathrm{C}+273
\end{aligned}
$$

Note 6: P1dB compression of the output amplifier cannot be achieved in the minimum gain state while complying with the absolute maximum rating for input RF power.

## PIn functions

GND (Pins 1, 8, 12, 15, 18, 20, 23): Ground. Pins are connected to each other internally. For best RF performance, all ground pins should be connected to the printed circuit board ground plane.
+IN (Pin 2): Positive Signal Input Pin. Has an internally generated DC Bias. A 10nF DC blocking capacitor is recommended.
-IN (Pin 3): Negative Signal Input Pin. Has an internally generated DC Bias. A 10nF DC blocking capacitor is recommended.
$V_{\text {CM }}$ (Pins 4, 5): Input Common Mode Voltage Pins. Two pins are tied together internally and serve as a virtual ground for the differential inputs, +IN and -IN. Capacitive decoupling to ground with 10 nF close to the pins is recommended to help terminate any residual common mode input signal.

Vcc (Pins 6, 13, 19, 24): Positive Power Supply. All four pins must be tied to the same voltage, usually 3.3V. Bypass each pin with 1000 pF and $0.1 \mu \mathrm{~F}$ capacitors close to the pins.

DECL1 (Pin 7): Decoupling Pin. Serves to reduce internal noise. Bypass to ground with a $0.1 \mu \mathrm{~F}$ capacitor close to the pin.
$+V_{G}($ Pin 9$)$ : Positive Gain Control Pin. Input signal pin used for positive mode gain control. Otherwise, pin is typically connected to $\mathrm{V}_{\text {REF }}$ for negative mode gain control. Pin is internally pulled to ground with a 10k resistor. In positive gain slope mode, the gain control slope is approximately $+32 \mathrm{~dB} / \mathrm{V}$ at 140 MHz with a gain control range of 0.1 V to 1.1V.
$V_{\text {REF }}$ (Pin 10): Internal Bias Voltage Pin. Typically tied to $-V_{G}$ pin for positive gain control or tied to $+V_{G}$ for negative gain control. Determines the midpoint voltage of the gain-vs- $\mathrm{V}_{\mathrm{G}}$ characteristic. Bypass to ground with $0.1 \mu \mathrm{~F}$ capacitor close to the pin. Not intended for use as an external reference voltage.

- $\mathrm{V}_{\mathrm{G}}$ (Pin 11): Negative Gain Control Pin. Input signal pin used for negative mode gain control. Otherwise, pin is typically connected to $\mathrm{V}_{\text {REF }}$ for positive mode gain control. Pin is internally pulled to ground with a 10k resistor. In negative gain slope mode, the gain control slope is approximately $-32 \mathrm{~dB} / \mathrm{V}$ at 140 MHz with a gain control range of 0.1 V to 1.1 V .
DECL2 (Pin 14): Decoupling Pin. Serves to reduce internal noise. Bypass to ground with a 1000pF capacitor close to the pin.
-OUT (Pin 16): Negative Amplifier Output Pin. A transformer with a center tap tied to $V_{C C}$ or a choke inductor is recommended to conduct DC quiescent current to the open-collector output device. For best performance, DC bias voltage to -OUT must be within 100 mV of $\mathrm{V}_{\text {Cc }}$.
+OUT (Pin 17): Positive Amplifier Output Pin. A transformer with a center tap tied to $V_{C C}$ or a choke inductor is recommended to conduct DC quiescent current to the open-collector output device. For best performance, DC bias voltage to +OUT must be within 100 mV of $\mathrm{V}_{\text {CC }}$.
$\overline{\mathrm{EN}}$ (Pin 21): Output Signal Enable Pin. Pin is internally pulled high with $100 \mathrm{k} \Omega$ to $\mathrm{V}_{\text {cc }}$. Assert pin to a low voltage to enable the output amplifier signal. Output amplifier impedance and DC current are not affected by the $\overline{E N}$ state. Connect pin to ground if enable function is not used.
$\overline{\text { SHDN }}$ (Pin 22): Shutdown Pin. Pin is internally pulled high with $100 \mathrm{k} \Omega$ to $\mathrm{V}_{\mathrm{CC}}$. Assert pin to a low voltage to shut down the circuit and greatly reduce the supply current. Proper sequencing of the $\overline{\mathrm{EN}}$ and $\overline{\mathrm{SHDN}}$ pins is required to avoid non-monotonic output signal behavior. See Applications Information section for details. Connect pin to $\mathrm{V}_{\text {CC }}$ if shutdown function is not used.
Exposed Pad (Pin 25): Ground. The Exposed Pad should have multiple via holes to an underlying ground plane for low inductance and good thermal dissipation.

## BLOCK DIAGRAM

## DC TEST CIRCUIT

## OPERATION

The LTC6412 employs an interpolated, tapped attenuator circuit architecture to generate the variable-gain characteristic of the amplifier. The tapped attenuator is fed to a buffer and output amplifier to complete the differential signal path shown in the Block Diagram. This circuit architecture provides good RF input power handling capability along with a constant output noise and output IP3 characteristic that are desirable for most IF signal chain applications. The internal control circuitry takes the gain control signal from the $\pm V_{G}$ terminals and converts this to an appropriate set of control signals to the attenuator ladder. The attenuator control circuit ensures that the linear-in- dB gain response is continuous and monotonic over the gain range for both slow and fast moving input control signals while exhibiting very little input impedance variation over gain. These design considerations result in a gain-vs- $\mathrm{V}_{\mathrm{G}}$ characteristic with a $\pm 0.1 \mathrm{~dB}$ ripple and a $0.5 \mu \mathrm{~s}$ gain response time that is slower than a similar digital step attenuator design.

An often overlooked characteristic of an analog-controlled VGA is upconverted amplitude modulation (AM) noise from the gain control terminals. The VGA behaves as a 2-quadrant multiplier, so some minimal care is required to avoid excessive AM sideband noise generation. The following table demonstrates the effect of the baseline
$20 \mathrm{nV} / \sqrt{\mathrm{Hz}}$ equivalent input control noise from the LTC6412 circuit along with the effect of a higher combined input noise due to a noisy external control circuit.

| CONTROL INPUT TOTAL NOISE <br> VOLTAGE (nV/ $\sqrt{\mathrm{Hz})}$ | PEAK AM NOISE AT 10kHz OFFSET <br> NEAR MAXIMUM GAIN (dBc/Hz) |
| :---: | :---: |
| 20 | -142 |
| 40 | -136 |
| 70 | -131 |
| 100 | -128 |
| 200 | -122 |

The baseline equivalent $20 \mathrm{nV} / \sqrt{\mathrm{Hz}}$ input noise is seen to produce worst-case AM sidebands of $-142 \mathrm{dBc} / \mathrm{Hz}$ which is near the $-147 \mathrm{dBm} / \mathrm{Hz}$ output noise floor at maximum gain for a nominal OdBm output signal. An input control noise voltage less than $80 \mathrm{nV} / \sqrt{\mathrm{Hz}}$ is generally recommended to avoid measurable AM sideband noise. While op amp control circuit output noise voltage is usually below $80 \mathrm{nV} / \sqrt{\mathrm{Hz}}$, some low power DAC outputs exceed $150 \mathrm{nV} / \sqrt{\mathrm{Hz}}$. DACs with output noise in the range of $100 \mathrm{nV} / \sqrt{\mathrm{Hz}}$ to $150 \mathrm{nV} / \sqrt{\mathrm{Hz}}$ can usually be accommodated with a suitable $2: 1$ or $3: 1$ resistor divider network on the DAC output to suppress the noise amplitude by the same ratio. Noisy DACs in excess of $150 \mathrm{nV} / \sqrt{\mathrm{Hz}}$ should be avoided if minimal AM noise is important in the application.

## APPLICATIONS INFORMATION

## Introduction

The LTC6412 is a high linearity, fully-differential analogcontrolled variable-gain amplifier (VGA) optimized for application frequencies in the range of 1 MHz to 500 MHz . The VGA architecture provides a constant OIP3 and constant output noise level (NF + Gain) over the 31dB gain-control range and thus exhibits a uniform spurious-free dynamic range (SFDR) over gain. This constant SFDR characteristic is ideal for use in receiver IF chains that are upstream from a signal sink such as a demodulator or ADC.

The low supply voltage requirements and fully differential design are compatible with many other LTC mixer, amplifier and ADC products for use in compact, Iow voltage, fully differential receiver chains. For non-differential systems, the $50 \Omega$ input impedance and $200 \Omega$ output impedance are easily converted to single-ended $50 \Omega$ ports with inexpensive $1: 1$ and $4: 1$ baluns.

## Gain Characteristics

The LTC6412 provides a continuously adjustable gain range of -14 dB to 17 dB that is linear-in- dB with respect to the control voltages applied to $+V_{G}$ and $-V_{G}$. These control pins can be operated with a differential signal, but it is more common to operate one of the $V_{G}$ pins with a single-ended control signal while connecting the other $V_{G}$ pin to the provided $V_{\text {REF }}$ pin. In this way, either a positive gain-control slope or negative gain-control slope is easily achieved:

Negative Gain-Control Slope. Tie $+V_{G}$ to $V_{\text {REF }}$ and apply gain control voltage to the $-V_{G}$ pin. Gain decreases with increasing $-V_{G}$ voltage.

Positive Gain-Control Slope. Tie $-V_{G}$ to $V_{\text {REF }}$ and apply gain control voltage to the $+V_{G}$ pin. Gain increases with increasing $+V_{G}$ voltage.
When connected in this typical single-ended configuration, the active control input range extends from 0.1V to 1.1V. This control input range can be extended using a resistor divider with a suitably low output resistance. For example, two series resistors of 1 k each would extend the control input range from 0.2 V to 2.2 V while providing an effective $500 \Omega$ Thevinin equivalent source resistance, a relatively small loading effect compared to the 10k input resistance of the $+V_{G} /-V_{G}$ terminals.

## Port Characteristics

The LTC6412 provides a nominal $50 \Omega$ differential input impedance and $200 \Omega$ differential output impedance over the operating frequency range.

The input impedance characteristic derives from the differential attenuator ladder shown in the Block Diagram. The internal circuit controls the RF connections to this attenuator ladder and generates the appropriate common mode DC voltage to this port. The differential attenuator ladder creates a virtual ground node that needs a capacitor bypass to ground at the $\mathrm{V}_{\mathrm{CM}}$ pin to effectively attenuate any common mode signal presented to the input port. The $+V_{I N}$ and $-V_{I N}$ pins are connected to the input signal through DC blocking capacitors as shown in Test Circuit A and Test Circuit B, Figures 1-4.

The output impedance characteristic derives from the opencollector equivalent circuit shown in Figure 7. The action of the differential shunt, lowpass filter, and internal feedback presents an effective differential output impedance of $200 \Omega$ to $300 \Omega$ between the + OUT and -OUT pins over the operating band. The $+V_{\text {OUt }}$ and $-V_{\text {OUT }}$ pins are connected to the output port using shunt inductors or a transformer to provide a DC path to the supply voltage. The DC block to the circuit output is usually accomplished using series capacitors. These blocking capacitors can be avoided if a flux transformer is used at the output. Figure 9 illustrates a few common inductor and balun transformer methods for coupling the AC signal and DC supply to the output pins. This is discussed further in the Typical Application Circuits section.

## Power Supplies

Inductance to the supply path can degrade the performance of the LTC6412. It is recommended that low inductance bypass capacitors are installed very close to each of the $V_{C C}$ pins. 1000 pF and $0.1 \mu \mathrm{~F}$ parallel capacitors are recommended with the smaller capacitor placed closer to the $V_{C C}$ pin. Do not leave any supply pins disconnected. For best performance, DC bias voltage to the +OUT and -OUT pins must be within 100 mV of $\mathrm{V}_{\mathrm{Cc}}$. The Exposed Pad on the underside of the package must be connected to ground with low inductance and low thermal resistance. Refer to details of DC1464A (TestCircuitA) for an example of proper

## APPLICATIONS INFORMATION

grounding and supply decoupling. Failure to provide low impedance supply and ground at high frequencies can cause oscillations and increased distortion.

## Enable/Shutdown

Both the $\overline{\mathrm{EN}}$ pin and $\overline{\mathrm{SHDN}}$ pinare self-biased to $\mathrm{V}_{\text {CC }}$ through their respective 100k pull-up resistors, so the default open-pin state is powered on with the output amplifier signal path disabled. Pulling the EN pin low completes the signal path from the attenuator ladder through the output amplifier. The EN pin essentially provides a fast muting function while the $\overline{\text { SHDN }}$ pin provides slower power on/off function.

For applications requiring the $\overline{\mathrm{SHDN}}$ function, it is recommended that the output amplifier signal path be disabled with a high $\overline{E N}$ voltage before transitioning the SHDN signal. When enabling the amplifier, allow at least 5 ms dwell time between the rising SHDN transition and the falling $\overline{\mathrm{EN}}$ transition to avoid non-monotonic output signal behavior though the VGA. The opposite delay sequence is recommended for the falling $\overline{\text { SHDN }}$ transition, but this is less critical as the output signal amplitude will drop abruptly regardless of the $\overline{\text { EN }}$ pin.

## Layout/Grounding

The high frequency performance of the LTC6412 requires special attention to proper RF grounding, bias decoupling and termination. The recommended PCB stack-up for a 4-layer board is shown below for $10 z$ copper clad FR-4 laminate with a relative dielectric constant, $\varepsilon_{r}=4.2-4.5$ at 1 GHz .

The topside metal and silkscreen drawings for TestCircuit A illustrate the recommended decoupling capacitor placement, signal routing and grounding. Ground vias directly beneaththe Exposed Padarecritical; use as manyas possible. Ground vias to the other ground pins are less critical.

## ESD

The LTC6412 is protected with reverse-biased ESD diodes on all I/O pins. If any I/O pin is forced one diode drop above the positive supply or one diode drop below the negative supply, then large currents may flow through the diodes. No damage to the devices will occur if the current is kept below 10 mA . The +OUT/-OUT pins have additional series diodes to the positive supply and can sustain approximately 2 V overshoot above the positive supply before conducting appreciable currents.

## Signal Compression Characteristics

The graph entitled, Input and Output P1dB, illustrates an important characteristic of the LTC6412 VGA. At gain settings above -5 dB , the output amplifier limits the linear power handling capability, but at gain settings below -5 dB , the input attenuator ladder limits the linear power handling capability. The linear input power limitations at minimum gain do not affect the overall performance of a signal chain if the preceding mixer or amplifier stage exhibits an OP1dB < 19dBm and an OIP3 < 50dBm.

## Test Circuits

The fully-differential nature of the LTC6412 design requires two test circuits to generate the performance information presented in this data sheet.
Test Circuit A is DC1464A, a 2-port demonstration circuit with input/output balun transformers to allow for direct connection to a 2-port network analyzer or other singleended $50 \Omega$ test system. The balun transformers limit the high and low frequency performance of the LTC6412 but allow for simple and reasonably accurate measurements from70MHz to 380MHz. The gain control signal is supplied to either of the $V_{G}$ turrets for $D C$ control measurements or through the $\mathrm{V}_{\text {GAIN }}$ SMA connector for transient control signal measurements. Clip leads to the gain control turrets are susceptible to noise pickup and should be lowpass

## APPLICATIONS INFORMATION

filtered to avoid AM upconversion artifacts. While using the $\pm V_{G}$ turrets, a $4.7 \mu \mathrm{~F}$ capacitor from the $\mathrm{V}_{\mathrm{GAII}}$ SMA input to ground provides an effective lowpass filter.

Typical data curves quoted for Test Circuit A are measured at the plane of the SMA connectors and are NOT corrected for any losses introduced by the input and output baluns, estimated at approximately 0.5 dB and 1.2 dB , respectively. All typical AC data reported in this data sheet correspond to Test Circuit A, except for mixed-mode S-parameters of the form Sdd21, Scc21, etc.

Test Circuit B uses a 4-port network analyzer to measure differential mode and common mode S-parameters beyond the frequency limitations imposed by the balun transformers and associated circuitry. A matching calibration set establishes the measurement reference planes shown in Test Circuit B. The output plane is defined at the edge of the package while the input plane is defined at the edge of the input pair of 0402 capacitors. The IC land and ground via pattern are identical to that shown for Test Circuit A. The ground via pattern directly beneath the package is critical to provide the proper RF ground to produce the RF characteristics quoted in this data sheet. All mixed-mode S-parameter typical data curves of the form SxyAB correspond to Test Circuit B following the definitions described in Figures 5 and 6.

## Typical Application Circuits

Grounding and supply decoupling should closely follow the suggested layout shown for Test Circuit A, but the input and output networks can be customized to suit various application requirements.
On the input side, the differential port impedance is very close to $50 \Omega$ over all gain settings and application frequencies. In a differential signal chain, the differential input signal is easily supplied from a preceding differential output stage with a suitable DC blocking capacitor of approximately 10 nF . If the system employs a single-ended input signal to the VGA, then a suitable balun is required to convert to a differential input signal. The passive conversion from $50 \Omega$ single-ended to $50 \Omega$ differential is mosteffectively accomplished with a $1: 1$ transmission-line balun such as the ETC1-1-13 or MABA-007159. These 1:1 balun devices are relatively inexpensive and offer excellent
electrical characteristics such as low loss, broad band response and good phase matching.

Figure 1. Top Silkscreen for DC1464A. Test Circuit A

On the output side, the differential port admittance is very close to $300 \Omega|\mid 1.5 p$ Facrossall gain settings and application frequencies. This output portcircuit must provide a path for DC output supply current as well as any balun, matching, or filtering functions required by the application. Thus, the design options for the output circuitry are more varied. A brief list of the more common output circuits is shown in Figure 9 along with a few design guidelines to estimate component values. Final design simulations should use the small-signal equivalent circuit model in Figure 8 to properly account for loading effects of the output terminals.

Figure 9a shows the simplest differential output configuration employing two suitable inductors, L1 = L2, to pass the DC supply current without loading the output nodes at the application frequency. The PCB trace widths

## APPLICATIONS INFORMATION

Figure 2. Top Metal for DC1464A. Test Circuit A
from the output pins should be narrow in keeping with the high impedance of these terminals; 8 to 10mil trace width on 1oz copper is a good choice. The $0.1 \mu \mathrm{~F}$ capacitors serve to DC block and decouple as needed. These capacitor values are adequate down to a few MHz and can be scaled down for higher application frequencies.

If bandpass filtering is needed at the VGA output of Figure 9a, then L1 and L2 can be designed to resonate with a shunt capacitor, $\mathrm{C}_{0}$, at the frequency of interest, $\omega=1 / \sqrt{C_{0}(\mathrm{~L} 1+\mathrm{L} 2)}$. Alternately, L1 = L2 can be designed to resonate with two separate capacitors, $\mathrm{C} 1=\mathrm{C} 2$, so any common mode noise is filtered as well.

Figure $9 b$ shows a further variation of the tuned differential output where the DC blocking capacitors are broughtinside the tank resonator to participate in the bandpass filter and transform the VGA output impedance to a lower value. Here too, the $\mathrm{C}_{0}$ capacitor can be split into two separate shunt capacitors to ground, so any common mode noise is filtered as well.

Figure 9c shows a flux transformer used to achieve a $50 \Omega$ single-ended output. The flux transformer does not provide the large bandwidth typical of the output transmission-line transformer shown in Figure 3, but it usually performs well over smaller bandwidths, especially when tuned with shunt capacitors (not shown). The flux transformer designeliminates DC blocking capacitors and is attractive in rugged applications where the amplifier output is subjected to ESD events and other forms of transient electrical overstress that do not pass through a typical RF flux transformer such as the MABAESO061.
Figure 9d shows a discrete LC balun suitable for bandwidths of approximately $15 \%$ to $30 \%$. Larger bandwidths are difficultto achieve with the number of components shown, and smaller bandwidths are often limited by component tolerance effects. Despite these limitations, the discrete LC balun can be a cost effective output circuit solution. At resonance, the tuned circuit produces an impedance transformation along with the differential-to-single-ended conversion.

## DC-Coupled Operation

The LTC6412 is intended for AC-coupled operation. The translation between the fixed input DC common mode voltage and higher open-collector output DC bias point makes it impractical to use in DC-coupled applications.

| Fixed Gain IF Amplifiers/ADC Drivers |  |  |
| $\begin{aligned} & \text { LT1993-2, LT1993-4, } \\ & \text { LT1993-10 } \end{aligned}$ | 800MHz Differential Amplifier/ADC Drivers | -72dBc IM3 at 70MHz 2V $\mathrm{P}_{\text {P-p }}$ Composite, $\mathrm{A}_{\mathrm{V}}=2 \mathrm{~V} / \mathrm{V}, 4 \mathrm{~V} / \mathrm{V}, 10 \mathrm{~V} / \mathrm{V}$ |
| LTC6400-8, LTC6400-14, LTC6400-20, LTC6400-26 | 1.8GHz Low Noise, Low Distortion Differential ADC Drivers | $\begin{aligned} & -71 \mathrm{dBc} \text { IM3 } \text { at } 240 \mathrm{MHz} 2 \mathrm{~V}_{\mathrm{P}-\mathrm{P}} \text { Composite, } \mathrm{I}_{\mathrm{S}}=90 \mathrm{~mA}, \mathrm{AV}_{\mathrm{V}}=8 \mathrm{~dB}, 14 \mathrm{~dB} \text {, } \\ & 20 \mathrm{~dB}, 26 \mathrm{~dB} \end{aligned}$ |
| $\begin{aligned} & \text { LTC6401-8, LTC6401-14, } \\ & \text { LTC6401-20, LTC6401-26 } \end{aligned}$ | 1.3GHz Low Noise, Low Distortion Differential ADC Drivers | -74 dBc IM3 at $140 \mathrm{MHz} 2 \mathrm{~V}_{\mathrm{P}-\mathrm{p}}$ Composite, $\mathrm{I}_{\mathrm{S}}=50 \mathrm{~mA}, \mathrm{AV}_{\mathrm{V}}=8 \mathrm{~dB}, 14 \mathrm{~dB}$, 20dB, 26dB |
| $\begin{aligned} & \text { LT6402-6, LT6402-12, } \\ & \text { LT6402-20 } \end{aligned}$ | 300MHz Differential Amplifier/ADC Drivers | -71 dBc IM3 at $20 \mathrm{MHz} 2 \mathrm{~V}_{\text {P-p }}$ Composite, $\mathrm{A}_{\mathrm{V}}=6 \mathrm{~dB}, 12 \mathrm{~dB}, 20 \mathrm{~dB}$ |
| LTC6410-6 | 1.4GHz Differential IF Amplifier with Configurable Input Impedance | OIP3 $=36 \mathrm{dBm}$ at 70 MHz , Flexible Interface to Mixer IF Port |
| LTC6416 | 2GHz, 16-Bit Differential ADC Buffer | -72 dBc IM2 at $300 \mathrm{MHz} 2 \mathrm{~V}_{\mathrm{p}-\mathrm{p}}$ Composite, $\mathrm{I}_{\mathrm{S}}=42 \mathrm{~mA}, \mathrm{e}_{\mathrm{N}}=2.8 \mathrm{nV} / \sqrt{\mathrm{Hz}}$, $\mathrm{A}_{\mathrm{V}}=0 \mathrm{~dB}, 300 \mathrm{MHz} \pm 0.1 \mathrm{~dB}$ Bandwidth |
| LTC6420-20 | Dual 1.8GHz Low Noise, Low Distortion Differential ADC Drivers | Dual Version of the LTC6400-20, $A_{V}=20 \mathrm{~dB}$ |
| LTC6421-20 | Dual 1.3GHz Low Noise, Low Distortion Differential ADC Drivers | Dual Version of the LTC6401-20, $\mathrm{A}_{V}=20 \mathrm{~dB}$ |
| IF Amplifiers/ADC Drivers with Digitally Controlled Gain |  |  |
| LT5514 | Ultralow Distortion IF Amplifier/ADC Driver with Digitally Controlled Gain | OIP3 $=47 \mathrm{dBm}$ at 100 MHz , Gain Range 10.5 dB to 33 dB by 1.5 dB |
| LT5524 | Low Distortion IF Amplifier/ADC Driver with Digitally Controlled Gain | OIP3 $=40 \mathrm{dBm}$ at 100 MHz , Gain Range 4.5 dB to 37 dB by 1.5 dB |
| LT5554 | High Dynamic Range 7-Bit Digitally Controlled IF VGA/ADC Driver | OIP3 $=46 \mathrm{dBm}$ at 200 MHz , Gain Range 1.725 to 17.6 dB by 0.125 dB |
| Baseband Differential Amplifiers |  |  |
| LT1994 | Low Noise, Low Distortion Differential Amplifier/ADC Driver | 16-Bit SNR, SFDR at 1MHz, Rail-to-Rail Outputs |
| LTC6403-1 | Low Noise Rail-to-Rail Output Differential Amplifier/ADC Driver | 16-Bit SNR, SFDR at 3MHz, Rail-to-Rail Outputs, $\mathrm{e}_{\mathrm{N}}=2.8 \mathrm{nV} / \sqrt{\mathrm{Hz}}$ |
| LTC6404-1, LTC6404-2 | Low Noise Rail-to-Rail Output Differential Amplifier/ADC Driver | 16-Bit SNR, SFDR at 10MHz, Rail-to-Rail Outputs, $e_{N}=1.5 \mathrm{nV} / \sqrt{\mathrm{Hz}}$, LTC6404-1 is Unity-Gain Stable, LTC6404-2 is Gain-of-2 Stable |
| LTC6406 | 3GHz Rail-to-Rail Input Differential Amplifier/ADC Driver | -65 dBc IM3 at $50 \mathrm{MHz} 2 \mathrm{~V}_{\text {P-p }}$ Composite, Rail-to-Rail Inputs, $\mathrm{e}_{\mathrm{N}}=1.6 \mathrm{nV} / \sqrt{\mathrm{Hz}}, 18 \mathrm{~mA}$ |
| LT6411 | Low Power Differential ADC Driver/Dual Selectable Gain Amplifier | -83 dBc IM3 at $70 \mathrm{MHz} 2 \mathrm{~V}_{\mathrm{p}-\mathrm{p}}$ Composite, $\mathrm{A}_{\mathrm{V}}=1,-1$ or $2,16 \mathrm{~mA}$, Excellent for Single-Ended to Differential Conversion |
| Low Noise DAC for Gain Control |  |  |
| LTC2630-10 | Low Power, Internal Reference, Single Supply 10-Bit DAC | SPI Input, 2.5V Output Range, Resistor Divide Output by $\sim 2: 1$ |
| LTC2640-10 | Low Power, Internal Reference, Single Supply 10-Bit DAC | SPI Input, 2.5V Output Range, Resistor Divide Output by $\sim 2: 1$ |
| LTC2641-12 | Low Noise, Low Power, Single Supply 12-Bit DAC | SPI Input, Low Glitch Impulse, Power-On to Zero-Scale |
| LTC2642-12 | Low Noise, Low Power, Single Supply 12-Bit DAC | SPI Input, Low Glitch Impulse, Power-On to Mid-Scale |

## X-ON Electronics

Largest Supplier of Electrical and Electronic Components
