TECHNOLOGY 1.6GHz Low Noise High Linearity Differential Buffer/16-Bit ADC Driver with Fast Clamp

## features

- 1.6GHz -3dB Small Signal Bandwidth
- Low Distortion Driving $50 \Omega$ Load, 2.4Vp-p Out $-100 \mathrm{dBc} /-69 \mathrm{dBc} \mathrm{HD} 2 / \mathrm{HD} 3$ at 140 MHz -80 dBc IM3 and 46 dBm OIP3 at 140 MHz $-100 \mathrm{dBc} /-66 \mathrm{dBc}$ HD2/HD3 at 380 MHz -68 dBc IM3 3 and 39 dBm OIP3 at 380 MHz
- $1.5 \mathrm{nV} / \sqrt{\mathrm{Hz}}$ Output Noise
- $4.3 \mathrm{pA} / \sqrt{H z}$ Input Current Noise
- Programmable High Speed, Fast Recovery Output Clamping
- 4.28VP-p Maximum Output Swing on a $50 \Omega$ Differential Load
- DC-Coupled Signal Path
- Operates on Single 4.75V to 5.25 V Supply
- Power: 615 mW on 5V, Can Be Reduced to 370 mW , Shutdown Mode 120mW
- $3 \mathrm{~mm} \times 4 \mathrm{~mm}$ 20-Lead QFN Package

## APPLICATIONS

- Differential ADC Driver
- CCD Buffer
- Cable Driver
- $50 \Omega$ Buffer
$\boldsymbol{\boxed { }}$, LT, LTC, LTM, Linear Technology and the Linear logo are registered trademarks of Linear Technology Corporation. All other trademarks are the property of their respective owners.

DESCRIPTION
The LTC ${ }^{\circledR} 6417$ is a differential unity gain buffer that can drive a $50 \Omega$ load with extremely low noise and excellent linearity. It is well suited for driving high speed 14- and 16-bit pipeline ADCs with input signals from DC to beyond 600 MHz . Differential input impedance is $18.5 \mathrm{k} \Omega$, allowing $1: 4$ and $1: 8$ transformers to be used at the input providing additional system gain in $50 \Omega$ systems.
With no external biasing or gain setting components and a flow-through pinout, the LTC6417 is very easy to use. It can be DC-coupled and has a common mode output offset of -60 mV . The LTC6417 input pins are internally biased to provide an output common mode voltage that is set by the voltage on the $\mathrm{V}_{\mathrm{CM}}$ pin for AC-coupled applications.
Supply current istypically 123 mA and the LTC6417 operates on supply voltages ranging from 4.75 V to 5.25 V . Power consumption can be reduced to 74 mA via the PWRADJ pin. The LTC6417 also has a hardware shutdown feature which reduces current consumption to 24 mA .
The LTC6417 features fast, adjustable output voltage clamping to help protect subsequent circuitry. The CLHI pin sets the maximum swing, while a symmetric minimum swing is set up internally. LTC6417 $\mathrm{V}_{\overline{O R}}$ pin will signal overrange when the clamps limit output voltage.
The LTC6417 is packaged in a 20 -lead $3 \mathrm{~mm} \times 4 \mathrm{~mm}$ QFN package. Pinout is optimized for placement directly adjacent to Linear Technology's high speed 14- and 16-bit ADCs.

## TYPICAL APPLICATION

LTC6417 Driving an LTC2209 16-Bit ADC at 140MHz IF

LTC6417 Driving LTC2209
16-Bit ADC 32K Point FFT, $\mathrm{f}_{\mathrm{IN}}=140 \mathrm{MHz},-1 \mathrm{dBFS}, \mathrm{PGA}=0$

Note 1: Stresses beyond those listed under Absolute Maximum Ratings may cause permanent damage to the device. Exposure to any Absolute Maximum Rating condition for extended periods may affect device reliability and lifetime.
Note 2: The LTC6417C/LTC6417l is guaranteed functional over the case temperature operating range of $-40^{\circ} \mathrm{C}$ to $105^{\circ} \mathrm{C} . \theta_{\mathrm{JC}}=6.8^{\circ} \mathrm{C} / \mathrm{W}$.

Note 3: The LTC6417C is guaranteed to meet specified performance from $0^{\circ} \mathrm{C}$ to $70^{\circ} \mathrm{C}$. It is designed, characterized and expected to meet specified performance from $-40^{\circ} \mathrm{C}$ and $105^{\circ} \mathrm{C}$ case temperature range but is not tested or QA sampled at these temperatures. The LT6417I is guaranteed to meet specified performance from $-40^{\circ} \mathrm{C}$ to $105^{\circ} \mathrm{C}$ case temperature range. Note 4: This parameter is pulse tested.

## PIn fUnCTIOnS

V+(Pins 1, 6, 11, 16): Positive Power Supply. Typically 5V. Split supplies are possible as long as the voltage between $\mathrm{V}^{+}$and GND is 4.75 V to 5.25 V . Bypass capacitors of 680 pF and $0.1 \mu \mathrm{~F}$ as close to the part as possible should be used between the supplies.
CLHI (Pin 2): High Side Clamp Voltage. The voltage applied to the CLHI pin defines the upper voltage limit of the $\mathrm{OUT}^{+}$and $\mathrm{OUT}^{-}$pins. This voltage should be set at least 300 mV above the upper voltage range of the ADC. On a 5 V supply, the CLHI pin will float to a 2.5 V default voltage. CLHI has a Thevenin equivalent of approximately $4.8 \mathrm{k} \Omega$ and can be overdriven by an external voltage. The CLHI pin should be bypassed with a high quality ceramic bypass capacitor of at least $0.01 \mu \mathrm{~F}$.
GND (Pins 3, 7, 10, 17, 20, Exposed Pad Pin 21): Negative Power Supply. Normally tied to ground. All pins and the exposed pad must be tied to the same voltage. GND may be tied to a voltage other than ground as long as the voltage between $\mathrm{V}^{+}$and GND is 4.75 V to 5.25 V . If the GND pins are not tied to ground, bypass each with 680pF and $0.1 \mu \mathrm{~F}$ capacitors as close to the package as possible. The exposed pad must be soldered to the printed circuit board ground plane for good heat transfer.

NC (Pins 4, 13): No Connection. These pins are not connected internally.

PWRADJ (Pin 5): Power Adjust Voltage. The voltage applied to this pin scales the bias current internal to the LTC6417. The PWRADJ pin will float to a 1.6 V default voltage. PWRADJ has a Thevenin equivalent resistance of approximately 14.5 k and can be overdriven by an external voltage. The PWRADJ pin should be bypassed with a high quality ceramic bypass capacitor of at least $0.01 \mu \mathrm{~F}$.
IN ${ }^{+}$, IN ${ }^{-}$(Pin 8, Pin 9): Non-inverting and inverting input pins of the buffer, respectively. These pins are high impedance, approximately 9.5 k . If AC-coupled, these pins will self bias to the voltage applied to the $\mathrm{V}_{\text {CM }}$ pin.
SHDN (Pin 12): This pin puts the LTC6417 in sleep mode when pulled high. If no voltage is applied to the SHDN pin, it floats down to the same potential as GND.
$\mathrm{V}_{\overline{\mathrm{OR}}}$ (Pin 14): Overrange Output. This pin, by default at 3.4 V , will be pulled down to GND, when one or both input signals go beyond the minimum or maximum swing set by the CLHI and $\mathrm{V}_{\mathrm{CM}}$ pins.
$V_{\text {CM }}$ (Pin 15): This pin sets the output common mode voltage seen at OUT+ and OUT- by driving $I \mathbb{N}^{+}$and $I \mathbb{N}^{-}$through a buffer with a high output resistance of 9.5 k . The $\mathrm{V}_{\mathrm{CM}}$ pin has a Thevenin equivalent resistance of approximately 2.7 k and can be overdriven by an external voltage. If no voltage is applied to $\mathrm{V}_{\text {CM }}$, it will float to a default voltage of approximately 1.25 V on a 5 V supply. The $\mathrm{V}_{\text {CM }}$ pin should be bypassed with a high quality ceramic bypass capacitor of at least $0.01 \mu \mathrm{~F}$.
OUT$^{-}$, OUT $^{+}$(Pin 18, Pin 19): Outputs.

## DC TEST CIRCUIT SCHEMATIC

## BLOCK DIAGRAM

LTC6417 Simplified Schematic

## APPLICATIONS InFORMATION

## Circuit Operation

The LTC6417 is a low noise and low distortion fully differential unity gain ADC driver with a -3 dB bandwidth spanning DC to 1.6 GHz , a differential input impedance of $18.5 \mathrm{k} \Omega$, and a differential output impedance of $3 \Omega$. The LTC6417 is composed of a fully differential buffer with output common mode voltage control circuitry and high speed voltage-limiting clamps at the output. Lowpass or bandpass filters are easily implemented with just a few external components. The LTC6417 is very flexible in terms of I/O coupling. It can be AC- or DC-coupled at the inputs, the outputs or both. When using the LTC6417 with DC-coupled inputs, best performance is obtained with an input common mode voltage between 1 V and 1.5 V . For AC-coupled operation, the LTC6417 will take the voltage applied to the $\mathrm{V}_{\mathrm{CM}}$ pin and use it to bias the inputs so that the output common mode voltage equals $\mathrm{V}_{\mathrm{CM}}$, thus no external circuitry is needed. The $\mathrm{V}_{\mathrm{CM}}$ pin has been designed to directly interface with the $V_{C M}$ pin found on Linear Technology's high speed ADC families.

## Input Impedance and Matching

The LTC6417 has a high differential input impedance of $18.5 \mathrm{k} \Omega$. The differential inputs may need to be terminated to a lower value impedance, e.g. $50 \Omega$, in order to provide an impedance match for the source. Figure 1 shows input matching and single-ended to differential conversion using a $1: 1$ balun, while Figure 2 shows a similar circuit using a 1:4 balun to achieve an additional 6dB of voltage gain. These circuits provide a wideband impedance match. The balun and matching resistors must be placed close to the input pins in order to minimize the rejection due to input mismatch. In Figures 1 and 2, the capacitor centertapping the two input termination resistors improves high frequency common mode rejection. As an alternative to this wideband approach, a narrowband impedance match can be used at the inputs of the LTC6417 for frequency selection and/or noise reduction.

Figure 1. Input Termination for Differential $50 \Omega$ Input Impedance Using a 1:1 Balun

Figure 2. Input Termination for Differential $50 \Omega$ Input Impedance Using a 1:4 Balun

## APPLICATIONS INFORMATION

The noise figure of the LTC6417 application circuit also depends upon the input termination. For example, the input 1:4 balun in Figure 2 improves noise figure by adding 6dB of voltage gain at the inputs. A trade-off between gain and noise is obvious when constant noise figure circle and constant gain circle are plotted within the same input Smith Chart. This technique can be used to determine the optimal source impedance for a given gain and noise requirement.

## Output Match and Filter

The LTC6417 provides an output resistance of $1.5 \Omega$ at each output. In most cases, the LTC6417 can be used to drive an ADC without back termination but for testing purposes, Figure 3 shows the LTC6417 driving a differential $50 \Omega$ load impedance using a $1: 1$ balun. If output
matching for the $1: 1$ balun is desired, resistors of $23.7 \Omega$ should be inserted in series with each LTC6417 output. This is shown in Figure 4 where the LTC6417 is driving a differential $100 \Omega$ load impedance.

As mentioned above, the LTC6417 can drive an ADC without external output impedance matching, but improved performance can usually be obtained with the addition of a few components. Figure 5 shows a 6th order bandpass filter with a 148 MHz center frequency, -3 dB points of 85MHz and 210MHz used for driving the LTC2209 16-bit ADC. In the passband the filter has less than 1 dB ripple. This higher order filter has a sharp roll-off outside its passband, therefore it rejects noise and suppresses distortion components in its stopband. To double the filter center frequency, halve the capacitor and inductor values, and maintain resistor values; this also doubles the filter bandwidth.

## APPLICATIONS INFORMATION

## Output Common Mode Adjustment

For AC-coupled applications, the output common mode voltage is set by the $\mathrm{V}_{\mathrm{CM}}$ pin. An internal buffer, as shown in Figure 6, couples the voltage on the $\mathrm{V}_{\mathrm{CM}}$ pin to the inputs via high impedance resistors. Because the input common mode voltage is approximately the same as the output common mode voltage, both are approximately equal to the voltage applied to the $\mathrm{V}_{\text {CM }}$ pin. For DC-coupled applications, the internal $V_{\text {CM }}$ is overdriven by the input signal. The $\mathrm{V}_{\mathrm{CM}}$ pin has a Thevenin equivalent resistance of 2.7 k and can be overdriven by an external voltage. The $V_{\text {CM }}$ pin floats to a default voltage of 1.25 V on a 5 V supply. The output common mode voltage is capable of tracking $\mathrm{V}_{\text {CM }}$ in a range from 0.29 V to 2.25 V on a 5.0 V supply. The $V_{\text {CM }}$ pin can be floated, but it should always be bypassed close to the LTC6417 with a $0.1 \mu \mathrm{~F}$ bypass capacitor to GND. When interfacing with A/D converters such as the LTC22xx families, the $V_{C M}$ pin can be connected to the $V_{C M}$ output pin of the ADC, as shown in Figure 5.

## Clamping, the CLHI Pin and the $\mathrm{V}_{\text {CM }}$ Pin

The CLHI pin is used to set the high side clamp voltage of the high speed internal circuitry.
This limits the single-ended maximum and minimum voltage excursion at each of the outputs. This feature is extremely important in applications with input signals having very large peak-to-average ratios such as cellular base station receivers.

Internal circuitry generates a symmetric low side clamp voltage with respect to the common mode voltage $\mathrm{V}_{\mathrm{CM}}$ (Figures 7 and 8). The LTC6417 clamp control circuitry features two additional mechanisms. First, internally imposed maximum swing of 2.5 V and minimum swing of 0.2 V ensure that the transistors do not go into deep saturation. This ensures a quick recovery after the clamps are released. Second, if CLHI voltage is less than $V_{\mathrm{CM}}$, internal CLLO starts to track CLHI. This limits output swing and protects output transistors. Since the clamp response is on the order of 5 ns to clamp and 1 ns to release, clamp circuit becomes less effective at frequencies beyond 160 MHz .

Figure 6. LTC6417 Internal Topology Showing the Common Mode Buffer Biasing the Inputs

Figure 7. Internal Circuitry Generating Symmetric Clamp Voltages with Respect to $\mathrm{V}_{\mathrm{CM}}$

Figure 8. Symmetric High- and Low-Side Clamp Voltages with Respect to $V_{C M}$

## APPLICATIONS InFORMATION

If a very large signal arrives at the LTC6417, the voltages applied to the CLHI and $\mathrm{V}_{\mathrm{CM}}$ pins will determine the maximum and minimum output swing. Once the input signal returns to the normal operating range, the LTC6417 returns to linear operation within 2 ns . For DC-coupled operation, the common mode of the input signals might be different than the voltage on the $\mathrm{V}_{\mathrm{CM}}$ pin. The minimum swing will still be set by the voltages applied to the $\mathrm{V}_{\text {CM }}$ and CLHI pins.

CLHI is a high impedance input. It has an input impedance of 4.8 k . On a 5 V supply, CLHI self-biases to 2.5 V . To limit the signal swing to a subsequent stage's power supply, e.g. an ADC such as the LTC2165, simply connect CLHI to the positive supply pin of the LTC2165. The CLHI pin should be bypassed with a $0.1 \mu \mathrm{~F}$ capacitor as close to the LTC6417 as possible.

## The $V_{\overline{0 R}}$ Pin

The $V_{\overline{O R}}$, overrange pin signals an overrange condition when one or both inputs exceed the minimum or maximum signal swing limits set by the CLHI and $\mathrm{V}_{\mathrm{CM}}$ pins.
The LTC6417 $\mathrm{V}_{\overline{O R}}$ pin can be used by a control system to limit the input power dynamically. This is very useful in applications where the overload response of the complete system would be too slow.

Figure 9. LTC6417 Internal Topology Showing $V_{0 R}$ Pin with Pull-Down Resistor and Clamp

The $V_{\overline{O R}}$ pin, as shown in Figure 9 , is internally connected to a current source sourcing 2 mA , plus an internal 20k resistor pull-down to GND. An internal clamp limits the maximum output to 3.4 V . As soon as one of the inputs goes beyond the limits, and therefore engages one of the clamps, the output current, hence, the $V_{\overline{O R}}$ voltage goes to zero. The dynamic response of the $\bigvee_{\overline{O R}}$ pin can be adjusted with an external resistor and an optional external capacitor. For a high speed operation, add a $50 \Omega$ resistor from $V_{\overline{O R}}$ to GND, resulting in a high speed signal with 100 mV swing.

## The PWRADJ Pin

The voltage applied to the PWRADJ pin scales the supply current and performance of the LTC6417. This is useful for reducing power consumption in applications where linearity of the LTC6417 exceeds the linearity of the other components in the system; hence LTC6417's linearity can bederated without effecting system performance.PWRADJ is a high impedance input. It has an input impedance of 14.5k. On a 5V supply, PWRADJ self-biases to 1.6V. For full power, simply connect PWRADJ to the positive supply $\mathrm{V}^{+}$. For minimum power, short the PWRADJ pin to GND. The PWRADJ pin should be bypassed with a $0.1 \mu \mathrm{~F}$ capacitor as close to the LTC6417 as possible. LTC6417 performance vs PWRADJ can be found in the graphs.

## The SHDN Pin

When pulled high, the SHDN pin puts the LTC6417 in sleep mode, significantly reducing supply current. SHDN is a high impedance input. It has an input impedance of $10.5 \mathrm{k} \Omega$. If the SHDN pin is not driven with an external voltage, it floats down to the same potential as GND, keeping the LTC6417 enabled. The SHDN pin should be bypassed with a $0.1 \mu \mathrm{~F}$ capacitor as close to the LTC6417 as possible.

In sleep mode, the input and output stages are turned off, but the input and output clamps are kept alive to protect the part against overvoltage.

The supply current in sleep mode is only 24 mA , instead of the typical 125 mA . But should the clamps turn on, the current drawn from the supply can be as high as 180 mA .

## APPLICATIONS INFORMATION

This can be avoided by following a few precautions when putting the LTC6417 in sleep mode:

- Do not force the outputs below the inputs, this will turn the output stages on.
- Either float CLHI or tie it to $\mathrm{V}_{\text {CC }}$. This will allow a wider signal range atthe inputs before the clamps are activated.
- Maintain the inputs below CLHI or 2.5 V whichever is lower, otherwise the input clamps will be activated.
- Do not short $V_{\text {CM }}$ or the outputs to GND, in either case the output clamps will turn on. Current drawn from the supply can be as high as 180 mA .
- Float the outputs if possible. The outputs will be pulled down by internal resistors to $\mathrm{V}_{\mathrm{CM}}$.
Heeding these precautions will protect the LTC6417 as well any part it is driving, while maintaining a low current consumption in sleep mode.

## Noise and Noise Figure

The LTC6417's differential input referred voltage and current noise densities are $1.5 \mathrm{nV} / \sqrt{\mathrm{Hz}}$ and $4.3 \mathrm{pA} / \sqrt{\mathrm{Hz}}$, respectively.
Before presenting a noise model, the circuit with the transformer in Figure 10 will be simplified. In Figure 11, the circuit is redrawn with the source impedance reflected to the secondary side of the transformer. The source impedance is multiplied by the impedance ratio m of the transformer. In Figure 12, noise sources associated with the amplifier and resistors have been added. Based on this noise model of the LTC6417, the total output noise power excluding the noise contribution of the source is:

$$
\begin{aligned}
\mathrm{e}_{\mathrm{nO}}^{2} & =\mathrm{e}_{\mathrm{ni}}^{2}+\left(\mathrm{i}_{\mathrm{ni}} \cdot \mathrm{R}_{\mathrm{EQ}}\right)^{2}+\mathrm{i}_{\mathrm{RT}}^{2} \cdot \mathrm{R}_{\mathrm{EQ}}^{2} \\
& =\mathrm{e}_{\mathrm{ni}}^{2}+\left(\mathrm{i}_{\mathrm{ni}} \cdot \mathrm{R}_{\mathrm{EQ}}\right)^{2}+\frac{4 \mathrm{kT}}{\mathrm{R}_{\mathrm{T}}} \cdot \mathrm{R}_{\mathrm{EQ}}^{2}
\end{aligned}
$$

where $R_{E Q}=m R_{S} \| R_{T}$ is the equivalent impedance seen at the input of the LTC6417. The output noise power due to the noise of source resistance is given by:

$$
\begin{aligned}
\mathrm{e}_{\mathrm{no}\left(\mathrm{mR} \mathrm{R}_{\mathrm{S}}\right.}{ }^{2} & =\mathrm{i}^{2}{ }_{m R_{S}} \cdot \mathrm{R}_{\mathrm{EQ}}^{2} \\
& =\frac{4 \mathrm{kT}}{m R_{S}} \cdot \mathrm{R}_{\mathrm{EQ}}^{2}
\end{aligned}
$$

Noise figure (NF) is calculated from the ratio of these noise powers:

$$
N F=10 \log \left(1+\frac{e_{n 0}^{2}}{e_{n o\left(m R_{S}\right)}^{2}}\right)
$$

Figure 10. LTC6417 with a Transformer

Figure 11. Source Resistance Referred to the Secondary

Figure 12. LTC6417 Simplified Noise Model

## APPLICATIONS InFORMATION

In most cases the termination resistor will be matched to the source resistance, e.g. $\mathrm{R}_{\mathrm{T}}=\mathrm{mR}_{\mathrm{S}}$. For the LTC6417 with a wide-band terminated transformer, a plot of output and input noise density and NF versus termination resistor is shown in Figure 13. To get the best noise performance in the system, use the LTC6417 matched to a transformer with high impedance ratio. Although the output noise density will be higher, noise figure will improve because of the additional gain realized in the transformer. An impedance ratio greater than 8 is not recommended, as the increased termination resistance with the LTC6417 input capacitance will limit signal bandwidth. Consult Table 2 for a quick estimate of the LTC6417's output noise density and NF for different transformer impedance ratios. Measured NF numbers will be higher as the simple noise model does not take the insertion loss in the transformer into account.

Table 2. Output Noise Density and NF of the LTC4617 with a Wide-Band Terminated Transformer, $\mathbf{R}_{\mathbf{S}}=50 \Omega$

| TRANSFORMER <br> IMPEDANCE <br> RATIO $\mathbf{m}$ | TERMINATION <br> RESISTOR $\mathbf{R}_{\mathbf{T}}$ <br> $(\boldsymbol{\Omega})$ | GAIN <br> $(\mathbf{V} / \mathbf{V})$ | OUTPUT NOISE <br> DENSITY $\mathbf{e}_{\mathbf{n}}$ <br> $(\mathbf{n V} / \sqrt{\mathrm{Hz})}$ | NF <br> $(\mathrm{dB})$ |

## Interfacing the LTC6417 to A/D Converters

The LTC6417 has been specially designed to interface directly with high speed $A / D$ converters. It is possible to drive the ADC directly from the LTC6417. In practice, however, better performance may be obtained by adding a few external components at the output of the LTC6417. Figure 5 shows the LTC6417 driving an LTC2209 16-bit ADC. The differential outputs of the LTC6417 are bandpass filtered, then drive the differential inputs of the LTC2209. In many applications, a filter like this is desirable to limit the wideband noise of the amplifier. This is especially true in high performance 16-bit designs. The minimum recommended network between the LTC6417 and the ADC is simply two $10 \Omega$ series resistors, which are used to help eliminate resonances associated with the stray capacitance of PCB traces and the stray inductance of the internal bond wires at the ADC input pins and the driver output pins.

## Single-Ended Signals

The LTC6417 has not been designed to convert singleended signals to differential signals. A single-ended input signal can be converted to a differential signal via a balun connected to the inputs of the LTC6417. Figure 5 shows the LTC6417 driven by a 1:4 transformer which provides 6 dB of voltage gain while also performing a single-ended to differential conversion.

## Power Supply Considerations

For best linearity, the LTC6417 should have a positive supply of $\mathrm{V}^{+}=5 \mathrm{~V}$. For ESD protection, the LTC6417 has an internal edge-triggered supply voltage clamp. The timing mechanism of the clamp enables the LTC6417's protection circuit during ESD events. This internal clamp can also be activated by voltage overshoot and rapid slew rate on the positive supply $\mathrm{V}^{+}$pin. The LTC6417 should not be hot-plugged into a powered socket because there is a risk of activating this internal ESD clamp circuit. Bypass capacitors of 680 pF and $0.1 \mu \mathrm{~F}$ should be connected to the $\mathrm{V}^{+}$pin, as close as possible to the LTC6417.

## Interfacing the LTC6417 with Active Mixers for Ultrawide IF Bandwidth

The LTC6417 is an excellent interface amplifier for use with active downconverting mixers like the LTC5567. By using

## APPLICATIONS INFORMATION

the LTC6417 as a post-amplifier for the LTC5567, it is possible to achieve IF bandwidths in excess of 500 MHz , while adding bandpass filtering. A key to achieving this extremely wide IF bandwidth is the use of pre-emphasis inductors in series with the LTC6417 inputs to compensate for the inherent rolloff caused by the LTC6417 input capacitance interacting with the interface impedance. In the example seen in Figure 14, a value of 33 nH for each pre-emphasis inductor gives excellent wideband performance. Figure 15 shows performance for various values of L . For $\mathrm{L}=33 \mathrm{nH}$, overall conversion gain remains within 1 dB from 90MHz to 590 MHz , resulting in 500 MHz of IF bandwidth.

## Test Circuits

Due to the fully differential design of the LTC6417 and its usefulness in applications both with and withoutADCs, two test circuits have been used to generate the information in this data sheet. Test circuit A is DC1660B, a two-port
demonstration circuit for the LTC6417. The board layout and the schematic are shown in Figures 16 and 17. These circuits include a $1: 4$ input balun and a 1:1 output balun for single-ended-to-differential conversion, allowing direct analysis using a2-port networkanalyzer. Including the input and output baluns, the -3 dB bandwidth is approximately 600 MHz . A 1:4 input balun before the LTC6417 inputs provides 6 dB of voltage gain, but results in better noise figure performance compared to a $1: 1$ input balun. Noise figure measurements for both input baluns can be found in the graphs.

Test circuit B is DC1685A. It consists of an LTC6417 driving an LTC2209 16-bit 153.6Msps ADC. It is intended for use in conjunction with DC890B (computer interface board) and proprietary Linear Technology evaluation software to evaluate the performance of both parts together. Both the DC1685A board layout and the schematic can be seen Figures 18 and 19.

## PACKAGE DESCRIPTION

Please refer to http://www.linear.com/designtools/packaging/ for the most recent package drawings.
UDC Package
20-Lead Plastic QFN ( $3 \mathrm{~mm} \times 4 \mathrm{~mm}$ )
(Reference LTC DWG \# 05-08-1742 Rev Ø)

RECOMMENDED SOLDER PAD PITCH AND DIMENSIONS APPLY SOLDER MASK TO AREAS THAT ARE NOT SOLDERED

NOTE:

1. DRAWING IS NOT A JEDEC PACKAGE OUTLINE
2. DRAWING NOT TO SCALE
3. ALL DIMENSIONS ARE IN MILLIMETERS
4. DIMENSIONS OF EXPOSED PAD ON BOTTOM OF PACKAGE DO NOT INCLUDE

MOLD FLASH. MOLD FLASH, IF PRESENT, SHALL NOT EXCEED 0.15 mm ON ANY SIDE
5. EXPOSED PAD SHALL BE SOLDER PLATED
6. SHADED AREA IS ONLY A REFERENCE FOR PIN 1 LOCATION

ON THE TOP AND BOTTOM OF PACKAGE

## TYPICAL APPLICATION

DC1685A Simplified Schematic with Suggested Output Termination for Driving an LTC2209 16-Bit ADC at 140MHz
