LTM4630-1

## 0.8\% DC and 3\% Transient Accuracy

## feATURES

- $\pm 0.8 \%$ Maximum Total DC Output Error Over Line, Load and Temperature (LTM4630-1A)
- $\pm 3 \%$ Transient Output Error with Minimum Output Capacitance
- Dual 18A or Single 36A Output
- 4.5V to 15 V Input, 0.6 V to 1.8 V Output Voltage Range
- Differential Remote Sense Amplifier
- Current Mode Control/Fast Transient Response
- Current Sharing Up to 144A
- $16 \mathrm{~mm} \times 16 \mathrm{~mm} \times 5.01 \mathrm{~mm}$ BGA Package

## APPLICATIONS

- FPGA, ASIC, $\mu$ Processor Core Voltage Regulation
- Information, Communication Systems

## DESCRIPTIOn

The LTM ${ }^{\circledR} 4630-1$ A/LTM4630-1B are dual 18A or single 36A output step-down $\mu$ Module ${ }^{\circledR}$ (micromodule) regulators with $\pm 0.8 \%$ (LTM4630-1A) and $\pm 1.5 \%$ (LTM4630-1B) total DC output error, respectively, with $\pm 3 \%$ transient output error. Included in the package are the switching controller, power FETs, inductors, and all supporting components. External compensation allowsforfasttransientresponseto minimize output capacitance when powering FPGAs, ASICs, and processors. With synchronized multiphase parallel current sharing, four LTM4630-1 devices can deliver up to 144A. The LTM4630-1 is offered in a $16 \mathrm{~mm} \times 16 \mathrm{~mm} \times 5.01$ BGA package.

## TYPICAL APPLICATION

1.2V Output Efficiency, $\mathrm{f}_{\mathrm{SW}}=500 \mathrm{kHz}$

$25 \%$ Load Step Transient Response, $\pm 3 \%$ Output Regulation Window. $12 V_{\text {IN }}, 1.2 V_{0 U T}, 36 \mathrm{~A}$ with $5 \times 220 \mu \mathrm{~F}$ Ceramic Cap

Note 1: Stresses beyond those listed under Absolute Maximum Ratings may cause permanent damage to the device. Exposure to any Absolute Maximum Rating condition for extended periods may affect device reliability and lifetime.
Note 2: The LTM4630-1 is tested under pulsed load conditions such that $T_{J} \approx T_{A}$. The LTM4630E-1 is guaranteed to meet specifications from $0^{\circ} \mathrm{C}$ to $125^{\circ} \mathrm{C}$ internal temperature. Specifications over the $-40^{\circ} \mathrm{C}$ to $125^{\circ} \mathrm{C}$ internal operating temperature range are assured by design, characterization and correlation with statistical process controls. The LTM4630l- 1 is guaranteed over the full $-40^{\circ} \mathrm{C}$ to $125^{\circ} \mathrm{C}$ internal operating temperature range. Note that the maximum ambient temperature consistent with these specifications is determined by specific operating conditions in conjunction with board layout, the rated package thermal impedance and other environmental factors.

Note 3: Two outputs are tested separately and the same testing condition is applied to each output.
Note 4: The switching frequency is programmable from 400 kHz to 750 kHz .
Note 5: LTM4630-1 device is designed to operate from 400 kHz to 750 kHz
Note 6: These parameters are tested at wafer sort.
Note 7: See output current derating curves for different $\mathrm{V}_{\text {IN }}, \mathrm{V}_{\text {OUT }}$ and $\mathrm{T}_{\mathrm{A}}$.

## TYPICAL PERFORMANCE CHARACTERISTICS

## PIN FUNCTIONS (Recommended to Use Test Points to Monitor Signal Pin Connections.)

4PACKAGE ROW AND COLUMN LABELING MAY VARY AMONG $\mu$ Module PRODUCTS. REVIEW EACH PACKAGE LAYOUT CAREFULLY.
$\mathrm{V}_{\text {OUT1 }}$ (A1-A5, B1-B5, C1-C4): Power Output Pins. Apply output load betweenthese pins and GND pins. Recommend placing output decoupling capacitance directly between these pins and GND pins. Review Table 4.
GND (A6-A7, B6-B7, D1-D4, D9-D12, E1-E4, E10-E12, F1-F3, F10-F12, G1, G3, G10, G12, H1-H7, H9-H12, J1, J5, J8, J12, K1, K5-K8, K12, L1, L12, M1, M12): Power Ground Pins for Both Input and Output Returns.
$V_{\text {Out2 }}$ (A8-A12, B8-B12, C9-C12): Power Output Pins. Apply output load between these pins and GND pins. Recommend placing output decoupling capacitance directly between these pins and GND pins. Review Table 4.
$\mathrm{V}_{\text {OUTS1 }}, \mathrm{V}_{\text {OUTS2 }}$ (C5, C8): This pin is connected to the top of the internal top feedback resistor for each output. The pin can be directly connected to its specific output, or connected to DIFFOUT when the remote sense amplifier is used. In paralleling modules, one of the $V_{\text {Outs }}$ pins is connected to the DIFFOUT pin in remote sensing ordirectly to $V_{\text {Out }}$ with no remote sensing. It is very important to connect these pins to either the DIFFOUT or $V_{\text {OUT }}$ since this is the feedback path, and cannot be left open. See the Applications Information section.
$\mathrm{f}_{\text {SET }}$ (C6): Frequency Set Pin. A $10 \mu \mathrm{~A}$ current is sourced from this pin. A resistor from this pin to ground sets a voltage that in turn programs the operating frequency. Alternatively, this pin can be driven with a DC voltage that can set the operating frequency. See the Applications Information section.

SGND (C7, D6, G6-G7, F6-F7): Signal Ground Pin. Return ground path for all analog and low power circuitry. Tie a single connection to the output capacitor GND in the application. See layout guidelines in Figure 14.
$\mathrm{V}_{\mathrm{FB} 1}, \mathrm{~V}_{\mathrm{FB} 2}$ (D5, D7): The Negative Input of the Error Amplifier for Each Channel. Internally, this pin is connected to $\mathrm{V}_{\text {Outs } 1}$ or $\mathrm{V}_{\text {Outs2 }}$ with a $60.4 \mathrm{k} \Omega$ precision resistor. Different output voltages can be programmed with an additional resistor between $V_{\text {FB }}$ and $G N D$ pins. In PolyPhase ${ }^{\ominus}$ operation, tying the $\mathrm{V}_{\text {FB }}$ pins together allows for parallel operation. See the Applications Information section for details. Do not drive this pin.
TRACK1, TRACK2 (E5, D8): Output Voltage Tracking Pin and Soft-Start Inputs. Each channel has a $1.3 \mu \mathrm{~A}$ pull-up current source. When one channel is configured to be master of the two channels, then a capacitor from this pin to ground will set a soft-start ramp rate. The remaining channel can be set up as the slave, and have the master's output applied through a voltage divider to the slave output's track pin. This voltage divider is equal to the slave output's feedback divider for coincidental tracking. See the Applications Information section.
COMP1, COMP2 (E6, E7): Current control threshold and error amplifier compensation point for each channel. The current comparator threshold increases with this control voltage. COMP pin internal has 10pF filter cap to SGND. An external RC filter circuit is required for control loop compensation. See Applications Information section. Tie the COMP pins together for parallel operation. Do not drive this pin.
DIFFP (E8): Positive input of the remote sense amplifier. This pin is connected to the remote sense point of the output voltage. See the Applications Information section.
DIFFN (E9): Negative input of the remote sense amplifier. This pin is connected to the remote sense point of the output GND. See the Applications Information section.
MODE_PLLIN (F4): Force Continuous Mode, Burst Mode Operation, or Pulse-Skipping Mode Selection Pin and External Synchronization Input to Phase Detector Pin. Connect this pin to SGND to force both channels into force continuous mode of operation. Connect to INTV CC to enable pulse-skipping mode of operation. Leaving the pin floating will enable Burst Mode operation. A clock on the pin will force both channels into continuous mode of operation and synchronized to the external clock applied to this pin.

## PIn FUNCTIOnS (Recommended to Use Test Points to Monitor Signal Pin Connections.)

RUN1, RUN2 (F5, F9): Run Control Pin. A voltage above 1.25 V will turn on each channel in the module. A voltage below 1.25 V on the RUN pin will turn off the related channel. Each RUN pin has a $1 \mu \mathrm{~A}$ pull-up current, once the RUN pin reaches 1.2 V an additional $4.5 \mu \mathrm{~A}$ pull-up current is added to this pin.
DIFFOUT (F8): Internal Remote Sense Amplifier Output. Connect this pin to $\mathrm{V}_{\text {OUTS1 }}$ or $\mathrm{V}_{\text {OUTS2 }}$ depending on which output is using remote sense. In parallel operation connect one of the $\mathrm{V}_{\text {OUTS }}$ pin to DIFFOUT for remote sensing.
SW1, SW2 (G2, G11): Switching node of each channel that is used for testing purposes. Also an R-C snubber network can be applied to reduce or eliminate switch node ringing, or otherwise leave floating. See the Applications Information section.

PHASMD (G4): Connect this pinto SGND, INTV ${ }_{\text {CC }}$, orfloating this pin to select the phase of CLKOUT to 60 degrees, 120 degrees, and 90 degrees respectively.
CLKOUT (G5): Clock output with phase control using the PHASMD pin to enable multiphase operation between devices. See the Applications Information section.

PG00D1, PGOOD2 (G9, G8): Output Voltage Power Good Indicator. Open drain logic output that is pulled to ground when the output voltage is not within $\pm 10 \%$ of the regulation point.

INTV $_{\text {CC }}$ (H8): Internal 5V Regulator Output. The control circuits and internal gate drivers are powered from this voltage. Decouple this pin to PGND with a $4.7 \mu \mathrm{~F}$ Iow ESR tantalum or ceramic. INTV ${ }_{\text {Cc }}$ is activated when either RUN1 or RUN2 is activated.

TEMP (J6): Onboard General Purpose Temperature Diode for Monitoring the VBE Junction Voltage Change with Temperature. See the Applications Information section.
EXTV ${ }_{\text {CC }}$ (J7): External power input that is enabled through a switch to $\mathrm{INTV}_{\text {CC }}$ whenever EXTV ${ }_{\text {CC }}$ is greater than 4.7V. Do not exceed 6V on this input, and connect this pin to $\mathrm{V}_{\text {IN }}$ when operating $\mathrm{V}_{\text {IN }}$ on 5 V . An efficiency increase will occur that is a function of the ( $\mathrm{V}_{\text {IN }}-$ INTV $\left._{\text {CC }}\right)$ multiplied by power MOSFET driver current. Typical current requirement is 30 mA . $\mathrm{V}_{\text {IN }}$ must be applied before $\mathrm{EXTV}_{\mathrm{CC}}$, and $\mathrm{EXTV}_{\mathrm{CC}}$ must be removed before $\mathrm{V}_{\mathrm{IN}}$.
VIN (M2-M11, L2-L11, J2-J4, J9-J11, K2-K4, K9-K11): Power Input Pins. Apply input voltage between these pins and GND pins. Recommend placing input decoupling capacitance directly between $\mathrm{V}_{\text {IN }}$ pins and GND pins.

## OPERATION

## Power Module Description

The LTM4630-1 is a dual-output standalone nonisolated switching mode DC/DC power supply with $\pm 0.8 \%$ total DC output error over line, load and temperature variation. It can provide two 18A outputs or single 36A output with few external input and output capacitors and setup components. This module provides precisely regulated output voltages programmable via external resistors from $0.6 \mathrm{~V}_{D C}$ to 1.8 V DC over 4.5 V to 15 V input voltages. The typical application schematic is shown in Figure 25.
The LTM4630-1 has dual integrated constant-frequency current mode regulators and built-in power MOSFET devices with fast switching speed. The typical switching frequency is 500 kHz . For switching-noise sensitive applications, it can be externally synchronized from 400 kHz to 780 kHz . A resistor can be used to program a free run frequency on the FSET pin. See the Applications Information section.

With current mode control, multi LTM4630-1s can be easily paralleled to provide up to 144A current with guaranteed perfect current sharing. Also, with current mode control, the LTM4630-1 module is able to achieve sufficient stability margins and a very fast $\pm 3 \%$ output transient response with a minimum number of output capacitors, even with all ceramic output capacitors.

This makes LTM4630-1 the best candidate when powering FPGAs, ASICs and processors in terms of DC accuracy, AC transient response, high output current and accuracy current sharing. See Applications Information section.

Current mode control provides cycle-by-cycle fast current limit and foldback current limit in an overcurrent condition. Internal overvoltage and undervoltage comparators pull the open-drain PGOOD outputs low if the output feedback voltage exits a $\pm 10 \%$ window around the regulation point. As the output voltage exceeds 10\% above regulation, the bottom MOSFET will turn on to clamp the output voltage. The top MOSFET will be turned off. This overvoltage protect is feedback voltage referred.

Pulling the RUN pins below 1.1V forces the regulators into a shutdown state, by turning off both MOSFETs. The TRACK pins are used for programming the output voltage ramp and voltage tracking during start-up or used for soft-starting the regulator. See the Applications Information section.
The LTM4630-1 has a built-in 10pF high frequency filter cap from COMP to SGND for each output. An external RC filtering circuit is required to achieve fast Type II control loop compensation. Table 4 provides a guide line for input, output capacitances and RC comp values for several operating conditions. The Linear Technology $\mu$ Module Power Design Tool (LTpowerCAD ${ }^{\text {TM }}$ ) will be provided for transient and stability analysis. The $\mathrm{V}_{\text {FB }}$ pin is used to program the output voltage with a single external resistor to ground. A differential remote sense amplifier is available for sensing the output voltage accurately on one of the outputs at the load point, or in parallel operation sensing the output voltage at the load point.
High efficiency at light loads can be accomplished with selectable Burst Mode operation or pulse-skipping operation using the MODE_PLLIN pin. These light Ioad features will accommodate battery operation. Efficiency graphs are provided for light load operation in the Typical PerformanceCharacteristics section. Seethe Applications Information section for details.

A general purpose temperature diode is included inside the module to monitor the temperature of the module. See the Applications Information section for details.

The switch pins are available for functional operation monitoring and a resistor-capacitor snubber circuit can be careful placed on the switch pin to ground to dampen any high frequency ringing on the transition edges. See the Applications Information section for details.

## APPLICATIONS InFORMATION

The typical LTM4630-1 application circuit is shown in Figure 25. External component selection is primarily determined by the maximum load current and output voltage. Refer to Table 4 for specific external capacitor requirements to achieve $\pm 3 \%$ transient response for a $25 \%$ or a $50 \%$ load step application.

## OUTPUT TOTAL DC ACCURACY AND AC TRANSIENT PERFORMANCE

In modern ASIC and FPGA power supply designs, a tight total voltage regulation window, $\pm 3 \%$ for example, is required of the supply powering the core and periphery. To meet this requirement, the supply's DC voltage variance plus any AC voltage variation which may occur during any load step transient must fall within this allowed window. The DC voltage variance is determined by the accuracies of the supply's reference voltage, resistor divider, Ioad regulation and line regulation over the operating temperature range. The AC voltage variance is determined by the supply's output voltage overshoot and undershoots in response to a load transient condition for a given output capacitor network.

Figure 2 shows a typical load step transient response waveform together with DC voltage accuracy variance. For a given allowable voltage regulation window, a tighter DC voltage accuracy allows more margin for the AC variation due to a load transient response. This increased margin for AC variation allows for a reduction in the total output capacitance required to meet the regulation window requirement. This allows for a reduced total solution cost and footprint area.

Figure 2. Typical Load Step Transient Response with DC Voltage Accuracy Variance

For example, in an FPGA core voltage application, for a 12 V input, 0.9 V output at 72 A design, a total overall $\pm 3 \%$ total voltage regulation window is required in responding to a $25 \%$ load step transient. Figure 3 illustrates the benefit of overall output capacitor reduction versus improved total DC accuracy by using $100 \mu \mathrm{~F}$ ceramic output capacitors.

Figure 3.Overall Output Capacitor vs Total DC Accuracy

## $\mathrm{V}_{\text {IN }}$ to $\mathrm{V}_{\text {OUT }}$ Step-Down Ratios

There are restrictions in the maximum $\mathrm{V}_{\text {IN }}$ and $\mathrm{V}_{\text {OUT }}$ stepdown ratio that can be achieved for a given input voltage. Each output of the LTM4630-1 is capable of $98 \%$ duty cycle, but the $\mathrm{V}_{\text {IN }}$ to $\mathrm{V}_{\text {OUT }}$ minimum dropout is still shown as a function of its load current and will limit output current capability related to high duty cycle on the top side switch. Minimum on-time $\mathrm{t}_{\mathrm{ON}(\mathrm{MIN})}$ is another consideration in operating at a specified duty cycle while operating at a certain frequency due to the fact that $\mathrm{t}_{\mathrm{ON}(\mathrm{MIN})}<\mathrm{D} / \mathrm{f}_{\mathrm{SW}}$, where $D$ is duty cycle and $f_{S w}$ is the switching frequency. $\mathrm{t}_{\mathrm{ON}(\mathrm{MIN})}$ is specified in the electrical parameters as 90 ns .

## Output Voltage Programming

The PWM controller has an internal 0.6 V reference voltage. As shown inthe Block Diagram, a60.4k』 internal feedback resistor connects between the $\mathrm{V}_{0 U T S 1}$ to $\mathrm{V}_{\mathrm{FB} 1}$ and $\mathrm{V}_{\text {OUTS2 }}$ to $\mathrm{V}_{\text {FB2 }}$. It is very important that these pins be connected to their respective outputs for proper feedback regulation. Overvoltage can occur if these $\mathrm{V}_{\text {OUTS1 }}$ and $\mathrm{V}_{\text {OUTS2 }}$ pins are left floating when used as individual regulators, or at least one of them is used in paralleled regulators. The output

## APPLICATIONS INFORMATION

voltage will default to 0.6 V with no feedback resistor on either $\mathrm{V}_{\text {FB1 }}$ or $\mathrm{V}_{\mathrm{FB} 2}$. Adding a resistor $\mathrm{R}_{\mathrm{FB}}$ from $\mathrm{V}_{\mathrm{FB}}$ pin to GND programs the output voltage:

$$
V_{\text {OUT }}=0.6 \mathrm{~V} \cdot \frac{60.4 \mathrm{k}+\mathrm{R}_{\mathrm{FB}}}{\mathrm{R}_{\mathrm{FB}}}
$$

Table 1. $\mathrm{V}_{\text {FB }}$ Resistor Table vs Various Output Voltages

| $\mathbf{V}_{\text {OUT }}$ | 0.6 V | 1.0 V | 1.2 V | 1.5 V | 1.8 V |
| :---: | :---: | :---: | :---: | :---: | :---: |
| $\mathbf{R}_{\mathrm{FB}}$ | Open | 90.9 k | 60.4 k | 40.2 k | 30.2 k |

For parallel operation of multiple channels the same feedback setting resistor can be used for the parallel design. This is done by connecting the $\mathrm{V}_{\text {OUTS1 }}$ to the output as shown in Figure 4, thus tying one of the internal 60.4 k resistors to the output. All of the $V_{\text {FB }}$ pins tie together with one programming resistor as shown in Figure 4.
In parallel operation, the $V_{F B}$ pins have an $I_{F B}$ current of 20 nA maximum each channel. To reduce output voltage error due to this current, an additional $\mathrm{V}_{\text {OUTS }}$ pin can be tied to $\mathrm{V}_{\text {OUT }}$, and an additional $R_{F B}$ resistor can be used to lower the total Thevenin equivalent resistance seen by this current. For example in Figure 4, the total Thevenin equivalent resistance of the $V_{F B}$ pin is $\left(60.4 \mathrm{k} / / \mathrm{R}_{F B}\right)$, which is 30.2 k where $\mathrm{R}_{F B}$ is equal to 60.4 k for a 1.2 V output. Four phases connected in parallel equates to a worse case feedback current of $4 \bullet I_{F B}=80 \mathrm{nA}$ maximum. The voltage error is $80 \mathrm{nA} \cdot 30.2 \mathrm{k}$ $=2.4 \mathrm{mV}$. If $\mathrm{V}_{\text {OUTS2 }}$ is connected, as shown in Figure 4, to $\mathrm{V}_{\text {OUT }}$, and another 60.4 k resistor is connected from $\mathrm{V}_{\text {FB2 }}$ to ground, then the voltage error is reduced to 1.2 mV . If the voltage error is acceptable then no additional connections are necessary. The onboard 60.4 k resistor is $0.5 \%$ accurate and the $\mathrm{V}_{\mathrm{FB}}$ resistor can be chosen by the user to be as accurate as needed. All COMP pins are tied together for current sharing between the phases. The TRACK/SS pins can be tied together and a single soft-start capacitor can be used to soft-start the regulator. The soft-start equation will need to have the soft-start current parameter increased by the number of paralleled channels. See Output Voltage Tracking section.

Figure 4. 4-Phase Parallel Configurations

## Input Capacitors

The LTM4630-1 module should be connected to a low acimpedance DC source. For the regulator input four $22 \mu \mathrm{~F}$ input ceramic capacitors are used for RMS ripple current. A 47 $\mu$ F to $100 \mu$ Fsurface mount aluminum electrolytic bulk capacitor can be used for more input bulk capacitance. This bulk input capacitor is only needed if the input source impedance is compromised by long inductive leads, traces or not enough source capacitance. If low impedance power planes are used, then this bulk capacitor is not needed.
For a buck converter, the switching duty-cycle can be estimated as:

$$
\mathrm{D}=\frac{\mathrm{V}_{\text {OUT }}}{\mathrm{V}_{\text {IN }}}
$$

## APPLICATIONS INFORMATION

Without considering the inductor current ripple, for each output, the RMS current of the input capacitor can be estimated as:

$$
I_{\mathrm{CIN}(\mathrm{RMS})}=\frac{\mathrm{I}_{\mathrm{OUT}(\mathrm{MAX})}}{\eta \%} \cdot \sqrt{D \cdot(1-\mathrm{D})}
$$

In the above equation, $\eta \%$ is the estimated efficiency of the power module. The bulk capacitor can be a switcherrated electrolytic aluminum capacitor, Polymer capacitor.

## Output Capacitors

The LTM4630-1 is designed for low output voltage ripple noise and good transient response. The bulk output capacitors defined as $\mathrm{C}_{\text {Out }}$ are chosen with low enough effective series resistance (ESR) to meet the output voltage ripple and transient requirements. Cout can be a low ESR tantalum capacitor, the low ESR polymer capacitor or ceramic capacitor. The typical output capacitance range for each output is from $200 \mu \mathrm{~F}$ to $470 \mu \mathrm{~F}$ per output channel. Additional output filtering may be required by the system designer, if further reduction of output ripples or dynamic transient spikes is required. Table 4 shows a matrix of different output voltages and output capacitors to minimize the voltage droop and overshoot to achieve $\pm 3 \%$ transient accuracy during a $25 \%$ load step. In multi LTM4630-1 paralleling applications, Table 4 RC compensation value is still valid in terms of having one set of RC filters on each of the paralleling modules while connecting all the COMP, FB and $V_{\text {OUT }}$ pins together. See Figure 28 and Multiphase Operation section. The table optimizes total equivalent ESR and total bulk capacitance to optimize the transient performance. Stability criteria are considered in the Table 4 matrix, and the Linear Technology $\mu$ Module Power Design Tool will be provided for stability analysis. Multiphase operation will reduce effective output ripple as a function of the number of phases. Application Note 77 discusses this noise reduction versus output ripple current cancellation, but the output capacitance should be considered carefully as a function of stability and transient response. The Linear Technology $\mu$ Module Power Design Tool can calculate the output ripple reduction as the number of implemented phases increases by N times. A small value
$10 \Omega$ to $50 \Omega$ resistor can be place in series from $V_{\text {OUT }}$ to the $V_{\text {OUTS }}$ pin to allow for a bode plot analyzer to inject a signal into the control loop and validate the regulator stability. The same resistor could be place in series from $V_{\text {Out }}$ to DIFFP and a bode plot analyzer could inject a signal into the control loop and validate the regulator stability.

## Burst Mode Operation

The LTM4630-1 is capable of Burst Mode operation on each regulator in which the power MOSFETs operate intermittently based on load demand, thus saving quiescent current. For applications where maximizing the efficiency at very light loads is a high priority, Burst Mode operation should be applied. Burst Mode operation is enabled with the MODE_PLLIN pin floating. During this operation, the peak current of the inductor is set to approximately one third of the maximum peak current value in normal operation even though the voltage at the COMP pin indicates a lower value. The voltage at the COMP pin drops when the inductor's average current is greater than the load requirement. As the COMP voltage drops below 0.5 V , the BURST comparator trips, causing the internal sleep line to go high and turn off both power MOSFETs.
In sleep mode, the internal circuitry is partially turned off, reducing the quiescent current to about $450 \mu \mathrm{~A}$ for each output. The load current is now being supplied from the output capacitors. When the output voltage drops, causing COMP to rise above 0.5 V , the internal sleep line goes low, and the LTM4630-1 resumes normal operation. The next oscillator cycle will turn on the top power MOSFET and the switching cycle repeats. Either regulator can be configured for Burst Mode operation.

## Pulse-Skipping Mode Operation

In applications where low output ripple and high efficiency at intermediate currents are desired, pulse-skipping mode should be used. Pulse-skipping operation allows the LTM4630-1 to skip cycles at low output loads, thus increasing efficiency by reducing switching loss. Tying the MODE_PLLIN pin to INTV $C$ enables pulse-skipping operation. At light loads the internal current comparator

## APPLICATIONS INFORMATION

may remain tripped for several cycles and force the top MOSFET to stay off for several cycles, thus skipping cycles. The inductor current does not reverse in this mode. This mode will maintain higher effective frequencies thus lower output ripple and lower noise than Burst Mode operation. Either regulator can beconfigured for pulse-skipping mode.

## Forced Continuous Operation

In applications where fixed frequency operation is more critical than low current efficiency, and where the lowest output ripple is desired, forced continuous operation should be used. Forced continuous operation can be enabled by tying the MODE_PLLIN pin to GND. In this mode, inductor current is allowed to reverse during low output loads, the COMP voltage is in control of the current comparator threshold throughout, and the top MOSFET always turns on with each oscillator pulse. During start-up, forced continuous mode is disabled and inductor current is prevented from reversing until the LTM4630-1's output voltage is in regulation. Either regulator can be configured for force continuous mode.

## Multiphase Operation

For outputloads that demand more than 18A of current, two outputs in LTM4630-1 or even multiple LTM4630-1s can be paralleled to run out of phase to provide more output current without increasing input and output voltage ripples. The MODE_PLLIN pin allows the LTM4630-1 to synchronize to an external clock (between 400 kHz and 780 kHz ) and the internal phase-locked-loop allows the LTM4630-1 to lock onto incoming clock phase as well. The CLKOUT signal can be connected to the MODE_PLLIN pin of the following stage to line up both the frequency and the phase of the entire system. Tying the PHASMD pin to INTV ${ }_{C C}$, SGND, or (floating) generates a phase difference (between MODE_PLLIN and CLKOUT) of 120 degrees, 60 degrees, or 90 degrees respectively. A total of 12 phases can be cascaded to run simultaneously with respect to each other by programming the PHASMD pin of each LTM4630-1 channel to different levels. Figure 5 shows a 2-phase design, 4-phase design and a 6-phase design example for clock phasing with the PHASMD table.

Figure 5. Examples of 2-Phase, 4-Phase, and 6-Phase Operation with PHASMD Table

## LTM4630-1

## APPLICATIONS INFORMATION

A multiphase power supply significantly reduces the amount of ripple current in both the input and output capacitors. The RMS input ripple current is reduced by, and the effective ripple frequency is multiplied by, the number of phases used (assuming that the input voltage is greater than the number of phases used times the output voltage). The output ripple amplitude is also reduced by the number of phases used when all of the outputs are tied together to achieve a single high output current design.
In multi LTM4630-1s parallel applications, $\mathrm{C}_{\text {TH }}$ and $\mathrm{R}_{\text {TH }}$ values in Table 4 are still valid to achieve a $\pm 3 \%$ transient response ina $25 \%$ load step. Connect one set of $R C$ ( $\mathrm{R}_{\text {TH }}$ and $\mathrm{C}_{\mathrm{TH}}$ ) network to the COMP pin of each paralleling module like a dual phase single output setup. Then connect the COMP pins, FB pins, TRACK/SS pin and $V_{\text {OUT }}$ pins from different modules together. See Figure 28 for an example
of parallel operation. LTpowerCAD Power Design Tool can also be used to optimize loop compensation and transient performance if only one set of RC ( $\mathrm{R}_{\text {TH }}$ and $\mathrm{C}_{\text {TH }}$ ) network is to be added to the common COMP pins.

The LTM4630-1 device is an inherently current mode controlled device, so parallel modules will have very good current sharing. This will balance the thermals on the design.

## Input RMS Ripple Current Cancellation

Application Note 77 provides a detailed explanation of multiphase operation. The input RMS ripple current cancellation mathematical derivations are presented, and a graph is displayed representing the RMS ripple current reduction as a function of the number of interleaved phases. Figure 6 shows this graph.

Figure 6. Input RMS Current Ratios to DC Load Current as a Function of Duty Cycle

# APPLICATIONS INFORMATION 

Frequency Selection and Phase-Lock Loop (MODE_PLLIN and fist Pins)

The LTM4630-1 device is operated over a range of frequencies to improve power conversion efficiency. It is recommended to operate the module at 500 kHz over the output range for the best efficiency and inductor current ripple.
The LTM4630-1 switching frequency can be set with an external resistor from the fiet pin to SGND. An accurate $10 \mu \mathrm{~A}$ current source into the resistor will set a voltage that programs the frequency or a DC voltage can be applied. Figure 7 shows a graph of frequency setting verses programming voltage. An external clock can be applied to the MODE_PLLIN pin from OV to INTV $C$ cc over a frequency range of 400 kHz to 780 kHz . The clock input high threshold is 1.6 V and the clock input low threshold is 1 V . The LTM4630-1 has the PLL loop filter components on board. The frequency setting resistor should always be present to set the initial switching frequency before locking to an external clock. Both regulators will operate in continuous mode while being externally clock.

The output of the PLL phase detector has a pair of complementary current sources that charge and discharge the internal filter network. When the external clock is applied

Figure 7. Operating Frequency vs $\mathrm{f}_{\text {SET }}$ Pin Voltage
then the f SET frequency resistor is disconnected with an internal switch, and the current sources control the frequency adjustment to lock to the incoming external clock. When no external clock is applied, then the internal switch is on, thus connecting the external $\mathrm{f}_{\mathrm{SET}}$ frequency set resistor for free run operation.

## Minimum On-Time

Minimum on-time $\mathrm{t}_{0 \mathrm{~N}}$ is the smallesttime duration that the LTM4630-1 is capable of turning on the top MOSFET on either channel. It is determined by internal timing delays, and the gate charge required turning on the top MOSFET. Low duty cycle applications may approach this minimum on-time limit and care should be taken to ensure that:

$$
\frac{V_{\text {OUT }}}{V_{\text {IN }} \cdot \text { FREQ }}>t_{\text {ON(MIN })}
$$

If the duty cycle falls below what can be accommodated by the minimum on-time, the controller will begin to skip cycles. The output voltage will continue to be regulated, but the output ripple and current will increase. The on-time can be increased by lowering the switching frequency. A good rule of thumb is to keep on-time longer than 110ns.

## Output Voltage Tracking

Output voltage tracking can be programmed externally using the TRACK pins. The output can be tracked up and down with another regulator. The master regulator's output is divided down with an external resistor divider that is the same as the slave regulator's feedback divider to implement coincident tracking. The LTM4630-1 uses an accurate 60.4 k resistor internally for the top feedback resistor for each channel. Figure 8 shows an example of coincident tracking. Equations:

$$
\text { SLAVE }=\left(1+\frac{60.4 \mathrm{k}}{\mathrm{R}_{\text {TA }}}\right) \cdot V_{\text {TRACK }}
$$

$V_{\text {TRACK }}$ is the track ramp applied to the slave's track pin. $V_{\text {TRACK }}$ has a control range of 0 V to 0.6 V , or the internal reference voltage. When the master's output is divided

## APPLICATIONS InFORMATION

down with the same resistor values used to set the slave's output, then the slave will coincident track with the master until it reaches its final value. The master will continue to its final value from the slave's regulation point. Voltage tracking is disabled when $\mathrm{V}_{\text {TRACK }}$ is more than 0.6 V . $\mathrm{R}_{\text {TA }}$ in Figure 8 will be equal to the $\mathrm{R}_{\mathrm{FB}}$ for coincident tracking. Figure 9 shows the coincident tracking waveforms.
The TRACK pin of the master can be controlled by a capacitor placed on the master regulator TRACK pin to ground. A $1.3 \mu \mathrm{~A}$ current source will charge the TRACK pin up to the reference voltage and then proceed up to $\mathrm{INTV}_{\text {CC. }}$. After the 0.6 V ramp, the TRACK pin will no longer be in control, and the internal voltage reference will control output regulation from the feedback divider. Foldback current limit is disabled during this sequence of turn-on during tracking or soft-starting. The TRACK pins are pulled low when the RUN pin is below 1.2V. The total soft-start time can be calculated as:

$$
\mathrm{t}_{\text {SOFT-START }}=\left(\frac{\mathrm{C}_{S S}}{1.3 \mu \mathrm{~A}}\right) \cdot 0.6
$$

Regardless of the mode selected by the MODE_PLLIN pin, the regulator channels will always start in pulse-skipping mode up to TRACK $=0.5 \mathrm{~V}$. Between TRACK $=0.5 \mathrm{~V}$ and 0.54 V , it will operate in forced continuous mode and revert to the selected mode once TRACK $>0.54 \mathrm{~V}$. In order to track with another channel once in steady state operation, the LTM4630-1 is forced into continuous mode operation as soon as $\mathrm{V}_{\mathrm{FB}}$ is below 0.54 V regardless of the setting on the MODE_PLLIN pin.

Ratiometric tracking can be achieved by a few simple calculations and the slew rate value applied to the master's TRACK pin. As mentioned above, the TRACK pin has a control range from 0 to 0.6 V . The master's TRACK pin
slew rate is directly equal to the master's output slew rate in Volts/Time. The equation:

$$
\frac{\mathrm{MR}}{\mathrm{SR}} \cdot 60.4 \mathrm{k}=\mathrm{R}_{\mathrm{TB}}
$$

where MR is the master's output slew rate and SR is the slave's output slew rate in Volts/Time. When coincident tracking is desired, then MR and SR are equal, thus $\mathrm{R}_{\mathrm{TB}}$ is equal the 60.4 k . $\mathrm{R}_{\mathrm{TA}}$ is derived from equation:

$$
R_{T A}=\frac{0.6 \mathrm{~V}}{\frac{V_{\text {FB }}}{60.4 \mathrm{~K}}+\frac{V_{\text {FB }}}{R_{F B}}-\frac{V_{\text {TRACK }}}{R_{T B}}}
$$

where $V_{F B}$ is the feedback voltage reference of the regulator, and $\mathrm{V}_{\text {TRACK }}$ is 0.6 V . Since $\mathrm{R}_{\text {TB }}$ is equal to the 60.4 k top feedback resistor of the slave regulator in equal slew rate or coincident tracking, then $R_{T A}$ is equal to $R_{F B}$ with $V_{F B}=V_{T R A C K}$. Therefore $R_{T B}=60.4 \mathrm{k}$, and $R_{T A}=60.4 \mathrm{k}$ in Figure 8.

In ratiometric tracking, a different slew rate maybe desired for the slave regulator. $R_{T B}$ can be solved for when $S R$ is slower than MR. Make sure that the slave supply slew rate is chosen to be fast enough so that the slave output voltage will reach it final value before the master output.

For example, $\mathrm{MR}=1.5 \mathrm{~V} / 1 \mathrm{~ms}$, and $\mathrm{SR}=1.2 \mathrm{~V} / 1 \mathrm{~ms}$. Then $R_{T B}=76.8 \mathrm{k}$. Solve for $\mathrm{R}_{\mathrm{TA}}$ to equal to 49.9 k .
Each of the TRACK pins will have the $1.3 \mu \mathrm{~A}$ current source on when a resistive divider is used to implement tracking on that specific channel. This will impose an offset on the TRACK pin input. Smaller values resistors with the same ratios as the resistor values calculated from the above equation can be used. For example, where the 60.4 k is used then a 6.04 k can be used to reduce the TRACK pin offset to a negligible value.

## APPLICATIONS INFORMATION

Figure 8. Example of Output Tracking Application Circuit

Figure 9. Output Coincident Tracking Waveform

## APPLICATIONS INFORMATION

## Power Good

The PGOOD pins are open drain pins that can be used to monitor valid output voltage regulation. This pin monitors a $10 \%$ window around the regulation point. A resistor can be pulled up to a particular supply voltage no greater than 6 V maximum for monitoring.

## Stability Compensation

The LTM4630-1 has a built-in 10pF high frequency filter capacitor from COMP to SGND on each output channel. An external RC filtering circuit is required to add from COMP to SGND to achieve fast Type II control loop compensation. Table 4 is provided for most application requirements. The Linear Technology $\mu$ Module Power Design Tool (LTpowerCAD) will be provided for other control loop optimization.

## Run Enable

The RUN pins have an enable threshold of 1.4 V maximum, typically 1.25 V with 150 mV of hysteresis. They control the turn on each of the channels and INTV ${ }_{c c}$. These pins can be pulled up to $\mathrm{V}_{\text {IN }}$ for 5 V operation, or a 5 V Zener diode can be placed on the pins and a 10 k to 100 k resistor can be placed up to higher than 5V input for enabling the channels. There is $1 \mu \mathrm{~A}$ pull-up current for each RUN pin. The LTM4630-1 will turn on with RUN floating. Please note RUN has a 6 V Abs Max voltage rating. The RUN pins can also be used for output voltage sequencing. In parallel operation the RUN pins can be tie together and controlled from a single control. See the Typical Application circuits in Figure 25.

## INTV $_{\text {cc }}$ and EXTV ${ }_{\text {cc }}$

The LTM4630-1 module has an internal 5V low dropout regulator that is derived from the input voltage. This regulator is used to power the control circuitry and the power MOSFET drivers. This regulator can source up to 70 mA , and typically uses $\sim 30 \mathrm{~mA}$ for powering the device at the maximum frequency. This internal 5 V supply is enabled by either RUN1 or RUN2.

EXTV ${ }_{\text {cc }}$ allows an external 5 V supply to power the LTM4630-1 and reduce power dissipation from the internal low dropout 5 V regulator. The power loss savings can be calculated by:

$$
\left(\mathrm{V}_{\text {IN }}-5 \mathrm{~V}\right) \cdot 30 \mathrm{~mA}=\mathrm{PLOSS}
$$

EXTV ${ }_{\text {CC }}$ has a threshold of 4.7 V for activation, and a maximum rating of 6 V . When using a 5 V input, connect this 5 V input to $\mathrm{EXTV}_{\text {CC }}$ also to maintain a 5 V gate drive level. EXTV ${ }_{\text {CC }}$ must sequence on after $\mathrm{V}_{\text {IN }}$, and EXTV $_{\text {CC }}$ must sequence off before $\mathrm{V}_{\mathbf{I N}}$.

## Differential Remote Sense Amplifier

An accurate differential remote sense amplifier is provided to sense low output voltages accurately at the remote load points. This is especially true for high current loads. The amplifier can be used on one of the two channels, or on a single parallel output. It is very important that the DIFFP and DIFFN are connected properly at the output, and DIFFOUT is connected to either $V_{\text {OUTS }}$ or $V_{\text {OUTS2 }}$. In parallel operation, the DIFFP and DIFFN are connected properly at the output, and DIFFOUT is connected to one of the $\mathrm{V}_{\text {outs }}$ pins. Review the parallel schematics in Figure 26 and review Figure 4.

## SW Pins

The SW pins are generally for testing purposes by monitoring these pins. These pins can also be used to dampen out switch node ringing caused by LC parasitic in the switched current paths. Usually a series R-C combination is used called a snubber circuit. The resistor will dampen the resonance and the capacitor is chosen to only affect the high frequency ringing across the resistor. If the stray inductance or capacitance can be measured or approximated then a somewhat analytical technique can be used to select the snubber values. The inductance is usually easier to predict. Itcombines the power path board inductance in combination with the MOSFET interconnect bond wire inductance.

## APPLICATIONS INFORMATION

First the SW pin can be monitored with a wide bandwidth scope with a high frequency scope probe. The ring frequency can be measured for its value. The impedance $Z$ can be calculated:

$$
Z_{(L)}=2 \pi f L
$$

where $f$ is the resonant frequency of the ring, and $L$ is the total parasitic inductance in the switch path. If a resistor is selected that is equal to $Z$, then the ringing should be dampened. The snubber capacitor value is chosen so that its impedance is equal to the resistor at the ring frequency. Calculated by: $Z_{(C)}=1 /(2 \pi f C)$. These values are a good place to start with. Modification to these components should be made to attenuate the ringing with the least amount of power loss.

## Temperature Monitoring

A diode connected PNP transistor is used for the TEMP monitor function by monitoring its voltage over temperature. The temperature dependence of this diode voltage can be understood in the equation:

$$
V_{D}=n V_{T} \ln \left(\frac{I_{D}}{I_{S}}\right)
$$

where $\mathrm{V}_{\mathrm{T}}$ is the thermal voltage ( $\mathrm{kT} / \mathrm{q}$ ), and n , the ideality factor, is 1 for the diode connected PNP transistor being used in the LTM4630. IS is expressed by the typical empirical equation:

$$
I_{S}=I_{0} \exp \left(\frac{-V_{G 0}}{V_{T}}\right)
$$

where $I_{0}$ is a process and geometry dependent current, ( $l_{0}$ is typically around 20k orders of magnitude larger than IS at room temperature) and $\mathrm{V}_{\mathrm{G} 0}$ is the band gap voltage of 1.2 V extrapolated to absolute zero or $-273^{\circ} \mathrm{C}$.

If we take the $I_{S}$ equation and substitute into the $V_{D}$ equation, then we get:

$$
V_{D}=V_{G O}-\left(\frac{k T}{q}\right) \ln \left(\frac{I_{0}}{I_{D}}\right), V_{T}=\frac{k T}{q}
$$

The expression shows that the diode voltage decreases (linearly if $\mathrm{I}_{0}$ were constant) with increasing temperature and constant diode current. Figure 10 shows a plot of $V_{D}$ vs Temperature over the operating temperature range of the LTM4630-1.
If we take this equation and differentiate it with respect to temperature T , then:

$$
\frac{d V_{D}}{d T}=-\frac{V_{G O}-V_{D}}{T}
$$

This $d V_{D} / d T$ term is the temperature coefficient equal to about $-2 \mathrm{mV} / \mathrm{K}$ or $-2 \mathrm{mV} /{ }^{\circ} \mathrm{C}$. The equation is simplified for the first order derivation.
Solving for $T, T=-\left(V_{G O}-V_{D}\right) /\left(d V_{D} / d T\right)$ provides the temperature.
1st Example: Figure 10 for $27^{\circ} \mathrm{C}$, or 300 K the diode voltage is 0.598 V , thus, $300 \mathrm{~K}=-(1200 \mathrm{mV}-598 \mathrm{mV}) /$ -2.0 mV/K)

2nd Example: Figure 10 for $75^{\circ} \mathrm{C}$, or 350 K the diode voltage is 0.50 V , thus, $350 \mathrm{~K}=-(1200 \mathrm{mV}-500 \mathrm{mV}) /$ $-2.0 \mathrm{mV} / \mathrm{K}$ )
Converting the Kelvin scale to Celsius is simply taking the Kelvin temp and subtracting 273 from it.
A typical forward voltage is given in the electrical characteristics section of the data sheet, and Figure 10 is the plot of this forward voltage. Measure this forward voltage at $27^{\circ} \mathrm{C}$ to establish a reference point. Then using the above

Figure 10. Diode Voltage $V_{D}$ vs Temperature $T(K)$ for Different Bias Currents

## APPLICATIONS INFORMATION

expression while measuring the forward voltage over temperature will provide a general temperature monitor. Connect a resistor between TEMP and $\mathrm{V}_{\text {IN }}$ to set the current to $100 \mu \mathrm{~A}$. See Figure 26 for an example.

## Thermal Considerations and Output Current Derating

The thermal resistances reported in the Pin Configuration section of the data sheet are consistent with those parameters defined by JESD51-9 and are intended for use with finite element analysis (FEA) software modeling tools that leverage the outcome of thermal modeling, simulation, and correlation to hardware evaluation performed on a $\mu$ Module package mounted to a hardware test board—also defined by JESD51-9 ("Test Boards for Area Array Surface Mount Package Thermal Measurements"). The motivation for providing these thermal coefficients is found in JESD 51-12 ("Guidelines for Reporting and Using Electronic Package Thermal Information").

Many designers may opt to use laboratory equipment and a test vehicle such as the demo board to anticipate the $\mu$ Module regulator's thermal performance in their application at various electrical and environmental operating conditions to compliment any FEA activities. Without FEA software, the thermal resistances reported in the Pin Configuration section are in-and-of themselves not relevant to providing guidance of thermal performance; instead, the derating curves provided in the data sheet can be used in a manner that yields insight and guidance pertaining to one's application-usage, and can be adapted to correlate thermal performance to one's own application.

The Pin Configuration section typically gives four thermal coefficients explicitly defined in JESD 51-12; these coefficients are quoted or paraphrased below:

1. $\theta_{\mathrm{JA}}$, the thermal resistance from junction to ambient, is the natural convection junction-to-ambient air thermal resistance measured in a one cubic foot sealed enclosure. This environment is sometimes referred to as "still air" although natural convection causes the air to move. This value is determined with the part mounted to a JESD 51-9 defined test board, which does not reflect an actual application or viable operating condition.
2. $\theta_{\mathrm{Jcbottom}}$, the thermal resistance from junction to the bottom of the product case, is the junction-to-board thermal resistance with all of the component power dissipation flowing through the bottom of the package. In the typical $\mu$ Module, the bulk of the heat flows out the bottom of the package, but there is always heat flow out into the ambient environment. As a result, this thermal resistance value may be useful for comparing packages but the test conditions don't generally match the user's application.
3. J јстор, $^{\text {, the thermal resistance from junction to top of }}$ the product case, is determined with nearly all of the component power dissipation flowing through the top of the package. As the electrical connections of the typical $\mu$ Module are on the bottom of the package, it is rare for an application to operate such that most of the heat flows from the junction to the top of the part. As in the case of $\theta_{\text {Jсвоттом }}$, this value may be useful for comparing packages but the test conditions don't generally match the user's application.
4. $\theta_{\mathrm{JB}}$, the thermal resistance from junction to the printed circuitboard, is the junction-to-board thermal resistance where almostall of the heat flows through the bottom of the $\mu$ Module and into the board, and is really the sum of the $\theta_{\text {Jcbottom }}$ and the thermal resistance of the bottom of the part through the solder joints and through a portion of the board. The board temperature is measured a specified distance from the package, using a two sided, two layer board. This board is described in JESD 51-9.
A graphical representation of the aforementioned thermal resistances is given in Figure 11; blue resistances are contained within the $\mu$ Module regulator, whereas green resistances are external to the $\mu$ Module.

As a practical matter, it should be clear to the reader that no individual or sub-group of the four thermal resistance parameters defined by JESD 51-12 or provided in the Pin Configuration section replicates or conveys normal operating conditions of a $\mu$ Module. For example, in normal board-mounted applications, never does 100\% of the device's total power loss (heat) thermally conduct exclusively through the top or exclusively through bottom of the

## APPLICATIONS INFORMATION

Figure 11. Graphical Representation of JESD51-12 Thermal Coefficients
$\mu$ Module—as the standard defines for $\theta_{\mathrm{JCtop}}$ and $\theta_{\mathrm{JCbottom}}$, respectively. In practice, power loss is thermally dissipated in both directions away from the package - granted, in the absence of a heat sink and airflow, a majority of the heat flow is into the board.
Within a SIP (system-in-package) module, be aware there are multiple power devices and components dissipating power, with a consequence that the thermal resistances relative to different junctions of components or die are not exactly linear with respect to total package power loss. To reconcile this complication without sacrificing modeling simplicity—but also, not ignoring practical realities-an approach has been taken using FEA software modeling along with laboratory testing in a controlled-environment chamber to reasonably define and correlate the thermal resistance values supplied in this data sheet: (1) Initially, FEA software is used to accurately build the mechanical geometry of the $\mu$ Module and the specified PCB with all of the correct material coefficients along with accurate power loss source definitions; (2) this model simulates a software-defined JEDEC environment consistent with JSED51-9 to predict power loss heat flow and temperature readings at different interfaces that enable the calculation of the JEDEC-defined thermal resistance values; (3) the model and FEA software is used to evaluate the $\mu$ Module with heat sink and airflow; (4) having solved for and analyzed
these thermal resistance values and simulated various operating conditions in the software model, a thorough laboratory evaluation replicates the simulated conditions with thermocouples within a controlled-environment chamber while operating the device at the same power loss as that which was simulated. An outcome of this process and due-diligence yields a set of derating curves provided in other sections of this data sheet. After these laboratory test have been performed and correlated to the $\mu$ Module model, then the $\theta_{\mathrm{JB}}$ and $\theta_{\mathrm{BA}}$ are summed together to correlate quite well with the $\mu$ Module model with no airflow or heat sinking in a properly define chamber. This $\theta_{\mathrm{JB}}+\theta_{\mathrm{BA}}$ value is shown in the Pin Configuration section and should accurately equal the $\theta_{\mathrm{JA}}$ value because approximately $100 \%$ of power loss flows from the junction through the board into ambient with no airflow or top mounted heat sink. Each system has its own thermal characteristics, therefore thermal analysis must be performed by the user in a particular system.

The LTM4630-1 module has been designed to effectively remove heat from both the top and bottom of the package. The bottom substrate material has very low thermal resistance to the printed circuit board. An external heat sink can be applied to the top of the device for excellent heat sinking with airflow.

## APPLICATIONS INFORMATION

Figures 12 and 13 show temperature plots of the LTM46301 with no heat sink and 200LFM airflow.

These plots equate to a paralleled 12 V to 1.0 V at 36 A design operating at $84.5 \%$ efficiency, and 12 V to 1.2 V at 36 A design operating at $86 \%$ efficiency.

## Safety Considerations

The LTM4630-1 modules do not provide isolation from $\mathrm{V}_{\text {IN }}$ to $\mathrm{V}_{\text {OUT }}$. There is no internal fuse. If required, a slow blow fuse with a rating twice the maximum input current needs to be provided to protect each unit from catastrophic failure. The device does support over current protection. A temperature diode is provided for monitoring internal temperature, and can be used to detect the need for thermal shutdown that can be done by controlling the RUN pin.

## Power Derating

The 1.0 V and 1.5 V power loss curves in Figures 15 and 16 can be used in coordination with the load current derating curves in Figures 17 to 24 for calculating an approximate $\Theta_{J A}$ thermal resistance forthe LTM4630-1 with various heat sinking and airflow conditions. The power loss curves are taken at room temperature, and are increased with a 1.35 to 1.4 multiplicative factor at $125^{\circ} \mathrm{C}$. These factors come from the fact that the power loss of the regulator increases about $45 \%$ from $25^{\circ} \mathrm{C}$ to $150^{\circ} \mathrm{C}$, thus a $50 \%$ spread over

Figure 12. Thermal Image 12V to 1.0V, 36A with 200LFM Airflow without Heat Sink
$125^{\circ} \mathrm{C}$ delta equates to $\sim 0.35 \% /{ }^{\circ} \mathrm{C}$ loss increase. A $125^{\circ} \mathrm{C}$ maximum junction minus $25^{\circ} \mathrm{C}$ room temperature equates to a $100^{\circ} \mathrm{C}$ increase. This $100^{\circ} \mathrm{C}$ increase multiplied by $0.35 \% /{ }^{\circ} \mathrm{C}$ equals a $35 \%$ power loss increase at the $125^{\circ} \mathrm{C}$ junction, thus the 1.35 multiplier.
The derating curves are plotted with CH 1 and CH 2 in parallel single output operation starting at 36A of load with low ambient temperature. The output voltages are 1.0 V and 1.5 V . These are chosen to include the lower and higher output voltage ranges for correlating the thermal resistance. Thermal models are derived from several temperature measurements in a controlled temperature chamber along with thermal modeling analysis.
The junction temperatures are monitored while ambient temperature is increased with and without airflow. The power loss increase with ambient temperature change is factored into the derating curves. The junctions are maintained at $\sim 120^{\circ} \mathrm{C}$ maximum while lowering output current or power while increasing ambient temperature. The decreased output current will decrease the internal module loss as ambient temperature is increased.
The monitored junction temperature of $120^{\circ} \mathrm{C}$ minus the ambient operating temperature specifies how much module temperature rise can be allowed. As an example in Figure 17, the load current is derated to $\sim 25 \mathrm{~A}$ at $\sim 86^{\circ} \mathrm{C}$ with

Figure 13. Thermal Image 12V to 1.2V, 36A with 200LFM Airflow without Heat Sink

## APPLICATIONS InFORMATION

no air or heat sink and the power loss for the 12 V to 1.0 V at 25 A output is a $\sim 5.5 \mathrm{~W}$ loss. The 5.5 W loss is calculated with the $\sim 4.1 \mathrm{~W}$ room temperature loss from the 12 V to 1.0 V power loss curve at 25 A , and the 1.35 multiplying factor at $125^{\circ} \mathrm{C}$ ambient. If the $86^{\circ} \mathrm{C}$ ambient temperature is subtracted from the $120^{\circ} \mathrm{C}$ junction temperature, then the difference of $34^{\circ} \mathrm{C}$ divided 5.5 W equals a $6.2^{\circ} \mathrm{C} / \mathrm{W} \Theta_{\mathrm{JA}}$ thermal resistance. Table 2 specifies a $7^{\circ} \mathrm{C} / \mathrm{W}$ value which is pretty close. The airflow graphs are more accurate due to the fact that the ambient temperature environment is controlled better with airflow. As an example in Figure 21, the load current is derated to $\sim 30 \mathrm{~A}$ at $\sim 72^{\circ} \mathrm{C}$ with 200LFM of airflow and the power loss for the 12 V to 1.5 V at 30 A output is a $\sim 7.9 \mathrm{~W}$ loss. The 7.9 W loss is calculated with the $\sim 5.9 \mathrm{~W}$ room temperature loss from the 12 V to 1.5 V power loss curve at 22A, and the 1.35 multiplying factor at $125^{\circ} \mathrm{C}$ ambient. If the $72^{\circ} \mathrm{C}$ ambient temperature is subtracted from the $120^{\circ} \mathrm{C}$ junction temperature, then the difference of $48^{\circ} \mathrm{C}$ divided 7.9 W equals a $6.0^{\circ} \mathrm{C} / \mathrm{W}$ $\theta_{\mathrm{JA}}$ thermal resistance. Table 2 specifies a $6.0^{\circ} \mathrm{C} / \mathrm{W}$ value which is pretty close. Tables 2 and 3 provide equivalent thermal resistances for 1.0 V and 1.5 V outputs with and without airflow and heat sinking.

The derived thermal resistances in Tables 2 and 3 for the various conditions can be multiplied by the calculated power loss as a function of ambient temperature to derive temperature rise above ambient, thus maximum junction temperature. Roomtemperature power loss can be derived from the efficiency curves and adjusted with the above ambient temperature multiplicative factors. The printed circuit board is a 1.6 mm thick four layer board with two ounce copper for the two outer layers and one ounce copper for the two inner layers. The PCB dimensions are $101 \mathrm{~mm} \times 114 \mathrm{~mm}$. The BGA heat sinks are listed in Table 3.

## Layout Checklist/Example

The high integration of LTM4630-1 makes the PCB board layout very simple and easy. However, to optimize its electrical and thermal performance, some layout considerations are still necessary.

- Use large PCB copper areas for high current paths, including $\mathrm{V}_{\text {IN }}, ~ G N D, \mathrm{~V}_{\text {OUT1 }}$ and $\mathrm{V}_{\text {OUT2 }}$. It helps to minimize the PCB conduction loss and thermal stress.
- Place high frequency ceramic input and output capacitors next to the $\mathrm{V}_{\text {IN }}$, PGND and $\mathrm{V}_{\text {OUT }}$ pins to minimize high frequency noise.
- Place a dedicated power ground layer underneath the unit.
- To minimize the via conduction loss and reduce module thermal stress, use multiple vias for interconnection between top layer and other power layers.
- Do not put via directly on the pad, unless they are capped or plated over.
- Use a separated SGND ground copper area for components connected to signal pins. Connect the SGND to GND underneath the unit.
- For parallel modules, tie the $\mathrm{V}_{0 U T}, \mathrm{~V}_{\mathrm{FB}}$, and COMP pins together. Use an internal layer to closely connect these pins together. The TRACK pin can be tied a common capacitor for regulator soft-start.
- Bring out test points on the signal pins for monitoring.

Figure 14 gives a good example of the recommended layout.

## REVISION HISTORY

| REV | DATE | DESCRIPTION | PAGE NUMBER |
| :---: | :---: | :--- | :---: |
| A | $08 / 15$ | Figure 3: Changed 2500 to 2600 for $1.2 \%$ Total DC Accuracy | 12 |

## PACKAGE PHOTO

## DESIGח RESOURCES

| SUBJECT | DESCRIPTION |
| :---: | :---: |
| $\mu$ Module Design and Manufacturing Resources | Design: Manufacturing: <br> - Selector Guides - Quick Start Guide <br> - Demo Boards and Gerber Files - PCB Design, Assembly and Manufacturing Guidelines <br> - Free Simulation Tools - Package and Board Level Reliability |
| $\mu$ Module Regulator Products Search | 1. Sort table of products by parameters and download the result as a spread sheet. <br> 2. Search using the Quick Power Search parametric table. |
| TechClip Videos | Quick videos detailing how to bench test electrical and thermal performance of $\mu$ Module products. |
| Digital Power System Management | Linear Technology's family of digital power supply management ICs are highly integrated solutions that offer essential functions, including power supply monitoring, supervision, margining and sequencing, and feature EEPROM for storing user configurations and fault logging. |

## RELATGD PARTS

| PART NUMBER | DESCRIPTION | COMMENTS |
| :--- | :--- | :--- |
| LTM4630 | Similar to LTM4630-1B But Without Guaranteed Transient Accuracy | On-board Compensation Circuitry; $\pm 1.5 \%$ Total Output DC <br> Accuracy |
| LTM4644 | Quad Output uModule Regulator | Quad 4A, Configurable Up to 16A |
| LTM4676 | $\mu$ Module Regulator with Digital Telemetry | PMBus Interface, On-Board EEPROM, Dual 13A, Single 26A |
| LTM4606 | Ultralow Noise | Low Ripple, Low EMI for Powering High-Speed I/0, 6A |
| LTM4641 | $\mu$ Module Regulator with Advanced Input and Load Protection | $10 \mathrm{~A}, 4.5 \mathrm{~V} \leq$ VIN $\leq 38 V$, Latchoff Overvoltage Protection, <br> Overvoltage Crowbar, UVLO, etc. |
