

10-Bit, Nonvolatile, Linear-Taper Digital Potentiometers

General Description

The MAX5481–MAX5484 10-bit (1024-tap) nonvolatile, linear-taper, programmable voltage-dividers and variable resistors perform the function of a mechanical potentiometer, but replace the mechanics with a pinconfigurable 3-wire serial SPITM-compatible interface or up/down digital interface. The MAX5481/MAX5482 are 3-terminal voltage-dividers and the MAX5483/MAX5484 are 2-terminal variable resistors.

The MAX5481-MAX5484 feature an internal, non-volatile, electrically erasable programmable read-only memory (EEPROM) that stores the wiper position for initialization during power-up. The 3-wire SPI-compatible serial interface allows communication at data rates up to 7MHz. A pin-selectable up/down digital interface is also available.

The MAX5481–MAX5484 are ideal for applications requiring digitally controlled potentiometers. Two end-to-end resistance values are available ($10k\Omega$ and $50k\Omega$) in a voltage-divider or a variable-resistor configuration (see the *Selector Guide*). The nominal resistor temperature coefficient is $35ppm/^{\circ}C$ end-to-end, and only $5ppm/^{\circ}C$ ratiometric, making these devices ideal for applications requiring low-temperature-coefficient voltage-dividers, such as low-drift, programmable gain-amplifiers.

The MAX5481–MAX5484 operate with either a $\pm 2.7V$ to $\pm 5.25V$ single power supply or $\pm 2.5V$ dual power supplies. These devices consume 400µA (max) of supply current when writing data to the nonvolatile memory and ± 1.0 µA (max) of standby supply current. The MAX5481–MAX5484 are available in a space-saving (3mm x 3mm), 16-pin TQFN, or a 14-pin TSSOP package and are specified over the extended (-40°C to ± 85 °C) temperature range.

Applications

Gain and Offset Low-Drift Programmable Adjustment Gain Amplifiers

LCD Contrast Adjustment Mechanical Potentiometer

Pressure Sensors Replacement

Ordering Information

PART	PIN-PACKAGE	TOP MARK
MAX5481ETE+	16 TQFN-EP*	ACP
MAX5481EUD+	14 TSSOP	_

Note: All devices are specified over the -40°C to +85°C operating temperature range.

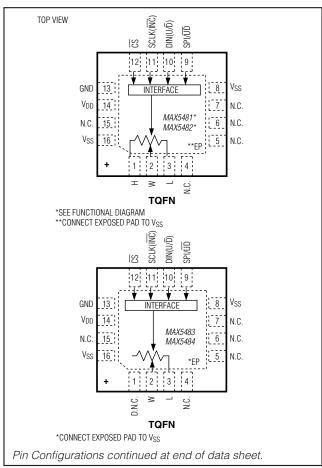

- +Denotes a lead(Pb)-free/RoHS-compliant package.
- *EP = Exposed pad.

Ordering Information continued at end of data sheet.

_____ Features

- ♦ 1024 Tap Positions
- ♦ Power-On Recall of Wiper Position from Nonvolatile Memory
- ♦ 16-Pin (3mm x 3mm x 0.8mm) TQFN or 14-Pin TSSOP Package
- ♦ 35ppm/°C End-to-End Resistance Temperature Coefficient
- ♦ 5ppm/°C Ratiometric Temperature Coefficient
- ♦ 10kΩ and 50kΩ End-to-End Resistor Values
- ♦ Pin-Selectable SPI-Compatible Serial Interface or Up/Down Digital Interface
- ◆ 1µA (max) Standby Current
- ♦ Single +2.7V to +5.25V Supply Operation
- ♦ Dual ±2.5V Supply Operation

Pin Configurations

Selector Guide appears at end of data sheet.

SPI is a trademark of Motorola, Inc.

- Note 1: 100% production tested at $T_A = +25$ °C and $T_A = +85$ °C. Guaranteed by design to $T_A = -40$ °C.
- Note 2: The DNL and INL are measured with the device configured as a voltage-divider with H = V_{DD} and L = V_{SS}. The wiper terminal (W) is unloaded and measured with a high-input-impedance voltmeter.
- **Note 3:** The DNL_R and INL_R are measured with D.N.C. unconnected and L = V_{SS} = 0V. For V_{DD} = +5V, the wiper terminal is driven with a source current of I_W = 80μ A for the $50k\Omega$ device and 400μ A for the $10k\Omega$ device. For V_{DD} = +3V, the wiper terminal is driven with a source current of 40μ A for the $50k\Omega$ device and 200μ A for the $10k\Omega$ device.
- Note 4: The wiper resistance is measured using the source currents given in Note 3.
- Note 5: The device draws higher supply current when the digital inputs are driven with voltages between (V_{DD} 0.5V) and (V_{GND} + 0.5V). See Supply Current vs. Digital Input Voltage in the *Typical Operating Characteristics*.
- Note 6: Wiper settling test condition uses the voltage-divider configuration with a 10pF load on W. Transition code from 00000 00000 to 01111 01111 and measure the time from $\overline{\text{CS}}$ going high to the wiper voltage settling to within 0.5% of its final value.

10-Bit, Nonvolatile, Linear-Taper Digital Potentiometers

Functional Diagrams

10-Bit, Nonvolatile, Linear-Taper Digital Potentiometers

Functional Diagrams (continued)

Detailed Description

The MAX5481/MAX5482 linear programmable voltage-dividers and the MAX5483/MAX5484 variable resistors feature 1024 tap points (10-bit resolution) (see the Functional Diagrams). These devices consist of multiple strings of equal resistor segments with a wiper contact that moves among the 1024 points through a pin-selectable 3-wire SPI-compatible serial interface or up/down interface. The MAX5481/MAX5483 provide a total end-to-end resistance of $10k\Omega$, and the MAX5482/MAX5484 have an end-to-end resistance of $50k\Omega$. The MAX5481/MAX5482 allow access to the high, low, and wiper terminals for a standard voltage-divider configuration.

MAX5481/MAX5482 Programmable Voltage-Dividers

The MAX5481/MAX5482 programmable voltage-dividers provide a weighted average of the voltage between the H and L inputs at the W output. Both devices feature 10-bit resolution and provide up to 1024 tap points between the H and L voltages. Ideally, the V_L voltage occurs at the wiper terminal (W) when all data bits are zero and the V_H voltage occurs at the wiper terminal when all data bits are one. The step size (1 LSB) voltage is equal to the voltage applied across terminals H and L divided by 2^{10} . Calculate the wiper voltage V_W as follows:

$$V_W(D) = D \left[\frac{V_{HL-} \left(|V_{FSE}| + |V_{ZSE}| \right)}{1023} \right] + V_L + |V_{ZSE}|$$

10-Bit, Nonvolatile, Linear-Taper Digital Potentiometers

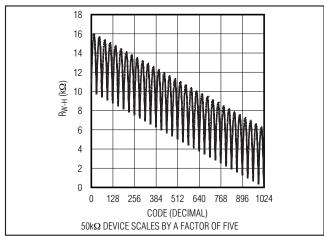

Figure 1. Resistance from W to H vs. Code (10k Ω Voltage-Divider)

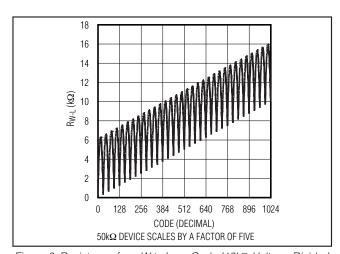

Figure 2. Resistance from W to L vs. Code (10k Ω Voltage-Divider)

where D is the decimal equivalent of the 10 data bits written (0 to 1023), V_{HL} is the voltage difference between the H and L terminals:

$$V_{FSE} = FSE \left[\frac{V_{HL}}{1024} \right]$$
, and $V_{ZSE} = ZSE \left[\frac{V_{HL}}{1024} \right]$

The MAX5481 includes a total end-to-end resistance value of $10k\Omega$ while the MAX5482 features an end-to-end resistance value of $50k\Omega$. These devices are not intended to be used as a variable resistor. Wiper current creates a nonlinear voltage drop in series with the wiper. To ensure temperature drift remains within specifications, do not pull current through the voltage-divider wiper. Connect the wiper to a high-impedance node. Figures 1 and 2 show the behavior of the MAX5481's resistance from W to H and from W to L. This does not apply to the variable-resistor devices

MAX5483/MAX5484 Variable Resistors

The MAX5483/MAX5484 provide a programmable resistance between W and L. The MAX5483 features a total end-to-end resistance value of $10k\Omega$, while the MAX5484 provides an end-to-end resistance value of $50k\Omega$. The programmable resolution of this resistance is equal to the nominal end-to-end resistance divided by 1024 (10-bit resolution). For example, each nominal segment resistance is 9.8Ω and 48.8Ω for the MAX5483 and the MAX5484, respectively.

Table 1. RwL at Selected Codes

CODE (DECIMAL)	MAX5483 (10kΩ DEVICE)	MAX5484 (50kΩ DEVICE)
(BEGINIAE)	R_{WL} (Ω)	R _{WL} (Ω)
0	70	110
1	80	160
512	5070	25,110
1023	10,070	50,110

The 10-bit data in the 10-bit latch register selects a wiper position from the 1024 possible positions, resulting in 1024 values for the resistance from W to L. Calculate the resistance from W to L (RwL) by using the following formula:

$$R_{WL}(D) = \frac{D}{1023} \times R_{W-L} + R_{Z}$$

where D is decimal equivalent of the 10 data bits written, Rw-L is the nominal end-to-end resistance, and Rz is the zero-scale error. Table 1 shows the values of RwL at selected codes for the MAX5483/MAX5484.

Digital Interface

Configure the MAX5481–MAX5484 by a pin-selectable, 3-wire, SPI-compatible serial data interface or an up/down interface. Drive SPI/UD high to select the 3-wire SPI-compatible interface. Pull SPI/UD low to select the up/down interface.

10-Bit, Nonvolatile, Linear-Taper Digital Potentiometers

^{*}D9 is the MSB and D0 is the LSB.

X = Don't care.

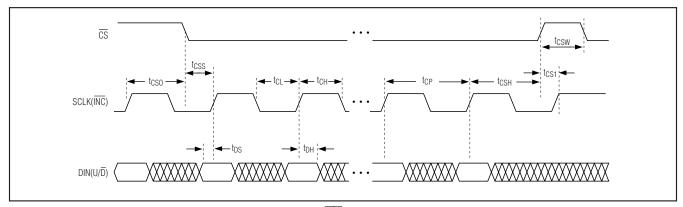

Figure 3. SPI-Compatible Serial-Interface Timing Diagram (SPI/UD = 1)

SPI-Compatible Serial Interface

Drive SPI/ \overline{UD} high to enable the 3-wire SPI-compatible serial interface (see Figure 3). This write-only interface contains three inputs: chip select (\overline{CS}), data in ($\overline{DIN(U/D)}$), and data clock ($\overline{SCLK(INC)}$). Drive \overline{CS} low to load the data at $\overline{DIN(U/D)}$ synchronously into the shift register on each $\overline{SCLK(INC)}$ rising edge.

The WRITE command (C1, C0 = 00) requires 24 clock cycles to transfer the command and data (Figure 4a). The COPY commands (C1, C0 = 10 or 11) use either eight clock cycles to transfer the command bits (Figure 4b) or 24 clock cycles with the last 16 data bits disregarded by the device.

After loading the data into the shift register, drive $\overline{\text{CS}}$ high to latch the data into the appropriate control register. Keep $\overline{\text{CS}}$ low during the entire serial data stream to avoid corruption of the data. Table 2 shows the command decoding.

Write Wiper Register

Data written to this register (C1, C0 = 00) controls the wiper position. The 10 data bits (D9–D0) indicate the position of the wiper. For example, if $DIN(U/\overline{D}) = 00\,0000\,0000$, the wiper moves to the position closest to L. If $DIN(U/\overline{D}) = 11\,1111\,1111$, the wiper moves closest to H.

This command writes data to the volatile random access memory (RAM), leaving the NV register unchanged. When the device powers up, the data stored in the NV register transfers to the wiper register, moving the wiper to the stored position. Figure 5 shows how to write data to the wiper register.

10-Bit, Nonvolatile, Linear-Taper Digital Potentiometers

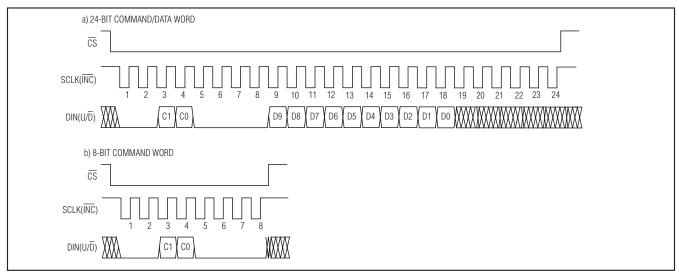

Figure 4. Serial SPI-Compatible Interface Format

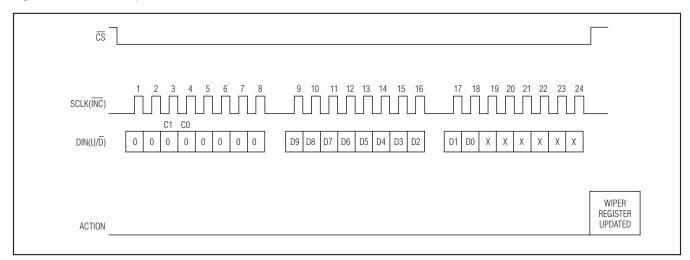

Figure 5. Write Wiper Register Operation

10-Bit, Nonvolatile, Linear-Taper Digital Potentiometers

Table 3. Truth Table

cs	DIN(U/D)	SCLK(INC)	W
L	L	\	Decrement
L	Н	\downarrow	Increment
L	X	1	No Change
Н	X	X	No Change
\downarrow	X	X	No Change
1	Χ	L	Position Not Stored
1	Χ	Н	Position Stored

↑ = Low-to-high transition.

 \downarrow = High-to-low transition.

X = Don't care.

Copy Wiper Register to NV Register

The copy wiper register to NV register command (C1, C0 = 10) stores the current position of the wiper to the NV register for use at power-up. Figure 6 shows how to copy data from wiper register to NV register. The operation takes up to 12ms (max) after \overline{CS} goes high to complete and no other operation should be performed until completion.

Copy NV Register to Wiper Register

The copy NV register to wiper register (C1, C0 = 11) restores the wiper position to the current value stored in the NV register. Figure 7 shows how to copy data from the NV register to the wiper register.

Digital Up/Down Interface

Figure 8 illustrates an up/down serial-interface timing diagram. In digital up/down interface mode (SPI/ \overline{UD} = 0), the logic inputs \overline{CS} , DIN(U/ \overline{D}), and SCLK(INC) control the wiper position and store it in nonvolatile memory (see Table 3). The chip-select (\overline{CS}) input enables the serial interface when low and disables the interface when high. The position of the wiper is stored in the nonvolatile register when \overline{CS} transitions from low to high while SCLK(\overline{INC}) is high.

When the serial interface is active $(\overline{CS} \text{ low})$, a high-to-low (falling edge) transition on SCLK(\overline{INC}) increments or decrements the internal 10-bit counter depending on the state of $\overline{DIN(U/\overline{D})}$. If $\overline{DIN(U/\overline{D})}$ is high, the wiper increments. If $\overline{DIN(U/\overline{D})}$ is low, the wiper decrements.

The device stores the value of the wiper position in the nonvolatile memory when $\overline{\text{CS}}$ transitions from low to high while $\text{SCLK}(\overline{\text{INC}})$ is high. The host system can disable

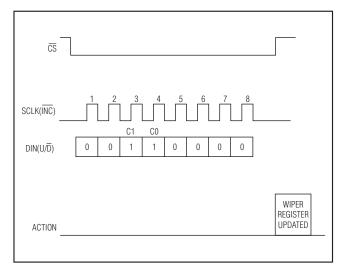

Figure 7. Copy NV Register to Wiper Register Operation

the serial interface and deselect the device without storing the latest wiper position in the nonvolatile memory by keeping SCLK(INC) low while taking CS high.

Upon power-up, the MAX5481–MAX5484 load the value of nonvolatile memory into the wiper register, and set the wiper position to the value last stored.

10-Bit, Nonvolatile, Linear-Taper Digital Potentiometers

Standby Mode

The MAX5481–MAX5484 feature a low-power standby mode. When the device is not being programmed, it enters into standby mode and supply current drops to 0.5µA (typ).

Nonvolatile Memory

The internal EEPROM consists of a nonvolatile register that retains the last value stored prior to power-down. The nonvolatile register is programmed to midscale at the factory. The nonvolatile memory is guaranteed for 50 years of wiper data retention and up to 200,000 wiper write cycles.

Power-Up

Upon power-up, the MAX5481–MAX5484 load the data stored in the nonvolatile wiper register into the volatile wiper register, updating the wiper position with the data stored in the nonvolatile wiper register.

Applications Information

The MAX5481–MAX5484 are ideal for circuits requiring digitally controlled adjustable resistance, such as LCD contrast control (where voltage biasing adjusts the display contrast), or programmable filters with adjustable gain and/or cutoff frequency.

Positive LCD Bias Control

Figures 9 and 10 show an application where a voltagedivider or a variable resistor is used to make an adjustable, positive LCD-bias voltage. The op amp provides buffering and gain to the voltage-divider network made by the programmable voltage-divider (Figure 9) or to a fixed resistor and a variable resistor (see Figure 10).

Programmable Gain and Offset AdjustmentFigure 11 shows an application where a voltage-divider and a variable resistor are used to make a programmable gain and offset adjustment.

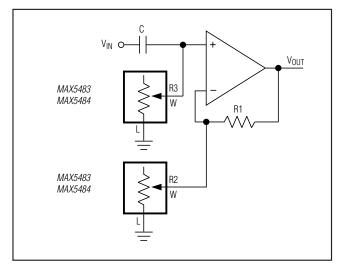

Figure 12. Programmable Filter

Programmable Filter

Figure 12 shows the configuration for a 1st-order programmable filter using two variable resistors. Adjust R2 for the gain and adjust R3 for the cutoff frequency. Use the following equations to estimate the gain (G) and the 3dB cutoff frequency (f_C):

$$G = 1 + \left(\frac{R1}{R2}\right)$$

$$f_C = \frac{1}{2\pi \times R3 \times C}$$
