build-date: 2021-01-04

build-version: githash: 1f2b413-dirty (pico-sdk: 04605c3-clean pico-examples: cc4c1c7-clean)

IP Contributors

Intellectual property from the following companies was used in RP2040:

- [ARM Limited](#) (M0+, UART, SPI)
- [Synopsys, Inc.](#) (I2C, SSI)
- [Taiwan Semiconductor Manufacturing Company Limited](#) (TSMC) (standard cells, memories)
- [Dolphin Design SAS](#) (Voltage Regulator, Power-on Reset/Brown-out Detector)
- [Aragio Solutions](#) (GPIO and Crystal Pad library)
- [Silicon Creations](#) (PLL)
- [GF Micro](#) (ADC, TS, USB PHY)

Legal Disclaimer Notice

TECHNICAL AND RELIABILITY DATA FOR RASPBERRY PI PRODUCTS (INCLUDING DATASHEETS) AS MODIFIED FROM TIME TO TIME ("RESOURCES") ARE PROVIDED BY RASPBERRY PI (TRADING) LTD ("RPTL") "AS IS" AND ANY EXPRESS OR IMPLIED WARRANTIES, INCLUDING, BUT NOT LIMITED TO, THE IMPLIED WARRANTIES OF MERCHANTABILITY AND FITNESS FOR A PARTICULAR PURPOSE ARE DISCLAIMED. TO THE MAXIMUM EXTENT PERMITTED BY APPLICABLE LAW IN NO EVENT SHALL RPTL BE LIABLE FOR ANY DIRECT, INDIRECT, INCIDENTAL, SPECIAL, EXEMPLARY, OR CONSEQUENTIAL DAMAGES (INCLUDING, BUT NOT LIMITED TO, PROCUREMENT OF SUBSTITUTE GOODS OR SERVICES; LOSS OF USE, DATA, OR PROFITS; OR BUSINESS INTERRUPTION) HOWEVER CAUSED AND ON ANY THEORY OF LIABILITY, WHETHER IN CONTRACT, STRICT LIABILITY, OR TORT (INCLUDING NEGLIGENCE OR OTHERWISE) ARISING IN ANY WAY OUT OF THE USE OF THE RESOURCES, EVEN IF ADVISED OF THE POSSIBILITY OF SUCH DAMAGE.

RPTL reserves the right to make any enhancements, improvements, corrections or any other modifications to the RESOURCES or any products described in them at any time and without further notice.

The RESOURCES are intended for skilled users with suitable levels of design knowledge. Users are solely responsible for their selection and use of the RESOURCES and any application of the products described in them. User agrees to indemnify and hold RPTL harmless against all liabilities, costs, damages or other losses arising out of their use of the RESOURCES.

RPTL grants users permission to use the RESOURCES solely in conjunction with the Raspberry Pi products. All other use of the RESOURCES is prohibited. No licence is granted to any other RPTL or other third party intellectual property right.

HIGH RISK ACTIVITIES. Raspberry Pi products are not designed, manufactured or intended for use in hazardous environments requiring fail safe performance, such as in the operation of nuclear facilities, aircraft navigation or communication systems, air traffic control, weapons systems or safety-critical applications (including life support systems and other medical devices), in which the failure of the products could lead directly to death, personal injury or severe physical or environmental damage ("High Risk Activities"). RPTL specifically disclaims any express or implied warranty of fitness for High Risk Activities and accepts no liability for use or inclusions of Raspberry Pi products in High Risk Activities.

Raspberry Pi products are provided subject to RPTL's [Standard Terms](#). RPTL's provision of the RESOURCES does not expand or otherwise modify RPTL's [Standard Terms](#) including but not limited to the disclaimers and warranties expressed in them.

1. Introduction	15
1.1. Why is the chip called RP2040?	15
1.2. Summary	15
1.3. The Chip	16
1.4. Pinout Reference	16
1.4.1. Pin Locations	17
1.4.2. Pin Descriptions	17
1.4.3. GPIO Functions	18
2. System Description	21
2.1. Bus Fabric	21
2.1.1. AHB-Lite Crossbar	22
2.1.1.1. Bus Priority	22
2.1.1.2. Bus Performance Counters	23
2.1.2. Atomic Register Access	24
2.1.3. APB Bridge	24
2.1.4. Narrow IO Register Writes	24
2.1.5. List of Registers	25
2.2. Address Map	28
2.2.1. Summary	28
2.2.2. Detail	29
2.3. Processor subsystem	31
2.3.1. SIO	31
2.3.1.1. CPUID	32
2.3.1.2. GPIO Control	32
2.3.1.3. Hardware Spinlocks	34
2.3.1.4. Inter-processor FIFOs (Mailboxes)	34
2.3.1.5. Integer Divider	35
2.3.1.6. Interpolator	36
2.3.1.6.1. Lane Operations	37
2.3.1.6.2. Blend Mode	40
2.3.1.6.3. Clamp Mode	42
2.3.1.6.4. Sample Use Case: Linear Interpolation	43
2.3.1.6.5. Sample Use Case: Simple Affine Texture Mapping	44
2.3.1.7. List of Registers	46
2.3.2. Interrupts	75
2.3.3. Event Signals	75
2.3.4. Debug	76
2.3.4.1. Software control of SWD pins	76
2.3.4.2. Rescue DP	76
2.4. Cortex-M0+	77
2.4.1. Features	77
2.4.1.1. Interfaces	77
2.4.1.2. Configuration	78
2.4.1.3. ARM architecture	78
2.4.2. Functional Description	78
2.4.2.1. Overview	78
2.4.2.2. Features	79
2.4.2.3. NVIC features	79
2.4.2.4. Debug features	79
2.4.2.4.1. Debug Access Port	80
2.4.2.5. MPU features	80
2.4.2.6. AHB-Lite interface	80

2.4.2.7. Single-cycle I/O port	80
2.4.2.8. Power Management Unit	80
2.4.2.8.1. Power Management	81
2.4.2.8.2. Wait For Event and Send Event	81
2.4.2.8.3. Wait For Interrupt	82
2.4.2.8.4. Wakeup Interrupt Controller	82
2.4.2.9. Reset Control	82
2.4.3. Programmer's model	83
2.4.3.1. About the programmer's model	83
2.4.3.2. Modes of operation and execution	83
2.4.3.3. Instruction set summary	83
2.4.3.4. Memory model	86
2.4.3.5. Processor core registers summary	87
2.4.3.6. Exceptions	87
2.4.3.6.1. Exception handling	87
2.4.4. System control	88
2.4.4.1. System control register summary	88
2.4.4.1.1. CPUID Register	88
2.4.5. NVIC	89
2.4.5.1. About the NVIC	89
2.4.5.1.1. SysTick timer	89
2.4.5.1.2. Low power modes	89
2.4.5.2. NVIC register summary	89
2.4.6. MPU	90
2.4.6.1. About the MPU	90
2.4.6.2. MPU register summary	90
2.4.7. Debug	90
2.4.8. List of Registers	91
2.5. Memory	104
2.5.1. ROM	105
2.5.2. SRAM	105
2.5.2.1. Other On-chip Memory	106
2.5.3. Flash	106
2.5.3.1. XIP Cache	107
2.5.3.2. Cache Flushing and Maintenance	108
2.5.3.3. SSI	108
2.5.3.4. Flash Streaming and Auxiliary Bus Slave	109
2.5.3.5. Performance Counters	109
2.5.3.6. List of XIP Registers	110
2.6. Boot Sequence	113
2.7. Bootrom	113
2.7.1. Bootrom Source	114
2.7.2. Processor Controlled Boot Sequence	114
2.7.2.1. Watchdog Boot	115
2.7.2.2. Flash Boot Sequence	115
2.7.2.3. Flash Second Stage	116
2.7.2.3.1. Checksum	116
2.7.3. Bootrom Contents	116
2.7.3.1. Bootrom Functions	117
2.7.3.1.1. Fast Bit Counting / Manipulation Functions	117
2.7.3.1.2. Fast Bulk Memory Fill / Copy Functions	118
2.7.3.1.3. Flash Access Functions	118
2.7.3.1.4. Debugging Support Functions	119
2.7.3.1.5. Miscellaneous Functions	120
2.7.3.2. Fast Floating Point Library	120
2.7.3.2.1. Implementation Details	120
2.7.3.2.2. Functions	121
2.7.3.3. Bootrom Data	127
2.7.4. USB Mass Storage Interface	127
2.7.4.1. The RPI-RP2 Drive	128

2.7.4.2. UF2 Format Details	128
2.7.5. USB PICOBOOT Interface	129
2.7.5.1. Identifying The Device	129
2.7.5.2. Identifying The Interface	129
2.7.5.3. Identifying The Endpoints	130
2.7.5.4. PICOBOOT Commands	130
2.7.5.4.1. EXCLUSIVE_ACCESS (0x01)	130
2.7.5.4.2. REBOOT (0x02)	131
2.7.5.4.3. FLASH_ERASE (0x03)	131
2.7.5.4.4. READ (0x84)	132
2.7.5.4.5. WRITE (0x05)	132
2.7.5.4.6. EXIT_XIP (0x06)	132
2.7.5.4.7. ENTER_XIP (0x07)	132
2.7.5.4.8. EXEC (0x08)	133
2.7.5.4.9. VECTORIZE_FLASH (0x09)	133
2.7.5.5. Control Requests	134
2.7.5.5.1. INTERFACE_RESET (0x41)	134
2.7.5.5.2. GET_COMMAND_STATUS (0x42)	134
2.8. Power Supplies	135
2.8.1. Digital IO Supply (IOVDD)	135
2.8.2. Digital Core Supply (DVDD)	136
2.8.3. On-Chip Voltage Regulator Input Supply (VREG_IOVDD)	136
2.8.4. USB PHY Supply (USB_IOVDD)	136
2.8.5. ADC Supply (ADC_IOVDD)	136
2.8.6. Power Supply Sequencing	137
2.8.7. Power Supply Schemes	137
2.8.7.1. Single 3.3V Supply	137
2.8.7.2. External Core Supply	138
2.8.7.3. 1.8V Digital IO with Functional USB and ADC	138
2.8.7.4. Single 1.8V Supply	139
2.9. On-Chip Voltage Regulator	139
2.9.1. Application Circuit	140
2.9.2. Operating Modes	140
2.9.2.1. Normal Operation Mode	140
2.9.2.2. High Impedance Mode	141
2.9.2.3. Shutdown Mode	141
2.9.3. Output Voltage Select	141
2.9.4. Status	141
2.9.5. Current Limit	141
2.9.6. List of Registers	141
2.9.7. Detailed Specifications	144
2.10. Power Control	144
2.10.1. Top-level Clock Gates	144
2.10.2. SLEEP State	145
2.10.3. DORMANT State	145
2.10.4. Memory Power Down	145
2.10.5. Programmer's Model	146
2.10.5.1. Sleep	146
2.10.5.2. Dormant	147
2.11. Chip-Level Reset	147
2.11.1. Overview	147
2.11.2. Power-on Reset	148
2.11.2.1. Detailed Specifications	148
2.11.3. Brown-out Detection	149
2.11.3.1. Detection Enable	149
2.11.3.2. Adjusting the Detection Threshold	150
2.11.3.3. Detailed Specifications	150
2.11.4. Supply Monitor	151
2.11.4.1. Detailed Specifications	151
2.11.5. External Reset	151

2.11.6. Rescue Debug Port Reset	151
2.11.7. Source of Last Reset	151
2.11.8. List of Registers	152
2.12. Power-On State Machine	152
2.12.1. Overview	152
2.12.2. Power On Sequence	152
2.12.3. Register Control	153
2.12.4. Interaction with Watchdog	153
2.12.5. List of registers	153
2.13. Subsystem Resets	156
2.13.1. Overview	156
2.13.2. Programmer's Model	157
2.13.3. Registers	158
2.14. Clocks	160
2.14.1. Overview	160
2.14.2. Clock sources	161
2.14.2.1. Ring Oscillator	161
2.14.2.1.1. Mitigating ROOSC frequency variation due to process	162
2.14.2.1.2. Mitigating ROOSC frequency variation due to voltage	162
2.14.2.1.3. Mitigating ROOSC frequency variation due to temperature	162
2.14.2.1.4. Automatic mitigation of ROOSC frequency variation due to PVT	162
2.14.2.1.5. Automatic overclocking using the ROOSC	163
2.14.2.2. Crystal Oscillator	163
2.14.2.3. External Clocks	163
2.14.2.4. Relaxation Oscillators	164
2.14.2.5. PLLs	164
2.14.3. Clock Generators	164
2.14.3.1. Multiplexers	165
2.14.3.2. Divider	165
2.14.3.3. Duty Cycle Correction	166
2.14.3.4. Clock Enables	166
2.14.3.4.1. Clock Enable Exceptions	166
2.14.3.4.2. System Sleep Mode	167
2.14.4. Frequency Counter	167
2.14.5. Resus	168
2.14.6. Programmer's Model	168
2.14.6.1. Configuring a clock generator	168
2.14.6.2. Using the frequency counter	171
2.14.6.3. Configuring a GPCLK	172
2.14.6.4. Enabling resus	172
2.14.6.5. Configuring sleep mode	172
2.14.7. List of registers	172
2.15. Crystal Oscillator (XOSC)	191
2.15.1. Overview	192
2.15.2. Usage	192
2.15.3. Startup Delay	192
2.15.4. DORMANT mode	192
2.15.5. XOSC COUNTER	193
2.15.6. Programmer's Model	193
2.15.7. List of registers	194
2.16. Ring Oscillator (ROOSC)	197
2.16.1. Overview	197
2.16.2. Frequency Variation	197
2.16.3. Dormant mode	197
2.16.4. Programmer's Model	198
2.16.5. List of registers	198
2.17. PLL	201
2.17.1. Overview	201
2.17.2. Calculating PLL parameters	202
2.17.2.1. Jitter vs Power Consumption	203

2.17.3. Configuration	204
2.17.4. List of registers	206
2.18. GPIO	207
2.18.1. Overview	208
2.18.2. Function Select	209
2.18.3. Interrupts	211
2.18.4. Pads	212
2.18.5. Software Examples	212
2.18.5.1. Select an IO function	213
2.18.5.2. Enable a GPIO interrupt	213
2.18.6. Registers	215
2.18.6.1. IO - User Bank	215
2.18.6.2. IO - QSPI Bank	281
2.18.6.3. Pad Control - User Bank	297
2.18.6.4. Pad Control - QSPI Bank	299
2.19. Sysinfo	301
2.19.1. Overview	301
2.19.2. List Of Registers	301
2.20. Syscfg	302
2.20.1. Overview	302
2.20.2. List of registers	302
3. PIO	306
3.1. Overview	306
3.2. Programmer's Model	307
3.2.1. PIO Programs	307
3.2.2. Control Flow	308
3.2.3. Registers	309
3.2.3.1. Output Shift Register (OSR)	309
3.2.3.2. Input Shift Register (ISR)	310
3.2.3.3. Shift Counters	310
3.2.3.4. Scratch Registers	311
3.2.3.5. FIFOs	311
3.2.4. Stalling	312
3.2.5. Pin Mapping	312
3.2.6. IRQ Flags	312
3.2.7. Interactions Between State Machines	313
3.3. PIO Assembler (pioasm)	313
3.3.1. Usage	313
3.3.2. Directives	314
3.3.3. Values	314
3.3.4. Expressions	315
3.3.5. Comments	315
3.3.6. Labels	315
3.3.7. Instructions	315
3.3.8. Output pass through	316
3.3.9. Language generators	317
3.3.9.1. c-sdk	318
3.3.9.2. python	320
3.3.9.3. hex	322
3.4. Instruction Set	322
3.4.1. Summary	322
3.4.2. JMP	323
3.4.2.1. Encoding	323
3.4.2.2. Operation	323
3.4.2.3. Assembler Syntax	323
3.4.3. WAIT	324
3.4.3.1. Encoding	324
3.4.3.2. Operation	324
3.4.3.3. Assembler Syntax	325
3.4.4. IN	325

3.4.4.1. Encoding	325
3.4.4.2. Operation	325
3.4.4.3. Assembler Syntax	326
3.4.5. OUT	326
3.4.5.1. Encoding	326
3.4.5.2. Operation	326
3.4.5.3. Assembler Syntax	327
3.4.6. PUSH	327
3.4.6.1. Encoding	327
3.4.6.2. Operation	327
3.4.6.3. Assembler Syntax	327
3.4.7. PULL	328
3.4.7.1. Encoding	328
3.4.7.2. Operation	328
3.4.7.3. Assembler Syntax	328
3.4.8. MOV	328
3.4.8.1. Encoding	328
3.4.8.2. Operation	329
3.4.8.3. Assembler Syntax	329
3.4.9. IRQ	330
3.4.9.1. Encoding	330
3.4.9.2. Operation	330
3.4.9.3. Assembler Syntax	330
3.4.10. SET	331
3.4.10.1. Encoding	331
3.4.10.2. Operation	331
3.4.10.3. Assembler Syntax	331
3.5. Functional Details	332
3.5.1. Side-set	332
3.5.2. Program Wrapping	333
3.5.3. FIFO Joining	334
3.5.4. Autopush and Autopull	335
3.5.4.1. Autopush Details	338
3.5.4.2. Autopull Details	338
3.5.5. Clock Dividers	339
3.5.6. GPIO Mapping	340
3.5.6.1. Output Priority	341
3.5.6.2. Input Mapping	341
3.5.6.3. Input Synchronisers	341
3.5.7. Forced and EXEC'd Instructions	342
3.6. Examples	343
3.6.1. Duplex SPI	343
3.6.2. WS2812 LEDs	347
3.6.3. UART TX	350
3.6.4. UART RX	352
3.6.5. Manchester Serial TX and RX	355
3.6.6. Differential Manchester (BMC) TX and RX	357
3.6.7. Addition	360
3.7. Outdated Examples	361
3.7.1. UART with CTSn and RTSn	362
3.7.2. PWM (4 varieties)	362
3.7.3. I2C	364
3.7.4. I2S	366
3.7.5. IRDA Receiver	366
3.7.6. APA102 LEDs	367
3.8. List of Registers	368
4. Peripherals	381
4.1. USB	381
4.1.1. Overview	381
4.1.1.1. Features	381

4.1.1.1.1. Device Mode	381
4.1.1.1.2. Host Mode	381
4.1.2. Architecture	381
4.1.2.1. USB PHY	382
4.1.2.2. Line state detection	382
4.1.2.3. Serial RX Engine	382
4.1.2.4. Serial TX Engine	383
4.1.2.5. DPSRAM	383
4.1.2.5.1. Layout	383
4.1.2.5.2. Endpoint control register	385
4.1.2.5.3. Buffer control register	386
4.1.2.6. Device Controller	386
4.1.2.6.1. SETUP	387
4.1.2.6.2. IN	387
4.1.2.6.3. OUT	387
4.1.2.6.4. Suspend and Resume	388
4.1.2.6.5. Errata	388
4.1.2.7. Host Controller	388
4.1.2.7.1. SETUP	389
4.1.2.7.2. IN	389
4.1.2.7.3. OUT	390
4.1.2.7.4. Interrupt Endpoints	390
4.1.2.8. VBUS Control	391
4.1.3. Programmer's Model	391
4.1.3.1. TinyUSB	391
4.1.3.2. Standalone device example	391
4.1.3.2.1. Device controller initialisation	392
4.1.3.2.2. Configuring the endpoint control registers for EP1 and EP2	393
4.1.3.2.3. Receiving a setup packet	393
4.1.3.2.4. Replying to a setup packet on EP0 IN	394
4.1.4. List of Registers	395
References	413
4.2. DMA	413
4.2.1. Configuring Channels	414
4.2.1.1. Read and Write Addresses	414
4.2.1.2. Transfer Count	415
4.2.1.3. Control/Status	415
4.2.2. Starting Channels	416
4.2.2.1. Aliases and Triggers	416
4.2.2.2. Chaining	417
4.2.2.3. Null Triggers and Chain Interrupts	417
4.2.3. Data Request (DREQ)	417
4.2.3.1. System DREQ Table	418
4.2.3.2. Credit-based DREQ Scheme	418
4.2.4. Interrupts	419
4.2.5. Additional Features	419
4.2.5.1. Pacing Timers	419
4.2.5.2. CRC Calculation	419
4.2.5.3. Channel Abort	420
4.2.5.4. Debug	420
4.2.6. Example Use Cases	420
4.2.7. List of Registers	420
4.3. UART	439
4.3.1. Overview	440
4.3.2. Functional description	440
4.3.2.1. AMBA APB interface	441
4.3.2.2. Register block	441
4.3.2.3. Baud rate generator	441
4.3.2.4. Transmit FIFO	441
4.3.2.5. Receive FIFO	441

4.3.2.6. Transmit logic	442
4.3.2.7. Receive logic	442
4.3.2.8. Interrupt generation logic	442
4.3.2.9. DMA interface	442

Chapter 1. Introduction

RP2040 is a low cost microcontroller device with the quality, cost and simplicity of the Raspberry Pi. Much like the Raspberry Pi is an accessible computer, the RP2040 is an accessible chip with everything you need to build a product.

The RP2040 is supported with both C/C++ and MicroPython cross-platform development environments, including easy access to runtime debugging. It has UF2 boot and floating-point routines baked into the chip. The in-built USB can act as both device and host. It has two symmetric processor cores and high internal bandwidth, making it useful for signal processing and video. The chip has a large amount of internal RAM but uses external flash, allowing you to choose how much memory you need.

1.1. Why is the chip called RP2040?

The post-fix numeral on RP2040 comes from the following,

1. Number of processor cores (2)
2. Loosely which type of processor (M0+)
3. $\text{floor}(\log_2(\text{ram} / 16\text{k}))$
4. $\text{floor}(\log_2(\text{nonvolatile} / 16\text{k}))$ or 0 if no onboard nonvolatile storage

see [Figure 1](#).

Figure 1. An explanation for the name of the RP2040 chip.

1.2. Summary

RP2040 is a low-cost, high-performance microcontroller device with flexible digital interfaces. Key features:

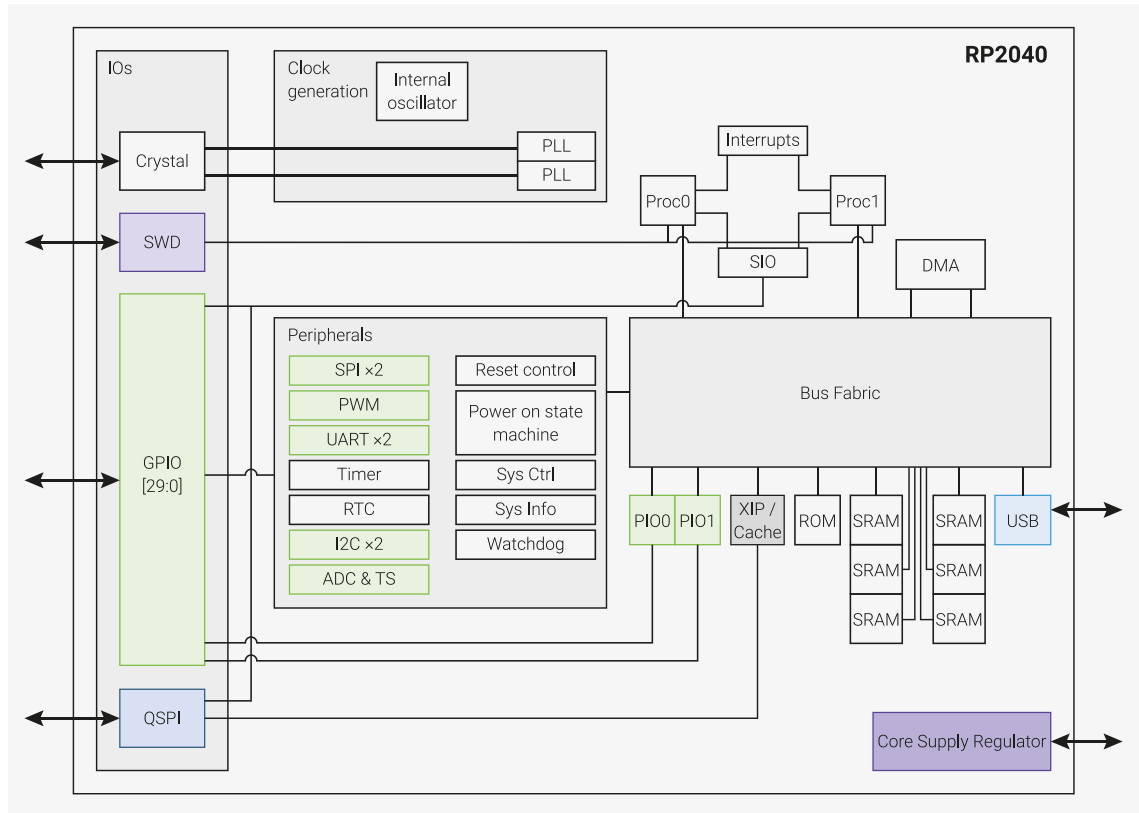

- Dual Cortex M0+ processor cores, up to 133 MHz
- 264 kB of embedded SRAM in 6 banks
- 30 multifunction GPIO
- 6 dedicated IO for SPI Flash (supporting XIP)
- Dedicated hardware for commonly used peripherals
- Programmable IO for extended peripheral support
- 4 channel ADC with internal temperature sensor, 0.5 MSa/s, 12 bit conversion

- USB 1.1 Host/Device

1.3. The Chip

RP2040 has a dual M0+ processor cores, DMA, internal memory and peripheral blocks connected via AHB/APB bus fabric.

Figure 2. A system overview of the RP2040 chip

Code may be executed directly from external memory through a dedicated SPI, DSPI or QSPI interface. A small cache improves performance for typical applications.

Debug is available via the SWD interface.

Internal SRAM is arranged in banks which can contain code or data and is accessed via dedicated AHB bus fabric connections, allowing bus masters to access separate bus slaves without being stalled.

DMA bus masters are available to offload repetitive data transfer tasks from the processors.

GPIO pins can be driven directly, or from a variety of dedicated logic functions.

Dedicated hardware for fixed functions such as SPI, I2C, UART.

Flexible configurable PIO controllers can be used to provide a wide variety of IO functions.

A USB controller with embedded PHY can be used to provide FS/LS Host or Device connectivity under software control.

Four ADC inputs which are shared with GPIO pins.

Two PLLs to provide a fixed 48MHz clock for USB or ADC, and a flexible system clock up to 133MHz.

An internal Voltage Regulator to supply the core voltage so the end product only needs supply the IO voltage.

1.4. Pinout Reference

This section provides a quick reference for pinout and pin functions. Full details, including electrical specifications and

package drawings, can be found in [Chapter 5](#).

1.4.1. Pin Locations

Figure 3. RP2040 Pinout for QFN-56 7x7mm (reduced ePad size)

1.4.2. Pin Descriptions

Table 1. The function of each pin is briefly described here. Full electrical specifications can be found in [Chapter 5](#).

Name	Description
GPIOx	General-purpose digital input and output. RP2040 can connect one of a number of internal peripherals to each GPIO, or control GPIOs directly from software.
GPIOx/ADCy	General-purpose digital input and output, with analogue-to-digital converter function. The RP2040 ADC has an analogue multiplexer which can select any one of these pins, and sample the voltage.
QSPIx	Interface to a SPI, Dual-SPI or Quad-SPI flash device, with execute-in-place support. These pins can also be used as software-controlled GPIOs, if they are not required for flash access.
USB_DM and USB_DP	USB controller, supporting Full Speed device and Full/Low Speed host. A 27Ω series termination resistor is required on each pin, but bus pullups and pulldowns are provided internally.
XIN and XOUT	Connect a crystal to RP2040's crystal oscillator. XIN can also be used as a single-ended CMOS clock input, with XOUT disconnected. The USB bootloader requires a 12 MHz crystal or 12 MHz clock input.
RUN	Global asynchronous reset pin. Reset when driven low, run when driven high. If no external reset is required, this pin can be tied directly to IOVDD.
SWCLK and SWDIO	Access to the internal Serial Wire Debug multi-drop bus. Provides debug access to both processors, and can be used to download code.

Name	Description
TESTEN	Factory test mode pin. Tie to GND.
GND	Single external ground connection, bonded to a number of internal ground pads on the RP2040 die.
IOVDD	Power supply for digital GPIOs, nominal voltage 1.8 V to 3.3 V
USB_IOVDD	Power supply for internal USB Full Speed PHY, nominal voltage 3.3 V
ADC_IOVDDD	Power supply for analogue-to-digital converter, nominal voltage 3.3 V
VREG_IOVDD	Power input for the internal core voltage regulator, nominal voltage 1.8 V to 3.3 V
VREG_VOUT	Power output for the internal core voltage regulator, nominal voltage 1.1 V, 100 mA max current
DVDD	Digital core power supply, nominal voltage 1.1 V. Can be connected to VREG_VOUT, or to some other board-level power supply.

1.4.3. GPIO Functions

General Purpose Input/Output (GPIO) Bank 0 Functions

Each individual GPIO pin can be connected to an internal peripheral via the GPIO functions defined below. Some internal peripherals appear in multiple places to allow some flexibility. SIO, PIO0 and PIO1 can connect to all GPIO pins.

	Function								
GPIO	F1	F2	F3	F4	F5	F6	F7	F8	F9
0	SPI0 RX	UART0 TX	I2C0 SDA	PWM0 A	SIO	PIO0	PIO1		USB OVCUR DET

26	SPI1 SCK	UART1 CTS	I2C1 SDA	PWM5 A	SIO	PI00	PI01		USB VBUS EN
27	SPI1 TX	UART1 RTS	I2C1 SCL	PWM5 B	SIO	PI00	PI01		USB OVCUR DET
28	SPI1 RX	UART0 TX	I2C0 SDA	PWM6 A	SIO	PI00	PI01		USB VBUS DET
29	SPI1 CSn	UART0 RX	I2C0 SCL	PWM6 B	SIO	PI00	PI01		USB VBUS EN

Table 2. GPIO bank 0 function descriptions

Function Name	Description
SPIx	Connect one of the internal PL022 SPI peripherals to GPIO
UARTx	Connect one of the internal PL011 UART peripherals to GPIO
I2Cx	Connect one of the internal DW I2C peripherals to GPIO
PWMx A/B	Connect a PWM slice to GPIO. There are eight PWM slices, each with two output channels (A/B). The B pin can also be used as an input, for frequency and duty cycle measurement.
SIO	Software control of GPIO, from the single-cycle IO (SIO) block. The SIO function (F5) must be selected for the processors to <i>drive</i> a GPIO, but the input is always connected, so software can check the state of GPIOs at any time.
PIOx	Connect one of the programmable IO blocks (PIO) to GPIO. PIO can implement a <i>wide</i> variety of interfaces, and has its own internal pin mapping hardware, allowing flexible placement of digital interfaces on bank 0 GPIOs. The PIO function (F6, F7) must be selected for PIO to <i>drive</i> a GPIO, but the input is always connected, so the PIOs can always see the state of all pins.
CLOCK GPINx	General purpose clock inputs. Can be routed to a number of internal clock domains on RP2040, e.g. to provide a 1 Hz clock for the RTC, or can be connected to an internal frequency counter.
CLOCK GPOUTx	General purpose clock outputs. Can drive a number of internal clocks (including PLL outputs) onto GPIOs, with optional integer divide.
USB OVCUR DET/VBUS DET/VBUS EN	USB power control signals to/from the internal USB controller

Chapter 2. System Description

This chapter describes the RP2040 key system features including processor, memory, how blocks are connected, clocks, resets, power, and IO. Refer to [Figure 2](#) for an overview diagram.

2.1. Bus Fabric

The RP2040 bus fabric routes addresses and data across the chip.

[Figure 4](#) shows the high-level structure of the bus fabric. The main AHB-Lite crossbar routes addresses and data between its 4 upstream ports and 10 downstream ports: up to four bus transfers can take place each cycle. All data paths are 32 bits wide. Memory devices have dedicated ports on the main crossbar, to satisfy their high bandwidth requirements. High-bandwidth AHB-Lite peripherals have a shared port on the crossbar, and an APB bridge provides bus access to system control registers and lower-bandwidth peripherals.

Figure 4. RP2040 bus fabric overview.

The bus fabric connects 4 AHB-Lite masters, i.e. devices which generate addresses:

- Processor core 0
- Processor core 1
- DMA controller Read port
- DMA controller Write port

These are routed through to 10 downstream ports on the main crossbar:

- ROM
- Flash XIP
- SRAM 0 to 5 (one port each)
- Fast AHB-Lite peripherals: PIO0, PIO1, USB, DMA control registers, XIP aux (one shared port)
- Bridge to all APB peripherals, and system control registers

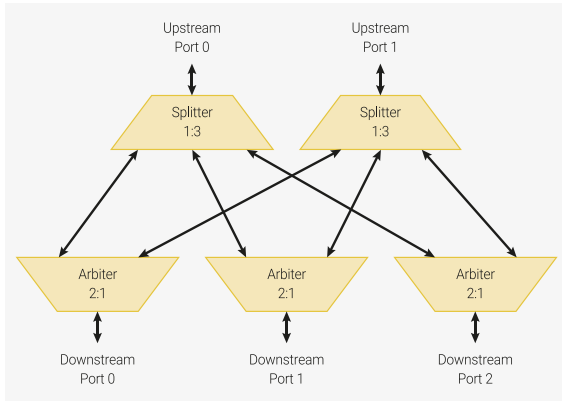

The four bus masters can access any four *different* crossbar ports simultaneously, the bus fabric does not add wait states to any AHB-Lite slave access. So at a system clock of 125 MHz the maximum sustained bus bandwidth is 2.0

GB/s. The system address map has been arranged to make this parallel bandwidth available to as many software use cases as possible – for example, the striped SRAM alias (SRAM) scatters main memory accesses across four crossbar ports (SRAM0...3), so that more memory accesses can proceed in parallel.

2.1.1. AHB-Lite Crossbar

At the centre of the RP2040 bus fabric is a 4:10 fully-connected crossbar. Its 4 upstream ports are connected to the 4 system bus masters, and the 10 downstream ports connect to the highest-bandwidth AHB-Lite slaves (namely the memory interfaces) and to lower layers of the fabric. Figure 5 shows the structure of a 2:3 AHB-Lite crossbar, arranged identically to the 4:10 crossbar on RP2040, but easier to show in the diagram.

Figure 5. A 2:3 AHB-Lite crossbar. Each upstream port connects to a splitter, which routes bus requests toward one of the 3 downstream ports, and routes responses back. Each downstream port connects to an arbiter, which safely manages concurrent access to the port.

The crossbar is built from two components:

- Splitters
 - Perform coarse address decode
 - Route requests (addresses, write data) to the downstream port indicated by the initial address decode
 - Route responses (read data, bus errors) from the correct arbiter back to the upstream port
- Arbiters
 - Manage concurrent requests to a downstream port
 - Route responses (read data, bus errors) to the correct splitter
 - Implement bus priority rules

The main crossbar on RP2040 consists of 4 1:10 splitters and 10 4:1 arbiters, with a mesh of 40 AHB-Lite bus channels between them. Note that, as AHB-Lite is a pipelined bus, the splitter may be routing back a response to an earlier request from downstream port A, whilst a new request to downstream port B is already in progress. This does not incur any cycle penalty.

2.1.1.1. Bus Priority

The arbiters in the main AHB-Lite crossbar implement a two-level bus priority scheme. Priority levels are configured per-master, using the `BUS_PRIORITY` register in the `BUSCTRL` register block.

When there are multiple simultaneous accesses to same arbiter, any requests from high-priority masters (priority level 1) will be considered before any requests from low-priority masters (priority 0). If multiple masters of the same priority level attempt to access the same slave simultaneously, a round-robin tie break is applied, i.e. the arbiter grants access to each master in turn.

NOTE

Priority arbitration only applies to multiple masters attempting to access the **same** slave on the same cycle. Accesses to different slaves, e.g. different SRAM banks, can proceed simultaneously.

When accessing a slave with zero wait states, such as SRAM (i.e. can be accessed once per system clock cycle), high-priority masters will never observe any slowdown or other timing effects caused by accesses from low-priority masters. This allows *guaranteed* latency and throughput for hard real time use cases; it does however mean a low-priority master may get stalled until there is a free cycle.

2.1.1.2. Bus Performance Counters

The performance counters automatically count accesses to the main AHB-Lite crossbar arbiters. This can assist in diagnosing performance issues, in high-traffic use cases.

There are four performance counters. Each is a 24-bit saturating counter. Counter values can be read from `BUSCTRL_PERFCTRx`, and cleared by writing any value to `BUSCTRL_PERFCTRx`. Each counter can count one of the 20 available events at a time, as selected by `BUSCTRL_PERFSELx`. The available bus events are:

PERFSEL _x	Event	Description
0	APB access, contested	Completion of an access to the APB arbiter (which is upstream of all APB peripherals), which was previously delayed due to an access by another master.
1	APB access	Completion of an access to the APB arbiter
2	FASTPERI access, contested	Completion of an access to the FASTPERI arbiter (which is upstream of PIOs, DMA config port, USB, XIP aux FIFO port), which was previously delayed due to an access by another master.
3	FASTPERI access	Completion of an access to the FASTPERI arbiter
4	SRAM5 access, contested	Completion of an access to the SRAM5 arbiter, which was previously delayed due to an access by another master.
5	SRAM5 access	Completion of an access to the SRAM5 arbiter
6	SRAM4 access, contested	Completion of an access to the SRAM4 arbiter, which was previously delayed due to an access by another master.
7	SRAM4 access	Completion of an access to the SRAM4 arbiter
8	SRAM3 access, contested	Completion of an access to the SRAM3 arbiter, which was previously delayed due to an access by another master.
9	SRAM3 access	Completion of an access to the SRAM3 arbiter
10	SRAM2 access, contested	Completion of an access to the SRAM2 arbiter, which was previously delayed due to an access by another master.
11	SRAM2 access	Completion of an access to the SRAM2 arbiter
12	SRAM1 access, contested	Completion of an access to the SRAM1 arbiter, which was previously delayed due to an access by another master.
13	SRAM1 access	Completion of an access to the SRAM1 arbiter
14	SRAM0 access, contested	Completion of an access to the SRAM0 arbiter, which was previously delayed due to an access by another master.
15	SRAM0 access	Completion of an access to the SRAM0 arbiter

PERFSEL x	Event	Description
16	XIP_MAIN access, contested	Completion of an access to the XIP_MAIN arbiter, which was previously delayed due to an access by another master.
17	XIP_MAIN access	Completion of an access to the XIP_MAIN arbiter
18	ROM access, contested	Completion of an access to the ROM arbiter, which was previously delayed due to an access by another master.
19	ROM access	Completion of an access to the ROM arbiter

2.1.2. Atomic Register Access

Each peripheral register block is allocated 4kB of address space, with registers accessed using one of 4 methods, selected by address decode.

- **Addr + 0x0000** : normal read write access
- **Addr + 0x1000** : atomic XOR on write
- **Addr + 0x2000** : atomic bitmask set on write
- **Addr + 0x3000** : atomic bitmask clear on write

This allows individual fields of a control register to be modified without performing a read-modify-write sequence in software: instead the changes are posted to the peripheral, and performed in-situ. Without this capability, it is difficult to safely access IO registers when an interrupt service routine is concurrent with code running in the foreground, or when the two processors are running code in parallel.

The four atomic access aliases occupy a total of 16 kB. Most peripherals on RP2040 provide this functionality natively, and atomic writes have the same timing as normal read/write access. Some peripherals (I2C, UART, SPI and SSI) instead have this functionality added using a bus interposer, which translates upstream atomic writes into downstream read-modify-write sequences, at the boundary of the peripheral. This extends the access time by two system clock cycles.

The SIO (Section 2.3.1), a single-cycle IO block attached directly to the cores' IO ports, does **not** support atomic accesses at the bus level, although some individual registers (e.g. GPIO) have set/clear/xor aliases.

2.1.3. APB Bridge

The APB bridge interfaces the high-speed main AHB-Lite interconnect to the lower-bandwidth peripherals. Whilst the AHB-Lite fabric offers zero-wait-state access everywhere, APB accesses have a cycle penalty:

- APB bus accesses take two cycles minimum (setup phase and access phase)
- The bridge adds an additional cycle to read accesses, as the bus request and response are registered
- The bridge adds **two** additional cycles to write accesses, as the APB setup phase can not begin until the AHB-Lite write data is valid

As a result, the throughput of the APB portion of the bus fabric is somewhat lower than the AHB-Lite portion. However, there is more than sufficient bandwidth to saturate the APB serial peripherals.

2.1.4. Narrow IO Register Writes

Memory-mapped IO registers on RP2040 ignore the width of bus read/write accesses. They treat all writes as though they were 32 bits in size. This means software can not use byte or halfword writes to modify part of an IO register: any write to an address where the 30 address MSBs match the register address will affect the contents of the entire register.

To update part of an IO register, without a read-modify-write sequence, the best solution on RP2040 is atomic

set/clear/XOR (see [Section 2.1.2](#)). Note that this is more flexible than byte or halfword writes, as any combination of fields can be updated in one operation.

Upon a 8-bit or 16-bit write (such as a `strb` instruction on the Cortex-M0+), an IO register will sample the entire 32-bit write databus. The Cortex-M0+ and DMA on RP2040 will always replicate narrow data across the bus:

Pico Examples: https://github.com/raspberrypi/pico-examples/tree/pre_release/system/narrow_io_write/narrow_io_write.c Lines 19 - 60

```

19 int main() {
20     setup_default_uart();
21
22     // We'll use WATCHDOG_SCRATCH0 as a convenient 32 bit read/write register
23     // that we can assign arbitrary values to
24     io_rw_32 *scratch32 = &watchdog_hw->scratch[0];
25     // Alias the scratch register as two halfwords at offsets +0x0 and +0x2
26     volatile uint16_t *scratch16 = (volatile uint16_t *) scratch32;
27     // Alias the scratch register as four bytes at offsets +0x0, +0x1, +0x2, +0x3:
28     volatile uint8_t *scratch8 = (volatile uint8_t *) scratch32;
29
30     // Show that we can read/write the scratch register as normal:
31     printf("Writing 32 bit value\n");
32     *scratch32 = 0xdeadbeef;
33     printf("Should be 0xdeadbeef: 0x%08x\n", *scratch32);
34
35     // We can do narrow reads just fine -- IO registers treat this as a 32 bit
36     // read, and the processor/DMA will pick out the correct byte lanes based
37     // on transfer size and address LSBs
38     printf("\nReading back 1 byte at a time\n");
39     // Little-endian!
40     printf("Should be ef be ad de: %02x %02x %02x %02x\n",
41           scratch8[0], scratch8[1], scratch8[2], scratch8[3]);
42
43     // The Cortex-M0+ and the RP2040 DMA replicate byte writes across the bus,
44     // and IO registers will sample the entire write bus always.
45     printf("\nWriting 8 bit value 0xa5 at offset 0\n");
46     scratch8[0] = 0xa5;
47     // Read back the whole scratch register in one go
48     printf("Should be 0xa5a5a5a5: 0x%08x\n", *scratch32);
49
50     // The IO register ignores the address LSBs [1:0] as well as the transfer
51     // size, so it doesn't matter what byte offset we use
52     printf("\nWriting 8 bit value at offset 1\n");
53     scratch8[1] = 0x3c;
54     printf("Should be 0x3c3c3c3c: 0x%08x\n", *scratch32);
55
56     // Halfword writes are also replicated across the write data bus
57     printf("\nWriting 16 bit value at offset 0\n");
58     scratch16[0] = 0xf00d;
59     printf("Should be 0xf00df00d: 0x%08x\n", *scratch32);
60 }

```

2.1.5. List of Registers

Table 3. List of BUSCTRL registers

Offset	Name	Info
0x00	BUS_PRIORITY	Set the priority of each master for bus arbitration.
0x04	BUS_PRIORITY_ACK	Bus priority acknowledge
0x08	PERFCTRO	Bus fabric performance counter 0

Offset	Name	Info
0x0c	PERFSEL0	Bus fabric performance event select for PERFCTR0
0x10	PERFCTR1	Bus fabric performance counter 1
0x14	PERFSEL1	Bus fabric performance event select for PERFCTR1
0x18	PERFCTR2	Bus fabric performance counter 2
0x1c	PERFSEL2	Bus fabric performance event select for PERFCTR2
0x20	PERFCTR3	Bus fabric performance counter 3
0x24	PERFSEL3	Bus fabric performance event select for PERFCTR3

BUS_PRIORITY Register

Description

Set the priority of each master for bus arbitration.

Table 4.
BUS_PRIORITY
Register

Bits	Name	Description	Type	Reset
31:13	Reserved.	-	-	-
12	DMA_W	0 - low priority, 1 - high priority	RW	0x0
11:9	Reserved.	-	-	-
8	DMA_R	0 - low priority, 1 - high priority	RW	0x0
7:5	Reserved.	-	-	-
4	PROC1	0 - low priority, 1 - high priority	RW	0x0
3:1	Reserved.	-	-	-
0	PROC0	0 - low priority, 1 - high priority	RW	0x0

BUS_PRIORITY_ACK Register

Description

Bus priority acknowledge

Table 5.
BUS_PRIORITY_ACK
Register

Bits	Name	Description	Type	Reset
31:1	Reserved.	-	-	-
0	NONAME	Goes to 1 once all arbiters have registered the new global priority levels. Arbiters update their local priority when servicing a new nonsequential access. In normal circumstances this will happen almost immediately.	RO	0x0

PERFCTR0 Register

Description

Bus fabric performance counter 0

Table 6. PERFCTR0 Register

Bits	Name	Description	Type	Reset
31:24	Reserved.	-	-	-
23:0	NONAME	Busfabric saturating performance counter 0 Count some event signal from the busfabric arbiters. Write any value to clear. Select an event to count using PERFSELO	WC	0x000000

PERFSELO Register

Description

Bus fabric performance event select for PERFCTR0

2.2. Address Map

The address map for the device is split in to sections as shown in [Table 14](#). Details are shown in the following sections. Unmapped address ranges raise a bus error when accessed.

2.2.1. Summary

Table 14. Address Map Summary

ROM	0x00000000
XIP	0x10000000
SRAM	0x20000000

APB Peripherals	0x40000000
AHB-Lite Peripherals	0x50000000
IOPORT Registers	0xd0000000
Cortex-M0+ internal registers	0xe0000000

2.2.2. Detail

ROM:

ROM_BASE	0x00000000
----------	------------

XIP:

XIP_BASE	0x10000000
XIP_NOALLOC_BASE	0x11000000
XIP_NOCACHE_BASE	0x12000000
XIP_NOCACHE_NOALLOC_BASE	0x13000000
XIP_CTRL_BASE	0x14000000
XIP_SRAM_BASE	0x15000000
XIP_SRAM_END	0x15004000
XIP_SSI_BASE	0x18000000

SRAM. SRAM0-3 striped:

SRAM_BASE	0x20000000
SRAM_STRIPED_BASE	0x20000000
SRAM_STRIPED_END	0x20040000

SRAM 4-5 are always non-striped:

SRAM4_BASE	0x20040000
SRAM5_BASE	0x20041000
SRAM_END	0x20042000

Non striped aliases of SRAM0-3:

SRAM0_BASE	0x21000000
SRAM1_BASE	0x21010000
SRAM2_BASE	0x21020000
SRAM3_BASE	0x21030000

APB Peripherals:

SYSINFO_BASE	0x40000000
SYSCFG_BASE	0x40004000

CLOCKS_BASE	0x40008000
RESETS_BASE	0x4000c000
PSM_BASE	0x40010000
IO_BANK0_BASE	0x40014000
IO_QSPI_BASE	0x40018000
PADS_BANK0_BASE	0x4001c000
PADS_QSPI_BASE	0x40020000
XOSC_BASE	0x40024000
PLL_SYS_BASE	0x40028000
PLL_USB_BASE	0x4002c000
BUSCTRL_BASE	0x40030000
UART0_BASE	0x40034000
UART1_BASE	0x40038000
SPI0_BASE	0x4003c000
SPI1_BASE	0x40040000
I2C0_BASE	0x40044000
I2C1_BASE	0x40048000
ADC_BASE	0x4004c000
PWM_BASE	0x40050000
TIMER_BASE	0x40054000
WATCHDOG_BASE	0x40058000
RTC_BASE	0x4005c000
ROSC_BASE	0x40060000
VREG_AND_CHIP_RESET_BASE	0x40064000
TBMAN_BASE	0x4006c000

AHB-Lite peripherals:

DMA_BASE	0x50000000
----------	------------

USB has a DPRAM at its base followed by registers:

USBCTRL_BASE	0x50100000
USBCTRL_DPRAM_BASE	0x50100000
USBCTRL_REGS_BASE	0x50110000

Remaining AHB-Lite peripherals:

PIO0_BASE	0x50200000
PIO1_BASE	0x50300000
XIP_AUX_BASE	0x50400000

IOPORT Peripherals:

SIO_BASE	0xd000000
----------	-----------

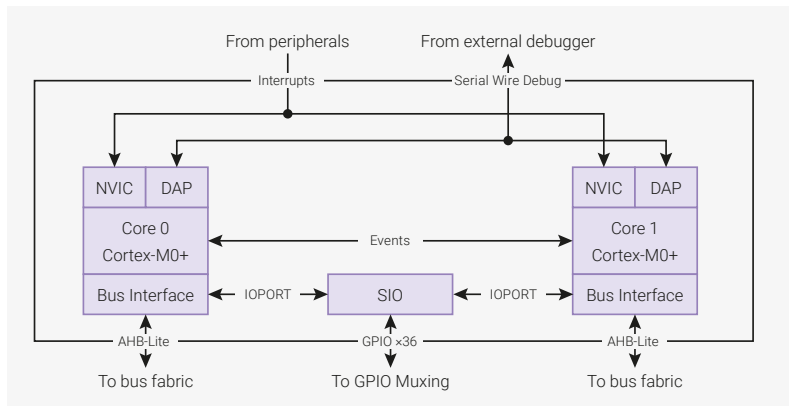

Cortex-M0+ Internal Peripherals:

PPB_BASE	0xe000000
----------	-----------

2.3. Processor subsystem

The RP2040 processor subsystem consists of two Arm Cortex-M0+ processors – each with its standard internal Arm CPU peripherals – alongside external peripherals for GPIO access and inter-core communication. Details of the Arm Cortex-M0+ processors, including the specific feature configuration used on RP2040, can be found in [Cortex-M0+](#).

Figure 6. Two Cortex-M0+ processors, each with a dedicated 32-bit AHB-Lite bus port, for code fetch, loads and stores. The SIO is connected to the single-cycle IOPORT bus of each processor, and provides GPIO access, two-way communications, and other core-local peripherals. Both processors can be debugged via a single multi-drop Serial Wire Debug bus. 26 interrupts (plus NMI) are routed to the NVIC and WIC on each processor.

The processors use a number of interfaces to communicate with the rest of the system:

- Each processor use its own independent 32-bit AHB-Lite bus to access memory and memory-mapped peripherals (more detail in [Bus Fabric](#))
- The single-cycle IO block provides high-speed, deterministic access to GPIOs via each processor’s IOPORT
- 26 system-level interrupts are routed to both processors
- A multi-drop Serial Wire Debug bus provides debug access to both processors from an external debug host

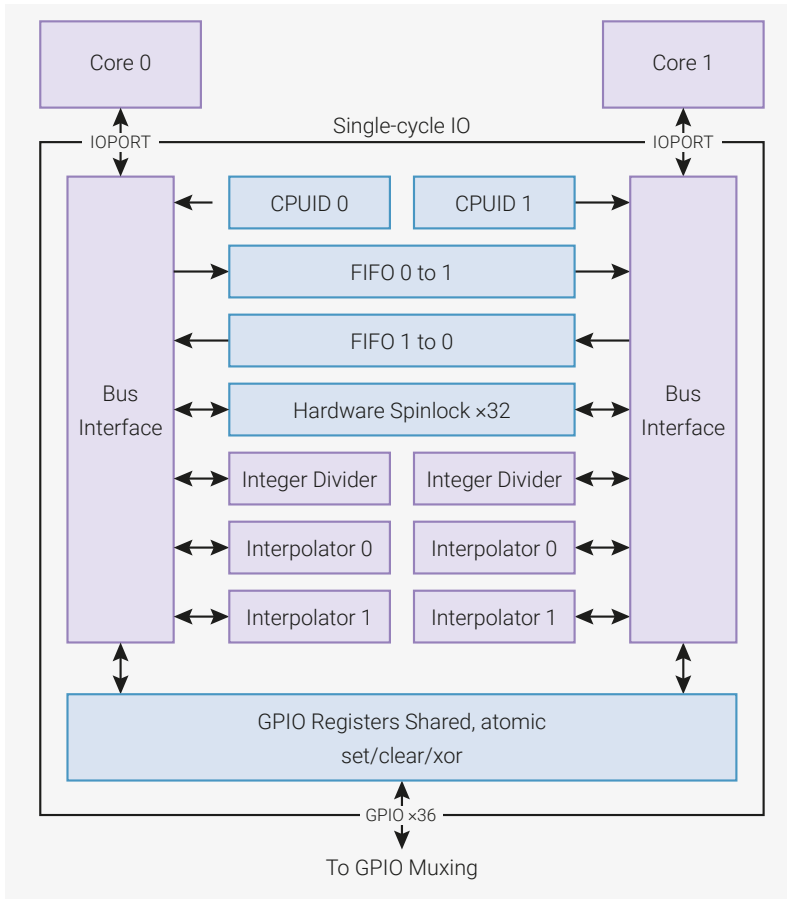

2.3.1. SIO

The Single-cycle IO block (SIO) contains several peripherals that require low-latency, deterministic access from the processors. It is accessed via each processor’s IOPORT: this is an auxiliary bus port on the Cortex-M0+ which can perform rapid 32-bit reads and writes. The SIO has a dedicated bus interface for each processor’s IOPORT, as shown in [Figure 7](#). Processors access their IOPORT with normal load and store instructions, directed to the special IOPORT address segment, 0xd0000000...0xdfffffff. The SIO appears as memory-mapped hardware within the IOPORT space.

i NOTE

The SIO is not connected to the main system bus due to its tight timing requirements. It can only be accessed by the processors, or by the debugger via the processor debug ports.

Figure 7. The single-cycle IO block contains memory-mapped hardware which the processors must be able to access quickly. The FIFOs and spinlocks support message passing and synchronisation between the two cores. The shared GPIO registers provide fast and concurrency-safe direct access to GPIO-capable pins. Some core-local arithmetic hardware can be used to accelerate common tasks on the processors.

All IOPORT reads and writes (and therefore all SIO accesses) take place in exactly one cycle, unlike the main AHB-Lite system bus, where the Cortex-M0+ requires two cycles for a load or store, and may have to wait longer due to contention from other system bus masters. This is vital for interfaces such as GPIO, which have tight timing requirements.

SIO registers are mapped to word-aligned addresses in the range `0xd0000000...0xd000017c`. The remainder of the IOPORT space is reserved for future use.

The SIO peripherals are described in more detail in the following sections.

2.3.1.1. CPUID

The register `CPUID` is the first register in the IOPORT space. Core 0 reads a value of 0 when accessing this address, and core 1 reads a value of 1. This is a convenient method for software to determine on which core it is running. This is checked during the initial boot sequence: both cores start running simultaneously, core 1 goes into a deep sleep state, and core 0 continues with the main boot sequence.

2.3.1.2. GPIO Control

The processors have access to GPIO registers for fast and direct control of pins with GPIO functionality. There are two identical sets of registers:

- `GPIO_x` for direct control of IO bank 0 (user GPIOs 0 to 29, starting at the LSB)
- `GPIO_HI_x` for direct control of the QSPI IO bank (in the order SCLK, SSn, SD0, SD1, SD2, SD3, starting at the LSB)

NOTE

To drive a pin with the SIO's GPIO registers, the GPIO multiplexer for this pin must first be configured to select the SIO GPIO function. See [Table 274](#).

These GPIO registers are *shared* between the two cores, and both cores can access them simultaneously. There are three registers for each bank:

- Output registers, [GPIO_OUT](#) and [GPIO_HI_OUT](#), are used to set the output level of the GPIO (1/0 for high/low)
- Output enable registers, [GPIO_OE](#) and [GPIO_HI_OE](#), are used to enable the output driver. 0 for high-impedance, 1 for drive high/low based on [GPIO_OUT](#) and [GPIO_HI_OUT](#).
- Input registers, [GPIO_IN](#) and [GPIO_HI_IN](#), allow the processor to sample the current state of the GPIOs

Reading [GPIO_IN](#) returns all 30 GPIO values (or 6 for [GPIO_HI_IN](#)) in a single read. Software can then mask out individual pins it is interested in.

Pico SDK: https://github.com/raspberrypi/pico-sdk/tree/pre_release/src/rp2_common/hardware_gpio/include/hardware/gpio.h Lines 292 - 294

```
292 static inline bool gpio_get(uint gpio) {
293     return !!(1ul << gpio) & sio_hw->gpio_in);
294 }
```

The **OUT** and **OE** registers also have atomic SET, CLR, and XOR aliases, which allows software to update a subset of the pins in one operation. This is vital not only for safe parallel GPIO access between the two cores, but also safe concurrent GPIO access in an interrupt handler and foreground code running on one core.

Pico SDK: https://github.com/raspberrypi/pico-sdk/tree/pre_release/src/rp2_common/hardware_gpio/include/hardware/gpio.h Lines 314 - 316

```
314 static inline void gpio_set_mask(uint32_t mask) {
315     sio_hw->gpio_set = mask;
316 }
```

Pico SDK: https://github.com/raspberrypi/pico-sdk/tree/pre_release/src/rp2_common/hardware_gpio/include/hardware/gpio.h Lines 323 - 325

```
323 static inline void gpio_clr_mask(uint32_t mask) {
324     sio_hw->gpio_clr = mask;
325 }
```

Pico SDK: https://github.com/raspberrypi/pico-sdk/tree/pre_release/src/rp2_common/hardware_gpio/include/hardware/gpio.h Lines 366 - 372

```
366 static inline void gpio_put(uint gpio, bool value) {
367     uint32_t mask = 1ul << gpio;
368     if (value)
369         gpio_set_mask(mask);
370     else
371         gpio_clr_mask(mask);
372 }
```

If both processors write to an **OUT** or **OE** register (or any of its SET/CLR/XOR aliases) on the same clock cycle, the result is as though core 0 wrote first, and core 1 wrote immediately afterward. For example, if core 0 SETs a bit, and core 1 simultaneously XORs it, the bit will be set to 0, irrespective of its original value.

NOTE

This is a conceptual model for the result that is produced when two cores write to a GPIO register simultaneously. The register does not actually contain this intermediate value at any point. In the previous example, if the pin is initially 0, and core 0 performs a SET while core 1 performs a XOR, the GPIO output remains low without any positive glitch.

2.3.1.3. Hardware Spinlocks

The SIO provides 32 hardware spinlocks, which can be used to manage mutually-exclusive access to shared software resources. Each spinlock is a one-bit flag, mapped to a different address (from [SPINLOCK0](#) to [SPINLOCK31](#)). Software interacts with each spinlock with one of the following operations:

- Read: attempt to claim the lock. Read value is nonzero if the lock was successfully claimed, or zero if the lock had already been claimed by a previous read.
- Write (any value): release the lock. The next attempt to claim the lock will be successful.

If both cores try to claim the same lock on the same clock cycle, core 0 succeeds.

Generally software will acquire a lock by repeatedly polling the lock bit ("spinning" on the lock) until it is successfully claimed. This is inefficient if the lock is held for long periods, so generally the spinlocks should be used to protect the short critical sections of higher-level primitives such as mutexes, semaphores and queues.

For debugging purposes, the current state of all 32 spinlocks can be observed via [SPINLOCK_ST](#).

2.3.1.4. Inter-processor FIFOs (Mailboxes)

The SIO contains two FIFOs for passing data, messages or ordered events between the two cores. Each FIFO is 32 bits wide, and eight entries deep. One of the FIFOs can only be written by core 0, and read by core 1. The other can only be written by core 1, and read by core 0.

Each core writes to its outgoing FIFO by writing to [FIFO_WR](#), and reads from its incoming FIFO by reading from [FIFO_RD](#). A status register, [FIFO_ST](#), provides the following status signals:

- Incoming FIFO contains data (**VLD**)
- Outgoing FIFO has room for more data (**RDY**)
- The incoming FIFO was read from while empty at some point in the past (**ROE**)
- The outgoing FIFO was written to while full at some point in the past (**WOF**)

Writing to the outgoing FIFO while full, or reading from the incoming FIFO while empty, does not affect the FIFO state. The current contents and level of the FIFO is preserved. However, this does represent some loss of data or reception of invalid data by the software accessing the FIFO, so a sticky error flag is raised (**ROE** or **WOF**).

The SIO has a FIFO IRQ output for each core, mapped to system IRQ numbers 15 and 16. The IRQ is asserted when any of **VLD**, **ROE** or **WOF** is 1 in that core's [FIFO_ST](#) register. If the corresponding interrupt line is enabled in the Cortex-M0+ NVIC, then the processor will take an interrupt each time data appears in its FIFO, or if it has performed some invalid FIFO operation (read on empty, write on full). Typically Core 0 will use IRQ15 and core 1 will use IRQ16. If the IRQs are used the other way round then it is difficult for the core that has been interrupted to correctly identify the reason for the interrupt as the core doesn't have access to the other core's FIFO status register.

The interrupt handler acknowledges the **ROE** and **WOF** flags by writing any value to [FIFO_ST](#). The **VLD** flag is cleared by reading data from the FIFO until empty.

The inter-processor FIFOs and the Cortex-M0+ Event signals are used by the Bootrom `wait_for_vector` routine, where core 1 remains in a sleep state until it is woken, and provided with its initial stack pointer, entry point and vector table through the FIFO.

2.3.1.5. Integer Divider

The SIO provides one 8-cycle signed/unsigned divide/modulo module to each of the cores. Calculation is started by writing a dividend and divisor to the two argument registers, **DIVIDEND** and **DIVISOR**. The divider calculates the quotient **/** and remainder **%** of this division over the next 8 cycles, and on the 9th cycle the results can be read from the two result registers **DIV_QUOTIENT** and **DIV_REMAINDER**. A 'ready' bit in register **DIV_CSR** can be polled to wait for the calculation to complete, or software can insert a fixed 8-cycle delay.

Pico SDK: https://github.com/raspberrypi/pico-sdk/tree/pre_release/src/rp2_common/hardware_divider/divider.S Lines 18 - 38

```

18 .macro __divider_delay
19     // delay 8 cycles
20     b 1f
21 1:  b 1f
22 1:  b 1f
23 1:  b 1f
24 1:
25 .endm
26
27 .align 2
28
29 function_with_section hw_divider_divmod_s32
30     ldr r3, =(SIO_BASE)
31     str r0, [r3, #SIO_DIV_SDIVIDEND_OFFSET]
32     str r1, [r3, #SIO_DIV_SDIVISOR_OFFSET]
33     __divider_delay
34     // return 64 bit value so we can efficiently return both (note quotient must be read
last)
35     ldr r1, [r3, #SIO_DIV_REMAINDER_OFFSET]
36     ldr r0, [r3, #SIO_DIV_QUOTIENT_OFFSET]
37     bx lr

```

i NOTE

Software is free to perform other non divider operations during these 8 cycles.

There are two aliases of the operand registers: writing to the signed alias (**DIV_SDIVIDEND** and **DIV_SDIVISOR**) will initiate a signed calculation, and the other (**DIV_UDIVIDEND** and **DIV_UDIVISOR**) will initiate an unsigned calculation.

Pico SDK: https://github.com/raspberrypi/pico-sdk/tree/pre_release/src/rp2_common/hardware_divider/divider.S Lines 44 - 52

```

44 function_with_section hw_divider_divmod_u32
45     ldr r3, =(SIO_BASE)
46     str r0, [r3, #SIO_DIV_UDIVIDEND_OFFSET]
47     str r1, [r3, #SIO_DIV_UDIVISOR_OFFSET]
48     __divider_delay
49     // return 64 bit value so we can efficiently return both (note quotient must be read
last)
50     ldr r1, [r3, #SIO_DIV_REMAINDER_OFFSET]
51     ldr r0, [r3, #SIO_DIV_QUOTIENT_OFFSET]
52     bx lr

```

i NOTE

A new calculation begins immediately with every write to an operand register, and a new operand write immediately squashes any calculation currently in progress. For example, when dividing many numbers by the same divisor, only `xDIVIDEND` needs to be written, and the signedness of each calculation is determined by whether `SDIVIDEND` or `UDIVIDEND` is written.

To support save and restore on interrupt handler entry/exit (or on e.g. an RTOS context switch), the result registers are also writable. Writing to a result register will cancel any operation in progress at the time. The `DIV_CSR.DIRTY` flag can help make save/restore more efficient: this flag is set when *any* divider register (operand or result) is written to, and cleared when the quotient is read.

i NOTE

When enabled, the default divider AEABI support maps C level `/` and `%` to the hardware divider. When building software using the Pico SDK and using the divider directly, it is important to read the quotient register *last*. This ensures the partial divider state will be correctly saved and restored by any interrupt code that uses the divider. You should read the quotient register whether you need the value or not.

The Pico SDK module `pico_divider` https://github.com/raspberrypi/pico-sdk/tree/pre_release/src/common/pico_divider/include/pico/divider.h provides both the AEABI implementation needed to hook the C `/` and `%` operators for both 32-bit and 64-bit integer division, as well as some additional C functions that return quotients and remainders at the same time. All of these functions correctly save and restore the hardware divider state (when dirty) so that they can be used in either user or IRQ handler code.

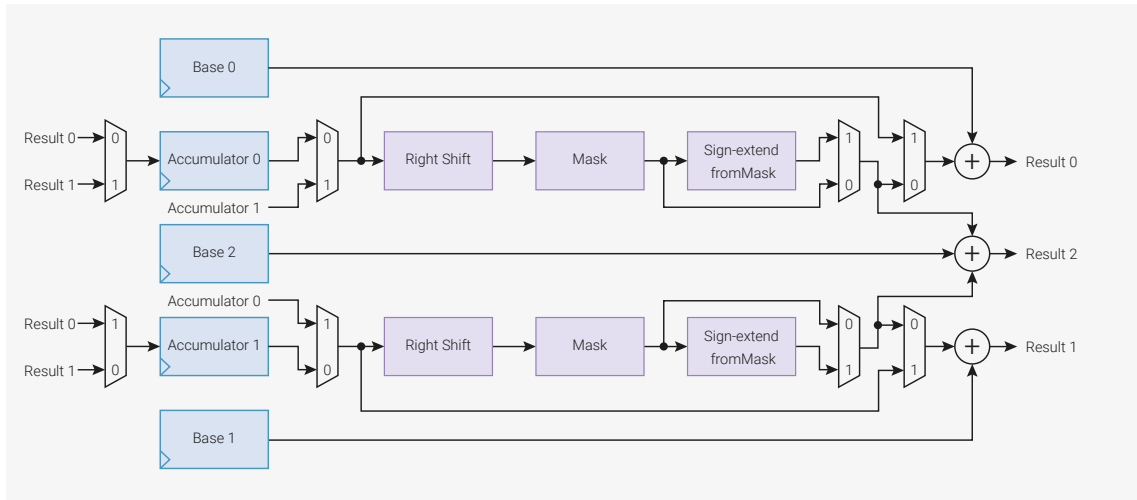

The Pico SDK module `hardware_divider` https://github.com/raspberrypi/pico-sdk/tree/pre_release/src/rp2_common/hardware_divider/include/hardware/divider.h provides lower level macros and helper functions for accessing the hardware divider, but these do not save and restore the hardware divider state (although this header does provide separate functions to do so).

2.3.1.6. Interpolator

Each core is equipped with two *interpolators* (`INTERP0` and `INTERP1`) which can accelerate tasks by combining certain pre-configured operations into a single processor cycle. Intended for cases where the pre-configured operation is repeated many times, this results in code which uses both fewer CPU cycles and fewer CPU registers in the time-critical sections of the code.

The interpolators are used to accelerate audio operations within the Pico SDK, but their flexible configuration makes it possible to optimise many other tasks such as quantization and dithering, table lookup address generation, affine texture mapping, decompression and linear feedback.

Figure 8. An interpolator. The two accumulator registers and three base registers have single-cycle read/write access from the processor. The interpolator is organised into two lanes, which perform masking, shifting and sign-extension operations on the two accumulators. This produces three possible results, by adding the intermediate shift/mask values to the three base registers. From left to right, the multiplexers on each lane are controlled by the following flags in the CTRL registers: CROSS_RESULT, CROSS_INPUT, SIGNED, ADD_RAW.

The processor can write or read any interpolator register in one cycle, and the results are ready on the next cycle. The processor can also perform an addition on one of the two accumulators **ACCUM0** or **ACCUM1** by writing to the corresponding **ACCUMx_ADD** register.

The three results are available in the read-only locations **PEEK0**, **PEEK1**, **PEEK2**. Reading from these locations does not change the state of the interpolator. The results are also aliased at the locations **POP0**, **POP1**, **POP2**; reading from a **POPx** alias returns the same result as the corresponding **PEEKx**, and simultaneously writes back the lane results to the accumulators. This can be used to advance the state of interpolator each time a result is read.

Additionally the interpolator supports simple fractional blending between two values as well as clamping values such that they lie within a given range.

The following example shows a trivial example of *popping* a lane result to produce simple iterative feedback.

Pico Examples: https://github.com/raspberrypi/pico-examples/tree/pre_release/interp/hello_interp/hello_interp.c Lines 11 - 23

```

11 void times_table() {
12     puts("9 times table:");
13
14     // Initialise lane 0 on interp0 on this core
15     interp_config cfg = interp_default_config();
16     interp_set_config(interp0, 0, &cfg);
17
18     interp0->accum[0] = 0;
19     interp0->base[0] = 9;
20
21     for (int i = 0; i < 10; ++i)
22         printf("%d\n", interp0->pop[0]);
23 }

```

NOTE

By sheer coincidence, the interpolators are extremely well suited to SNES MODE7-style graphics routines. For example, on each core, **INTERP0** can provide a stream of tile lookups for some affine transform, and **INTERP1** can provide offsets into the tiles for the same transform.

2.3.1.6.1. Lane Operations

Figure 9. Each lane of each interpolator can be configured to perform mask, shift and sign-extension on one of the accumulators. This is fed into adders which produces final results, which may optionally be fed back into the accumulators with each read. The datapath can be configured using a handful of 32-bit multiplexers. From left to right, these are controlled by the following CTRL flags: CROSS_RESULT, CROSS_INPUT, SIGNED, ADD_RAW.

Each lane performs these three operations, in sequence:

- A right shift by `CTRL_LANEx_SHIFT` (0 to 31 bits)
- A mask of bits from `CTRL_LANEx_MASK_LSB` to `CTRL_LANEx_MASK_MSB` inclusive (each ranging from bit 0 to bit 31)
- A sign extension from the top of the mask, i.e. take bit `CTRL_LANEx_MASK_MSB` and OR it into all more-significant bits, if `CTRL_LANEx_SIGNED` is set

For example, if:

- `ACCUM0 = 0xdeadbeef`
- `CTRL_LANE0_SHIFT = 8`
- `CTRL_LANE0_MASK_LSB = 4`
- `CTRL_LANE0_MASK_MSB = 7`
- `CTRL_SIGNED = 1`

Then lane 0 would produce the following results at each stage:

- Right shift by 8 to produce `0x00deadbe`
- Mask bits 7 to 4 to produce `0x00deadbe & 0x000000f0 = 0x000000b0`
- Sign-extend up from bit 7 to produce `0xfffffb0`

In software:

Pico Examples: https://github.com/raspberrypi/pico-examples/tree/pre_release/interp/hello_interp/hello_interp.c Lines 25 - 46

```

25 void moving_mask() {
26     interp_config cfg = interp_default_config();
27     interp0->accum[0] = 0x1234abcd;
28
29     puts("Masking:");
30     printf("ACCUM0 = %08x\n", interp0->accum[0]);
31     for (int i = 0; i < 8; ++i) {
32         // LSB, then MSB. These are inclusive, so 0,31 means "the entire 32 bit register"
33         interp_config_mask(&cfg, i * 4, i * 4 + 3);
34         interp_set_config(interp0, 0, &cfg);
35         // Reading from ACCUMx_ADD returns the raw lane shift and mask value, without BASEx
        added
36         printf("Nibble %d: %08x\n", i, interp0->add_raw[0]);
37     }
38
39     puts("Masking with sign extension:");
40     interp_config_signed(&cfg, true);
41     for (int i = 0; i < 8; ++i) {
42         interp_config_mask(&cfg, i * 4, i * 4 + 3);
43         interp_set_config(interp0, 0, &cfg);
44         printf("Nibble %d: %08x\n", i, interp0->add_raw[0]);
45     }
46 }

```

The above example should print:

```

ACCUM0 = 1234abcd
Nibble 0: 0000000d
Nibble 1: 000000c0
Nibble 2: 00000b00
Nibble 3: 0000a000
Nibble 4: 00040000
Nibble 5: 00300000
Nibble 6: 02000000
Nibble 7: 10000000
Masking with sign extension:
Nibble 0: ffffffff
Nibble 1: ffffffc0
Nibble 2: fffffb00
Nibble 3: ffffa000
Nibble 4: 00040000
Nibble 5: 00300000
Nibble 6: 02000000
Nibble 7: 10000000

```

Changing the result and input multiplexers can create feedback between the accumulators. This is useful e.g. for audio dithering.

Pico Examples: https://github.com/raspberrypi/pico-examples/tree/pre_release/interp/hello_interp/hello_interp.c Lines 48 - 63

```

48 void cross_lanes() {
49     interp_config cfg = interp_default_config();
50     interp_config_cross_result(&cfg, true);
51     // ACCUM0 gets lane 1 result:
52     interp_set_config(interp0, 0, &cfg);
53     // ACCUM1 gets lane 0 result:
54     interp_set_config(interp0, 1, &cfg);
55
56     interp0->accum[0] = 123;
57     interp0->accum[1] = 456;
58     interp0->base[0] = 1;
59     interp0->base[1] = 0;
60     puts("Lane result crossover:");
61     for (int i = 0; i < 10; ++i)
62         printf("PEEK0, POP1: %d, %d\n", interp0->peek[0], interp0->pop[1]);
63 }

```

This should print:

```

PEEK0, POP1: 124, 456
PEEK0, POP1: 457, 124
PEEK0, POP1: 125, 457
PEEK0, POP1: 458, 125
PEEK0, POP1: 126, 458
PEEK0, POP1: 459, 126
PEEK0, POP1: 127, 459
PEEK0, POP1: 460, 127
PEEK0, POP1: 128, 460
PEEK0, POP1: 461, 128

```

2.3.1.6.2. Blend Mode

Blend mode is available on **INTERP0** on each core, and is enabled by the **CTRL_LANE0_BLEND** control flag. It performs linear interpolation, which we define as follows:

$$x = x_0 + \alpha(x_1 - x_0), \text{ for } 0 \leq \alpha < 1$$

Where x_0 is the register **BASE0**, x_1 is the register **BASE1**, and α is a fractional value formed from the least significant 8 bits of the lane 1 shift and mask value.

Blend mode has the following differences from normal mode:

- **PEEK0, POP0** return the 8-bit alpha value (the 8 LSBs of the lane 1 shift and mask value), with zeroes in result bits 31 down to 24.
- **PEEK1, POP1** return the linear interpolation between **BASE0** and **BASE1**
- **PEEK2, POP2** do not include lane 1 result in the addition (i.e. it is **BASE2** + lane 0 shift and mask value)

The result of the linear interpolation is equal to **BASE0** when the alpha value is 0, and equal to **BASE0** + 255/256 * (**BASE1** - **BASE0**) when the alpha value is all-ones.

Pico Examples: https://github.com/raspberrypi/pico-examples/tree/pre_release/interp/hello_interp/hello_interp.c Lines 65 - 84

```

65 void simple_blend1() {
66     puts("Simple blend 1:");
67
68     interp_config cfg = interp_default_config();
69     interp_config_blend(&cfg, true);
70     interp_set_config(interp0, 0, &cfg);
71
72     cfg = interp_default_config();
73     interp_set_config(interp0, 1, &cfg);
74
75     interp0->base[0] = 500;
76     interp0->base[1] = 1000;
77
78     for (int i = 0; i <= 6; i++) {
79         // set fraction to value between 0 and 255
80         interp0->accum[1] = 255 * i / 6;
81         // ≈ 500 + (1000 - 500) * i / 6;
82         printf("%d\n", (int) interp0->peek[1]);
83     }
84 }

```

This should print (note the 255/256 resulting in 998 not 1000):

```

500
582
666
748
832
914
998

```

CTRL_LANE1_SIGNED controls whether **BASE0** and **BASE1** are sign-extended for this interpolation (this sign extension is required because the interpolation produces an intermediate product value 40 bits in size). **CTRL_LANE0_SIGNED** continues to control the sign extension of the lane 0 intermediate result in **PEEK2, POP2** as normal.

Pico Examples: https://github.com/raspberrypi/pico-examples/tree/pre_release/interp/hello_interp/hello_interp.c Lines 87 - 118

```

87 void print_simple_blend2_results(bool is_signed) {
88     // Lane 1 signed flag controls whether base 0/1 are treated as signed or unsigned
89     interp_config cfg = interp_default_config();
90     interp_config_signed(&cfg, is_signed);
91     interp_set_config(interp0, 1, &cfg);
92
93     for (int i = 0; i <= 6; i++) {
94         interp0->accum[1] = 255 * i / 6;
95         if (is_signed) {
96             printf("%d\n", (int) interp0->peek[1]);
97         } else {
98             printf("0x%08x\n", (uint) interp0->peek[1]);
99         }
100     }
101 }
102
103 void simple_blend2() {
104     puts("Simple blend 2:");
105
106     interp_config cfg = interp_default_config();
107     interp_config_blend(&cfg, true);
108     interp_set_config(interp0, 0, &cfg);
109
110     interp0->base[0] = -1000;
111     interp0->base[1] = 1000;
112
113     puts("signed:");
114     print_simple_blend2_results(true);
115
116     puts("unsigned:");
117     print_simple_blend2_results(false);
118 }

```

This should print:

```

signed:
-1000
-672
-336
-8
328
656
992
unsigned:
0xfffffc18
0xd5fffd60
0xaaafffeb0
0x80fffff8
0x56000148
0x2c000290
0x010003e0

```

Finally, in blend mode when using the **BASE_1AND0** register to send a 16-bit value to each of **BASE0** and **BASE1** with a single 32-bit write, the sign-extension of these 16-bit values to full 32-bit values during the write is controlled by **CTRL_LANE1_SIGNED** for both bases, as opposed to non-blend-mode operation, where **CTRL_LANE0_SIGNED** affects extension into **BASE0** and **CTRL_LANE1_SIGNED** affects extension into **BASE1**.

Pico Examples: https://github.com/raspberrypi/pico-examples/tree/pre_release/interp/hello_interp/hello_interp.c Lines 121 - 142

```

121 void simple_blend3() {
122     puts("Simple blend 3:");
123
124     interp_config cfg = interp_default_config();
125     interp_config_blend(&cfg, true);
126     interp_set_config(interp0, 0, &cfg);
127
128     cfg = interp_default_config();
129     interp_set_config(interp0, 1, &cfg);
130
131     interp0->accum[1] = 128;
132     interp0->base01 = 0x30005000;
133     printf("0x%08x\n", (int) interp0->peek[1]);
134     interp0->base01 = 0xe000f000;
135     printf("0x%08x\n", (int) interp0->peek[1]);
136
137     interp_config_signed(&cfg, true);
138     interp_set_config(interp0, 1, &cfg);
139
140     interp0->base01 = 0xe000f000;
141     printf("0x%08x\n", (int) interp0->peek[1]);
142 }

```

This should print:

```

0x00004000
0x0000e800
0xffffe800

```

2.3.1.6.3. Clamp Mode

Clamp mode is available on **INTERP1** on each core, and is enabled by the **CTRL_LANE0_CLAMP** control flag. In clamp mode, the **PEEK0/POP0** result is the lane value (shifted, masked, sign-extended **ACCUM0**) clamped between **BASE0** and **BASE1**. In other words, if the lane value is greater than **BASE1**, a value of **BASE1** is produced; if less than **BASE0**, a value of **BASE0** is produced; otherwise, the value passes through. No addition is performed. The signedness of these comparisons is controlled by the **CTRL_LANE0_SIGNED** flag.

Other than this, the interpolator behaves the same as in normal mode.

Pico Examples: https://github.com/raspberrypi/pico-examples/tree/pre_release/interp/hello_interp/hello_interp.c Lines 188 - 206

```

188 void clamp() {
189     puts("Clamp:");
190     interp_config cfg = interp_default_config();
191     interp_config_clamp(&cfg, true);
192     interp_config_shift(&cfg, 2);
193     // set mask according to new position of sign bit..
194     interp_config_mask(&cfg, 0, 29);
195     // ...so that the shifted value is correctly sign extended
196     interp_config_signed(&cfg, true);
197     interp_set_config(interp1, 0, &cfg);
198
199     interp1->base[0] = 0;
200     interp1->base[1] = 255;
201
202     for (int i = -1024; i <= 1024; i += 256) {

```

```

203     interp1->accum[0] = i;
204     printf("%d\t%d\n", i, (int) interp1->peek[0]);
205 }
206 }

```

This should print:

```

-1024  0
-768   0
-512   0
-256   0
0       0
256    64
512    128
768    192
1024   255

```

2.3.1.6.4. Sample Use Case: Linear Interpolation

Linear interpolation is a more complete example of using blend mode in conjunction with other interpolator functionality:

In this example, `ACCUM0` is used to track a fixed point (integer/fraction) position within a list of values to be interpolated. Lane 0 is used to produce an address into the value array for the integer part of the position. The fractional part of the position is shifted to produce a value from 0-255 for the blend. The blend is performed between two consecutive values in the array.

Finally the fractional position is updated via a single write to `ACCUM0_ADD_RAW`.

Pico Examples: https://github.com/raspberrypi/pico-examples/tree/pre_release/interp/hello_interp/hello_interp.c Lines 144 - 186

```

144 void linear_interpolation() {
145     puts("Linear interpolation:");
146     const int uv_fractional_bits = 12;
147
148     // for lane 0
149     // shift and mask XXXX XXXX XXXX XXXX XXXX FFFF FFFF FFFF (accum 0)
150     // to           0000 0000 000X XXXX XXXX XXXX XXXX XXX0
151     // i.e. non fractional part times 2 (for uint16_t)
152     interp_config cfg = interp_default_config();
153     interp_config_shift(&cfg, uv_fractional_bits - 1);
154     interp_config_mask(&cfg, 1, 32 - uv_fractional_bits);
155     interp_config_blend(&cfg, true);
156     interp_set_config(interp0, 0, &cfg);
157
158     // for lane 1

```

This method is used for fast approximate audio upscaling in the Pico SDK

2.3.1.6.5. Sample Use Case: Simple Affine Texture Mapping

Simple affine texture mapping can be implemented by using fixed point arithmetic for texture coordinates, and stepping a fixed amount in each coordinate for every pixel in a scanline. The integer part of the texture coordinates are used to form an address within the texture to lookup a pixel color.

By using two lanes, all three base values and the `CTRL_LANEx_ADD_RAW` flag, it is possible to reduce what would be quite an expensive CPU operation to a single cycle iteration using the interpolator.

Pico Examples: https://github.com/raspberrypi/pico-examples/tree/pre_release/interp/hello_interp/hello_interp.c Lines 209 - 267

```

209 void texture_mapping_setup(uint8_t *texture, uint texture_width_bits, uint
    texture_height_bits,
210                             uint uv_fractional_bits) {
211     interp_config cfg = interp_default_config();
212     // set add_raw flag to use raw (un-shifted and un-masked) lane accumulator value when
    adding
213     // it to the the lane base to make the lane result
214     interp_config_add_raw(&cfg, true);
215     interp_config_shift(&cfg, uv_fractional_bits);
216     interp_config_mask(&cfg, 0, texture_width_bits - 1);

```

```

217     interp_set_config(interp0, 0, &cfg);
218
219     interp_config_shift(&cfg, uv_fractional_bits - texture_width_bits);
220     interp_config_mask(&cfg, texture_width_bits, texture_width_bits + texture_height_bits -
221     1);
221     interp_set_config(interp0, 1, &cfg);
222
223     interp0->base[2] = (uintptr_t) texture;
224 }
225
226 void texture_mapped_span(uint8_t *output, uint32_t u, uint32_t v, uint32_t du, uint32_t dv,
227     uint count) {
228     // u, v are texture coordinates in fixed point with uv_fractional_bits fractional bits
229     // du, dv are texture coordinate steps across the span in same fixed point.

CPUID Register

Description

Processor core identifier

Table 16. CPUID Register

Bits	Name	Description	Type	Reset
31:0	NONAME	Value is 0 when read from processor core 0, and 1 when read from processor core 1.	RO	-

GPIO_IN Register

Description

Input value for GPIO pins

Table 17. GPIO_IN Register

Bits	Name	Description	Type	Reset
31:30	Reserved.	-	-	-
29:0	NONAME	Input value for GPIO0...29	RO	0x00000000

GPIO_HI_IN Register

Description

Input value for QSPI pins

Table 18. GPIO_HI_IN Register

Bits	Name	Description	Type	Reset
31:6	Reserved.	-	-	-
5:0	NONAME	Input value on QSPI IO in order 0..5: SCLK, SSn, SD0, SD1, SD2, SD3	RO	0x00

GPIO_OUT Register

Description

GPIO output value

Table 19. GPIO_OUT Register

Bits	Name	Description	Type	Reset
31:30	Reserved.	-	-	-
29:0	NONAME	Set output level (1/0 -> high/low) for GPIO0...29. Reading back gives the last value written, NOT the input value from the pins. If core 0 and core 1 both write to GPIO_OUT simultaneously (or to a SET/CLR/XOR alias), the result is as though the write from core 0 took place first, and the write from core 1 was then applied to that intermediate result.	RW	0x00000000

GPIO_OUT_SET Register

Description

GPIO output value set

Table 20. GPIO_OUT_SET Register

Bits	Name	Description	Type	Reset
31:30	Reserved.	-	-	-
29:0	NONAME	Perform an atomic bit-set on GPIO_OUT, i.e. <code>GPIO_OUT = wdata</code>	RW	0x00000000

GPIO_OUT_CLR Register

Description

GPIO output value clear

Table 21. GPIO_OUT_CLR Register

Bits	Name	Description	Type	Reset
31:30	Reserved.	-	-	-
29:0	NONAME	Perform an atomic bit-clear on GPIO_OUT, i.e. <code>GPIO_OUT &= ~wdata</code>	RW	0x00000000

GPIO_OUT_XOR Register

Description

GPIO output value XOR

Table 22. GPIO_OUT_XOR Register

Bits	Name	Description	Type	Reset
31:30	Reserved.	-	-	-
29:0	NONAME	Perform an atomic bitwise XOR on GPIO_OUT, i.e. <code>GPIO_OUT ^= wdata</code>	RW	0x00000000

GPIO_OE Register

Description

GPIO output enable

Table 23. GPIO_OE Register

Bits	Name	Description	Type	Reset
31:30	Reserved.	-	-	-
29:0	NONAME	Set output enable (1/0 -> output/input) for GPIO0...29. Reading back gives the last value written. If core 0 and core 1 both write to GPIO_OE simultaneously (or to a SET/CLR/XOR alias), the result is as though the write from core 0 took place first, and the write from core 1 was then applied to that intermediate result.	RW	0x00000000

GPIO_OE_SET Register

Description

GPIO output enable set

Table 24. GPIO_OE_SET Register

Bits	Name	Description	Type	Reset
31:30	Reserved.	-	-	-
29:0	NONAME	Perform an atomic bit-set on GPIO_OE, i.e. <code>GPIO_OE = wdata</code>	RW	0x00000000

GPIO_OE_CLR Register

Description

GPIO output enable clear

Table 25. GPIO_OE_CLR Register

Bits	Name	Description	Type	Reset
31:30	Reserved.	-	-	-
29:0	NONAME	Perform an atomic bit-clear on GPIO_OE, i.e. <code>GPIO_OE &= ~wdata</code>	RW	0x00000000

GPIO_OE_XOR Register

Description

GPIO output enable XOR

Table 26. GPIO_OE_XOR Register

Bits	Name	Description	Type	Reset
31:30	Reserved.	-	-	-
29:0	NONAME	Perform an atomic bitwise XOR on GPIO_OE, i.e. <code>GPIO_OE ^= wdata</code>	RW	0x00000000

GPIO_HI_OUT Register

Description

QSPI output value

Table 27.
GPIO_HI_OUT Register

Bits	Name	Description	Type	Reset
31:6	Reserved.	-	-	-
5:0	NONAME	Set output level (1/0 -> high/low) for QSPI IO0...5. Reading back gives the last value written, NOT the input value from the pins. If core 0 and core 1 both write to GPIO_HI_OUT simultaneously (or to a SET/CLR/XOR alias), the result is as though the write from core 0 took place first, and the write from core 1 was then applied to that intermediate result. FIFO_ST Register

Description

Status register for inter-core FIFOs (mailboxes).

There is one FIFO in the core 0 -> core 1 direction, and one core 1 -> core 0.

Both are 32 bits wide and 8 words deep.

Core 0 can see the read side of the 1->0 FIFO (RX), and the write side of 0->1 FIFO (TX).

Core 1 can see the read side of the 0->1 FIFO (RX), and the write side of 1->0 FIFO (TX).

Table 35. FIFO_ST Register

Bits	Name	Description	Type	Reset
31:4	Reserved.	-	-	-

Bits	Name	Description	Type	Reset
3	ROE	Sticky flag indicating the RX FIFO was read when empty. This read was ignored by the FIFO.	WC	0x0
2	WOF	Sticky flag indicating the TX FIFO was written when full. This write was ignored by the FIFO.	WC	0x0
1	RDY	Value is 1 if this core's TX FIFO is not full (i.e. if FIFO_WR is ready for more data)	RO	0x1
0	VLD	Value is 1 if this core's RX FIFO is not empty (i.e. if FIFO_RD is valid)	RO	0x0

FIFO_WR Register

Description

Write access to this core's TX FIFO

Table 36. FIFO_WR Register

Bits	Name	Description	Type	Reset
31:0	NONAME		WF	0x00000000

FIFO_RD Register

Description

Read access to this core's RX FIFO

Table 37. FIFO_RD Register

Bits	Name	Description	Type	Reset
31:0	NONAME		RF	-

SPINLOCK_ST Register

Description

Spinlock state
 A bitmap containing the state of all 32 spinlocks (1=locked).
 Mainly intended for debugging.

Table 38. SPINLOCK_ST Register

Bits	Name	Description	Type	Reset
31:0	NONAME		RO	0x00000000

DIV_UDIVIDEND Register

Description

Divider unsigned dividend
 Write to the DIVIDEND operand of the divider, i.e. the p in p / q .
 Any operand write starts a new calculation. The results appear in QUOTIENT, REMAINDER.
 UDIVIDEND/SDIVIDEND are aliases of the same internal register. The U alias starts an unsigned calculation, and the S alias starts a signed calculation.

Table 39. DIV_UDIVIDEND Register

Bits	Name	Description	Type	Reset
31:0	NONAME		RW	0x00000000

DIV_UDIVISOR Register

Description

Divider unsigned divisor
 Write to the DIVISOR operand of the divider, i.e. the q in p / q .
 Any operand write starts a new calculation. The results appear in QUOTIENT, REMAINDER.
 UDIVIDEND/SDIVIDEND are aliases of the same internal register. The U alias starts an unsigned calculation, and the S alias starts a signed calculation.

Table 40.
 DIV_UDIVISOR
 Register

Bits	Name	Description	Type	Reset
31:0	NONAME		RW	0x00000000

DIV_SDIVIDEND Register

Description

Divider signed dividend
 The same as UDIVIDEND, but starts a signed calculation, rather than unsigned.

Table 41.
 DIV_SDIVIDEND
 Register

Bits	Name	Description	Type	Reset
31:0	NONAME		RW	0x00000000

DIV_SDIVISOR Register

Description

Divider signed divisor
 The same as UDIVISOR, but starts a signed calculation, rather than unsigned.

Table 42.
 DIV_SDIVISOR
 Register

Bits	Name	Description	Type	Reset
31:0	NONAME		RW	0x00000000

DIV_QUOTIENT Register

Description

Divider result quotient
 The result of $DIVIDEND / DIVISOR$ (division). Contents undefined while CSR_READY is low.
 For signed calculations, QUOTIENT is negative when the signs of DIVIDEND and DIVISOR differ.
 This register can be written to directly, for context save/restore purposes. This halts any in-progress calculation and sets the CSR_READY and CSR_DIRTY flags.
 Reading from QUOTIENT clears the CSR_DIRTY flag, so should read results in the order REMAINDER, QUOTIENT if CSR_DIRTY is used.

Table 43.
 DIV_QUOTIENT
 Register

Bits	Name	Description	Type	Reset
31:0	NONAME		RW	0x00000000

DIV_REMAINDER Register

Description

Divider result remainder
 The result of $DIVIDEND \% DIVISOR$ (modulo). Contents undefined while CSR_READY is low.
 For signed calculations, REMAINDER is negative only when DIVIDEND is negative.
 This register can be written to directly, for context save/restore purposes. This halts any in-progress calculation and sets the CSR_READY and CSR_DIRTY flags.

Table 44.
DIV_REMAINDER
Register

Bits	Name	Description	Type	Reset
31:0	NONAME		RW	0x00000000

DIV_CSR Register

Description

Control and status register for divider.

Table 45. DIV_CSR
Register

Bits	Name	Description	Type	Reset
31:2	Reserved.	-	-	-
1	DIRTY	Changes to 1 when any register is written, and back to 0 when QUOTIENT is read. Software can use this flag to make save/restore more efficient (skip if not DIRTY). If the flag is used in this way, it's recommended to either read QUOTIENT only, or REMAINDER and then QUOTIENT, to prevent data loss on context switch.	RO	0x0
0	READY	Reads as 0 when a calculation is in progress, 1 otherwise. Writing an operand (xDIVIDEND, xDIVISOR) will immediately start a new calculation, no matter if one is already in progress. Writing to a result register will immediately terminate any in-progress calculation and set the READY and DIRTY flags.	RO	0x1

INTERP0_ACCUM0 Register

Description

Read/write access to accumulator 0

Table 46.
INTERP0_ACCUM0
Register

Bits	Name	Description	Type	Reset

INTERP0_CTRL_LANE0 Register

Description

Control register for lane 0

Table 57.
INTERP0_CTRL_LANE
0 Register

Bits	Name	Description	Type	Reset
31:26	Reserved.	-	-	-
25	OVERF	Set if either OVERF0 or OVERF1 is set.	RO	0x0
24	OVERF1	Indicates if any masked-off MSBs in ACCUM1 are set.	RO	0x0
23	OVERF0	Indicates if any masked-off MSBs in ACCUM0 are set.	RO	0x0
22	Reserved.	-	-	-
21	BLEND	Only present on INTERP0 on each core. If BLEND mode is enabled: - LANE1 result is a linear interpolation between BASE0 and BASE1, controlled by the 8 LSBs of lane 1 shift and mask value (a fractional number between 0 and 255/256ths) - LANE0 result does not have BASE0 added (yields only the 8 LSBs of lane 1 shift+mask value) - FULL result does not have lane 1 shift+mask value added (BASE2 + lane 0 shift+mask) LANE1 SIGNED flag controls whether the interpolation is signed or unsigned.	RW	0x0
20:19	FORCE_MSB	ORed into bits 29:28 of the lane result presented to the processor on the bus. No effect on the internal 32-bit datapath. Handy for using a lane to generate sequence of pointers into flash or SRAM.	RW	0x0
18	ADD_RAW	If 1, mask + shift is bypassed for LANE0 result. This does not affect FULL result.	RW	0x0

Bits	Name	Description	Type	Reset
17	CROSS_RESULT	If 1, feed the opposite lane's result into this lane's accumulator on POP.	RW	0x0
16	CROSS_INPUT	If 1, feed the opposite lane's accumulator into this lane's shift + mask hardware. Takes effect even if ADD_RAW is set (the CROSS_INPUT mux is before the shift+mask bypass)	RW	0x0
15	SIGNED	If SIGNED is set, the shifted and masked accumulator value is sign-extended to 32 bits before adding to BASE0, and LANE0 PEEK/POP appear extended to 32 bits when read by processor.	RW	0x0
14:10	MASK_MSB	The most-significant bit allowed to pass by the mask (inclusive) Setting MSB < LSB may cause chip to turn inside-out	RW	0x00
9:5	MASK_LSB	The least-significant bit allowed to pass by the mask (inclusive)	RW	0x00
4:0	SHIFT	Logical right-shift applied to accumulator before masking	RW	0x00

INTERP0_CTRL_LANE1 Register

Description

Control register for lane 1

Table 58.
INTERP0_CTRL_LANE

2.3.2. Interrupts

Each core is equipped with a standard ARM Nested Vectored Interrupt Controller (NVIC) which has 32 interrupt inputs. Each NVIC has the same interrupts routed to it, with the exception of the GPIO interrupts: there is one GPIO interrupt per bank, per core. These are completely independent, so e.g. core 0 can be interrupted by GPIO 0 in bank 0, and core 1 by GPIO 1 in the same bank.

On RP2040, only the lower 26 IRQ signals are connected on the NVIC, and IRQs 26 to 31 are tied to zero (never firing). The core can still be forced to enter the relevant interrupt handler by writing bits 26 to 31 in the NVIC **ISPR** register.

Table 110. Interrupts

IRQ	Interrupt Source	IRQ	Interrupt Source	IRQ	Interrupt Source	IRQ	Interrupt Source	IRQ	Interrupt Source
0	TIMER_IRQ_0	6	XIP_IRQ	12	DMA_IRQ_1	18	SPI0_IRQ	24	I2C1_IRQ
1	TIMER_IRQ_1	7	PIO0_IRQ_0	13	IO_IRQ_BANK0	19	SPI1_IRQ	25	RTC_IRQ
2	TIMER_IRQ_2	8	PIO0_IRQ_1	14	IO_IRQ_QSPI	20	UART0_IRQ		
3	TIMER_IRQ_3	9	PIO1_IRQ_0	15	SIO_IRQ_PROC0	21	UART1_IRQ		
4	PWM_IRQ_WRAP	10	PIO1_IRQ_1	16	SIO_IRQ_PROC1	22	ADC_IRQ_FIFO		
5	USBCTRL_IRQ	11	DMA_IRQ_0	17	CLOCKS_IRQ	23	I2C0_IRQ		

The 26 system IRQ signals are masked (NMI mask) and then ORed together creating the NMI signal for the core. The NMI mask for each core can be configured using **PROC0_NMI_MASK** and **PROC1_NMI_MASK** in the Syscfg register block. Each of these registers has one bit for each system interrupt, and the each core's NMI is asserted if a system interrupt is asserted **and** the corresponding NMI mask bit is set for that core.

CAUTION

If the watchdog is armed, and some bits are set on the core 1 NMI mask, the RESETS block (and hence Syscfg) should be included in the watchdog reset list. Otherwise, following a watchdog event, core 1 NMI may be asserted when the core enter the bootrom. It is safe for core 0 to take an NMI when entering the bootrom (the handler will clear the NMI mask).

2.3.3. Event Signals

The Cortex-M0+ can enter a sleep state until an "event" (or interrupt) takes place, using the **WFE** instruction. It can also generate events, using the **SEV** instruction. On RP2040 the event signals are cross-wired between the two processors, so that an event sent by one processor will be received on the other.

NOTE

the event flag is "sticky", so if both processors send an event (**SEV**) simultaneously, and then both go to sleep (**WFE**), they will both wake immediately, rather than getting stuck in a sleep state.

While in a **WFE** (or **WFI**) sleep state, the processor can shut off its internal clock gates, consuming much less power. When **both** processors are sleeping, and the DMA is inactive, RP2040 as a whole can enter a sleep state, disabling clocks on unused infrastructure such as the busfabric, and waking automatically when one of the processors wakes. See [Section 2.10.2](#).

2.3.4. Debug

The 2-wire Serial Wire Debug (SWD) port provides access to hardware and software debug features including:

- Loading firmware into SRAM or external flash memory
- Control of processor execution: run/halt, step, set breakpoints, other standard Arm debug functionality
- Access to processor architectural state
- Access to memory and memory-mapped IO via the system bus

The SWD bus is exposed on two dedicated pins and is immediately available after power-on.

Debug access is via independent DAPs (one per core) attached to a shared multidrop SWD bus (SWD v2). Each DAP will only respond to debug commands if correctly addressed by a SWD **TARGETSEL** command; all others tristate their outputs. Additionally, a Rescue DP (see section [Section 2.3.4.2](#)) is available which is connected to system control features. Default addresses of each debug port are given below:

- Core 0: **0x01002927**
- Core 1: **0x11002927**
- Rescue DP: **0xf1002927**

The Instance IDs (top 4 bits of ID above) can be changed via a sysconfig register which may be useful in a multichip application. However note that ID=0xf is reserved for the internal Rescue DP (see section [Section 2.3.4.2](#)).

Figure 10. RP2040 Debugging

TO DO: LIAM: Link to getting started book for practical use of how to do this

2.3.4.1. Software control of SWD pins

The SWD pins for Core 0 and Core 1 can be bit-banded via registers in syscfg (see [DBGFORCE](#)). This means that Core 1 could run a USB application that allows debug of Core 0, or similar.

2.3.4.2. Rescue DP

The Rescue DP (debug port) is available over the SWD bus and is only intended for use in the specific case where the chip

has locked up, for example if code has been programmed into flash which permanently halts the system clock: in such a case, the normal debugger can not communicate with the processors to return the system to a working state, so more drastic action is needed. A `rescue` is invoked by setting the `CDBGPWRUPREQ` bit in the Rescue DP's CTRL/STAT register.

This causes a hard reset of the chip (functionally similar to a power-on-reset), and sets a flag in the Chip Level Reset block to indicate that a rescue reset took place. The bootrom checks this flag almost immediately in the initial boot process (before watchdog, flash or USB boot), acknowledges by clearing the bit, then halts the processor. This leaves the system in a safe state, with the system clock running, so that the debugger can reattach to the cores and load fresh code.

TO DO: LIAM: link to example of how to do this in the getting started/hardware design or similar book

2.4. Cortex-M0+

ARM Documentation

Excerpted from the [Cortex-M0+ Technical Reference Manual](#). Used with permission.

The ARM Cortex-M0+ processor is a very low gate count, highly energy efficient processor that is intended for microcontroller and deeply embedded applications that require an area optimized, low-power processor.

2.4.1. Features

The ARM Cortex-M0+ processor features and benefits are:

- Tight integration of system peripherals reduces area and development costs.
- Thumb instruction set combines high code density with 32-bit performance.
- Support for single-cycle I/O access.
- Power control optimization of system components.
- Integrated sleep modes for low-power consumption.
- Fast code execution enables running the processor with a slower clock or increasing sleep mode time.
- Optimized code fetching for reduced flash and ROM power consumption.
- Hardware multiplier.
- Deterministic, high-performance interrupt handling for time-critical applications.
- Deterministic instruction cycle timing.
- Support for system level debug authentication.
- Serial Wire Debug reduces the number of pins required for debugging.

2.4.1.1. Interfaces

The interfaces included in the processor for external access include:

- External AHB-Lite interface to busfabric
- Debug Access Port (DAP)
- Single-cycle I/O Port to SIO peripherals

2.4.1.2. Configuration

Each processor is configured with the following features:

- Architectural clock gating (for power saving)
- Little Endian bus access
- Four Breakpoints
- Debug support (via 2-wire debug pins [SWD/SWCLK](#))
- 32-bit instruction fetch (to match 32-bit data bus)
- IOPORT (for low latency access to local peripherals (see [SIO](#)))
- 26 interrupts
- 8 MPU regions
- All registers reset on powerup
- Fast multiplier (MULS 32x32 single cycle)
- SysTick timer
- Vector Table Offset Register ([VTOR](#))
- 34 WIC (Wake-up Interrupt Controller) lines (32 IRQ and NMI, RXEV)
- DAP feature: Halt event support
- DAP feature: SerialWire debug interface (protocol 2 with multidrop support)
- DAP feature: Micro Trace Buffer (MTB) is not implemented

Architectural clock gating allows the processor core to support SLEEP and DEEPSLEEP power states by disabling the clock to parts of the processor core. Note that power gating is not supported.

Each M0+ core has its own interrupt controller which can individually mask out interrupt sources as required. The same interrupts are routed to both M0+ cores.

2.4.1.3. ARM architecture

The processor implements the ARMv6-M architecture profile. See the [ARMv6-M Architecture Reference Manual](#), and for further details refer to the [ARM Cortex M0+ Technical Reference Manual](#).

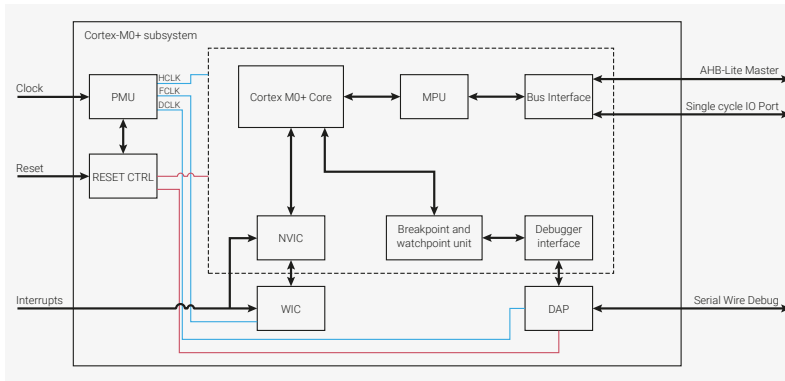

2.4.2. Functional Description

2.4.2.1. Overview

The Cortex-M0+ processor is a configurable, multistage, 32-bit RISC processor. It has an AMBA AHB-Lite interface and includes an NVIC component. It also has hardware debug, single-cycle I/O interfacing, and memory-protection functionality. The processor can execute Thumb code and is compatible with other Cortex-M profile processors.

[Figure 11](#) shows the functional blocks of the processor and surrounding blocks.

Figure 11. Cortex M0+
Functional block
diagram

2.4.2.2. Features

The M0+ features:

- The ARMv6-M Thumb® instruction set.
- Thumb-2 technology.
- An ARMv6-M compliant 24-bit SysTick timer.
- A 32-bit hardware multiplier. This is the standard single-cycle multiplier
- The ability to have deterministic, fixed-latency, interrupt handling.
- Load/store multiple instructions that can be abandoned and restarted to facilitate rapid interrupt handling.
- C Application Binary Interface compliant exception model. This is the ARMv6-M, C Application Binary Interface (C-ABI) compliant exception model that enables the use of pure C functions as interrupt handlers.
- Low power sleep-mode entry using Wait For Interrupt (WFI), Wait For Event (WFE) instructions, or the return from interrupt sleep-on-exit feature.

2.4.2.3. NVIC features

The Nested Vectored Interrupt Vontroller (NVIC) features are:

- 26 external interrupt inputs, each with four levels of priority.
- Dedicated Non-Maskable Interrupt (NMI) input (which can be driven from any standard interrupt source)
- Support for both level-sensitive and pulse-sensitive interrupt lines.
- Wake-up Interrupt Controller (WIC), providing ultra-low power sleep mode support.
- Relocatable vector table.

Further details available in [Section 2.4.5](#).

2.4.2.4. Debug features

Debug features are:

- Four hardware breakpoints.
- Two watchpoints.
- Program Counter Sampling Register (PCSR) for non-intrusive code profiling.
- Single step and vector catch capabilities.

- Support for unlimited software breakpoints using BKPT instruction.
- Non-intrusive access to core peripherals and zero-waitstate system slaves through a compact bus matrix. A debugger can access these devices, including memory, even when the processor is running.
- Full access to core registers when the processor is halted.
- CoreSight compliant debug access through a Debug Access Port (DAP) supporting Serial Wire debug connections.

2.4.2.4.1. Debug Access Port

The processor is implemented with a low gate count Debug Access Port (DAP). The low gate count Debug Access Port (DAP) provides a Serial Wire debug-port, and connects to the processor slave port to provide full system-level debug access. For more information on DAP, see the ADI v5.1 version of the ARM Debug Interface v5, Architecture Specification

2.4.2.5. MPU features

Memory Protection Unit (MPU) features are:

- Eight user-configurable memory regions.
- Eight sub-region disables per region.
- Execute never (XN) support.
- Default memory map support.

Further details available in [Section 2.4.6](#).

2.4.2.6. AHB-Lite interface

Transactions on the AHB-Lite interface are always marked as non-sequential. Processor accesses and debug accesses share the external interface to external AHB peripherals. The processor accesses take priority over debug accesses. Any vendor specific components can populate this bus.

i NOTE

Instructions are only fetched using the AHB-Lite interface. To optimize performance, the Cortex-M0+ processor fetches ahead of the instruction it is executing. To minimize power consumption, the fetch ahead is limited to a maximum of 32 bits.

2.4.2.7. Single-cycle I/O port

The processor implements a single-cycle I/O port that provides high speed access to tightly-coupled peripherals, such as general-purpose-I/O (GPIO). The port is accessible both by loads and stores from either the processor or the debugger. You cannot execute code from the I/O port.

2.4.2.8. Power Management Unit

Each processor has its own Power Management Unit (PMU) which allows power saving by turning off clocks to parts of the processor core. There are no separate power domains on RP2040.

The PMU runs from the processor clock which is controlled from the chip level clocks block. The PMU can control the following clock domains within the processor:

- A debug clock containing the processor debug resources and the rest of the DAP.
- A system clock containing the NVIC.

- A processor clock containing the core and associated interfaces

Control is limited to clock enable/disable. When enabled, all domains run at the same clock speed.

The PMU also interfaces with the WIC, to ensure that power-down and wake-up behaviors are transparent to software and work with clocking and sleeping requirements. This includes SLEEP or DEEPSLEEP support as controlled in SCR register.

2.4.2.8.1. Power Management

RP2040 ARM Cortex M0+ uses ARMv6-M which supports the use of Wait For Interrupt (WFI) and Wait For Event (WFE) instructions as part of system power management:

WFI provides a mechanism for hardware support of entry to one or more sleep states. Hardware can suspend execution until a wakeup event occurs.

WFE provides a mechanism for software to suspend program execution until a wakeup condition occurs with minimal or no impact on wakeup latency. Both WFI and WFE are hint instructions that might have no effect on program execution. Normally, they are used in software idle loops that resume program execution only after an interrupt or event of interest occurs.

NOTE

Code using WFE and WFI must handle any spurious wakeup events caused by a debug halt or other reasons.

Refer to the SDK and ARMv6-M guide for further information.

2.4.2.8.2. Wait For Event and Send Event

RP2040 can support software-based synchronization to system events using the Send-Event (SEV) and WFE hint instructions. Software can:

- use the WFE instruction to indicate that it is able to suspend execution of a process or thread until an event occurs, permitting hardware to enter a low power state.
- rely on a mechanism that is transparent to software and provides low latency wakeup.

The WFE mechanism relies on hardware and software working together to achieve energy saving. For example, stalling execution of a processor until a device or another processor has set a flag:

- the hardware provides the mechanism to enter the WFE low-power state.
- software enters a polling loop to determine when the flag is set:
- the polling processor issues a WFE instruction as part of a polling loop if the flag is clear.
- an event is generated (hardware interrupt or Send-Event instruction from another processor) when the flag is set.

WFE wake up events

The following events are WFE wake up events:

- the execution of an SEV instruction on the other processor
- any exception entering the pending state if SEVONPEND in the System Control Register is set to 1.
- an asynchronous exception at a priority that preempts any currently active exceptions.
- a debug event with debug enabled.

The Event Register

The Event Register is a single bit register. When set, an Event Register indicates that an event has occurred, since the register was last cleared, that might prevent the processor having to suspend operation on issuing a WFE instruction. The following conditions apply to the Event Register:

- A reset clears the Event Register.

- Any **WFE** wakeup event, or the execution of an exception return instruction, sets the Event Register.
- A **WFE** instruction clears the Event Register.
- Software cannot read or write the value of the Event Register directly.

The Send-Event instruction

The Send-Event (**SEV**) instruction causes an event to be signaled to the other processor. The Send-Event instruction generates a wakeup event.

The Wait For Event instruction

The action of the **WFE** instruction depends on the state of the Event Register:

- If the Event Register is set, the instruction clears the register and returns immediately.
- If the Event Register is clear the processor can suspend execution and enter a low-power state. It can remain in that state until the processor detects a **WFE** wakeup event or a reset. When the processor detects a **WFE** wakeup event, the **WFE** instruction completes.

WFE wakeup events can occur before a **WFE** instruction is issued. Software using the **WFE** mechanism must tolerate spurious wake up events, including multiple wakeups.

2.4.2.8.3. Wait For Interrupt

RP2040 supports Wait For Interrupt through the hint instruction, **WFI**.

When a processor issues a **WFI** instruction it can suspend execution and enter a low-power state. It can remain in that state until the processor detects one of the following **WFI** wake up events:

- A reset.
- An asynchronous exception at a priority that, if **PRIMASK.PM** was set to 0, would preempt any currently active exceptions.

Note

If **PRIMASK.PM** is set to 1, an asynchronous exception that has a higher group priority than any active exception results in a **WFI** instruction exit. If the group priority of the exception is less than or equal to the execution group priority, the exception is ignored.

- If debug is enabled, a debug event.
- A **WFI** wakeup event.

The **WFI** instruction completes when the hardware detects a **WFI** wake up event, or earlier if the implementation chooses.

The processor recognizes **WFI** wake up events only after issuing the **WFI** instruction.

2.4.2.8.4. Wakeup Interrupt Controller

The Wakeup Interrupt Controller (**WIC**) is used to wake the processor from a **DEEPSLEEP** state as controlled by the **SCR** register. In a **DEEPSLEEP** state clocks to the processor core and **NVIC** are not running. It can take a few cycles to wake from a **DEEPSLEEP** state.

The **WIC** takes inputs from the receive event signal (from the other processor), 32 interrupts lines, and **NMI**.

For more power saving, RP2040 supports system level power saving modes as defined in [Section 2.10](#) which also includes code examples.

2.4.2.9. Reset Control

The Cortex M0+ Reset Control block controls the following resets:

- Debug reset
- M0+ core reset
- PMU reset

After power up, both processors are released from reset (see details in [Section 2.12.2](#)). This releases reset to Debug, M0+ core and PMU.

Once running, resets can be triggered from the Debugger, NVIC (using `AIRCR.SYSRESETREQ`), or the RP2040 Power On State Machine controller (see details in [Power-On State Machine](#)). The NVIC only resets the Cortex-M0+ processor core (not the Debug or PMU), whereas the Power On State Machine controller can reset the processor subsystem which asserts all resets in the subsystem (Debug, M0+ core, PMU).

2.4.3. Programmer’s model

2.4.3.1. About the programmer’s model

The ARMv6-M Architecture Reference Manual provides a complete description of the programmer’s model. This chapter gives an overview of the Cortex-M0+ programmer’s model that describes the implementation-defined options. It also contains the ARMv6-M Thumb instructions it uses and their cycle counts for the processor. Additional details are in following chapters

- [Section 2.4.4](#) summarizes the system control features of the programmer’s model.
- [Section 2.4.5](#) summarizes the NVIC features of the programmer’s model.
- [Section 2.3.4](#) summarizes the Debug features of the programmer’s model.

2.4.3.2. Modes of operation and execution

See the ARMv6-M Architecture Reference Manual for information about the modes of operation and execution.

2.4.3.3. Instruction set summary

The processor implements the ARMv6-M Thumb instruction set, including a number of 32-bit instructions that use Thumb-2 technology. The ARMv6-M instruction set comprises:

- All of the 16-bit Thumb instructions from ARMv7-M excluding CBZ, CBNZ and IT.
- The 32-bit Thumb instructions BL, DMB, DSB, ISB, MRS and MSR.

[Table 111](#) shows the Cortex-M0+ instructions and their cycle counts. The cycle counts are based on a system with zero wait-states.

Table 111. Cortex-M0+ instruction summary

	Data memory	DMB	3
	Data synchronization	DSB	3

Table Notes

- ^a 2 if to AHB interface or SCS, 1 if to single-cycle I/O port.
- ^b N is the number of elements in the list.
- ^c N is the number of elements in the list including PC or LR.
- ^d 2 if taken, 1 if not-taken.
- ^e Cycle count depends on processor and debug configuration.
- ^f Excludes time spent waiting for an interrupt or event.
- ^g Executes as NOP.

See the ARMv6-M Architecture Reference Manual for more information about the ARMv6-M Thumb instructions.

2.4.3.4. Memory model

The processor contains a bus matrix that arbitrates the processor core and Debug Access Port (DAP) memory accesses to both the external memory system and to the internal NVIC and debug components.

Priority is always given to the processor to ensure that any debug accesses are as non-intrusive as possible. For a zero wait-state system, all debug accesses to system memory, NVIC, and debug resources are completely non-intrusive for typical code execution.

The system memory map is ARMv6-M architecture compliant, and is common both to the debugger and processor accesses. Transactions are routed as follows:

- All accesses below `0xd0000000` or above `0xffffffff` appear as AHB-Lite transactions on the AHB-Lite master port of the processor.
- Accesses in the range `0xd0000000` to `0xdfffffff` are handled by the SIO.
- Accesses in the range `0xe0000000` to `0xffffffff` are handled within the processor and do not appear on the AHB-Lite master port of the processor.

The processor supports only word size accesses in the range `0xd0000000 - 0xffffffff`.

Table 112 shows the code, data, and device suitability for each region of the default memory map. This is the memory map used by implementations when the MPU is disabled. The attributes and permissions of all regions, except that targeting the Cortex-M0+ NVIC and debug components, can be modified using an implemented MPU.

Table 112. M0+ Default memory map usage

Address range	Code	Data	Device
<code>0xf0000000 - 0xffffffff</code>	No	No	Yes
<code>0xe0000000 - 0xffffffff</code>	No	No	No ^a
<code>0xa0000000 - 0xdfffffff</code>	No	No	Yes
<code>0x60000000 - 0x9fffffff</code>	Yes	Yes	No
<code>0x40000000 - 0x5fffffff</code>	No	No	Yes
<code>0x20000000 - 0x3fffffff</code>	Yes	Yes	No

Address range	Code	Data	Device
0x00000000 - 0x1fffffff	Yes	Yes	No

^a. Space reserved for Cortex-M0+ NVIC and debug components.

Note

Regions not marked as suitable for code behave as eXecute-Never (XN) and generate a HardFault exception if code attempts to execute from this location.

See the ARMv6-M Architecture Reference Manual for more information about the memory model.

2.4.3.5. Processor core registers summary

Table 113 shows the processor core register set summary. Each of these registers is 32 bits wide.

Table 113. M0+ processor core register set summary

Name	Description
R0-R12	R0-R12 are general-purpose registers for data operations.
MSP/PSP (R13)	The Stack Pointer (SP) is register R13. In Thread mode, the CONTROL register indicates the stack pointer to use, Main Stack Pointer (MSP) or Process Stack Pointer (PSP).
LR (R14)	The Link Register (LR) is register R14. It stores the return information for subroutines, function calls, and exceptions.
PC (R15)	The Program Counter (PC) is register R15. It contains the current program address. PSR The Program Status Register (PSR) combines: * Application Program Status Register (APSR). * Interrupt Program Status Register (IPSR). * Execution Program Status Register (EPSR). These registers provide different views of the PSR.
PRIMASK	The PRIMASK register prevents activation of all exceptions with configurable priority.
CONTROL	The CONTROL register controls the stack used, the code privilege level, when the processor is in Thread mode.

Note

See the ARMv6-M Architecture Reference Manual for information about the processor core registers and their addresses, access types, and reset values.

2.4.3.6. Exceptions

This section describes the exception model of the processor.

2.4.3.6.1. Exception handling

The processor implements advanced exception and interrupt handling, as described in the ARMv6-M Architecture Reference Manual. To minimize interrupt latency, the processor abandons any load-multiple or store-multiple instruction to take any pending interrupt. On return from the interrupt handler, the processor restarts the load-multiple or store-multiple instruction from the beginning.

This means that software must not use load-multiple or store-multiple instructions when a device is accessed in a memory region that is read-sensitive or sensitive to repeated writes. The software must not use these instructions in any case where repeated reads or writes might cause inconsistent results or unwanted side-effects.

The processor implementation can **TO DO (NICK): what do we have ?** ensure that a fixed number of cycles are required for the NVIC to detect an interrupt signal and the processor fetch the first instruction of the associated interrupt handler. If this is done, the highest priority interrupt is jitter-free. See the documentation supplied by the processor implementer for more information. #TO DO: (NICK) That will be us then #

To reduce interrupt latency and jitter, the Cortex-M0+ processor implements both interrupt late-arrival and interrupt tail-chaining mechanisms, as defined by the ARMv6-M architecture. The worst case interrupt latency, for the highest priority active interrupt in a zero wait-state system not using jitter suppression, is 15 cycles.

The processor exception model has the following implementation-defined behavior in addition to the architecture specified behavior:

- Exceptions on stacking from HardFault to NMI lockup at NMI priority.
- Exceptions on unstacking from NMI to HardFault lockup at HardFault priority.

2.4.4. System control

2.4.4.1. System control register summary

Table 114 gives the system control registers. Each of these registers is 32 bits wide.

Table 114. M0+ System control registers

Name	Description
SYST_CSR	SysTick Control and Status Register
SYST_RVR	SysTick Reload Value Register
SYST_CVR	SysTick Current Value Register
SYST_CALIB	SysTick Calibration value Register
CPUID	See CPUID Register
ICSR	Interrupt Control State Register
AIRCR	Application Interrupt and Reset Control Register
CCR	Configuration and Control Register
SHPR2	System Handler Priority Register
SHPR3	System Handler Priority Register
SHCSR	System Handler Control and State Register
VTOR	Vector table Offset Register
ACTLR	Auxiliary Control Register

Note

- All system control registers are only accessible using word transfers. Any attempt to read or write a halfword or byte is Unpredictable.
- See the List of Registers or ARMv6-M Architecture Reference Manual for more information about the system control registers, and their addresses and access types, and reset values.

2.4.4.1.1. CPUID Register

The CPUID contains the part number, version, and implementation information that is specific to the processor.

2.4.5. NVIC

2.4.5.1. About the NVIC

External interrupt signals connect to the NVIC, and the NVIC prioritizes the interrupts. Software can set the priority of each interrupt. The NVIC and the Cortex-M0+ processor core are closely coupled, providing low latency interrupt processing and efficient processing of late arriving interrupts.

All NVIC registers are only accessible using word transfers. Any attempt to read or write a halfword or byte individually is unpredictable.

NVIC registers are always little-endian.

Processor exception handling is described in Exceptions section.

2.4.5.1.1. SysTick timer

A 24-bit SysTick system timer, extends the functionality of both the processor and the NVIC and provides:

- A 24-bit system timer (SysTick).
- Additional configurable priority SysTick interrupt.

The SysTick timer uses a 1us pulse as a clock enable. This is generated in the watchdog block as timer_tick. Accuracy of SysTick timing depends upon accuracy of this timer_tick. The SysTick timer can also run from the system clock (see [SYST_CALIB](#)).

See the ARMv6-M Architecture Reference Manual for more information.

2.4.5.1.2. Low power modes

The implementation includes a WIC. This enables the processor and NVIC to be put into a very low-power sleep mode leaving the WIC to identify and prioritize interrupts.

The processor fully implements the Wait For Interrupt (WFI), Wait For Event (WFE) and the Send Event (SEV) instructions. In addition, the processor also supports the use of SLEEPONEXIT, that causes the processor core to enter sleep mode when it returns from an exception handler to Thread mode. See the ARMv6-M Architecture Reference Manual for more information.

2.4.5.2. NVIC register summary

Table 115 shows the NVIC registers. Each of these registers is 32 bits wide.

Table 115. M0+ NVIC registers

Name	Description
NVIC_ISER	Interrupt Set-Enable Register.
NVIC_ICER	Interrupt Clear-Enable Register.
NVIC_ISPR	Interrupt Set-Pending Register.
NVIC_ICPR	Interrupt Clear-Pending Register.
NVIC_IPR0 - NVIC_IPR7	Interrupt Priority Registers.

Note

See the List of Registers or ARMv6-M Architecture Reference Manual for more information about the NVIC registers and their addresses, access types, and reset values.

2.4.6. MPU

2.4.6.1. About the MPU

The MPU is a component for memory protection which allows the processor to support the ARMv6 Protected Memory System Architecture model. The MPU provides full support for:

- Eight unified protection regions.
- Overlapping protection regions, with ascending region priority:
 - 7 = highest priority.
 - 0 = lowest priority.
- Access permissions.
- Exporting memory attributes to the system.

MPU mismatches and permission violations invoke the HardFault handler. See the ARMv6-M Architecture Reference Manual for more information.

You can use the MPU to:

- Enforce privilege rules.
- Separate processes.
- Manage memory attributes.

2.4.6.2. MPU register summary

Table 116 shows the MPU registers. Each of these registers is 32 bits wide.

Table 116. M0+ MPU registers

Name	Description
MPU_TYPE	MPU Type Register.
MPU_CTRL	MPU Control Register.
MPU_RNR	MPU Region Number Register.
MPU_RBAR	MPU Region Base Address Register.
MPU_RASR	MPU Region Attribute and Size Register.

Note

- See the ARMv6-M Architecture Reference Manual for more information about the MPU registers and their addresses, access types, and reset values.
- The MPU supports region sizes from 256-bytes to 4Gb, with 8-sub regions per region.

2.4.7. Debug

Basic debug functionality includes processor halt, single-step, processor core register access, Reset and HardFault Vector Catch, unlimited software breakpoints, and full system memory access. See the ARMv6-M Architecture Reference Manual.

The debug features for this device are:

- A breakpoint unit supporting 4 hardware breakpoints.
- A watchpoint unit supporting 2 watchpoints.

2.4.8. List of Registers

Table 117. List of M0PLUS registers

Offset	Name	Info
0xe010	SYST_CSR	SysTick Control and Status Register
0xe014	SYST_RVR	SysTick Reload Value Register
0xe018	SYST_CVR	SysTick Current Value Register
0xe01c	SYST_CALIB	SysTick Calibration Value Register
0xe100	NVIC_ISER	Interrupt Set-Enable Register
0xe180	NVIC_ICER	Interrupt Clear-Enable Register
0xe200	NVIC_ISPR	Interrupt Set-Pending Register
0xe280	NVIC_ICPR	Interrupt Clear-Pending Register
0xe400	NVIC_IPR0	Interrupt Priority Register 0
0xe404	NVIC_IPR1	Interrupt Priority Register 1
0xe408	NVIC_IPR2	Interrupt Priority Register 2
0xe40c	NVIC_IPR3	Interrupt Priority Register 3
0xe410	NVIC_IPR4	Interrupt Priority Register 4
0xe414	NVIC_IPR5	Interrupt Priority Register 5
0xe418	NVIC_IPR6	Interrupt Priority Register 6
0xe41c	NVIC_IPR7	Interrupt Priority Register 7
0xed00	CPUID	CPUID Base Register
0xed04	ICSR	Interrupt Control and State Register
0xed08	VTOR	Vector Table Offset Register
0xed0c	AIRCR	Application Interrupt and Reset Control Register
0xed10	SCR	System Control Register
0xed14	CCR	Configuration and Control Register
0xed1c	SHPR2	System Handler Priority Register 2
0xed20	SHPR3	System Handler Priority Register 3
0xed24	SHCSR	System Handler Control and State Register
0xed90	MPU_TYPE	MPU Type Register
0xed94	MPU_CTRL	MPU Control Register
0xed98	MPU_RNR	MPU Region Number Register
0xed9c	MPU_RBAR	MPU Region Base Address Register
0xeda0	MPU_RASR	MPU Region Attribute and Size Register

SYST_CSR Register

Description

Use the SysTick Control and Status Register to enable the SysTick features.

Table 118. SYST_CSR Register

Bits	Name	Description	Type	Reset
31:17	Reserved.	-	-	-
16	COUNTFLAG	Returns 1 if timer counted to 0 since last time this was read. Clears on read by application or debugger.	RO	0x0
15:3	Reserved.	-	-	-
2	CLKSOURCE	SysTick clock source. Always reads as one if SYST_CALIB reports NOREF. Selects the SysTick timer clock source: 0 = External reference clock. 1 = Processor clock.	RW	0x0
1	TICKINT	Enables SysTick exception request: 0 = Counting down to zero does not assert the SysTick exception request. 1 = Counting down to zero to asserts the SysTick exception request.	RW	0x0
0	ENABLE	Enable SysTick counter: 0 = Counter disabled. 1 = Counter enabled.	RW	0x0

SYST_RVR Register

Description

Use the SysTick Reload Value Register to specify the start value to load into the current value register when the counter reaches 0. It can be any value between 0 and 0x00FFFFFF. A start value of 0 is possible, but has no effect because the SysTick interrupt and COUNTFLAG are activated when counting from 1 to 0. The reset value of this register is UNKNOWN.

To generate a multi-shot timer with a period of N processor clock cycles, use a RELOAD value of N-1. For example, if the SysTick interrupt is required every 100 clock pulses, set RELOAD to 99.

Table 119. SYST_RVR Register

Bits	Name	Description	Type	Reset
31:24	Reserved.	-	-	-
23:0	RELOAD	Value to load into the SysTick Current Value Register when the counter reaches 0.	RW	0x000000

SYST_CVR Register

Description

Use the SysTick Current Value Register to find the current value in the register. The reset value of this register is UNKNOWN.

Table 120. SYST_CVR Register

Bits	Name	Description	Type	Reset
31:24	Reserved.	-	-	-
23:0	CURRENT	Reads return the current value of the SysTick counter. This register is write-clear. Writing to it with any value clears the register to 0. Clearing this register also clears the COUNTFLAG bit of the SysTick Control and Status Register.	RW	0x000000

SYST_CALIB Register

Description

Use the SysTick Calibration Value Register to enable software to scale to any required speed using divide and multiply.

Table 121. SYST_CALIB Register

Bits	Name	Description	Type	Reset
31	NOREF	If reads as 1, the Reference clock is not provided - the CLKSOURCE bit of the SysTick Control and Status register will be forced to 1 and cannot be cleared to 0.	RO	0x0
30	SKEW	If reads as 1, the calibration value for 10ms is inexact (due to clock frequency).	RO	0x0
29:24	Reserved.	-	-	-
23:0	TENMS	An optional Reload value to be used for 10ms (100Hz) timing, subject to system clock skew errors. If the value reads as 0, the calibration value is not known.	RO	0x000000

NVIC_ISER Register

Description

Use the Interrupt Set-Enable Register to enable interrupts and determine which interrupts are currently enabled.

If a pending interrupt is enabled, the NVIC activates the interrupt based on its priority. If an interrupt is not enabled, asserting its interrupt signal changes the interrupt state to pending, but the NVIC never activates the interrupt, regardless of its priority.

Table 122. NVIC_ISER Register

Bits	Name	Description	Type	Reset
31:0	SETENA	Interrupt set-enable bits. Write: 0 = No effect. 1 = Enable interrupt. Read: 0 = Interrupt disabled. 1 = Interrupt enabled.	RW	0x00000000

NVIC_ICER Register

Description

Use the Interrupt Clear-Enable Registers to disable interrupts and determine which interrupts are currently enabled.

Table 123. NVIC_ICER Register

Bits	Name	Description	Type	Reset
31:0	CLRENA	Interrupt clear-enable bits. Write: 0 = No effect. 1 = Disable interrupt. Read: 0 = Interrupt disabled. 1 = Interrupt enabled.	RW	0x00000000

NVIC_ISPR Register

Description

The NVIC_ISPR forces interrupts into the pending state, and shows which interrupts are pending.

Table 124. NVIC_ISPR Register

Bits	Name	Description	Type	Reset
31:0	SETPEND	Interrupt set-pending bits. Write: 0 = No effect. 1 = Changes interrupt state to pending. Read: 0 = Interrupt is not pending. 1 = Interrupt is pending. Note: Writing 1 to the NVIC_ISPR bit corresponding to: An interrupt that is pending has no effect. A disabled interrupt sets the state of that interrupt to pending.	RW	0x00000000

NVIC_ICPR Register

Description

Use the Interrupt Clear-Pending Register to clear pending interrupts and determine which interrupts are currently pending.

Table 125. NVIC_ICPR Register

Bits	Name	Description	Type	Reset
31:0	CLRPEND	Interrupt clear-pending bits. Write: 0 = No effect. 1 = Removes pending state and interrupt. Read: 0 = Interrupt is not pending. 1 = Interrupt is pending.	RW	0x00000000

NVIC_IPR0 Register

Description

Use the Interrupt Priority Registers to assign a priority from 0 to 3 to each of the available interrupts. 0 is the highest priority, and 3 is the lowest.

Note: Writing 1 to an NVIC_ICPR bit does not affect the active state of the corresponding interrupt.

These registers are only word-accessible

Table 126. NVIC_IPR0 Register

Bits	Name	Description	Type	Reset
31:30	IP_3	Priority of interrupt 3	RW	0x0
29:24	Reserved.	-	-	-

Bits	Name	Description	Type	Reset
23:22	IP_2	Priority of interrupt 2	RW	0x0
21:16	Reserved.	-	-	-
15:14	IP_1	Priority of interrupt 1	RW	0x0
13:8	Reserved.	-	-	-
7:6	IP_0	Priority of interrupt 0	RW	0x0
5:0	Reserved.	-	-	-

NVIC_IPR1 Register

Description

Use the Interrupt Priority Registers to assign a priority from 0 to 3 to each of the available interrupts. 0 is the highest priority, and 3 is the lowest.

Table 127. NVIC_IPR1 Register

Bits	Name	Description	Type	Reset
31:30	IP_7	Priority of interrupt 7	RW	0x0
29:24	Reserved.	-	-	-
23:22	IP_6	Priority of interrupt 6	RW	0x0
21:16	Reserved.	-	-	-
15:14	IP_5	Priority of interrupt 5	RW	0x0
13:8	Reserved.	-	-	-
7:6	IP_4	Priority of interrupt 4	RW	0x0
5:0	Reserved.	-	-	-

NVIC_IPR2 Register

Description

Use the Interrupt Priority Registers to assign a priority from 0 to 3 to each of the available interrupts. 0 is the highest priority, and 3 is the lowest.

Table 128. NVIC_IPR2 Register

Bits	Name	Description	Type	Reset
31:30	IP_11	Priority of interrupt 11	RW	0x0
29:24	Reserved.	-	-	-
23:22	IP_10	Priority of interrupt 10	RW	0x0
21:16	Reserved.	-	-	-
15:14	IP_9	Priority of interrupt 9	RW	0x0
13:8	Reserved.	-	-	-
7:6	IP_8	Priority of interrupt 8	RW	0x0
5:0	Reserved.	-	-	-

NVIC_IPR3 Register

Description

Use the Interrupt Priority Registers to assign a priority from 0 to 3 to each of the available interrupts. 0 is the highest priority, and 3 is the lowest.

Table 129. NVIC_IPR3 Register

Bits	Name	Description	Type	Reset
31:30	IP_15	Priority of interrupt 15	RW	0x0
29:24	Reserved.	-	-	-
23:22	IP_14	Priority of interrupt 14	RW	0x0
21:16	Reserved.	-	-	-
15:14	IP_13	Priority of interrupt 13	RW	0x0
13:8	Reserved.	-	-	-
7:6	IP_12	Priority of interrupt 12	RW	0x0
5:0	Reserved.	-	-	-

NVIC_IPR4 Register**Description**

Use the Interrupt Priority Registers to assign a priority from 0 to 3 to each of the available interrupts. 0 is the highest priority, and 3 is the lowest.

Table 130. NVIC_IPR4 Register

Bits	Name	Description	Type	Reset
31:30	IP_19	Priority of interrupt 19	RW	0x0
29:24	Reserved.	-	-	-
23:22	IP_18	Priority of interrupt 18	RW	0x0
21:16	Reserved.	-	-	-
15:14	IP_17	Priority of interrupt 17	RW	0x0
13:8	Reserved.	-	-	-
7:6	IP_16	Priority of interrupt 16	RW	0x0
5:0	Reserved.	-	-	-

NVIC_IPR5 Register**Description**

Use the Interrupt Priority Registers to assign a priority from 0 to 3 to each of the available interrupts. 0 is the highest priority, and 3 is the lowest.

Table 131. NVIC_IPR5 Register

Bits	Name	Description	Type	Reset
31:30	IP_23	Priority of interrupt 23	RW	0x0
29:24	Reserved.	-	-	-
23:22	IP_22	Priority of interrupt 22	RW	0x0
21:16	Reserved.	-	-	-
15:14	IP_21	Priority of interrupt 21	RW	0x0
13:8	Reserved.	-	-	-

Bits	Name	Description	Type	Reset
7:6	IP_20	Priority of interrupt 20	RW	0x0
5:0	Reserved.	-	-	-

NVIC_IPR6 Register

Description

Use the Interrupt Priority Registers to assign a priority from 0 to 3 to each of the available interrupts. 0 is the highest priority, and 3 is the lowest.

Table 132. NVIC_IPR6 Register

Bits	Name	Description	Type	Reset
31:30	IP_27	Priority of interrupt 27	RW	0x0
29:24	Reserved.	-	-	-
23:22	IP_26	Priority of interrupt 26	RW	0x0
21:16	Reserved.	-	-	-
15:14	IP_25	Priority of interrupt 25	RW	0x0
13:8	Reserved.	-	-	-
7:6	IP_24	Priority of interrupt 24	RW	0x0
5:0	Reserved.	-	-	-

NVIC_IPR7 Register

Description

Use the Interrupt Priority Registers to assign a priority from 0 to 3 to each of the available interrupts. 0 is the highest priority, and 3 is the lowest.

Table 133. NVIC_IPR7 Register

Bits	Name	Description	Type	Reset
31:30	IP_31	Priority of interrupt 31	RW	0x0
29:24	Reserved.	-	-	-
23:22	IP_30	Priority of interrupt 30	RW	0x0
21:16	Reserved.	-	-	-
15:14	IP_29	Priority of interrupt 29	RW	0x0
13:8	Reserved.	-	-	-
7:6	IP_28	Priority of interrupt 28	RW	0x0
5:0	Reserved.	-	-	-

CPUID Register

Description

Read the CPU ID Base Register to determine: the ID number of the processor core, the version number of the processor core, the implementation details of the processor core.

Table 134. CPUID Register

Bits	Name	Description	Type	Reset
31:24	IMPLEMENTER	Implementor code: 0x41 = ARM	RO	0x41
23:20	VARIANT	Major revision number n in the rnpm revision status: 0x0 = Revision 0.	RO	0x0
19:16	ARCHITECTURE	Constant that defines the architecture of the processor: 0xC = ARMv6-M architecture.	RO	0xc
15:4	PARTNO	Number of processor within family: 0xC60 = Cortex-M0+	RO	0xc60
3:0	REVISION	Minor revision number m in the rnpm revision status: 0x1 = Patch 1.	RO	0x1

ICSR Register

Description

Use the Interrupt Control State Register to set a pending Non-Maskable Interrupt (NMI), set or clear a pending PendSV, set or clear a pending SysTick, check for pending exceptions, check the vector number of the highest priority pending exception, check the vector number of the active exception.

Table 135. ICSR Register

Bits	Name	Description	Type	Reset
31	NMIPENDSET	Setting this bit will activate an NMI. Since NMI is the highest priority exception, it will activate as soon as it is registered. NMI set-pending bit. Write: 0 = No effect. 1 = Changes NMI exception state to pending. Read: 0 = NMI exception is not pending. 1 = NMI exception is pending. Because NMI is the highest-priority exception, normally the processor enters the NMI exception handler as soon as it detects a write of 1 to this bit. Entering the handler then clears this bit to 0. This means a read of this bit by the NMI exception handler returns 1 only if the NMI signal is reasserted while the processor is executing that handler.	RW	0x0
30:29	Reserved.	-	-	-
28	PENDSVSET	PendSV set-pending bit. Write: 0 = No effect. 1 = Changes PendSV exception state to pending. Read: 0 = PendSV exception is not pending. 1 = PendSV exception is pending. Writing 1 to this bit is the only way to set the PendSV exception state to pending.	RW	0x0
27	PENDSVCLR	PendSV clear-pending bit. Write: 0 = No effect. 1 = Removes the pending state from the PendSV exception.	RW	0x0

Bits	Name	Description	Type	Reset
26	PENDSTSET	SysTick exception set-pending bit. Write: 0 = No effect. 1 = Changes SysTick exception state to pending. Read: 0 = SysTick exception is not pending. 1 = SysTick exception is pending.	RW	0x0
25	PENDSTCLR	SysTick exception clear-pending bit. Write: 0 = No effect. 1 = Removes the pending state from the SysTick exception. This bit is WO. On a register read its value is Unknown.	RW	0x0
24	Reserved.	-	-	-
23	ISRPREEMPT	The system can only access this bit when the core is halted. It indicates that a pending interrupt is to be taken in the next running cycle. If C_MASKINTS is clear in the Debug Halting Control and Status Register, the interrupt is serviced.	RO	0x0
22	ISRPENDING	External interrupt pending flag	RO	0x0
21	Reserved.	-	-	-
20:12	VECTPENDING	Indicates the exception number for the highest priority pending exception: 0 = no pending exceptions. Non zero = The pending state includes the effect of memory-mapped enable and mask registers. It does not include the PRIMASK special-purpose register qualifier.	RO	0x000
11:9	Reserved.	-	-	-
8:0	VECTACTIVE	Active exception number field. Reset clears the VECTACTIVE field.	RO	0x000

VTOR Register

Description

The VTOR holds the vector table offset address.

Table 136. VTOR Register

Bits	Name	Description	Type	Reset
31:8	TBLOFF	Bits [31:8] of the indicate the vector table offset address.	RW	0x000000
7:0	Reserved.	-	-	-

AIRCR Register

Description

Use the Application Interrupt and Reset Control Register to: determine data endianness, clear all active state information from debug halt mode, request a system reset.

Table 137. AIRCR Register

Bits	Name	Description	Type	Reset
31:16	VECTKEY	Register key: Reads as Unknown On writes, write 0x05FA to VECTKEY, otherwise the write is ignored.	RW	0x0000
15	ENDIANESS	Data endianness implemented: 0 = Little-endian.	RO	0x0
14:3	Reserved.	-	-	-
2	SYSRESETREQ	Writing 1 to this bit causes the SYSRESETREQ signal to the outer system to be asserted to request a reset. The intention is to force a large system reset of all major components except for debug. The C_HALT bit in the DHCSR is cleared as a result of the system reset requested. The debugger does not lose contact with the device.	RW	0x0
1	VECTCLRACTIVE	Clears all active state information for fixed and configurable exceptions. This bit: is self-clearing, can only be set by the DAP when the core is halted. When set: clears all active exception status of the processor, forces a return to Thread mode, forces an IPSR of 0. A debugger must re-initialize the stack.	RW	0x0
0	Reserved.	-	-	-

SCR Register

Description

System Control Register. Use the System Control Register for power-management functions: signal to the system when the processor can enter a low power state, control how the processor enters and exits low power states.

Table 138. SCR Register

Bits	Name	Description	Type	Reset
31:5	Reserved.	-	-	-
4	SEVONPEND	Send Event on Pending bit: 0 = Only enabled interrupts or events can wakeup the processor, disabled interrupts are excluded. 1 = Enabled events and all interrupts, including disabled interrupts, can wakeup the processor. When an event or interrupt becomes pending, the event signal wakes up the processor from WFE. If the processor is not waiting for an event, the event is registered and affects the next WFE. The processor also wakes up on execution of an SEV instruction or an external event.	RW	0x0
3	Reserved.	-	-	-
2	SLEEPDEEP	Controls whether the processor uses sleep or deep sleep as its low power mode: 0 = Sleep. 1 = Deep sleep.	RW	0x0

Bits	Name	Description	Type	Reset
1	SLEEPONEXIT	Indicates sleep-on-exit when returning from Handler mode to Thread mode: 0 = Do not sleep when returning to Thread mode. 1 = Enter sleep, or deep sleep, on return from an ISR to Thread mode. Setting this bit to 1 enables an interrupt driven application to avoid returning to an empty main application.	RW	0x0
0	Reserved.	-	-	-

CCR Register

Description

The Configuration and Control Register permanently enables stack alignment and causes unaligned accesses to result in a Hard Fault.

Table 139. CCR Register

Bits	Name	Description	Type	Reset
31:10	Reserved.	-	-	-
9	STKALIGN	Always reads as one, indicates 8-byte stack alignment on exception entry. On exception entry, the processor uses bit[9] of the stacked PSR to indicate the stack alignment. On return from the exception it uses this stacked bit to restore the correct stack alignment.	RO	0x0
8:4	Reserved.	-	-	-
3	UNALIGN_TRP	Always reads as one, indicates that all unaligned accesses generate a HardFault.	RO	0x0
2:0	Reserved.	-	-	-

SHPR2 Register

Description

System handlers are a special class of exception handler that can have their priority set to any of the priority levels. Use the System Handler Priority Register 2 to set the priority of SVCall.

Table 140. SHPR2 Register

Bits	Name	Description	Type	Reset
31:30	PRL11	Priority of system handler 11, SVCall	RW	0x0
29:0	Reserved.	-	-	-

SHPR3 Register

Description

System handlers are a special class of exception handler that can have their priority set to any of the priority levels. Use the System Handler Priority Register 3 to set the priority of PendSV and SysTick.

Table 141. SHPR3 Register

Bits	Name	Description	Type	Reset
31:30	PRL15	Priority of system handler 15, SysTick	RW	0x0
29:24	Reserved.	-	-	-

Bits	Name	Description	Type	Reset
23:22	PRI_14	Priority of system handler 14, PendSV	RW	0x0
21:0	Reserved.	-	-	-

SHCSR Register

Description

Use the System Handler Control and State Register to determine or clear the pending status of SVCcall.

Table 142. SHCSR Register

Bits	Name	Description	Type	Reset
31:16	Reserved.	-	-	-
15	SVCALLPENDED	Reads as 1 if SVCcall is Pending. Write 1 to set pending SVCcall, write 0 to clear pending SVCcall.	RW	0x0
14:0	Reserved.	-	-	-

MPU_TYPE Register

Description

Read the MPU Type Register to determine if the processor implements an MPU, and how many regions the MPU supports.

Table 143. MPU_TYPE Register

Bits	Name	Description	Type	Reset
31:24	Reserved.	-	-	-
23:16	IREGION	Instruction region. Reads as zero as ARMv6-M only supports a unified MPU.	RO	0x00
15:8	DREGION	Number of regions supported by the MPU.	RO	0x08
7:1	Reserved.	-	-	-
0	SEPARATE	Indicates support for separate instruction and data address maps. Reads as 0 as ARMv6-M only supports a unified MPU.	RO	0x0

MPU_CTRL Register

Description

Use the MPU Control Register to enable and disable the MPU, and to control whether the default memory map is enabled as a background region for privileged accesses, and whether the MPU is enabled for HardFaults and NMLs.

Table 144. MPU_CTRL Register

Bits	Name	Description	Type	Reset
31:3	Reserved.	-	-	-

Bits	Name	Description	Type	Reset
2	PRIVDEFENA	Controls whether the default memory map is enabled as a background region for privileged accesses. This bit is ignored when ENABLE is clear. 0 = If the MPU is enabled, disables use of the default memory map. Any memory access to a location not covered by any enabled region causes a fault. 1 = If the MPU is enabled, enables use of the default memory map as a background region for privileged software accesses. When enabled, the background region acts as if it is region number -1. Any region that is defined and enabled has priority over this default map.	RW	0x0
1	HFNMENA	Controls the use of the MPU for HardFaults and NMIs. Setting this bit when ENABLE is clear results in UNPREDICTABLE behaviour. When the MPU is enabled: 0 = MPU is disabled during HardFault and NMI handlers, regardless of the value of the ENABLE bit. 1 = the MPU is enabled during HardFault and NMI handlers.	RW	0x0
0	ENABLE	Enables the MPU. If the MPU is disabled, privileged and unprivileged accesses use the default memory map. 0 = MPU disabled. 1 = MPU enabled.	RW	0x0

MPU_RNR Register

Description

Use the MPU Region Number Register to select the region currently accessed by MPU_RBAR and MPU_RASR.

Table 145. MPU_RNR Register

Bits	Name	Description	Type	Reset
31:4	Reserved.	-	-	-
3:0	REGION	Indicates the MPU region referenced by the MPU_RBAR and MPU_RASR registers. The MPU supports 8 memory regions, so the permitted values of this field are 0-7.	RW	0x0

MPU_RBAR Register

Description

Read the MPU Region Base Address Register to determine the base address of the region identified by MPU_RNR. Write to update the base address of said region or that of a specified region, with whose number MPU_RNR will also be updated.

Table 146. MPU_RBAR Register

Bits	Name	Description	Type	Reset
31:8	ADDR	Base address of the region.	RW	0x000000
7:5	Reserved.	-	-	-

Bits	Name	Description	Type	Reset
4	VALID	On writes, indicates whether the write must update the base address of the region identified by the REGION field, updating the MPU_RNR to indicate this new region. Write: 0 = MPU_RNR not changed, and the processor: Updates the base address for the region specified in the MPU_RNR. Ignores the value of the REGION field. 1 = The processor: Updates the value of the MPU_RNR to the value of the REGION field. Updates the base address for the region specified in the REGION field. Always reads as zero.	RW	0x0
3:0	REGION	On writes, specifies the number of the region whose base address to update provided VALID is set written as 1. On reads, returns bits [3:0] of MPU_RNR.	RW	0x0

MPU_RASR Register

Description

Use the MPU Region Attribute and Size Register to define the size, access behaviour and memory type of the region identified by MPU_RNR, and enable that region.

Table 147. MPU_RASR Register

Bits	Name	Description	Type	Reset
31:16	ATTRS	The MPU Region Attribute field. Use to define the region attribute control. 28 = XN: Instruction access disable bit: 0 = Instruction fetches enabled. 1 = Instruction fetches disabled. 26:24 = AP: Access permission field 18 = S: Shareable bit 17 = C: Cacheable bit 16 = B: Bufferable bit	RW	0x0000
15:8	SRD	Subregion Disable. For regions of 256 bytes or larger, each bit of this field controls whether one of the eight equal subregions is enabled.	RW	0x00
7:6	Reserved.	-	-	-
5:1	SIZE	Indicates the region size. Region size in bytes = $2^{(SIZE+1)}$. The minimum permitted value is 7 (b00111) = 256Bytes	RW	0x00
0	ENABLE	Enables the region.	RW	0x0

2.5. Memory

RP2040 has embedded ROM and SRAM, and access to external Flash via a QSPI interface. Details of internal memory are given below.

2.5.1. ROM

A 16kB read-only memory (ROM) is at address `0x00000000`. The ROM contents are fixed at the time the silicon is manufactured. It contains:

- Initial startup routine
- Flash boot sequence
- Flash programming routines
- USB mass storage device with UF2 support
- Utility libraries such as fast floating point

The boot sequence of the chip is defined in [Section 2.7.2](#), and the ROM contents is described in more detail in [Bootrom](#). The full source code for the RP2040 bootrom is available at:

<https://github.com/raspberrypi/pico-bootrom>

The ROM offers single-cycle read-only bus access, and is on a dedicated AHB-Lite arbiter, so it can be accessed simultaneously with other memory devices. Attempting to write to the ROM has no effect (no bus fault is generated).

2.5.2. SRAM

There is a total of 264kB of on-chip SRAM. Physically this is partitioned into six banks, as this vastly improves memory bandwidth for multiple masters, but software may treat it as a single 264kB memory region. There are no restrictions on what is stored in each bank: processor code, data buffers, or a mixture. There are four 16k x 32-bit banks (64kB each) and two 1k x 32-bit banks (4kB each).

Each SRAM bank is accessed via a dedicated AHB-Lite arbiter. This means different bus masters can access different SRAM banks in parallel, so up to four 32-bit SRAM accesses can take place every system clock cycle (one per master).

SRAM is mapped to system addresses starting at `0x20000000`. The first 256kB address region is word-striped across the four larger banks, which provides a significant memory parallelism benefits for most use cases.

Consecutive words in the system address space are routed to different RAM banks as shown in [Table 148](#).

Table 148. SRAM bank0/1/2/3 striped mapping.

System address	SRAM Bank	SRAM word address
<code>0x20000000</code>	Bank 0	0
<code>0x20000004</code>	Bank 1	0
<code>0x20000008</code>	Bank 2	0
<code>0x2000000c</code>	Bank 3	0
<code>0x20000010</code>	Bank 0	1
<code>0x20000014</code>	Bank 1	1
<code>0x20000018</code>	Bank 2	1
<code>0x2000001c</code>	Bank 3	1
<code>0x20000020</code>	Bank 0	2
<code>0x20000024</code>	Bank 1	2
<code>0x20000028</code>	Bank 2	2
<code>0x2000002c</code>	Bank 3	2
etc		

The next two 4kB regions (starting at `0x20040000` and `0x20041000`) are mapped directly to the smaller, 4kB memory banks.

Software *may* choose to use these for per-core purposes, e.g. stack and frequently-executed code, guaranteeing that the processors never stall on these accesses. However, like all SRAM on RP2040, these banks have single-cycle access from *all* masters providing no other masters are accessing the bank in the same cycle, so it is reasonable to treat memory as a single 264kB device.

The four 64kB banks are also available at a non-striped mirror. The four 64kB regions starting at `0x21000000`, `0x21010000`, `0x21020000`, `0x21030000` are each mapped directly to one of the four 64kB SRAM banks. Software can explicitly allocate data and code across the physical memory banks, for improved memory performance in exceptionally demanding cases. This is often unnecessary, as memory striping usually provides sufficient parallelism with less software complexity.

The non-striped mirror starts at an offset of +16MB above the base of SRAM, as this is the maximum offset that allows ARMv6M subroutine calls between the smaller banks and the non-striped larger banks.

2.5.2.1. Other On-chip Memory

Besides the 264kB main memory, there are two other dedicated RAM blocks that may be used in some circumstances:

- If flash XIP caching is disabled, the cache becomes available as a 16kB memory starting at `0x15000000`
- If the USB is not used, the USB data DPRAM can be used as a 4kB memory starting at `0x50100000`

This gives a total of 284kB of on-chip SRAM. There are no restrictions on how these memories are used, e.g. it is possible to execute code from the USB data RAM if you choose.

2.5.3. Flash

External Flash is accessed via the QSPI interface using the execute-in-place (XIP) hardware. This allows an external flash memory to be addressed and accessed by the system as though it were internal memory. Bus reads to a 16MB memory window starting at `0x10000000` are translated into a serial flash transfer, and the result is returned to the master that initiated the read. This process is transparent to the master, so a processor can execute code from the external flash without first copying the code to internal memory, hence "execute in place". An internal cache remembers the contents of recently-accessed flash locations, which accelerates the average bandwidth and latency of the interface.

Once correctly configured by RP2040's bootrom and the flash second stage, the XIP hardware is largely transparent, and software can treat flash as a large read-only memory. However, it does provide a number of additional features to serve more demanding software use cases.

Figure 12. Flash execute-in-place (XIP) subsystem. System accesses via the main AHB-Lite slave are decoded to determine if they are XIP accesses, direct accesses to the SSI e.g. for configuration, or accesses to various other hardware and control registers in the XIP subsystem. XIP accesses are first looked up in the cache, to accelerate accesses to recently-used data. If the data is not found in the cache, an external serial access is generated via the SSI, and the resulting data is stored in the cache and forwarded on to the system bus.

NOTE

The serial flash interface is configured by the flash second stage when using the Pico SDK to run at an integer divider of the system clock. All the included second stage boot implementations support a `PICO_FLASH_SPI_CLKDIV` setting (e.g. defaulted to 4 in https://github.com/raspberrypi/pico-sdk/tree/pre_release/src/rp2_common/boot_stage2/boot2_w25q080.S to make the default interface speed $125/4 = 31.25$ MHz). This divider can be overridden by specifying `PICO_FLASH_SPI_CLKDIV` in the particular board config header used with the Pico SDK.

2.5.3.1. XIP Cache

The cache is 16 kB, two way set-associative, 1 cycle hit. It is internal to the XIP subsystem, and only affects accesses to XIP flash, so software does not have to consider cache coherence, unless performing flash programming operations. It caches reads from a 24-bit flash address space, which is mirrored multiple times in the RP2040 address space, each alias having different caching behaviour. The eight MSBs of the system address are used for segment decode, leaving 24 bits for flash addressing, so the maximum supported flash size (for XIP operation) is 16MB. The available mirrors are:

- `0x10...` XIP access, cacheable, allocating - Normal cache operation
- `0x11...` XIP access, cacheable, non-allocating - Check for hit, don't update cache on miss
- `0x12...` XIP access, non-cacheable, allocating - Don't check for hit, always update cache
- `0x13...` XIP access, non-cacheable, non-allocating - Bypass cache completely
- `0x15...` Use XIP cache as SRAM bank, mirrored across entire segment

If the cache is disabled, via the `CTRL_EN` register bit, then all four of the XIP aliases (`0x10` to `0x13`) will bypass the cache, and access the flash directly. This has a significant impact on XIP code execution performance.

Access to the `0x15...` segment produces a bus error unless the cache is disabled. Once the cache is disabled, this region behaves as an additional 16 kB SRAM bank. Reads and writes are one cycle, but there is a wait state on consecutive write-read sequences, i.e. there is no write forwarding buffer.

2.5.3.2. Cache Flushing and Maintenance

The **FLUSH** register allows the entire cache contents to be flushed. This is necessary if software has reprogrammed the flash contents, and needs to clear out stale data and code, without performing a reboot.

Flushing the cache whilst accessing flash data (perhaps initiating the flush on one core whilst another core may be executing code from flash data) is a safe operation, but any master accessing flash data while the flush is in progress will be stalled until completion. The flush is implemented by zeroing the cache tag memory using an internal counter, which takes around 2000 clock cycles.

A complete cache flush dramatically slows subsequent code execution, until the cache "warms up" again. There is an alternative, which allows cache contents corresponding to only a certain address range to be invalidated. A write to the **0x10...** mirror will look up the addressed location in the cache, and delete any matching entry found. Writing to all word-aligned locations in an address range (e.g. a flash sector that has just been erased and reprogrammed) therefore eliminates the possibility of stale cached data in this range, without suffering the effects of a complete cache flush.

Pico Examples: https://github.com/raspberrypi/pico-examples/tree/pre_release/flash/cache_perfctr/flash_cache_perfctr.c Lines 30 - 55

```

30 // Flush cache to make sure we miss the first time we access test_data
31 xip_ctrl_hw->flush = 1;
32 while (!(xip_ctrl_hw->stat & XIP_STAT_FLUSH_READY_BITS))
33     tight_loop_contents();
34
35 // Clear counters (write any value to clear)
36 xip_ctrl_hw->ctr_acc = 1;
37 xip_ctrl_hw->ctr_hit = 1;
38
39 (void) *test_data_ptr;
40 check(xip_ctrl_hw->ctr_hit == 0 && xip_ctrl_hw->ctr_acc == 1,
41     "First access to data should miss");
42
43 (void) *test_data_ptr;
44 check(xip_ctrl_hw->ctr_hit == 1 && xip_ctrl_hw->ctr_acc == 2,
45     "Second access to data should hit");
46
47 // Write to invalidate individual cache lines (64 bits)
48 // Writes must be directed to the cacheable, allocatable alias (address 0x10.....)
49 *test_data_ptr = 0;
50 (void) *test_data_ptr;
51 check(xip_ctrl_hw->ctr_hit == 1 && xip_ctrl_hw->ctr_acc == 3,
52     "Should miss after invalidation");
53 (void) *test_data_ptr;
54 check(xip_ctrl_hw->ctr_hit == 2 && xip_ctrl_hw->ctr_acc == 4,
55     "Second access after invalidation should hit again");

```

2.5.3.3. SSI

The execute-in-place functionality is provided by the SSI interface, documented in **SSI**. It supports 1, 2 or 4-bit SPI flash interfaces (SPI, DSPI and QSPI), and can insert either an instruction prefix or mode continuation bits on each XIP access. This includes the possibility of issuing a standard **03h** serial flash read command for each access, allowing virtually any serial flash device to be used. The maximum SPI clock frequency is half the system clock frequency.

The SSI can also be used as a standard FIFO-based SPI master, with DMA support. This mode is used by the bootrom to extract the second stage bootloader from external flash (see [Section 2.7.2](#)). The bus interposer allows an atomic set, clear or XOR operation to be posted to SSI control registers, in the same manner as other memory-mapped IO on RP2040. This is described in more detail in [Section 2.1.2](#).

2.5.3.4. Flash Streaming and Auxiliary Bus Slave

As the flash is generally much larger than SRAM, it's often useful to stream chunks of data into memory from flash. It's convenient to have the DMA stream this data in the background while software in the foreground is doing other things, and it's even more convenient if code can continue to execute from flash whilst this takes place.

This doesn't interact well with standard XIP operation, because of the lengthy bus stalls forced on the DMA whilst the SSI is performing serial transfers. These stalls are tolerable for a processor, because an in-order processor tends to have nothing better to do while waiting for an instruction fetch to retire, and because typical code execution tends to have much higher cache hit rates than bulk streaming of infrequently accessed data. In contrast, stalling the DMA prevents any *other* active DMA channels from making progress during this time, which slows overall DMA throughput.

The `STREAM_ADDR` and `STREAM_CTR` registers are used to program a linear sequence of flash reads, which the XIP subsystem will perform in the background in a best-effort fashion. To minimise impact on code being executed from flash whilst the stream is ongoing, the streaming hardware has lower priority access to the SSI than regular XIP accesses, and there is a brief cooldown (seven cycles) between the last XIP cache miss and resuming streaming. This helps to avoid increase in initial access latency on XIP cache miss.

Pico Examples: https://github.com/raspberrypi/pico-examples/tree/pre_release/flash/xip_stream/flash_xip_stream.c Lines 45 - 48

```
45     while (!(xip_ctrl_hw->stat & XIP_STAT_FIFO_EMPTY))
46         (void) xip_ctrl_hw->stream_fifo;
47     xip_ctrl_hw->stream_addr = (uint32_t) &random_test_data[0];
48     xip_ctrl_hw->stream_ctr = count_of(random_test_data);
```

The streamed data is pushed to a small FIFO, which generates DREQ signals, telling the DMA to collect the streamed data. As the DMA does not initiate a read until *after* the data has been read from flash, the DMA is not stalled when accessing the data.

Although this scheme ensures that the data is ready in the streaming FIFO once the DREQ is asserted, the DMA can still be stalled if another master is currently stalled on the XIP slave, e.g. due to a cache miss. This is solved by the auxiliary bus slave, which is a simple bus interface providing access only to the streaming FIFO. This slave is exposed on the `FASTPERI` arbiter, which services only native AHB-Lite peripherals which don't generate wait states, so the DMA will never experience stalls when accessing the FIFO at this address, assuming it has high bus priority.

Pico Examples: https://github.com/raspberrypi/pico-examples/tree/pre_release/flash/xip_stream/flash_xip_stream.c Lines 58 - 70

```
58     const uint dma_chan = 0;
59     dma_channel_config cfg = dma_channel_get_default_config(dma_chan);
60     channel_config_set_read_increment(&cfg, false);
61     channel_config_set_write_increment(&cfg, true);
62     channel_config_set_dreq(&cfg, DREQ_XIP_STREAM);
63     dma_channel_configure(
64         dma_chan,
65         &cfg,
66         (void *) buf, // Write addr
67         (const void *) XIP_AUX_BASE, // Read addr
68         count_of(random_test_data), // Transfer count
69         true // Start immediately!
70     );
```

2.5.3.5. Performance Counters

The XIP subsystem provides two performance counters. These are 32 bits in size, saturate upon reaching `0xffffffff`, and are cleared by writing any value. They count:

1. The total number of XIP accesses, to any alias

- 2. The number of XIP accesses which resulted in a cache hit

For common use cases, this allows the cache hit rate to be profiled.

2.5.3.6. List of XIP Registers

Table 149. List of XIP registers

Offset	Name	Info
0x00	CTRL	Cache control
0x04	FLUSH	Cache Flush control
0x08	STAT	Cache Status
0x0c	CTR_HIT	Cache Hit counter
0x10	CTR_ACC	Cache Access counter
0x14	STREAM_ADDR	FIFO stream address
0x18	STREAM_CTR	FIFO stream control
0x1c	STREAM_FIFO	FIFO stream data

CTRL Register

Description

Cache control

Table 150. CTRL Register

Bits	Name	Description	Type	Reset
31:4	Reserved.	-	-	-
3	POWER_DOWN	When 1, the cache memories are powered down. They retain state, but can not be accessed. This reduces static power dissipation. Writing 1 to this bit forces CTRL_EN to 0, i.e. the cache cannot be enabled when powered down. Cache-as-SRAM accesses will produce a bus error response when the cache is powered down.	RW	0x0
2	Reserved.	-	-	-
1	ERR_BADWRITE	When 1, writes to any alias other than 0x0 (caching, allocating) will produce a bus fault. When 0, these writes are silently ignored. In either case, writes to the 0x0 alias will deallocate on tag match, as usual.	RW	0x1

Bits	Name	Description	Type	Reset
0	EN	When 1, enable the cache. When the cache is disabled, all XIP accesses will go straight to the flash, without querying the cache. When enabled, cacheable XIP accesses will query the cache, and the flash will not be accessed if the tag matches and the valid bit is set. If the cache is enabled, cache-as-SRAM accesses have no effect on the cache data RAM, and will produce a bus error response.	RW	0x1

FLUSH Register

Description

Cache Flush control

Table 151. FLUSH Register

Bits	Name	Description	Type	Reset
31:1	Reserved.	-	-	-
0	NONAME	Write 1 to flush the cache. This clears the tag memory, but the data memory retains its contents. (This means cache-as-SRAM contents is not affected by flush or reset.) Reading will hold the bus (stall the processor) until the flush completes. Alternatively STAT can be polled until completion.	SC	0x0

STAT Register

Description

Cache Status

Table 152. STAT Register

Bits	Name	Description	Type	Reset
31:3	Reserved.	-	-	-
2	FIFO_FULL	When 1, indicates the XIP streaming FIFO is completely full. The streaming FIFO is 2 entries deep, so the full and empty flag allow its level to be ascertained.	RO	0x0
1	FIFO_EMPTY	When 1, indicates the XIP streaming FIFO is completely empty.	RO	0x1
0	FLUSH_READY	Reads as 0 while a cache flush is in progress, and 1 otherwise. The cache is flushed whenever the XIP block is reset, and also when requested via the FLUSH register.	RO	0x0

CTR_HIT Register

Description

Cache Hit counter

Table 153. CTR_HIT Register

Bits	Name	Description	Type	Reset
31:0	NONAME	A 32 bit saturating counter that increments upon each cache hit, i.e. when an XIP access is serviced directly from cached data. Write any value to clear.	WC	0x00000000

CTR_ACC Register

Description

Cache Access counter

Table 154. CTR_ACC Register

Bits	Name	Description	Type	Reset
31:0	NONAME	A 32 bit saturating counter that increments upon each XIP access, whether the cache is hit or not. This includes noncacheable accesses. Write any value to clear.	WC	0x00000000

STREAM_ADDR Register

Description

FIFO stream address

Table 155. STREAM_ADDR Register

Bits	Name	Description	Type	Reset
31:2	NONAME	The address of the next word to be streamed from flash to the streaming FIFO. Increments automatically after each flash access. Write the initial access address here before starting a streaming read.	RW	0x00000000
1:0	Reserved.	-	-	-

STREAM_CTR Register

Description

FIFO stream control

Table 156.
STREAM_CTR Register

Bits	Name	Description	Type	Reset
31:22	Reserved.	-	-	-
21:0	NONAME	Write a nonzero value to start a streaming read. This will then progress in the background, using flash idle cycles to transfer a linear data block from flash to the streaming FIFO. Decrements automatically (1 at a time) as the stream progresses, and halts on reaching 0. Write 0 to halt an in-progress stream, and discard any in-flight read, so that a new stream can immediately be started (after draining the FIFO and reinitialising STREAM_ADDR)	RW	0x000000

STREAM_FIFO Register

Description

FIFO stream data

Table 157.
STREAM_FIFO Register

Bits	Name	Description	Type	Reset
31:0	NONAME	Streamed data is buffered here, for retrieval by the system DMA. This FIFO can also be accessed via the XIP_AUX slave, to avoid exposing the DMA to bus stalls caused by other XIP traffic.	RF	0x00000000

2.6. Boot Sequence

Several components of the RP2040 work together to get to a point where the processors are out of reset and able to run the [Bootrom](#). The bootrom is software that is built into the chip, performing the "processor controlled" part of the boot sequence. We will refer to the steps before the processor is running as the "hardware controlled" boot sequence.

The hardware controlled boot sequence is as follows:

- Power is applied to the chip and the **RUN** pin is high. (If **RUN** is low then the chip will be held in reset.)
- The [On-Chip Voltage Regulator](#) waits until the digital core supply (DVDD) is stable
- The [Power-On State Machine](#) is started. To summarise the sequence:
 - The [Ring Oscillator](#) is started, providing a clock source to the clock generators. **clk_sys** and **clk_ref** are now running at a relatively low frequency (typically 6.5MHz).
 - The reset controller ([Subsystem Resets](#)), the execute-in-place hardware ([Execute-In-Place](#)), memories (see [SRAM](#) and [ROM](#)), [Bus Fabric](#), and [Processor Subsystem](#) is taken out of reset.
 - Processor core 0 and core 1 begin to execute the [Bootrom](#).

2.7. Bootrom

The Bootrom size is limited to 16 kB. It contains: The Bootrom size is limited to 16 kB. It contains:

- Processor core 0 initial boot sequence.

- Processor core 1 low power wait and launch protocol.
- USB MSC class-compliant bootloader with UF2 support for downloading code/data to FLASH or RAM.
- USB PICOBBOOT bootloader interface for advanced management.
- Routines for programming and manipulating the external flash.
- Fast single-precision floating point library.
- Fast bit counting / manipulation functions.
- Fast memory fill / copy functions.

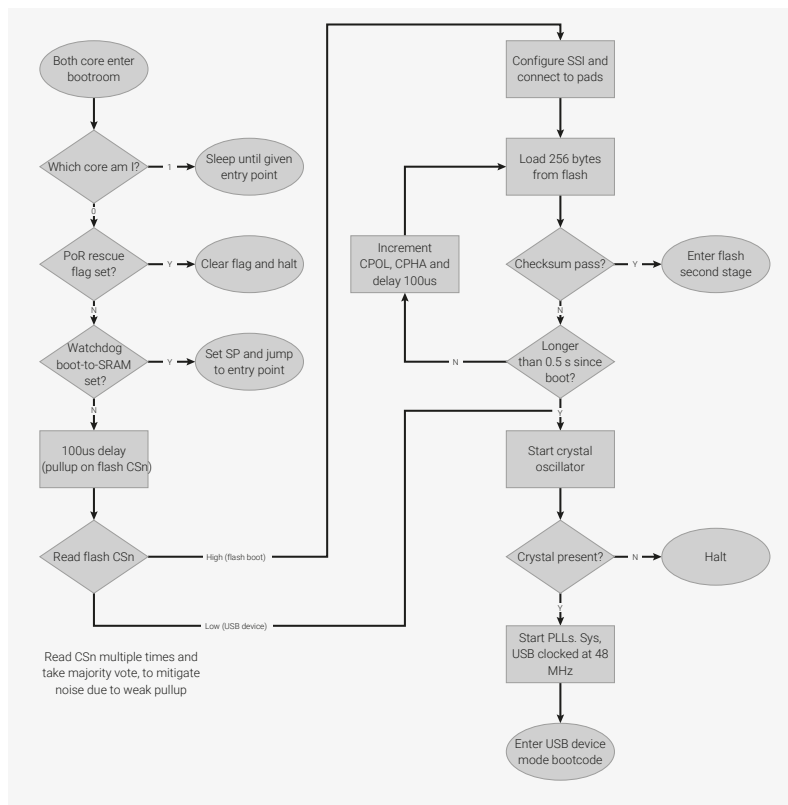

2.7.1. Bootrom Source

The bootrom source can be found at <https://github.com/raspberrypi/pico-bootrom>.

2.7.2. Processor Controlled Boot Sequence

A flow diagram of the boot sequence is given in Figure 13.

Figure 13. RP2040 Boot Sequence

After the hardware controlled boot sequence described in [Boot Sequence](#), the processor controlled boot sequence starts:

- Reset to both processors released: both enter ROM at same location
- Processors check SIO.CPUID
 - Processor 1 goes to sleep (WFE with SCR.SLEEPDEEP enabled) and remains asleep until woken by user code, via the mailbox
 - Processor 0 continues executing from ROM
- If power up event was from Rescue DP, clear this flag and **halt immediately**

- The debug host (which initiated the rescue) will provide further instruction.
- If watchdog scratch registers set to indicate pre-loaded code exists in SRAM, jump to that code
- Check if SPI CS pin is tied low ("bootrom button"), and skip flash boot if so.
- Set up IO muxing, pad controls on QSPI pins, and initialise Synopsys SSI for standard SPI mode
- Issue XIP exit sequence, in case flash is still in an XIP mode and has not been power-cycled
- Copy 256 bytes from SPI to internal SRAM (SRAM5) and check for valid CRC32 checksum
- If checksum passes, assume what we have loaded is a valid flash second stage
- Start executing the loaded code from SRAM (SRAM5)
- If no valid image found in SPI after 0.5 seconds of attempting to boot, drop to USB device boot
- USB device boot: appear as a USB Mass Storage Device
 - Can program the SPI flash, or load directly into SRAM and run, by dragging and dropping an image in UF2 format.
 - Also supports an extended PICOBOOT interface

2.7.2.1. Watchdog Boot

Watchdog boot allows users to install their own boot handler, and divert control away from the main boot sequence on non-POR/BOR resets. It also simplifies running code over the JTAG test interface. It recognises the following values written to the watchdog's upper scratch registers:

- Scratch 4: magic number `0xb007c0d3`
- Scratch 5: Entry point XORed with magic `-0xb007c0d3` (`0x4ff83f2d`)
- Scratch 6: Stack pointer
- Scratch 7: Entry point

If either of the magic numbers mismatch, watchdog boot does not take place. If the numbers match, the Bootrom zeroes scratch 4 before transferring control, so that the behaviour does not persist over subsequent reboots.

2.7.2.2. Flash Boot Sequence

One of the main challenges of a warm flash boot is forcing the external flash from XIP mode to a mode where it will accept standard SPI commands. There is no standard method to discontinue XIP on an unknown flash. The Bootrom provides a best-effort sequence with broad compatibility, which is as follows:

- `CSn=1, IO[3:0]=4'b0000` (via pull downs to avoid contention), issue x32 clocks
- `CSn=0, IO[3:0]=4'b1111` (via pull ups to avoid contention), issue x32 clocks
- `CSn=1`
- `CSn=0, MOSI=1'b1` (driven low-Z, all other IOs Hi-Z), issue x16 clocks

This is designed to miss the XIP continuation codes on Cypress, Micron and Winbond parts. If the device is already in SPI mode, it interprets this sequence as two `FFh NOP` instructions, which should be ignored.

As this is best effort only, there may be some devices which obstinately remain in XIP mode. There are then two options:

- Use a less efficient XIP mode where each transfer has an SPI instruction prefix, so the flash device remains communicative in SPI mode.
- Boot code installs a compatible XIP exit sequence in SRAM, and configures the watchdog such that a warm boot will jump straight into this sequence, foregoing our canned sequence.

After issuing the XIP exit sequence, the Bootrom attempts to read in the second stage from flash using standard `03h` serial read commands, which are near-universally supported. Since the Bootrom is immutable, it aims for compatibility rather than performance.

2.7.2.3. Flash Second Stage

The flash second stage must configure the SSI and the external flash for the best possible execute-in-place performance. This includes interface width, SCK frequency, SPI instruction prefix and an XIP continuation code for address-data only modes. Generally some operation can be performed on the external flash so that it does not require an instruction prefix on each access, and will simply respond to addresses with data.

Until the SSI is correctly configured for the attached flash device, it is not possible to access flash via the XIP address window. Additionally, the Synopsys SSI can not be reconfigured at all without first disabling it. Therefore the second stage must be copied from flash to SRAM by the bootrom, and executed in SRAM.

Alternatively, the second stage can simply shadow an image from external flash into SRAM, and not configure execute-in-place.

This is the **only** job of the second stage. All other chip setup (e.g. PLLs, Voltage Regulator) can be performed by platform initialisation code executed over the XIP interface, once the second stage has run.

2.7.2.3.1. Checksum

The last four bytes of the image loaded from flash (which we hope is a valid flash second stage) are a CRC32 checksum of the first 252 bytes. The parameters of the checksum are:

- Polynomial: `0x04c11db7`
- Input reflection: no
- Output reflection: no
- Initial value: `0xffffffff`
- Final XOR: `0x00000000`
- Checksum value appears as little-endian integer at end of image

The Bootrom makes 128 attempts of approximately 4ms each for a total of approximately 0.5 seconds before giving up and dropping into USB code to load and checksum the second stage with varying SPI parameters. If it sees a checksum pass it will immediately jump into the 252-byte payload which contains the flash second stage.

2.7.3. Bootrom Contents

Some of the bootrom is dedicated to the implementation of the boot sequence and USB boot interfaces. There is also code in the bootrom useful to user programs. [Table 158](#) shows the fixed memory layout of the first handful of words in the Bootrom which are instrumental in locating other content within the bootrom.

Table 158. Bootrom contents at fixed (well known) addresses

Address	Contents	Description
<code>0x00000000</code>	32 bit pointer	Initial boot stack pointer
<code>0x00000004</code>	32 bit pointer	Pointer to boot reset handler function
<code>0x00000008</code>	32 bit pointer	Pointer to boot NMI handler function
<code>0x0000000c</code>	32 bit pointer	Pointer to boot Hard fault handler function
<code>0x00000010</code>	'M', 'u', <code>0x01</code>	Magic
<code>0x00000013</code>	byte	Bootrom version
<code>0x00000014</code>	16 bit pointer	Pointer to a public function lookup table (<code>rom_func_table</code>)

0x00000016	16 bit pointer	Pointer to a public data lookup table (<code>rom_data_table</code>)
0x00000018	16 bit pointer	Pointer to a helper function (<code>rom_table_lookup()</code>)

2.7.3.1. Bootrom Functions

The Bootrom contains a number of public functions that provide useful RP2040 functionality that might be needed in the absence of any other code on the device, as well as highly optimized versions of certain key functionality that would otherwise have to take up space in most user binaries.

These functions are normally made available to the user by the Pico SDK, however a lower level method is provided to locate them (their locations may change with each Bootrom release) and call them directly.

Assuming the three bytes starting at address `0x00000010` are ('M', 'u', `0x01`) then the three halfwords starting at offset `0x00000014` are valid.

These three values can be used to dynamically locate other functions or data within the Bootrom. The version byte at offset `0x00000013` is informational and should not be used to infer the exact location of any functions.

The following code from the Pico SDK shows how the three 16-bit pointers are used to lookup other functions or data.

Pico SDK: https://github.com/raspberrypi/pico-sdk/tree/pre-release/src/rp2_common/pico_bootrom/bootrom.c Lines 10 - 28

```

10 // Bootrom function: rom_table_lookup
11 // Returns the 32 bit pointer into the ROM if found or NULL otherwise.
12 typedef void (*rom_table_lookup_fn)(uint16_t *table, uint32_t code);
13
14 // Convert a 16 bit pointer stored at the given rom address into a 32 bit pointer
15 #define rom_hword_as_ptr(rom_address) (void *) (uintptr_t) (*(uint16_t *) rom_address)
16
17 void *rom_func_lookup(uint32_t code) {
18     rom_table_lookup_fn rom_table_lookup = (rom_table_lookup_fn) rom_hword_as_ptr(0x18);
19     uint16_t *func_table = (uint16_t *) rom_hword_as_ptr(0x14);
20     return rom_table_lookup(func_table, code);
21 }
22
23 void *rom_data_lookup(uint32_t code) {
24     rom_table_lookup_fn rom_table_lookup = (rom_table_lookup_fn) rom_hword_as_ptr(0x18);
25     uint16_t *data_table = (uint16_t *) rom_hword_as_ptr(0x16);
26     return rom_table_lookup(data_table, code);
27 }

```

The `code` parameter correspond to the `CODE` values in the tables below, and is calculated as follows:

```

uint32_t rom_table_code(char c1, char c2) {
    return (c2 << 8) | c1;
}

```

2.7.3.1.1. Fast Bit Counting / Manipulation Functions

These are optimized versions of common bit counting / manipulation functions.

In general you do not need to call these methods directly as the Pico SDK `pico_aeabi_bits` library replaces the corresponding standard compiler library functions by default so that the standard functions such as `__builtin_popcount` or `__clzdi2` uses the corresponding Bootrom implementations automatically (see [pico_bit_ops](#) for more details).

These functions have changed in speed slightly between version 1 (V1) of the bootrom and version 2 (v2). Fast Bit

Counting / Manipulation Functions.

CODE	Cycles Avg V1	Cycles Avg V2	Description
'P', '3'	18	20	<code>uint32_t _popcount32(uint32_t value)</code>
			Return a count of the number of 1 bits in <code>value</code> .
'R', '3'	21	22	<code>uint32_t _reverse32(uint32_t value)</code>
			Return the bits of <code>value</code> in the reverse order.
'L', '3'	13	9.6	<code>uint32_t _clz32(uint32_t value)</code>
			Return the number of consecutive high order 0 bits of <code>value</code> . If <code>value</code> is zero, returns 32.
'T', '3'	12	11	<code>uint32_t _ctz32(uint32_t value)</code>
			Return the number of consecutive low order 0 bits of <code>value</code> . If <code>value</code> is zero, returns 32.

2.7.3.1.2. Fast Bulk Memory Fill / Copy Functions

These are highly optimized bulk memory fill and copy functions commonly provided by most language runtimes.

In general you do not need to call these methods directly as the Pico SDK `pico_earabi_mem` library replaces the corresponding standard ARM EABI functions by default so that the standard C library functions e.g. `memcpy` or `memset` use the Bootrom implementations automatically (see [pico_memory](#) for more details).

Table 159. Optimized Bulk Memory Fill / Copy Functions

CODE	Description
'M', 'S'	<code>uint8_t *_memset(uint8_t *ptr, uint8_t c, uint32_t n)</code>
	Sets <code>n</code> bytes start at <code>ptr</code> to the value <code>c</code> and returns <code>ptr</code> .
'M', '4'	<code>uint32_t *_memset4(uint32_t *ptr, uint8_t c, uint32_t n)</code>
	Sets <code>n</code> bytes start at <code>ptr</code> to the value <code>c</code> and returns <code>ptr</code> . Note this is a slightly more efficient variant of <code>_memset</code> that may only be used if <code>ptr</code> is word aligned.
'M', 'C'	<code>uint8_t *_memcpy(uint8_t *dest, uint8_t *src, uint32_t n)</code>
	Copies <code>n</code> bytes starting at <code>src</code> to <code>dest</code> and returns <code>dest</code> . The results are undefined if the regions overlap.
'C', '4'	<code>uint8_t *_memcpy44(uint32_t *dest, uint32_t *src, uint32_t n)</code>
	Copies <code>n</code> bytes starting at <code>src</code> to <code>dest</code> and returns <code>dest</code> . The results are undefined if the regions overlap. Note this is a slightly more efficient variant of <code>_memcpy</code> that may only be used if <code>dest</code> and <code>src</code> are word aligned.

2.7.3.1.3. Flash Access Functions

These are low level flash helper functions.

Table 160. Flash Access Functions

CODE	Description
'I', 'F'	<code>void _connect_internal_flash(void)</code>
	Restore all QSPI pad controls to their default state, and connect the SSI to the QSPI pads

'E', 'X'	<code>void _flash_exit_xip(void)</code> First set up the SSI for serial-mode operations, then issue the fixed XIP exit sequence described in Section 2.7.2.2 . Note that the bootrom code uses the IO forcing logic to drive the CS pin, which must be cleared before returning the SSI to XIP mode (e.g. by a call to <code>_flash_flush_cache</code>). This function configures the SSI with a fixed SCK clock divisor of /6.
'R', 'E'	<code>void _flash_range_erase(uint32_t addr, size_t count, uint32_t block_size, uint8_t block_cmd)</code> Erase a <code>count</code> bytes, starting at <code>addr</code> (offset from start of flash). Optionally, pass a block erase command e.g. <code>08h</code> <code>block_erase</code> , and the size of the block erased by this command – this function will use the larger block erase where possible, for much higher erase speed. <code>addr</code> must be aligned to a 4096-byte sector, and <code>count</code> must be a multiple of 4096 bytes.
'R', 'P'	<code>void flash_range_program(uint32_t addr, const uint8_t *data, size_t count)</code> Program <code>data</code> to a range of flash addresses starting at <code>addr</code> (offset from the start of flash) and <code>count</code> bytes in size. <code>addr</code> must be aligned to a 256-byte boundary, and <code>count</code> must be a multiple of 256.
'F', 'C'	<code>void _flash_flush_cache(void)</code> Flush and enable the XIP cache. Also clears the IO forcing on QSPI CSn, so that the SSI can drive the flash chip select as normal.
'C', 'X'	<code>void _flash_enter_cmd_xip(void)</code> Configure the SSI to generate a standard <code>03h</code> serial read command, with 24 address bits, upon each XIP access. This is a very slow XIP configuration, but is very widely supported. The debugger calls this function after performing a flash erase/programming operation, so that the freshly-programmed code and data is visible to the debug host, without having to know exactly what kind of flash device is connected.

A typical call sequence for erasing a flash sector from user code would be:

- `_connect_internal_flash`
- `_flash_exit_xip`
- `_flash_range_erase(addr, 1 << 12, 1 << 16, 0xd8)`
- `_flash_flush_cache`
- Either a call to `_flash_enter_cmd_xip` or call into a flash second stage that was previously copied out into SRAM

Note that, in between the first and last calls in this sequence, the SSI is **not** in a state where it can handle XIP accesses, so the code that calls the intervening functions must be located in SRAM. The Pico SDK `hardware_flash` library hides these details.

2.7.3.1.4. Debugging Support Functions

These two methods simplify the task of calling code on the device and then returning control to the debugger.

Table 161. Debugging Support Functions

CODE	Description
'D', 'T'	<code>_debug_trampoline</code> Simple debugger trampoline for break-on-return. This methods helps the debugger call ROM routines without setting hardware breakpoints. The function address is passed in <code>r7</code> and args are passed through <code>r0 ... r3</code> as per ABI. This method does not return but executes a <code>BKPT #0</code> at the end.

'D', 'E'	<code>_debug_trampoline_end</code>
	This is the address of the final <code>BKPT #0</code> instruction of <code>debug_trampoline</code> . This can be compared with the program counter to detect completion of the <code>debug_trampoline</code> call.

2.7.3.1.5. Miscellaneous Functions

These remaining functions don't fit in other categories and are exposed in the Pico SDK via the `pico_bootrom` library (see `pico_bootrom`).

Table 162. Miscellaneous Functions

CODE	Description
'U', 'B'	<p><code>void _reset_to_usb_boot(uint32_t gpio_activity_pin_mask, uint32_t disable_interface_mask)</code></p> <p>Resets the RP2040 and uses the watchdog facility to re-start in USB boot mode:</p> <ul style="list-style-type: none"> • <code>gpio_activity_pin_mask</code> is provided to enable an "activity light" via GPIO attached LED for the USB Mass Storage Device: <ul style="list-style-type: none"> ◦ <code>0</code> No pins are used as per a cold boot. ◦ Otherwise one bit per GPIO pin indicating which GPIO pins should be set to output and raised whenever there is mass storage activity from the host. • <code>disable_interface_mask</code> may be used to control the exposed USB interfaces: <ul style="list-style-type: none"> ◦ <code>0</code> To enable both interfaces (as per a cold boot) ◦ <code>1</code> To disable the USB Mass Storage Interface (see Section 2.7.4) ◦ <code>2</code> To disable the USB PICOBOT Interface (see Section 2.7.5)
'W', 'V'	<p><code>_wait_for_vector</code></p> <p>This is the method that is entered by core 1 on reset to wait to be launched by core 0. There are few cases where you should call this method (resetting core 1 is much better). This method does not return and should only ever be called on core 1.</p>
'E', 'C'	<p><code>deprecated</code></p> <p>Do not use this function</p>

2.7.3.2. Fast Floating Point Library

The Bootrom contains an optimized single-precision floating point implementation. The function pointers for these are kept in a single structure found via the `rom_data_lookup` table (see [Section 2.7.3.3](#)).

2.7.3.2.1. Implementation Details

There is always a trade-off between speed and size. Whilst the overall goal for the floating-point routines is to achieve good performance within a small footprint, the emphasis is more on improved performance for the basic operations (add, subtract, multiply, divide and square root) and more on reduced footprint for the scientific functions (trigonometric functions, logarithms and exponentials).

The IEEE single- and double-precision data formats are used throughout, but in the interests of reducing code size, input denormals are treated as zero, input NaNs are treated as infinities, output denormals are flushed to zero, and output NaNs are rendered as infinities. Only the round-to-nearest, even-on-tie rounding mode is supported. Traps are not supported.

The five basic operations return results that are always correctly rounded.

The scientific functions always return results within 1 ULP (unit in last place) of the exact result. In many cases results are

better.

The scientific functions are calculated using internal fixed-point representations so accuracy (as measured in ULP error rather than in absolute terms) is poorer in situations where converting the result back to floating point entails a large normalising shift. This occurs, for example, when calculating the sine of a value near a multiple of pi, the cosine of a value near an odd multiple of pi/2, or the logarithm of a value near 1. Accuracy of the tangent function is also poorer when the result is very large. Although covering these cases is possible, it would add considerably to the code footprint, and there are few types of program where accuracy in these situations is essential.

The sine, cosine and tangent functions also only operate correctly over a limited range: $-128 < x < +128$ for single-precision arguments x and $-1024 < x < +1024$ for double-precision x. This is to avoid the need to (at least in effect) store the value of pi to high precision within the code, and hence saves code space. Accurate range reduction over a wider range of arguments can be done externally to the library if required, but again there are few situations where this would be needed.

NOTE

The Pico SDK cos/sin functions perform this range reduction, so accept the full range of arguments, though are slower for inputs outside of these ranges.

2.7.3.2.2. Functions

These functions follow the standard ARM EABI for passing floating point values.

You do not need to call these methods directly as the Pico SDK `pico_float` and `pico_double` libraries used by default replace the *ARM EABI Float functions* such that C/C++ level code (or indirectly code in languages such as *MicroPython* that are implemented in C) use these Bootrom functions automatically for the corresponding floating point operations.

Some of these functions do not behave exactly the same as some of the corresponding C library functions. For that reason if you are using the Pico SDK it is strongly advised that you simply use the regular `math.h` functions or those in `pico/float.h` or `pico/double.h` and not try to call into the bootrom directly.

Note that double-precision floating point support is not present in version 1 of the bootrom, but the above mentioned `pico_double` library in the SDK will take care of pulling in any extra code needed for version 1.

NOTE

for more information on using floating point in the Pico SDK, and real world timings (noting also that some conversion functions are re-implemented in the Pico SDK to be faster) see [floating point support](#).

Table 163. Single-precision Floating Point Function Table. Timings are average time in us over random (worst case) input. Functions with timing of N/A are not present in that ROM version, and the function pointer should be considered invalid. The functions (and table entries) from offset 0x54 onwards are only present in the V2 ROM.

Offset	V1 Cycles (Avg)	V2 Cycles (Avg)	Description
Functions common to V1 and V2 of the bootrom			
0x00	71	71	<code>float_fadd(float a, float b)</code> Return a + b
0x04	74	74	<code>float_fsub(float a, float b)</code> Return a - b
0x08	69	58	<code>float_fmud(float a, float b)</code> Return a * b
0x0c	71	71	<code>float_fdiv(float a, float b)</code> Return a / b

0x10	N/A	N/A	deprecated
			Do not use this function
0x14	N/A	N/A	deprecated
			Do not use this function
0x18	63	63	float _fsqrt(float v)
			Return \sqrt{v} or <i>-Infinity</i> if v is negative. (Note V1 returns <i>+Infinity</i> in this case)
0x1c	37	40	int _float2int(float v)
			Convert a float to a signed integer, rounding towards <i>-Infinity</i> , and clamping the result to lie within the range -0x80000000 to 0x7FFFFFFF
0x20	36	39	int _float2fix(float v, int n)
			Convert a float to a signed fixed point integer representation where <i>n</i> specifies the position of the binary point in the resulting fixed point representation - e.g. <code>_float2fix(0.5f, 16) == 0x8000</code> . This method rounds towards <i>-Infinity</i> , and clamps the resulting integer to lie within the range -0x80000000 to 0x7FFFFFFF
0x24	38	39	uint _float2uint(float v)
			Convert a float to an unsigned integer, rounding towards <i>-Infinity</i> , and clamping the result to lie within the range 0x00000000 to 0xFFFFFFFF
0x28	38	38	uint _float2ufix(float v, int n)
			Convert a float to an unsigned fixed point integer representation where <i>n</i> specifies the position of the binary point in the resulting fixed point representation, e.g. <code>_float2ufix(0.5f, 16) == 0x8000</code> . This method rounds towards <i>-Infinity</i> , and clamps the resulting integer to lie within the range 0x00000000 to 0xFFFFFFFF
0x2c	55	55	float _int2float(int v)
			Convert a signed integer to the nearest float value, rounding to even on tie
0x30	53	53	float _fix2float(int32_t v, int n)
			Convert a signed fixed point integer representation to the nearest float value, rounding to even on tie. <i>n</i> specifies the position of the binary point in fixed point, so $f = nearest(v / 2^n)$
0x34	54	54	float _uint2float(uint32_t v)
			Convert an unsigned integer to the nearest float value, rounding to even on tie
0x38	52	52	float _ufix2float(uint32_t v, int n)
			Convert an unsigned fixed point integer representation to the nearest float value, rounding to even on tie. <i>n</i> specifies the position of the binary point in fixed point, so $f = nearest(v / 2^n)$
0x3c	603	587	float _fcos(float angle)
			Return the cosine of <i>angle</i> . <i>angle</i> is in radians, and must be in the range -128 to 128
0x40	593	577	float _fsin(float angle)
			Return the sine of <i>angle</i> . <i>angle</i> is in radians, and must be in the range -128 to 128

0x44	669	653	<p><code>float _ftan(float angle)</code></p> <p>Return the tangent of <i>angle</i>. <i>angle</i> is in radians, and must be in the range -128 to 128</p>
0x48	N/A	N/A	<p>deprecated</p> <p>Do not use this function</p>
0x4c	542	524	<p><code>float _fexp(float v)</code></p> <p>Return the exponential value of <i>v</i>, i.e. so e^v</p>
0x50	810	789	<p><code>float _fln(float v)</code></p> <p>Return the natural logarithm of <i>v</i>. If $v <= 0$ return <i>-Infinity</i></p>
Functions (and table entries) present in the V2 bootrom only			
0x54	N/A	25	<p><code>int _fcmp(float a, float b)</code></p> <p>Compares two floating point numbers, returning:</p> <ul style="list-style-type: none"> • 0 if $a == b$ • -1 if $a < b$ • 1 if $a > b$
0x58	N/A	667	<p><code>float _fatan2(float y, float x)</code></p> <p>Computes the arc tangent of y/x using the signs of arguments to determine the correct quadrant</p>
0x5c	N/A	62	<p><code>float _int642float(int64_t v)</code></p> <p>Convert a signed 64-bit integer to the nearest float value, rounding to even on tie</p>
0x60	N/A	60	<p><code>float _fix642float(int64_t v, int n)</code></p> <p>Convert a signed fixed point 64-bit integer representation to the nearest float value, rounding to even on tie. <i>n</i> specifies the position of the binary point in fixed point, so $f = nearest(v / 2^n)$</p>
0x64	N/A	58	<p><code>float _uint642float(uint64_t v)</code></p> <p>Convert an unsigned 64-bit integer to the nearest float value, rounding to even on tie</p>
0x68	N/A	57	<p><code>float _ufix642float(uint64_t v, int n)</code></p> <p>Convert an unsigned fixed point 64-bit integer representation to the nearest float value, rounding to even on tie. <i>n</i> specifies the position of the binary point in fixed point, so $f = nearest(v / 2^n)$</p>
0x6c	N/A	54	<p><code>_float2int64</code></p> <p>Convert a float to a signed 64-bit integer, rounding towards <i>-Infinity</i>, and clamping the result to lie within the range <code>-0x8000000000000000</code> to <code>0x7FFFFFFFFFFFFFFF</code></p>

0x70	N/A	53	<code>_float2fix64</code>
			Convert a float to a signed fixed point 64-bit integer representation where <i>n</i> specifies the position of the binary point in the resulting fixed point representation - e.g. <code>_float2fix(0.5f, 16) == 0x8000</code> . This method rounds towards <i>-Infinity</i> , and clamps the resulting integer to lie within the range <code>-0x8000000000000000</code> to <code>0x7FFFFFFFFFFFFFFF</code>
0x74	N/A	42	<code>_float2uint64</code>
			Convert a float to an unsigned 64-bit integer, rounding towards <i>-Infinity</i> , and clamping the result to lie within the range <code>0x0000000000000000</code> to <code>0xFFFFFFFFFFFFFFF</code>
0x78	N/A	41	<code>_float2ufix64</code>
			Convert a float to an unsigned fixed point 64-bit integer representation where <i>n</i> specifies the position of the binary point in the resulting fixed point representation, e.g. <code>_float2ufix(0.5f, 16) == 0x8000</code> . This method rounds towards <i>-Infinity</i> , and clamps the resulting integer to lie within the range <code>0x0000000000000000</code> to <code>0xFFFFFFFFFFFFFFF</code>
0x7c	N/A	15	<code>double _float2double(float v)</code>
			Converts a float to a double

Note that the V2 bootrom contains an equivalent table of functions for double-precision floating point operations. The offsets are the same, however where there was now float there is double (and vice versa for the float<->double conversion)

Table 164. Double-precision Floating Point Function Table. Timings are average time in us over random (worst case) input. Functions with timing of N/A are not present in that ROM version, and the function pointer should be considered invalid. The functions (and table entries) from offset 0x54 onwards are only present in the V2 ROM.

Offset	V2 Cycles (Avg)	Description
0x00	91	<code>double _dadd(double a, double b)</code>
		Return a + b
0x04	95	<code>double _dsub(double a, double b)</code>
		Return a - b
0x08	155	<code>double _dmul(double a, double b)</code>
		Return a * b
0x0c	183	<code>double _ddiv(double a, double b)</code>
		Return a / b
0x10	N/A	deprecated
		Do not use this function
0x14	N/A	deprecated
		Do not use this function
0x18	169	<code>double _dsqrt(double v)</code>
		Return \sqrt{v} or <i>-Infinity</i> if <i>v</i> is negative.
0x1c	75	<code>int _double2int(double v)</code>
		Convert a double to a signed integer, rounding towards <i>-Infinity</i> , and clamping the result to lie within the range <code>-0x80000000</code> to <code>0x7FFFFFFF</code>

Offset	V2 Cycles (Avg)	Description
0x20	74	<code>int _double2fix(double v, int n)</code>
		Convert a double to a signed fixed point integer representation where n specifies the position of the binary point in the resulting fixed point representation - e.g. <code>_double2fix(0.5f, 16) == 0x8000</code> . This method rounds towards <i>-Infinity</i> , and clamps the resulting integer to lie within the range <code>-0x80000000</code> to <code>0x7FFFFFFF</code>
0x24	63	<code>uint _double2uint(double v)</code>
		Convert a double to an unsigned integer, rounding towards <i>-Infinity</i> , and clamping the result to lie within the range <code>0x00000000</code> to <code>0xFFFFFFFF</code>
0x28	62	<code>uint _double2ufix(double v, int n)</code>
		Convert a double to an unsigned fixed point integer representation where n specifies the position of the binary point in the resulting fixed point representation, e.g. <code>_double2ufix(0.5f, 16) == 0x8000</code> . This method rounds towards <i>-Infinity</i> , and clamps the resulting integer to lie within the range <code>0x00000000</code> to <code>0xFFFFFFFF</code>
0x2c	69	<code>double _int2double(int v)</code>
		Convert a signed integer to the nearest double value, rounding to even on tie
0x30	68	<code>double _fix2double(int32_t v, int n)</code>
		Convert a signed fixed point integer representation to the nearest double value, rounding to even on tie. n specifies the position of the binary point in fixed point, so $f = nearest(v / 2^n)$
0x34	64	<code>double _uint2double(uint32_t v)</code>
		Convert an unsigned integer to the nearest double value, rounding to even on tie
0x38	62	<code>double _ufix2double(uint32_t v, int n)</code>
		Convert an unsigned fixed point integer representation to the nearest double value, rounding to even on tie. n specifies the position of the binary point in fixed point, so $f = nearest(v / 2^n)$
0x3c	1617	<code>double _dcos(double angle)</code>
		Return the cosine of $angle$. $angle$ is in radians, and must be in the range -1024 to 1024
0x40	1618	<code>double _dsin(double angle)</code>
		Return the sine of $angle$. $angle$ is in radians, and must be in the range -1024 to 1024
0x44	1891	<code>double _dtan(double angle)</code>
		Return the tangent of $angle$. $angle$ is in radians, and must be in the range -1024 to 1024
0x48	N/A	deprecated
		Do not use this function
0x4c	804	<code>double _dexp(double v)</code>
		Return the exponential value of v , i.e. so e^v

Offset	V2 Cycles (Avg)	Description
0x50	428	<code>double _dln(double v)</code>
		Return the natural logarithm of v. If $v \leq 0$ return <i>-Infinity</i>
0x54	39	<code>int _dcmp(double a, double b)</code>
		Compares two floating point numbers, returning: <ul style="list-style-type: none"> • 0 if $a == b$ • -1 if $a < b$ • 1 if $a > b$
0x58	2168	<code>double _datan2(double y, double x)</code>
		Computes the arc tangent of y/x using the signs of arguments to determine the correct quadrant
0x5c	55	<code>double _int642double(int64_t v)</code>
		Convert a signed 64-bit integer to the nearest double value, rounding to even on tie
0x60	56	<code>double _dix642double(int64_t v, int n)</code>
		Convert a signed fixed point 64-bit integer representation to the nearest double value, rounding to even on tie. n specifies the position of the binary point in fixed point, so $f = nearest(v / 2^n)$
0x64	50	<code>double _uint642double(uint64_t v)</code>
		Convert an unsigned 64-bit integer to the nearest double value, rounding to even on tie
0x68	49	<code>double _ufix642double(uint64_t v, int n)</code>
		Convert an unsigned fixed point 64-bit integer representation to the nearest double value, rounding to even on tie. n specifies the position of the binary point in fixed point, so $f = nearest(v / 2^n)$
0x6c	64	<code>_double2int64</code>
		Convert a double to a signed 64-bit integer, rounding towards <i>-Infinity</i> , and clamping the result to lie within the range <code>-0x8000000000000000</code> to <code>0x7FFFFFFFFFFFFFFF</code>
0x70	63	<code>_double2fix64</code>
		Convert a double to a signed fixed point 64-bit integer representation where n specifies the position of the binary point in the resulting fixed point representation - e.g. <code>_double2fix(0.5f, 16) == 0x8000</code> . This method rounds towards <i>-Infinity</i> , and clamps the resulting integer to lie within the range <code>-0x8000000000000000</code> to <code>0x7FFFFFFFFFFFFFFF</code>
0x74	53	<code>_double2uint64</code>
		Convert a double to an unsigned 64-bit integer, rounding towards <i>-Infinity</i> , and clamping the result to lie within the range <code>0x0000000000000000</code> to <code>0xFFFFFFFFFFFFFFF</code>

Offset	V2 Cycles (Avg)	Description
0x78	52	<code>_double2ufix64</code>
		Convert a double to an unsigned fixed point 64-bit integer representation where <i>n</i> specifies the position of the binary point in the resulting fixed point representation, e.g. <code>_double2ufix(0.5f, 16) == 0x8000</code> . This method rounds towards <i>-Infinity</i> , and clamps the resulting integer to lie within the range <code>0x0000000000000000</code> to <code>0xFFFFFFFFFFFFFFF</code>
0x7c	23	<code>float _double2float(double v)</code>
		Converts a double to a float

2.7.3.3. Bootrom Data

The Bootrom data table (`rom_data_table`) contains the following pointers.

Table 165. Bootrom data pointers

CODE	Value (16 bit pointer)	Description
'C', 'R'	<code>const char *copyright_string</code>	
		The Raspberry Pi Trading Ltd copyright string.
'G', 'R'	<code>const uint32_t *git_revision</code>	
		The 8 most significant hex digits of the Bootrom git revision.
'F', 'S'	<code>fplib_start</code>	
		The start address of the floating point library code and data. This and <code>fplib_end</code> along with the individual function pointers in <code>soft_float_table</code> can be used to copy the floating point implementation into RAM if desired.
'S', 'F'	<code>soft_float_table</code>	
		See Table 163 for the contents of this table.
'F', 'E'	<code>fplib_end</code>	
		The end address of the floating point library code and data.
'S', 'D'	<code>soft_double_table</code>	
		This entry is only present in the V2 bootrom. See Table 164 for the contents of this table.
'P', '8'		<i>deprecated</i> . This entry is not present in the V2 bootrom; do not use it.
'R', '8'		<i>deprecated</i> . This entry is not present in the V2 bootrom; do not use it.
'L', '8'		<i>deprecated</i> . This entry is not present in the V2 bootrom; do not use it.
'T', '8'		<i>deprecated</i> . This entry is not present in the V2 bootrom; do not use it.

2.7.4. USB Mass Storage Interface

The Bootrom provides a standard USB bootloader that makes a writeable drive available for copying code to the RP2040 using UF2 files (see Section 2.7.4.2).

A UF2 file copied to the drive is downloaded and written to Flash or RAM, and the device is automatically rebooted, making it trivial to download and run code on the RP2040 using only a USB connection.

2.7.4.1. The RPI-RP2 Drive

The RP2040 appears as a standard 128MB flash drive named *RPI-RP2* formatted as a single partition with FAT16. There are only ever two actual files visible on the drive specified.

- **INFO_UF2.TXT** - contains a string description of the UF2 bootloader and version.
- **INDEX.HTM** - redirects to information about the RP2040 device.

Any type of files may be written to the USB drive from the host, however in general these are not stored, and only *appear* to be so because of caching on the host side.

When a *UF2* file is written to the device however, the special contents are recognized and data is written to specified locations in RAM or Flash. On the completed download of an entire valid *UF2* file, the RP2040 automatically reboots to run the newly downloaded code.

i NOTE

The **INDEX.HTM** file is currently redirected to <https://pico.raspberrypi.org/getting-started>

2.7.4.2. UF2 Format Details

There are requirements on a *UF2* file to be valid to download to the RP2040. It is important that you always use valid *UF2* files (as for example generated by [\[elf2uf2\]](#)), as invalid files may be partially written and then silently fail. Note that on some operating systems you may receive a disk write error on failure, but this is not guaranteed. **TO DO: GRAHAM: link elf2uf2 to the appropriate content, after it's been added**

- All data destined for the device must be in a *UF2* block with **familyID** present and set to **0xe48bff56**, and a **payload_size** of **256**.
- All data must be destined for (and fit entirely within) the following memory ranges (depending on the type of binary being downloaded which is determined by the address of the first *UF2* block encountered):
 - a. A regular flash binary
 - **0x10000000-0x11000000** *Flash*: All blocks must be targeted at 256 byte alignments. Writes beyond the end of physical flash will wrap back to the beginning of flash.
 - b. A *RAM only* binary
 - **0x20000000-0x20042000** *Main RAM*: Blocks can be positioned with byte alignment.
 - **0x15000000-0x15004000** *Flash Cache*: (since flash is not being targeted, the Flash Cache is available for use as RAM with same properties as *Main RAM*).

Note that traditionally *UF2* has only been used to write to Flash, but this is more a limitation of using the metadata free **.BIN** file as the source to generate the *UF2* file. RP2040 takes full advantage of the inherent flexibility of *UF2* to support the full range of binaries in the richer **.ELF** format produced by the build to be used as the source for the *UF2* file.

- The **numBlocks** must specify a total size of the binary that fits in the regions specified above
- A change of **numBlocks** or the binary type (determined by *UF2* block target address) will discard the current transfer in progress.
- All data must be in blocks without the **UF2_FLAG_NOT_MAIN_FLASH** marking which relates to content to be ignored rather than Flash vs RAM.

Note that flash is erased a 4K sector at a time, so writing to only a subset of a 4K flash sector will leave the rest of that flash sector undefined. Beyond that there is no requirement that a binary be contiguous.

Note that a binary is considered "downloaded" when each of the **numBlocks** blocks has been seen at least once in the course of a single valid transfer. The data for a block is only written the first time in case of the host resending duplicate blocks.

Note that after downloading a regular flash binary, a reset is performed after which the flash binary second stage (at address `0x10000000` - the start of flash) will be entered (if valid) via the bootrom.

A downloaded *RAM Only* binary is entered by watchdog reset into the start of the binary, which is calculated as the lowest address of a downloaded block (with Main RAM considered lower than Flash Cache if both are present).

Finally it is possible for host software to temporarily disable *UF2* writes via the *PICOB00T* interface to prevent interference with operations being performed via that interface (see below), in which case any *UF2* file write in progress will be aborted.

2.7.5. USB PICOB00T Interface

The *PICOB00T* interface is a low level USB protocol for interacting with the RP2040 while it is in USB boot mode. This interface may be used concurrently with the USB Mass Storage Interface.

It provides for flexible reading from and writing to RAM or Flash, rebooting, executing code on the device and a handful of other management functions.

Constants and structures related to the interface can be found in the Pico SDK header https://github.com/raspberrypi/pico-sdk/tree/pre_release/src/common/boot_picoboot/include/boot/picoboot.h

2.7.5.1. Identifying The Device

A RP2040 device is recognized by the *Vendor ID* and *Product ID* in its device descriptor (shown in [Table 166](#)).

Table 166. RP2040 Boot Device Descriptor

Field	Value
bLength	18
bDescriptorType	1
bcdUSB	1.10
bDeviceClass	0
bDeviceSubClass	0
bDeviceProtocol	0
bMaxPacketSize0	64
idVendor	0x2e8a
idProduct	0x0003
bcdDevice	1.00
iManufacturer	1
iProduct	2
iSerial	3
bNumConfigurations	1

2.7.5.2. Identifying The Interface

The *PICOB00T* interface is recognized by the "Vendor Specific" *Interface Class* and the zero *Interface Sub Class* and *Interface Protocol* (shown in [Table 167](#)). Note that you should not rely on the interface number, as that is dependent on whether the device is also exposing the Mass Storage Interface. Note also that the device equally may not be exposing the *PICOB00T* interface at all, so you should not assume it is present.

Table 167. PICOBOOT Interface Descriptor

Field	Value
bLength	9
bDescriptorType	4
bInterfaceNumber	varies
bAlternateSetting	0
bNumEndpoints	2
bInterfaceClass	0xff (vendor specific)
bInterfaceSubClass	0
bInterfaceProtocol	0
iInterface	0

2.7.5.3. Identifying The Endpoints

The PICOBOOT interface provides a single *BULK OUT* and a single *BULK IN* endpoint. These can be identified by their direction and type. You should not rely on endpoint numbers.

2.7.5.4. PICOBOOT Commands

The two bulk endpoints are used for sending commands and retrieved successful command results. All commands are exactly 32 bytes (see Table 168) and sent to the *BULK OUT* endpoint.

Table 168. PICOBOOT Command Definition

Offset	Name	Description
0x00	dMagic	The value 0x431fd10b
0x04	dToken	A user provided token to identify this request by
0x08	bCmdId	The ID of the command. Note that the top bit indicates data transfer direction (0x80 = IN)
0x09	bCmdSize	Number of bytes of valid data in the <i>args</i> field
0x0a	reserved	0x0000
0x0c	dTransferLength	The number of bytes the host expects to send or receive over the bulk channel
0x10	args	16 bytes of command specific data padded with zeros

If a command sent is invalid or not recognized, the bulk endpoints will be stalled. Further information will be available via the *GET_COMMAND_STATUS* request (see Section 2.7.5.5.2).

Following the initial 32 byte packet, if *dTransferLength* is non-zero, then that many bytes are transferred over the bulk pipe and the command is completed with an empty packet in the opposite direction. If *dTransferLength* is zero then command success is indicated by an empty IN packet.

The following commands are supported (note common fields *dMagic*, *dToken*, *reserved* are omitted for clarity)

2.7.5.4.1. EXCLUSIVE_ACCESS (0x01)

Claim or release exclusive access for writing to the RP2040 over USB (versus the Mass Storage Interface)

Table 169. PIC0BOOT Exclusive access command structure

Offset	Name	Value / Description	
0x08	bCmdId	0x01 (EXCLUSIVE_ACCESS)	
0x09	bCmdSize	0x01	
0x0c	dTransferLength	0x00000000	
0x10	bExclusive	NOT_EXCLUSIVE (0)	No restriction on USB Mass Storage operation
		EXCLUSIVE (1)	Disable USB Mass Storage writes (the host should see them as write protect failures, but in any case any active <i>UF2</i> download will be aborted)
		EXCLUSIVE_AND_EJECT (2)	Lock the USB Mass Storage Interface out by marking the drive media as not present (ejecting the drive)

2.7.5.4.2. REBOOT (0x02)

Reboots the RP2040 out of USB boot mode. Note that USB boot mode might be re-entered if rebooting to flash and no valid second stage bootloader is found.

Table 170. PIC0BOOT Reboot access command structure

Offset	Name	Value / Description	
0x08	bCmdId	0x02 (REBOOT)	
0x09	bCmdSize	0x0c	
0x0c	dTransferLength	0x00000000	
0x10	dPC	The address to start executing from. Valid values are:	
		0x00000000	Reboot via the standard Flash boot mechanism
		RAM address	Reboot via watchdog and start executing at the specified address in RAM
0x14	dSP	Initial stack pointer post reboot (only used if booting into RAM)	
0x18	dDelayMS	Number of milliseconds to delay prior to reboot	

2.7.5.4.3. FLASH_ERASE (0x03)

Erases a contiguous range of flash sectors.

Table 171. PIC0BOOT Flash erase command structure

Offset	Name	Value / Description	
0x08	bCmdId	0x03 (FLASH_ERASE)	
0x09	bCmdSize	0x08	
0x0c	dTransferLength	0x00000000	
0x10	dAddr	The address in flash to erase, starting at this location. This must be sector (4K) aligned	
0x14	dSize	The number of bytes to erase. This must be an exact multiple number of sectors (4K)	

2.7.5.4.4. READ (0x84)

Read a contiguous memory (Flash or RAM or ROM) range from the RP2040

Table 172. PIC0BOOT
Read memory
command (Flash,
RAM, ROM) structure

Offset	Name	Value / Description
0x08	bCmdId	0x84 (READ)
0x09	bCmdSize	0x08
0x0c	dTransferLength	Must be the same as dSize
0x10	dAddr	The address to read from. May be in Flash or RAM or ROM
0x14	dSize	The number of bytes to read

2.7.5.4.5. WRITE (0x05)

Writes a contiguous memory range of memory (Flash or RAM) on the RP2040.

Table 173. PIC0BOOT
Write memory
command (Flash,
RAM) structure

Offset	Name	Value / Description
0x08	bCmdId	0x05 (WRITE)
0x09	bCmdSize	0x08
0x0c	dTransferLength	Must be the same as dSize
0x10	dAddr	The address to write from. May be in Flash or RAM, however must be page (256 byte) aligned if in Flash. Note the flash must be erased first or the results are undefined.
0x14	dSize	The number of bytes to write. If writing to flash and the size is not an exact multiple of pages (256 bytes) then the last page is zero-filled to the end.

2.7.5.4.6. EXIT_XIP (0x06)

Exit Flash XIP mode. This first initialises the SSI for serial transfers, and then issues the XIP exit sequence given in [Section 2.7.2.2](#), to attempt to make the flash responsive to standard serial SPI commands. The SSI is configured with a fixed clock divisor of /6, so the USB bootloader will drive SCLK at 8 MHz.

Table 174. PIC0BOOT
Exit Execute in place
(XIP) command
structure

Offset	Name	Value / Description
0x08	bCmdId	0x06 (EXIT_XIP)
0x09	bCmdSize	0x00
0x0c	dTransferLength	0x00000000

2.7.5.4.7. ENTER_XIP (0x07)

Enter Flash XIP mode. This configures the SSI to issue a standard **03h** serial read command, with 24 address clocks and 32 data clocks, for every XIP access. This is a slow but very widely supported way to read flash. The intent of this function is to make flash easily accessible (i.e. just access addresses in the **0x10.....** segment) without having to know the details of exactly what kind of flash is connected. This mode is suitable for executing code from flash, but is much slower than e.g. QSPI XIP access.

Table 175. PIC0BOOT
Enter Execute in place
(XIP) command

Offset	Name	Value / Description
0x08	bCmdId	0x07 (ENTER_XIP)

Offset	Name	Value / Description
0x09	bCmdSize	0x00
0x0c	dTransferLength	0x00000000

2.7.5.4.8. EXEC (0x08)

Executes a function on the device. This function takes no arguments and returns no results, so it must communicate via RAM. Execution of this method will block any other commands as well as Mass Storage Interface *UF2* writes, so should only be used in exclusive mode and with extreme care (and it should save and restore registers as per the ARM EABI). This method is called from a regular (non IRQ) context, and has a very limited stack, so the function should use its own.

Table 176. PIC0BOOT
Execute function on
device command
structure

Offset	Name	Value / Description
0x08	bCmdId	0x08 (EXEC)
0x09	bCmdSize	0x04
0x0c	dTransferLength	0x00000000
0x10	dAddr	Function address to execute at (a thumb bit will be added for you since you will have forgotten).

2.7.5.4.9. VECTORIZE_FLASH (0x09)

Requests that that the vector table of flash access functions used internally by the Mass Storage and PIC0BOOT interfaces be copied into RAM, such that the method implementations can be replaced with custom versions (For example, if the board uses flash that does not support standard commands)

Table 177. PIC0BOOT
Vectorise flash
command structure

Offset	Name	Value / Description
0x08	bCmdId	0x09 (VECTORIZE_FLASH)
0x09	bCmdSize	0x04
0x0c	dTransferLength	0x00000000
0x10	dAddr	Pointer to where to place vector table in RAM

Flash function vector table

```

struct {
    uint32_t size; // 28
    uint32_t (*do_flash_enter_cmd_xip)();
    uint32_t (*do_flash_exit_xip)();
    uint32_t (*do_flash_erase_sector)();
    uint32_t (*do_flash_erase_range)(uint32_t addr, uint32_t size);
    uint32_t (*do_flash_page_program)(uint32_t addr, uint8_t *data);
    uint32_t (*do_flash_page_read)(uint32_t addr, uint8_t *data);
};
    
```

These methods have the same signature and arguments as the corresponding flash access functions in the bootrom (see [Section 2.7.3.1.3](#)).

Note that the host must subsequently update the RAM copy of this table via an **EXEC** command running on the RP2040 as any write to RAM from the host via a PIC0BOOT **WRITE** that overlaps this (now active in RAM) vector table will cause a reset to the use of the default ROM Flash function vector table.

2.7.5.5. Control Requests

The following requests are sent to the interface via the default control pipe.

2.7.5.5.1. INTERFACE_RESET (0x41)

The host sends this control request to reset the PICOBOOT interface. This command:

- Clears the HALT condition (if set) on each of the bulk endpoints
- Aborts any in-process PICOBOOT or Mass Storage transfer and any flash write (this method is the only way to kill a stuck flash transfer).
- Clears the previous command result
- Removes EXCLUSIVE_ACCESS and remounts the Mass Storage drive if it was ejected due to exclusivity.

Table 178. PICOBOOT Reset PICOBOOT interface control

bmRequestType	bRequest	wValue	wIndex	wLength	Data
00100001b	01000001b	0000h	Interface	0000h	none

This command responds with an empty packet on success.

2.7.5.5.2. GET_COMMAND_STATUS (0x42)

Retrieve the status of the last command (which may be a command still in progress). Successful completion of a PICOBOOT Protocol Command is acknowledged over the bulk pipe, however if the operation is still in progress or has failed (stalling the bulk pipe), then this method can be used to determine the operation's status.

Table 179. PICOBOOT Get last command status control

bmRequestType	bRequest	wValue	wIndex	wLength	Data
00100001b	01000010b	0000h	Interface	0000h	none

The command responds with the following 16 byte response

Table 180. PICOBOOT Get last command status control response

Offset	Name	Description
0x00	dToken	The user token specified with the command

Offset	Name	Description	
0x04	dStatusCode	OK (0)	The command completed successfully (or is still in progress)
		UNKNOWN_CMD (1)	The ID of the command was not recognized
		INVALID_CMD_LENGTH (2)	The length of the command request was incorrect
		INVALID_TRANSFER_LENGTH (3)	The data transfer length was incorrect given the command
		INVALID_ADDRESS (4)	The address specified was invalid for the command type; i.e. did not match the type Flash/RAM that the command was expecting
		BAD_ALIGNMENT (5)	The address specified was not correctly aligned according to the requirements of the command
		INTERLEAVED_WRITE (6)	A Mass Storage Interface <i>UF2</i> write has interfered with the current operation. The command was abandoned with unknown status. Note this will not happen if you have <i>exclusive</i> access.
		REBOOTING (7)	The device is in the process of rebooting, so the command has been ignored.
		UNKNOWN_ERROR (8)	Some other error occurred.
0x08	bCmdId	The ID of the command	
0x09	bInProgress	1 if the command is still in progress	0 otherwise
0x0a	reserved	(6 zero bytes)	

2.8. Power Supplies

RP2040 requires five separate power supplies. However, in most applications, several of these can be combined and connected to a single power source. In a typical application, only a single 3.3V supply will be required. See [Section 2.8.7.1, "Single 3.3V Supply"](#).

The power supplies and a number of potential power supply schemes are described in the following sections. Detailed power supply parameters are provided in [Section 5.3, "Power Supplies"](#).

2.8.1. Digital IO Supply (IOVDD)

IOVDD supplies the chip's digital IO, and should be powered at a nominal voltage between 1.8V and 3.3V. The supply voltage sets the external signal level for the digital IO and should be chosen based on the signal level required. See [Section 5.2.3, "Pin Specifications"](#) for details. All digital IOs share the same power supply and operate at the same signal level.

IOVDD should be decoupled with a 100nF capacitor close to each of the chip's IOVDD pins.

⚠ CAUTION

If the digital IO is powered at a nominal 1.8V, the IO input thresholds should be adjusted via the [VOLTAGE_SELECT](#) register. By default, the IO input thresholds are valid when the digital IO is powered at a nominal voltage between 2.5V and 3.3V. See [Section 2.18, "GPIO"](#) for details. Powering the IO at 1.8V with input thresholds set for a 2.5V to 3.3V supply is a safe operating mode, but will result in input thresholds that do not meet specification. Powering the IO at voltages greater than a nominal 1.8V with input thresholds set for a 1.8V supply may result in damage to the chip.

2.8.2. Digital Core Supply (DVDD)

DVDD supplies the chip's core digital logic, and should be powered at a nominal 1.1V. A dedicated on-chip voltage regulator is provided to allow DVDD to be generated from the digital IO supply (IOVDD) or another nominally 1.8V to 3.3V supply. The connection between the output pin of the on-chip regulator (VREG_VOOUT) and the DVDD supply pins is made off-chip, allowing DVDD to be powered from an off-chip power source if required.

DVDD should be decoupled with a 100nF capacitor close to each of the chip's DVDD pins.

2.8.3. On-Chip Voltage Regulator Input Supply (VREG_IOVDD)

VREG_IOVDD is the input supply for the on-chip voltage regulator. It should be powered at a nominal voltage between 1.8V and 3.3V. To reduce the number of external power supplies, VREG_IOVDD can use the same power source as the digital IO supply (IOVDD).

A 1µF capacitor should be connected between VREG_IOVDD and ground close to the chip's VREG_IOVDD pin.

⚠ CAUTION

VREG_IOVDD also powers the chip's power-on reset and brown-out detection blocks, so it must be powered even if the on-chip voltage regulator is not used.

For more details on the on-chip voltage regulator see [On-Chip Voltage Regulator](#).

2.8.4. USB PHY Supply (USB_IOVDD)

USB_IOVDD supplies the chip's USB PHY, and should be powered at a nominal 3.3V. To reduce the number of external power supplies, USB_IOVDD can use the same power source as the digital IO supply (IOVDD), assuming IOVDD is also powered at 3.3V. If IOVDD is not powered at 3.3V, a separate 3.3V supply will be required for the USB PHY, see [Section 2.8.7.3, "1.8V Digital IO with Functional USB and ADC"](#). In applications where the USB PHY is never used, USB_IOVDD can be tied to any supply with a nominal voltage between 1.8V and 3.3V. See [Section 2.8.7.4, "Single 1.8V Supply"](#) for an example. USB_IOVDD should not be left unconnected.

USB_IOVDD should be decoupled with a 100nF capacitor close to the chip's USB_IOVDD pin.

2.8.5. ADC Supply (ADC_IOVDD)

ADC_IOVDD supplies the chip's Analogue to Digital Converter (ADC). It can be powered at a nominal voltage between 1.8V and 3.3V, but the performance of the ADC will be compromised at voltages below 2.97V. To reduce the number of external power supplies, ADC_IOVDD can use from the same power source as the digital IO supply (IOVDD).

NOTE

It is safe to supply ADC_IOVDD at a higher or lower voltage than IOVDD, e.g. to power the ADC at 3.3V, for optimum performance, while supporting 1.8V signal levels on the digital IO. But the voltage on the ADC analogue inputs must not exceed IOVDD, e.g. if IOVDD is powered at 1.8V, the voltage on the ADC inputs should be limited to 1.8V. Voltages greater than IOVDD will result in leakage currents through the ESD protection diodes. See [Section 5.2.3, "Pin Specifications"](#) for details.

ADC_IOVDD should be decoupled with a 100nF capacitor close to the chip's ADC_IOVDD pin.

2.8.6. Power Supply Sequencing

RP2040's power supplies may be powered up or down in any order. However, small transient currents may flow in the ADC supply (ADC_IOVDD) if it is powered up before, or powered down after, the digital core supply (DVDD). This will not damage the chip, but can be avoided by powering up DVDD before or at the same time as ADC_IOVDD, and powering down DVDD after or at the same time as ADC_IOVDD. In the most common power supply scheme, where the chip is powered from a single 3.3V supply, DVDD will be powered up shortly after ADC_IOVDD due to the startup time of the on-chip voltage regulator. This is acceptable behaviour. See [Section 2.8.7.1, "Single 3.3V Supply"](#).

2.8.7. Power Supply Schemes

2.8.7.1. Single 3.3V Supply

In most applications, RP2040 will be powered from a single 3.3V supply, as shown in [Figure 14](#). The digital IO (IOVDD), USB PHY (USB_IOVDD) and ADC (ADC_IOVDD) will be powered directly from the 3.3V supply, and the 1.1V digital core supply (DVDD) will be regulated from the 3.3V supply by the on-chip voltage regulator. Note that the regulator output pin (VREG_VOUT) must be connected to the chip's DVDD pins off-chip.

For more details on the on-chip voltage regulator see [On-Chip Voltage Regulator](#).

Figure 14. powering the chip from a single 3.3V supply (simplified diagram omitting decoupling components)

2.8.7.2. External Core Supply

The digital core (DVDD) can be powered directly from an external 1.1V supply, rather than from the on-chip regulator, as shown in [Figure 15](#). This approach may make sense if a suitable external regulator is available elsewhere in the system, or for low power applications where an efficient switched-mode regulator could be used instead of the less efficient linear on-chip voltage regulator.

If an external core supply is used, the output of on-chip voltage regulator (VREG_VOUT) should be left unconnected. However, power must still be provided to the regulator input (VREG_IOVDD) to supply the chip's power-on reset and brown-out detection blocks. The on-chip voltage regulator will power-on as soon as VREG_IOVDD is available, but can be shutdown under software control once the chip is out of reset. See [On-Chip Voltage Regulator](#) for details.

Figure 15. using an external core supply

2.8.7.3. 1.8V Digital IO with Functional USB and ADC

Applications with digital IO signal levels less than 3.3V will require a separate 3.3V supply for the USB PHY and ADC, as the USB PHY does not meet specification at voltages below 3.135V and ADC performance is compromised at voltages below 2.97V. [Figure 16](#) shows an example application with the digital IO (IOVDD) powered at 1.8V and a separate 3.3V supply for the USB PHY (USB_IOVDD) and ADC (ADC_IOVDD). In this example, the voltage regulator input (VREG_IOVDD) is connected to the 1.8V supply, though it could equally have been connected to the 3.3V supply. Connecting it to the 1.8V supply will reduce overall power consumption if the 1.8V supply is generated by an efficient switched-mode regulator.

Figure 16. supporting 1.8V IO while using USB and the ADC

2.8.7.4. Single 1.8V Supply

If a functional USB PHY and optimum ADC performance are not required, RP2040 can be powered from a single supply of less than 3.3V. Figure 17 shows an example with a single 1.8V supply. In this example, the core supply (DVDD) is regulated from the 1.8V supply by the on-chip voltage regulator.

Figure 17. powering the chip from a single 1.8V supply

2.9. On-Chip Voltage Regulator

RP2040 includes an on-chip voltage regulator, allowing the digital core supply (DVDD) to be generated from an external, nominally 1.8V to 3.3V, power supply. In most cases, the regulator's input supply will share an external power source with

the chip's digital IO supply IOVDD, simplifying the overall power supply requirements.

To allow the chip to start up, the voltage regulator is enabled by default and will power-on as soon as its input supply is available. Once the chip is out of reset, the regulator can be disabled, placed into a high impedance state, or have its output voltage adjusted, under software control. The output voltage can be set in the range 0.80V to 1.30V in 50mV steps, but is set to a nominal 1.1V at initial power-on, or after a reset event. The voltage regulator can supply up to 100mA.

Although intended to provide the chip's digital core supply (DVDD), the voltage regulator can be used for other purposes if DVDD is powered directly from an external power supply.

2.9.1. Application Circuit

Figure 18. voltage regulator application circuit

The regulator must have 1µF capacitors placed close to its input (VREG_IOVDD) and output (VREG_VOUT) pins.

2.9.2. Operating Modes

The voltage regulator operates in one of three modes. The mode to be used being selected by writing to the **EN** and **HIZ** fields in the **VREG** register, as shown in [Table 181](#). At initial power-on, or following a reset event, the voltage regulator will be in *Normal Operation* mode.

Table 181. Voltage Regulator Mode Select

Mode	EN	HIZ
Normal Operation ^a	1	0
High Impedance	1	1
Shutdown	0	X

^a the voltage regulator will be in normal mode at initial power-on or following a reset event

2.9.2.1. Normal Operation Mode

In Normal Operation mode, the voltage regulator's output is in regulation at the selected voltage, and the regulator is able to supply power.

2.9.2.2. High Impedance Mode

In High Impedance mode, the voltage regulator is disabled and its output pin (VREG_VOUT) is set to a high impedance state. In this mode, the regulator's power consumption is minimised. This mode allows a load connected to VREG_VOUT to be powered from a power source other than the on-chip regulator. This could allow, for example, the load to be initially powered from the on-chip voltage regulator, and then switched to an external regulator under software control. The external regulator would also need to support a high impedance mode, with only one regulator supplying the load at a time. The supply voltage is maintained by the regulator's output capacitor during the brief period when both regulators are in high impedance mode.

2.9.2.3. Shutdown Mode

In Shutdown mode, the voltage regulator is disabled, power consumption is minimized and the regulator's output pin (VREG_VOUT) is pulled to 0V.

Shutdown mode is only useful if the voltage regulator is not providing the RP2040's digital core supply (DVDD). If the regulator is supplying DVDD, and brown-out detection is enabled, entering shutdown mode will cause a reset event and the voltage regulator will return to normal mode. If brown-out detection isn't enabled, the voltage regulator will shut down and will remain in shutdown mode until its input supply (VREG_IOVDD) is power cycled.

2.9.3. Output Voltage Select

The required output voltage can be selected by writing to the **VSEL** field in the **VREG** register. The voltage regulator's output voltage can be set in the range 0.80V to 1.30V in 50mV intervals. The regulator output voltage is set to 1.1V at initial power-on or following a reset event. For details, see the **VREG** register description.

Note that RP2040 may not operate reliably with its digital core supply (DVDD) at a voltage other than 1.1V.

2.9.4. Status

The **VREG** register contains a single status field, **ROK**, which indicates whether the voltage regulator's output is being correctly regulated.

At power on, **ROK** remains low until the regulator has started up and the output voltage reaches the ROK assertion threshold (**ROK_{TH.ASSERT}**). It then remains high until the voltage drops below the ROK deassertion threshold (**ROK_{TH.DEASSERT}**), remaining low until the output voltage is above the assertion threshold again. **ROK_{TH.ASSERT}** is nominally 90% of the selected output voltage, 0.99V if the selected output voltage is 1.1V, and **ROK_{TH.DEASSERT}** is nominally 87% of the selected output voltage, 0.957V if the selected output voltage is 1.1V.

Note that adjusting the output voltage to a higher voltage will cause **ROK** to go low until the assertion threshold for the higher voltage is reached. **ROK** will also go low if the regulator is placed in high impedance mode.

2.9.5. Current Limit

The voltage regulator includes a current limit to prevent the load current exceeding the maximum rated value. The output voltage will not be regulated and will drop below the selected value when the current limit is active.

2.9.6. List of Registers

The voltage regulator shares a register address space with the chip-level reset subsystem. The registers for both subsystems are listed here. Only, the **VREG** register is part of the voltage register subsystem. The **BOD** and **CHIP_RESET** registers are part of the chip-level reset subsystem. The shared address space is referred to as **vreg_and_chip_reset** elsewhere in this document.

Table 182. List of VREG_AND_CHIP_RES ET registers

2.9.7. Detailed Specifications

Table 186. Voltage Regulator Detailed Specifications

Parameter	Description	Min	Typ	Max	Units
V_{VREG_IOVDD}	input supply voltage	1.63	1.8 - 3.3	3.63	V
ΔV_{VREG_VOUT}	output voltage variation	-3		+3	% of selected output voltage
I_{MAX}	output current			100	mA
I_{LIMIT}	current limit	150	350	450	mA
ROK_{TH_ASSERT}	ROK assertion threshold	87	90	93	% of selected output voltage
$ROK_{TH_DEASSERT}$	ROK deassertion threshold	84	87	90	% of selected output voltage
$t_{POWER-ON}^a$	power-up time		275	350	μ s

^a values will vary with load current and capacitance on VREG_VOUT. Conditions: EN = 1, load current = 0mA, VREG_IOVDD ramps up in 100 μ s

2.10. Power Control

RP2040 provides a range of options for reducing dynamic power:

- Top-level clock gating of individual peripherals and functional blocks
- Automatic control of top-level clock gates based on processor sleep state
- On-the-fly changes to system clock frequency or system clock source (e.g. switch to internal ring oscillator, and disable PLLs and crystal oscillator)
- Zero-dynamic-power DORMANT state, waking on GPIO event or RTC IRQ

All digital logic on RP2040 is in a single core power domain. The following options are available for static power reduction:

- Placing memories into state-retaining power down state
- Power gating on peripherals that support this, e.g. ADC, temperature sensor

2.10.1. Top-level Clock Gates

Each clock domain (for example, the system clock) may drive a large number of distinct hardware blocks, not all of which may be required at once. To avoid unnecessary power dissipation, each individual endpoint of each clock (for example, the UART system clock input) may be disabled at any time.

Enabling and disabling a clock gate is glitch-free. If a peripheral clock is temporarily disabled, and subsequently re-enabled, the peripheral will be in the same state as prior to the clock being disabled. No reset or reinitialisation should be required.

Clock gates are controlled by two sets of registers: the WAKE_ENx registers (starting at [WAKE_EN0](#)) and SLEEP_ENx registers (starting at [SLEEP_EN0](#)). These two sets of registers are identical at the bit level, each possessing a flag to control each clock endpoint. The WAKE_EN registers specify which clocks are enabled whilst the system is awake, and the SLEEP_ENx registers select which clocks are enabled while the processor is in the SLEEP state ([Section 2.10.2](#)).

The two Cortex-M0+ processors do not have externally-controllable clock gates. Instead, the processors gate the clocks of their subsystems autonomously, based on execution of **WFI/WFE** instructions, and external Event and IRQ signals.

2.10.2. SLEEP State

RP2040 enters the SLEEP state when all of the following are true:

- Both processors are asleep (e.g. in a **WFE** or **WFI** instruction)
- The system DMA has no outstanding transfers on any channel

RP2040 exits the SLEEP state when either processor is awoken by an interrupt.

When in the SLEEP state, the top-level clock gates are masked by the SLEEP_ENx registers (<starting at [SLEEP_EN0](#)), rather than the WAKE_ENx registers. This permits more aggressive pruning of the clock tree when the processors are asleep.

i NOTE

Though it is possible for a clock to be enabled during SLEEP and disabled outside of SLEEP, this is generally not useful

For example, if the system is sleeping until a character interrupt from a UART, the entire system except for the UART can be clock-gated (SLEEP_ENx = all-zeroes except for CLK_SYS_UART0 and CLK_PERL_UART0). This includes system infrastructure such as the bus fabric.

When the UART asserts its interrupt, and wakes a processor, RP2040 leaves SLEEP mode, and switches back to the WAKE_ENx clock mask. At the minimum this should include the bus fabric, and the memory devices containing the processor's stack and interrupt vectors.

A system-level clock request handshake holds the processors off the bus until the clocks are re-enabled.

2.10.3. DORMANT State

The DORMANT state is a true zero-dynamic-power sleep state, where all clocks (and all oscillators) are disabled. The system can awake from the DORMANT state upon a GPIO event (high/low level or rising/falling edge), or an RTC interrupt: this restarts one of the oscillators (either ring oscillator or crystal oscillator), and ungates the oscillator output once it is stable. System state is retained, so code execution resumes immediately upon leaving the DORMANT state.

Note that, if relying on the RTC ([Section 4.9](#)) to wake from the DORMANT state, the RTC must have some external clock source. The RTC accepts clock frequencies as low as 1 Hz.

Note also that DORMANT does not halt PLLs. To avoid unnecessary power dissipation, software should power down PLLs before entering the DORMANT state, and power up and reconfigure the PLLs again after exiting.

The DORMANT state is entered by writing a keyword to the DORMANT register in whichever oscillator is active (either ring oscillator [Ring Oscillator](#) or crystal oscillator [Crystal Oscillator](#)). If both are active then the one providing the processor clock must be stopped last because it will stop software from executing.

2.10.4. Memory Power Down

The main system memories (SRAM0...5, mapped to bus addresses **0x20000000** to **0x20041fff**), as well as the USB DPRAM, can be powered down via the [MEMPOWERDOWN](#) register in the Syscfg registers (see [Syscfg](#)). When powered down, memories retain their current contents, but cannot be accessed. Static power is reduced.

CAUTION

Memories must not be accessed when powered down. Doing so can corrupt memory contents.

When powering a memory back up, a 20 ns delay is required before accessing the memory again.

The XIP cache (see [Execute-In-Place](#)) can also be powered down, with `CTRL.POWER_DOWN`. The XIP hardware will not generate cache accesses whilst the cache is powered down. Note that this is unlikely to produce a net power savings if code continues to execute from XIP, due to the comparatively high voltages and switching capacitances of the external QSPI bus.

2.10.5. Programmer's Model

2.10.5.1. Sleep

The `hello_sleep` example, https://github.com/raspberrypi/pico-examples/tree/pre_release/sleep/hello_sleep/hello_sleep.c, demonstrates sleep mode. The `hello_sleep` application (and underlying SDK functions) take the following steps:

- Run all clocks in the system from XOSC
- Configure an alarm in the RTC for 10 seconds in the future
- Set `clk_rtc` as the only clock running in sleep mode using the `SLEEP_ENx` registers (see [SLEEP_EN0](#))
- Enable deep sleep in the processor
- Call `__wfi` on processor which will put the processor into deep sleep until woken by the RTC interrupt
- The RTC interrupt clears the alarm and then calls a user supplied callback function
- The callback function ends the example application

NOTE

It is necessary to enable deep sleep on both `proc0` and `proc1` and call `__wfi`, as well as ensure the DMA is stopped to enter sleep mode.

`hello_sleep` makes use of functions in `hardware_sleep` of the Pico SDK. In particular, `sleep_goto_sleep_until` puts the processor to sleep until woken up by an RTC time assumed to be in the future.

Pico SDK: https://github.com/raspberrypi/pico-sdk/tree/pre_release/src/rp2_common/hardware_sleep/sleep.c Lines 105 - 120

```

105 void sleep_goto_sleep_until(datetime_t *t, rtc_callback_t callback) {
106     // We should have already called the sleep_run_from_dormant_source function
107     assert(dormant_source_valid(_dormant_source));
108
109     // Turn off all clocks when in sleep mode except for RTC
110     clocks_hw->sleep_en0 = CLOCKS_SLEEP_EN0_CLK_RTC_RTC_BITS;
111     clocks_hw->sleep_en1 = 0x0;
112
113     rtc_set_alarm(t, callback);
114
115     // Enable deep sleep at the proc
116     scb_hw->scr = M0PLUS_SCR_SLEEPDEEP_BITS;
117
118     // Go to sleep
119     __wfi();
120 }
```

2.10.5.2. Dormant

The `hello_dormant` example, https://github.com/raspberrypi/pico-examples/tree/pre_release/sleep/hello_dormant/hello_dormant.c, demonstrates dormant mode. The example takes the following steps:

- Run all clocks in the system from XOSC
- Configure a GPIO interrupt for the "dormant_wake" hardware which can wake both the ROSC and XOSC from dormant mode
- Put the XOSC into dormant mode which stops all processor execution (and all other clocked logic on the chip) immediately
- When GPIO 10 goes high, the XOSC is started again and execution of the program continues

`hello_dormant` uses `sleep_goto_dormant_until_pin` under the hood:

Pico SDK: https://github.com/raspberrypi/pico-sdk/tree/pre_release/src/rp2_common/hardware_sleep/sleep.c Lines 132 - 153

```

132 void sleep_goto_dormant_until_pin(uint gpio_pin, bool edge, bool high) {
133     bool low = !high;
134     bool level = !edge;
135
136     // Configure the appropriate IRQ at IO bank 0
137     assert(gpio_pin <= NUM_BANK0_GPIO);
138
139     uint32_t event = 0;
140
141     if (level && low) event = IO_BANK0_DORMANT_WAKE_INTE0_GPIO0_LEVEL_LOW_BITS;
142     if (level && high) event = IO_BANK0_DORMANT_WAKE_INTE0_GPIO0_LEVEL_HIGH_BITS;
143     if (edge && high) event = IO_BANK0_DORMANT_WAKE_INTE0_GPIO0_EDGE_HIGH_BITS;
144     if (edge && low) event = IO_BANK0_DORMANT_WAKE_INTE0_GPIO0_EDGE_LOW_BITS;
145
146     gpio_set_dormant_irq_enabled(gpio_pin, event, true);
147
148     _go_dormant();
149     // Execution stops here until woken up
150
151     // Clear the irq so we can go back to dormant mode again if we want
152     gpio_acknowledge_irq(gpio_pin, event);
153 }
```

2.11. Chip-Level Reset

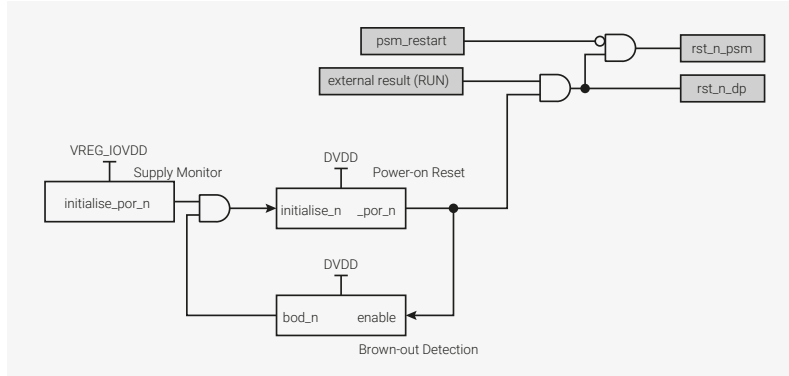

2.11.1. Overview

The chip-level reset subsystem resets the whole chip, placing it in a default state. This happens at initial power-on, during a power supply brown-out event or when the chip's RUN pin is taken low. The chip can also be reset via the Rescue Debug Port. See [Section 2.3.4.2, "Rescue DP"](#) for details.

The subsystem has two reset outputs. `rst_n_psm`, which resets the whole chip, except the debug port, and `rst_n_dp`, which only resets the Rescue DP. Both resets are held low at initial power-on, during a brown-out event or when RUN is low. `rst_n_psm` can additionally be held low by the Rescue DP via the subsystem's `psm_restart` input. This allows the chip to be reset via the Rescue DP without resetting the Rescue DP itself. The subsystem releases chip level reset by taking `rst_n_psm` high, handing control to the Power-on State Machine, which continues to start up the chip. See [Power-On State Machine](#) for details.

The chip level reset subsystem is shown in [Figure 19](#), and more information is available in the following sections.

Figure 19. The chip-level reset subsystem

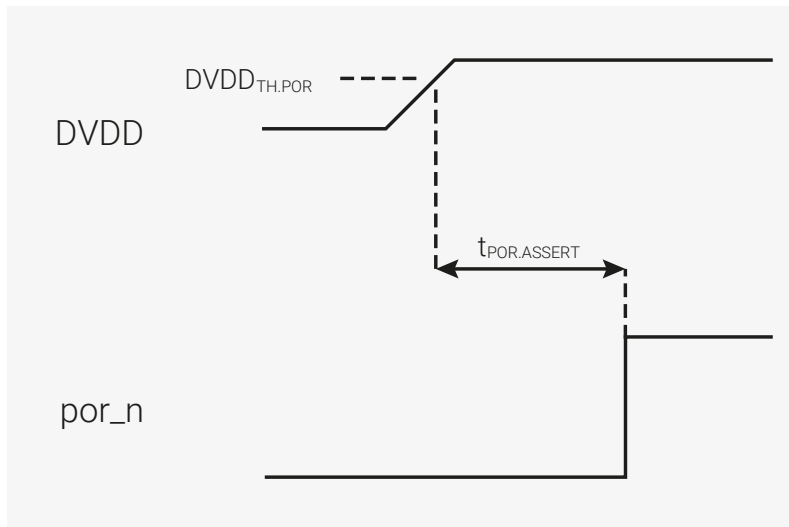

2.11.2. Power-on Reset

The power-on reset block makes sure the chip starts up cleanly when power is first applied by holding it in reset until the digital core supply (DVDD) can reliably power the chip’s core logic. The block holds its `por_n` output low until DVDD has been above the *power-on reset threshold* ($DVDD_{TH,POR}$) for a period greater than the *power-on reset assertion delay* ($t_{POR,ASSERT}$). Once high, `por_n` remains high even if DVDD subsequently falls below $DVDD_{TH,POR}$, unless brown-out detection is enabled. The behaviour of `por_n` when power is applied is shown in Figure 20.

$DVDD_{TH,POR}$ is fixed at a nominal 0.957V, which should result in a threshold between 0.924V and 0.99V. The threshold assumes a nominal DVDD of 1.1V at initial power-on, and `por_n` may never go high if a lower voltage is used. Once the chip is out of reset, DVDD can be reduced without `por_n` going low, as long as brown-out detection has been disabled or a suitable threshold voltage has been set.

Figure 20. A power-on reset cycle

2.11.2.1. Detailed Specifications

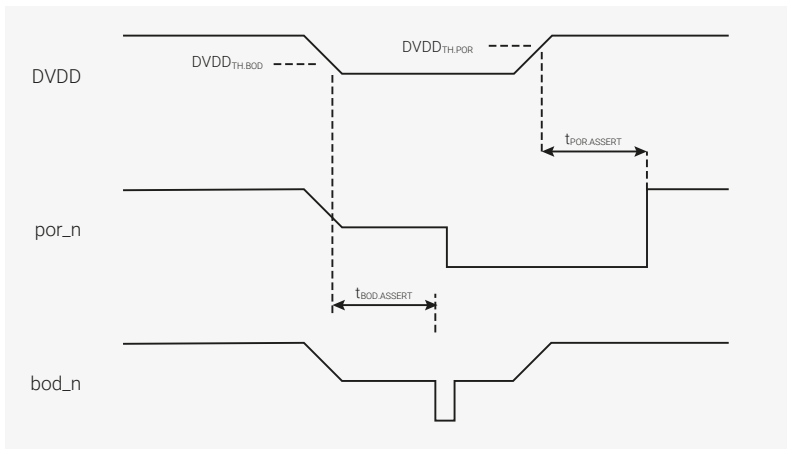

Table 187. Power-on Reset Parameters

Parameter	Description	Min	Typ	Max	Units
DVDD _{TH,POR}	power-on reset threshold	0.924	0.957	0.99	V
t _{POR,ASSERT}	power-on reset assertion delay		3	10	µs

2.11.3. Brown-out Detection

The brown-out detection block prevents unreliable operation by initiating a power-on reset cycle if the digital core supply (DVDD) drops below a safe operating level. The block's **bod_n** output is taken low if DVDD drops below the *brown-out detection threshold* (DVDD_{TH,BOD}) for a period longer than the *brown-out detection assertion delay* (t_{BOD,ASSERT}). This re-initialises the power-on reset block, which resets the chip, by taking its **por_n** output low, and holds it in reset until DVDD returns to a safe operating level. Figure 21 shows a brown-out event and the subsequent power-on reset cycle.

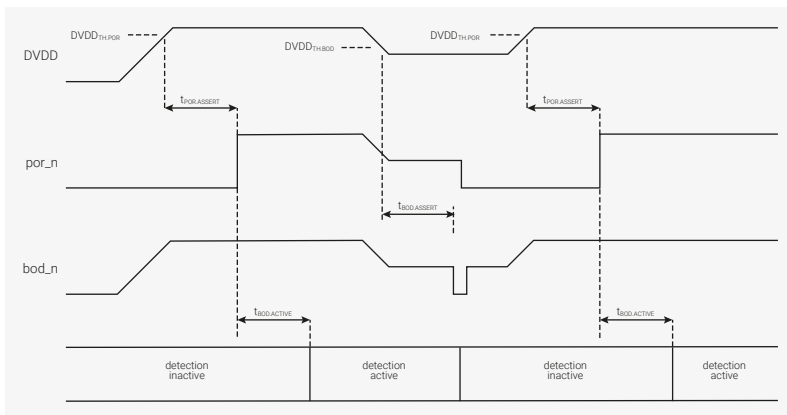

Figure 21. A brown-out detection cycle

2.11.3.1. Detection Enable

Brown-out detection is automatically enabled at initial power-on or after a brown-out initiated reset. There is, however, a short delay, the *brown-out detection activation delay* (t_{BOD,ACTIVE}), between **por_n** going high and detection becoming active. This is shown in Figure 22.

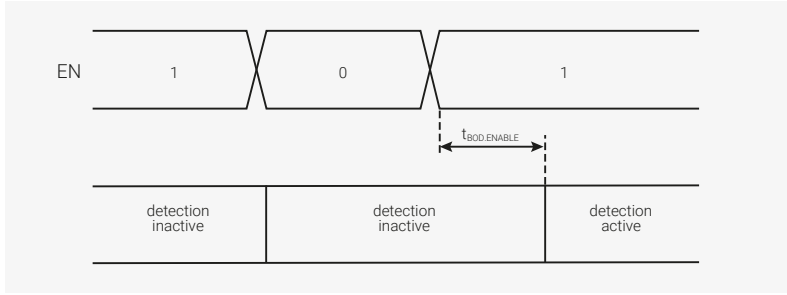

Figure 22. Activation of brown-out detection at initial power-on and following a brown-out event.

Once the chip is out of reset, detection can be disabled under software control. This also saves a small amount of power. If detection is subsequently re-enabled, there will be another short delay, the *brown-out detection enable delay* (t_{BOD,ENABLE}), before it becomes active again. This is shown in Figure 23.

Detection is disabled by writing a zero to the **EN** field in the **BOD** register and is re-enabled by writing a one to the same field. The block's **bod_n** output is high when detection is disabled.

Figure 23. Disabling and enabling brown-out detection

Detection is re-enabled if the BOD register is reset, as this sets the register’s EN field to one. Again, detection will become active after a delay equal to the *brown-out detection enable delay* ($t_{BOD.ENABLE}$).

NOTE

If the BOD register is reset by a power-on or brown-out initiated reset, the delay between the register being reset and brown-out detection becoming active will be equal to the *brown-out detection activation delay* ($t_{BOD.ACTIVE}$). The delay will be equal to the *brown-out detection enable delay* ($t_{BOD.ENABLE}$) for all other reset sources.

2.11.3.2. Adjusting the Detection Threshold

The *brown-out detection threshold* ($DVDD_{TH.BOD}$) has a nominal value of 0.86V at initial power-on or after a reset event. This should result in a detection threshold between 0.83V and 0.89V. Once out of reset, the threshold can be adjusted under software control. The new detection threshold will take effect after the *brown-out detection programming delay* ($t_{BOD.PROG}$). An example of this is shown in Figure 24.

The threshold is adjusted by writing to the VSEL field in the BOD register. See the BOD register description for details.

Figure 24. Adjusting the brown-out detection threshold

2.11.3.3. Detailed Specifications

Table 188. Brown-out Detection Parameters

Parameter	Description	Min	Typ	Max	Units
$DVDD_{TH.BOD}$	brown-out detection threshold	96.5	100	103.5	% of selected threshold voltage
$t_{BOD.ACTIVE}$	brown-out detection activation delay		55	80	μ s

Parameter	Description	Min	Typ	Max	Units
$t_{\text{BOD.ASSERT}}$	brown-out detection assertion delay		3	10	μs
$t_{\text{BOD.ENABLE}}$	brown-out detection enable delay		35	55	μs
$t_{\text{BOD.PROG}}$	brown-out detection programming delay		20	30	μs

2.11.4. Supply Monitor

The power-on and brown-out reset blocks are powered by the on-chip voltage regulator’s input supply (VREG_IOVDD). The blocks are initialised when power is first applied, but may not be reliably re-initialised if power is removed and then reapplied before VREG_IOVDD has dropped to a sufficiently low level. To prevent this happening, VREG_IOVDD is monitored and the power-on reset block is re-initialised if it drops below the *VREG_IOVDD activation threshold* ($V_{\text{REG_IOVDD_TH.ACTIVE}}$). $V_{\text{REG_IOVDD_TH.ACTIVE}}$ is fixed at a nominal 1.1V, which should result in a threshold between 0.87V and 1.26V. This threshold does not represent a safe operating voltage. It is the voltage that VREG_IOVDD must drop below to reliably re-initialise the power-on reset block. For safe operation, VREG_IOVDD must be at a nominal voltage between 1.8V and 3.3V.

2.11.4.1. Detailed Specifications

Table 189. Voltage Regulator Input Supply Monitor Parameters

Parameter	Description	Min	Typ	Max	Units
$V_{\text{REG_IOVDD_TH.ACTIVE}}$	VREG_IOVDD activation threshold	0.87	1.1	1.26	V

2.11.5. External Reset

The chip can also be reset by taking its RUN pin low. Taking RUN low will hold the chip in reset irrespective of the state of the core power supply (DVDD) and the power-on reset / brown-out detection blocks. The chip will come out of reset as soon as RUN is taken high, if all other reset sources have been released. RUN can be used to extend the initial power-on reset, or can be driven from an external source to start and stop the chip as required. If RUN is not used, it should be tied high.

2.11.6. Rescue Debug Port Reset

The chip can also be reset via the Rescue Debug Port. This allows the chip to be recovered from a locked up state. In addition to resetting the chip, a Rescue Debug Port reset also sets the `PSM_RESTART_FLAG` in the `CHIP_RESET` register. This is checked by the bootcode at startup, causing it to enter a safe state if the bit is set. See Section 2.3.4.2, “Rescue DP” for more information.

2.11.7. Source of Last Reset

The source of the most recent chip-level reset can be determined by reading the state of the `HAD_POR`, `HAD_RUN` and `HAD_PSM_RESTART` fields in the `CHIP_RESET` register. A one in the `HAD_POR` field indicates a power supply related reset, i.e.

either a power-on or brown-out initiated reset, a one in the `HAD_RUN` field indicates the chip was last reset by the RUN pin, and a one in the `HAD_PSM_RESTART` field indicates the chip has been reset via Rescue Debug Port. There should never be more than one field set to one.

2.11.8. List of Registers

The chip-level reset subsystem shares a register address space with the on-chip voltage regulator. The registers for both subsystems are listed in Section 2.9.6. The shared address space is referred to as `vreg_and_chip_reset` elsewhere in this document.

2.12. Power-On State Machine

2.12.1. Overview

The power-on state machine is responsible for removing the reset from various hardware blocks in a specific order. Each peripheral in the power-on state machine is controlled by a `rst_n` active-low reset signal and generates a `rst_done` active-high reset done signal. The power-on state machine deasserts the reset to each peripheral, waits for that peripheral to assert its `rst_done` and then deasserts the reset to the next peripheral. An important use of this is to wait for a clock source to be running cleanly in the chip before the reset to the clock generators is deasserted. This avoids potentially glitchy clocks being distributed to the chip.

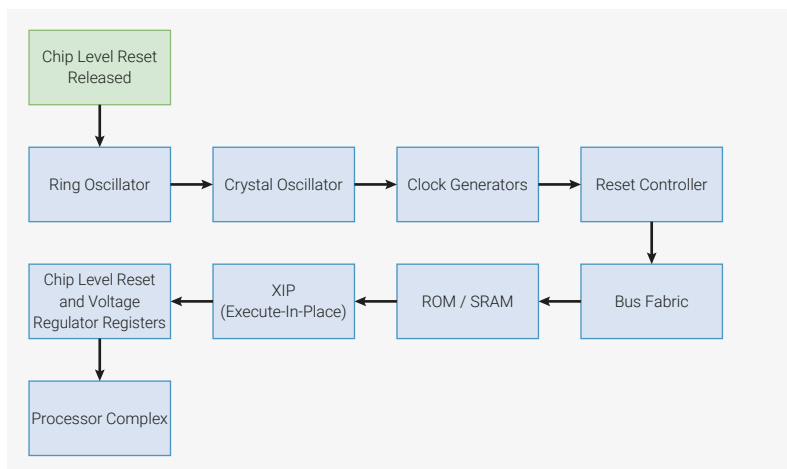

The power-on state machine is itself taken out of reset when the Chip-Level Reset subsystem confirms that the digital core supply (DVDD) is powered and stable, and the RUN pin is high. The power-on state machine takes a number of other blocks out of reset at this point via its `rst_n_run` output. This is used to reset things that need to be reset at start-up but must not be reset if the power-on state machine is restarted. This list includes:

- Power on logic in the ring oscillator and crystal oscillator
- Clock dividers which must keep on running during a power-on state machine restart (`clk_ref` and `clk_sys`)
- Watchdog (contains scratch registers which need to persist through a soft-restart of the power-on state machine)

TO DO: JACK Diagram needs changing to remove Crystal Oscillator box- See JIRA PICODOC-168

2.12.2. Power On Sequence

Figure 25. Power-On State Machine Sequence.

The power-on state machine sequence is as follows:

- Chip-Level Reset subsystem deasserts power-on state machine reset once digital core supply (DVDD) is powered and stable, and RUN pin is high (`rst_n_run` is also deasserted at this point)

- Ring Oscillator is started. `rst_done` is asserted once the ripple counter has seen a sufficient number of clock edges to indicate the ring oscillator is stable
- Crystal Oscillator reset is deasserted. The crystal oscillator is not started at this point, so `rst_done` is asserted instantly.
- `clk_ref` and `clk_sys` clock generators are taken out of reset. In the initial configuration `clk_ref` is running from the ring oscillator with no divider. `clk_sys` is running from `clk_ref`. These clocks are needed for the rest of the sequence to progress.

The rest of the sequence is fairly simple, with the following coming out of reset in order one by one:

- Reset Controller - used to reset all non-boot peripherals
- Chip-Level Reset and Voltage Regulator registers - used by the bootrom to check the boot state of the chip. In particular, the `PSM_RESTART_FLAG` flag in the `CHIP_RESET` register can be set via SWD to indicate to the boot code that there is bad code in flash and it should stop executing. The reset state of the `CHIP_RESET` register is determined by the Chip-Level Reset subsystem and is not affected by reset coming from the power-on state machine
- XIP (Execute-In-Place) - used by the bootrom to execute code from an external SPI flash
- ROM and SRAM - Boot code is executed from the ROM. SRAM is used by processors and Bus Fabric.
- Bus Fabric - Allows the processors to communicate with peripherals
- Processor complex - Finally the processors can start running

The final thing to come out of reset is the processor complex. This includes both `proc0` and `proc1`. Both processors will start executing the bootcode from ROM. One of the first things the bootrom does is read the core id. At this point, `proc1` will go to sleep leaving `proc0` to continue with the bootrom execution. The processor complex has its own reset control and various low-power modes which is why both the `proc0` and `proc1` resets come off at start of day, despite `proc0` only being needed for the bootrom.

2.12.3. Register Control

The power-on state machine is a fully automated piece of hardware. It requires no input from the user to work. There are register controls that can be used to override and see the status of the power-on state machine for debugging. For example, if a peripheral was stuck in reset and never asserted its `rst_done` signal the resets for all peripherals after it could still be deasserted using the `FRCE_ON` register. There is also a `WDSEL` register which is used to decide what should be reset by a Watchdog reset.

2.12.4. Interaction with Watchdog

The power-on state machine can be restarted from a software-programmable position if the Watchdog fires. For example, in the case the processor is stuck in an infinite loop, or the programmer has somehow misconfigured the chip. It is important to note that if a peripheral in the power-on state machine has the `WDSEL` bit set, every peripheral after it in the power-on sequence will also be reset because the `rst_done` of the selected peripheral will be deasserted, asserting `rst_n` for the remaining peripherals.

2.12.5. List of registers

Table 190. List of PSM registers

Offset	Name	Info
0x0	<code>FRCE_ON</code>	Force block out of reset (i.e. power it on)
0x4	<code>FRCE_OFF</code>	Force into reset (i.e. power it off)
0x8	<code>WDSEL</code>	Set to 1 if the watchdog should reset this
0xc	<code>DONE</code>	Is the subsystem ready?

FRCE_ON Register

2.13. Subsystem Resets

2.13.1. Overview

The reset controller allows software control of the resets to all of the peripherals that are not critical to boot the processor in RP2040. This includes:

- USB Controller
- PIO
- Peripherals such as UART, I2C, SPI, PWM, Timer, ADC
- PLLs
- IO and Pad registers

The full list can be seen in the register descriptions.

Everything reset from the reset controller is in reset at the start of day. It is up to the processor to remove the resets to the peripherals it wants to use. Note that if you are using the Pico SDK some peripherals may already be out of reset.

2.13.2. Programmer's Model

The Pico SDK defines a struct to represent the resets registers.

Pico SDK: https://github.com/raspberrypi/pico-sdk/tree/pre_release/src/rp2040/hardware_structs/include/hardware/structs/resets.h Lines 13 - 19

```
13 typedef struct {
14     io_rw_32 reset;
15     io_rw_32 wdsel;
16     io_rw_32 reset_done;
17 } resets_hw_t;
18
19 #define resets_hw ((resets_hw_t *const)RESETS_BASE)
```

Three registers are defined:

- reset: this register contains a bit for each peripheral that can be reset. If the bit is set to **1** then the reset is asserted. If the bit is cleared then the reset is deasserted.
- wdsel: if the bit is set then this peripheral will be reset if the watchdog fires (note that the power on state machine can potentially reset the whole reset controller, which will reset everything)
- reset_done: a bit for each peripheral, that gets set once the peripheral is out of reset. This allows software to wait for this status bit in case the peripheral has some initialisation to do before it can be used.

The reset functions in the Pico SDK are defined as follows:

Pico SDK: https://github.com/raspberrypi/pico-sdk/tree/pre_release/src/rp2_common/hardware_resets/include/hardware/resets.h Lines 75 - 77

```
75 static inline void unreset_block(uint32_t bits) {
76     hw_clear_bits(&resets_hw->reset, bits);
77 }
```

Pico SDK: https://github.com/raspberrypi/pico-sdk/tree/pre_release/src/rp2_common/hardware_resets/include/hardware/resets.h Lines 75 - 77

```
75 static inline void unreset_block(uint32_t bits) {
76     hw_clear_bits(&resets_hw->reset, bits);
77 }
```

Pico SDK: https://github.com/raspberrypi/pico-sdk/tree/pre_release/src/rp2_common/hardware_resets/include/hardware/resets.h Lines 84 - 88

```
84 static inline void unreset_block_wait(uint32_t bits) {
85     hw_clear_bits(&resets_hw->reset, bits);
86     while (~resets_hw->reset_done & bits)
87         tight_loop_contents();
88 }
```

An example use of these is in the UART driver, where the driver defines a `uart_reset` function, selecting a different bit of the reset register depending on the uart specified:

Pico SDK: https://github.com/raspberrypi/pico-sdk/tree/pre_release/src/rp2_common/hardware_uart/uart.c Lines 30 - 38

```
30 static inline void uart_reset(uart_inst_t *uart) {
31     invalid_params_if(UART, uart != uart0 && uart != uart1);
32     reset_block(uart_hw_index(uart) ? RESETS_RESET_UART1_BITS : RESETS_RESET_UART0_BITS);
33 }
34
```

```

35 static inline void uart_unreset(uart_inst_t *uart) {
36     invalid_params_if(UART, uart != uart0 && uart != uart1);
37     unreset_block_wait(uart_hw_index(uart) ? RESETS_RESET_UART1_BITS :
        RESETS_RESET_UART0_BITS);
38 }

```

2.14. Clocks

2.14.1. Overview

The clocks block provides independent clocks to on-chip and external components. It takes inputs from a variety of clock sources allowing the user to trade off performance against cost, board area and power consumption. From these sources it uses multiple clock generators to provide the required clocks. This architecture allows the user flexibility to start and stop clocks independently and to vary some clock frequencies whilst maintaining others at their optimum frequencies.

Figure 26. Clocks overview

For very low cost or low power applications where precise timing is not required, the chip can be run from the internal Ring Oscillator (ROSC). Alternatively the user can provide external clocks or construct simple relaxation oscillators using the GPIOs and appropriate external passive components. Where timing is more critical, the Crystal Oscillator (XOSC) can provide an accurate reference to the 2 on-chip PLLs to provide fast clocking at precise frequencies.

The clock generators select from the clock sources and optionally divide the selected clock before outputting through enable logic which provides automatic clock disabling in SLEEP mode.

An on-chip frequency counter facilitates debugging of the clock setup and also allows measurement of the frequencies of external clocks. The on-chip resus component restarts the system clock from a known good clock if it is accidentally stopped. This allows the software debugger to access registers and debug the problem.

The chip has an ultra-low power mode called DORMANT in which all on-chip clock sources are stopped to save power. External sources are not stopped and can be used to provide a clock to the on-chip RTC which can provide an alarm to wake the chip from DORMANT mode. Alternatively the GPIO interrupts can be configured to wake the chip from DORMANT mode in response to an external event.

Up to 4 generated clocks can be output to GPIOs at up to 50MHz. This allows the user to supply clocks to external devices, thus reducing component counts in power, space and cost sensitive applications.

2.14.2. Clock sources

The RP2040 can be run from a variety of clock sources. This flexibility allows the user to optimise the clock setup for performance, cost, board area and power consumption. The sources include the on-chip [Ring Oscillator](#), the [Crystal Oscillator](#), external clocks from GPIOs and the PLLs [PLL](#).

The list of clock sources is different per clock generator and can be found as enumerated values in the [CTRL](#) register. See [CLK_SYS_CTRL](#) as an example.

2.14.2.1. Ring Oscillator

The on-chip [Ring Oscillator](#) requires no external components. It runs automatically from power-up and is used to clock the processors during the initial boot stages. The startup frequency is typically 6MHz but varies with PVT (Process, Voltage

and Temperature). The frequency is likely to be in the range 4-8MHz and is guaranteed to be in the range 1-12MHz.

For low cost applications where frequency accuracy is unimportant, the chip can continue to run from the ROSC. If greater performance is required the frequency can be increased by programming the registers as described in [Ring Oscillator](#). The frequency will vary with PVT (Process, Voltage and Temperature) so the user must take care to avoid exceeding the maximum frequencies described in the clock generators section. This variation can be mitigated in various ways if the user wants to continue running from the ROSC at a frequency close to the maximum. Alternatively the user can use an external clock or the XOSC to provide a stable reference clock and use the PLLs to generate the higher frequencies. However, this will require external components, will cost board area and will increase power consumption.

If an external clock or the XOSC is used then the ROSC can be stopped to save power. However, the reference clock generator and the system clock generator must be switched to an alternate source before doing so.

The ROSC is not affected by SLEEP mode. If required the frequency can be reduced before entering SLEEP mode to save power. On entering DORMANT mode the ROSC is automatically stopped and is restarted in the same configuration when exiting DORMANT mode. If the ROSC is driving clocks at close to their maximum frequencies then it is recommended to drop the frequency before entering SLEEP or DORMANT mode to allow for frequency variation due to changes in environmental conditions during SLEEP or DORMANT mode.

If the user wants to use the ROSC clock externally then it can be output to a GPIO pin using one of the clk_gpclk0-3 generators.

The following sections describe techniques for mitigating PVT variation of the ROSC frequency. They also provide some interesting design challenges for use in teaching both the effects of PVT and writing software to control real time functions.

i NOTE

The ROSC frequency varies with PVT so the user can send its output to the frequency counter and use it to measure any 1 of these 3 variables if the other 2 are known.

2.14.2.1.1. Mitigating ROSC frequency variation due to process

Process varies for two reasons. Firstly the chips leave the factory with a spread of process parameters which cause variation in the ROSC frequency across chips. Secondly, process parameters vary slightly as the chip ages, though this will only be observable over many thousands of hours of operation. So, to mitigate for process variation, the user can characterise individual chips and program the ROSC frequency accordingly. This is an adequate solution for small numbers of chips but is not suitable for volume production. In such applications the user should consider using the automatic mitigation techniques described below.

2.14.2.1.2. Mitigating ROSC frequency variation due to voltage

Supply voltage varies for two reasons. Firstly, the power supply itself may vary, and secondly, there will be varying on-chip IR drop as chip activity varies. If the application has a minimum performance target then the user needs to calibrate for that application and adjust the ROSC frequency to ensure it always exceeds the minimum required.

2.14.2.1.3. Mitigating ROSC frequency variation due to temperature

Temperature varies for two reasons. Firstly, the ambient temperature may vary, and secondly, the chip temperature will vary as chip activity varies due to self-heating. This can be mitigated by stabilising the temperature using a temperature controlled environment and passive or active cooling. Alternatively the user can track the temperature using the on-chip temperature sensor and adjust the ROSC frequency so it remains within the required bounds.

2.14.2.1.4. Automatic mitigation of ROSC frequency variation due to PVT

Techniques for automatic ROSC frequency control avoid the need to calibrate individual chips but require periodic access to a clock reference or to a time reference. If a clock reference is available then it can be used to periodically measure the

ROSC frequency and adjust it accordingly. The reference could be the on-chip XOSC which can be turned on periodically for this purpose. This may be useful in a very low power application where it is too costly to run the XOSC continuously and too costly to use the PLLs to achieve high frequencies. If a time reference is available then the user should clock the on-chip RTC from the ROSC and periodically compare it against the time reference, then adjust the ROSC frequency as necessary. Using these techniques the ROSC frequency will drift due to VT variation so the user must take care that these variations do not allow the ROSC frequency to drift out of the acceptable range.

2.14.2.1.5. Automatic overclocking using the ROSC

The datasheet maximum frequencies for any digital device are quoted for worst case PVT. Most chips in most normal environments can run significantly faster than the quoted maximum and can therefore be overclocked. If the RP2040 is running from the ROSC then both the ROSC and the digital components are similarly affected by PVT, so, as the ROSC gets faster, the processors can also run faster. This means the user can overclock from the ROSC then rely on the ROSC frequency tracking with PVT variations. The tracking of ROSC frequency and the processor capability is not perfect and currently there is insufficient data to specify a safe ROSC setting for this mode of operation, so some experimentation is required.

This mode of operation will maximise processor performance but will lead to variations in the time taken to complete a task, which may be unacceptable in some applications. Also, if the user wants to use frequency sensitive interfaces such as USB or UART then the XOSC and PLL must be used to provide a precise clock for those components.

2.14.2.2. Crystal Oscillator

The [Crystal Oscillator](#) provides a precise, stable clock reference and should be used where accurate timing is required and no suitable external clocks are available. The frequency is determined by the external crystal and the oscillator supports frequencies in the range 1MHz to 15MHz. The on-chip PLLs can be used to synthesise higher frequencies if required. The reference design uses a 12MHz crystal. Using the XOSC and the PLLs, the on-chip components can be run at their maximum frequencies. Appropriate margin is built into the design to tolerate up to 1000ppm variation in the XOSC frequency.

The XOSC is inactive on power up. If required it must be enabled in software. XOSC startup takes several milliseconds and the software must wait for the XOSC_STABLE flag to be set before starting the PLLs and before changing any clock generators to use it. Prior to that the output from the XOSC may be non-existent or may have very short pulse widths which will corrupt logic if used. Once it is running the reference clock (clk_ref) and the system clock (clk_sys) can be switched to run from the XOSC and the ROSC can be stopped to save power.

The XOSC is not affected by SLEEP mode. It is automatically stopped and restarted in the same configuration when entering and exiting DORMANT mode.

If the user wants to use the XOSC clock externally then it can be output to a GPIO pin using one of the clk_gpclk0-3 generators. It cannot be taken directly from the XIN or XOUT pins.

2.14.2.3. External Clocks

If adequate clocks exist in the application then they can be used to clock the RP2040 either on their own or in conjunction with the XOSC or ROSC. This will potentially save power and will allow components on the RP2040 to be run synchronously with external components to simplify data transfer between chips. External clocks can be input on the GPIN0 & GPIN1 GPIO inputs and on the XIN input to the XOSC. If the XIN input is used in this way the XOSC must be configured to pass through the XIN signal. All 3 inputs are limited to 50MHz but the on-chip PLLs can be used to synthesise higher frequencies from the XIN input if required. If the frequency accuracy of the external clocks is poorer than 1000ppm then the generated clocks should not be run at their maximum frequencies because they may exceed their design margins.

Once the external clocks are running, the reference clock (clk_ref) and the system clock (clk_sys) can be switched to run from the external clocks and the ROSC can be stopped to save power.

The external clock sources are not affected by SLEEP mode or DORMANT mode.

2.14.2.4. Relaxation Oscillators

If the user wants to use external clocks to replace or supplement the other clock sources but does not have an appropriate clock available, then 1 or 2 relaxation oscillators can be constructed using external passive components. Simply send the clock source (GPIN0 or GPIN1) to one of the gpclk0-3 generators, invert it through the GPIO logic and connect back to the clock source input via an RC circuit.

Figure 27. Simple relaxation oscillator example

The frequency of clocks generated from relaxation oscillators will depend on the delay through the chip and the drive current from the GPIO output both of which vary with PVT. They will also depend on the quality and accuracy of the external components. It may be possible to improve the frequency accuracy using more elaborate external components such as ceramic resonators but that will increase cost and complexity and can never rival the XOSC. For that reason they are not discussed here. Given that these oscillators will not achieve 1000ppm then they cannot be used to drive internal clocks at their maximum frequencies.

The relaxation oscillators are not affected by SLEEP mode or DORMANT mode.

2.14.2.5. PLLs

The PLLs (PLL) are used to provide fast clocks when running from the XOSC or from an external clock source. In a fully featured application the USB PLL provides a fixed 48MHz clock to the ADC and USB while `clk_rtc` and `clk_ref` are driven from the XOSC or external source. This allows the user to drive `clk_sys` from the system PLL and vary the frequency according to demand to save power without having to change the setups of the other clocks. `clk_peri` can be driven either from the fixed frequency USB PLL or from the variable frequency system PLL. If `clk_sys` never needs to exceed 48MHz then one PLL can be used and the divider in the `clk_sys` clock generator can be used to scale the `clk_sys` frequency according to demand.

When a PLL is started, its output cannot be used until the PLL locks as indicated by the LOCK bit in the STATUS register. Thereafter the PLL output cannot be used during changes to the reference clock divider, the output dividers or the bypass mode. The output can be used during feedback divisor changes with the proviso that the output frequency may overshoot or undershoot on large changes to the feedback divisor. For more information see [PLL](#).

If the PLL reference clock is accurate to 1000ppm then the PLLs can be used to drive clocks at their maximum frequency because the frequency of the generated clocks will be within the margins allowed in the design.

The PLLs are not affected by SLEEP mode. If the user wants to save power in SLEEP mode then all clock generators must be switched away from the PLLs and they must be stopped in software before entering SLEEP mode. The PLLs are not stopped and restarted automatically when entering and exiting DORMANT mode. If they are left running on entry to DORMANT mode they will be corrupted and will generate out of control clocks that will consume power unnecessarily. This happens because their reference clock from XOSC will be stopped. It is therefore essential to switch all clock generators away from the PLLs and stop the PLLs in software before entering DORMANT mode.

2.14.3. Clock Generators

The clock generators are built on a standard design which incorporates clock source multiplexing, division, duty cycle correction and SLEEP mode enabling. To save chip area and power, the individual clock generators do not support all features

Figure 28. A generic clock generator

2.14.3.1. Multiplexers

The first multiplexer is referred to as the auxiliary mux and is a conventional design whose output will glitch when changing the select control. Clock glitches are to be avoided at all costs because they may corrupt the logic running on that clock. The clock generator output therefore cannot be used during such changes. If the clock generator has a glitchless mux, then that mux can be switched to an alternate source during the transition. If it does not have a glitchless mux then the divider must be disabled during the transition. The divider requires 2 cycles of the source clock to stop the output and 2 cycles of the new source to restart the output. The user must wait for the generator to stop before changing the auxiliary mux, therefore must be aware of the source clock frequency.

The second multiplexer switches glitchlessly, therefore the clock generator can continue running during changes of source clock. The glitchless mux is only implemented for always-on clocks. On RP2040 the always-on clocks are the reference clock (clk_ref) and the system clock (clk_sys). Such clocks must run continuously unless the chip is in DORMANT mode. The glitchless mux has a status output (SELECTED) which indicates which source is selected and can be read from software to confirm that a change of clock source has been completed.

The recommended control sequences are as follows.

To switch the glitchless mux:

- switch the glitchless mux to an alternate source
- poll the SELECTED register until the switch is completed

To switch the auxiliary mux when the generator has a glitchless mux:

- switch the glitchless mux to an alternate source
- poll the SELECTED register until the switch is completed
- change the auxiliary mux select control
- switch the glitchless mux back to the auxiliary mux output
- if required, poll the SELECTED register until the switch is completed

To switch the auxiliary mux when the generator does not have a glitchless mux:

- disable the clock divider
- wait for the generated clock to stop (2 cycles of the clock source)
- change the auxiliary mux select control
- enable the clock divider
- if required, wait for the clock generator to restart (2 cycles of the clock source)

2.14.3.2. Divider

A fully featured divider divides by 1 or a fractional number in the range 2.0 to $2^{24} \cdot 0.01$. Fractional division is achieved by toggling between 2 integer divisors therefore it yields a jittery clock which may not be suitable for some applications. For example, when dividing by 2.4 the divider will divide by 2 for 3 cycles and by 3 for 2 cycles. For divisors with large integer components the jitter will be much smaller and less critical.

Figure 29. An example of fractional division.

All dividers support on-the-fly divisor changes meaning the output clock will switch cleanly from one divisor to another. So the clock generator does not need to be stopped during clock divisor changes. It does this by synchronising the divisor change to the end of the clock cycle. Similarly, the enable is synchronised to the end of the clock cycle so will not generate glitches when the clock generator is enabled or disabled. Clock generators for always-on clocks are permanently enabled and therefore do not have an enable control.

In the event that a clock generator locks up and never completes the current clock cycle it can be forced to stop using the KILL control. This may result in an output glitch which may corrupt the logic driven by the clock. It is therefore recommended the destination logic is reset prior to this operation. It is worth mentioning that this clock generator design has been used in numerous chips and has never been known to lock up. The KILL control is inelegant and unnecessary and should not be used as an alternative to the enable. Clock generators for always-on clocks are permanently active and therefore do not have a KILL control.

2.14.3.3. Duty Cycle Correction

The divider operates on the rising edge of the input clock and so does not generate an even duty cycle clock when dividing by odd numbers.

Divide by 3 will give a duty cycle of 33.3%, divide by 5 will be 40% etc. If enabled, the duty cycle correction logic will shift the falling edge of the output clock to the falling edge of the input clock and restore a 50% duty cycle. The duty cycle correction can be enabled and disabled while the clock is running. It will not operate when dividing by an even number.

Figure 30. An example of duty cycle correction.

2.14.3.4. Clock Enables

Each clock goes to multiple destinations and, with a few exceptions, there are 2 enables for each destination. The **WAKE_EN** registers are used to enable the clocks when the system is awake and the **SLEEP_EN** registers are used to enable the clocks when the system is in sleep mode. The purpose of these enables is to reduce power in the clock distribution networks for components that are not being used. It is worth noting that a component which is not clocked will retain its configuration so can be restarted quickly.

NOTE

The **WAKE_EN** and **SLEEP_EN** registers reset to **0x1**, which means that by default all clocks are enabled. The programmer only needs to use this feature if they desire a low-power design.

2.14.3.4.1. Clock Enable Exceptions

The cores do not have clock enables because they require a clock at all times to manage their own power saving features.

clk_sys_busfabric cannot be disabled in wake mode because that would prevent the cores from accessing any chip registers, including those that control the clock enables.

`clk_sys_clocks` does not have a wake mode enable because disabling it would prevent the cores from accessing the clocks control registers.

The gpclks do not have clock enables.

2.14.3.4.2. System Sleep Mode

System sleep mode is entered automatically when both cores are in sleep and the DMA has no outstanding transactions. In system sleep mode, the clock enables described in the previous paragraphs are switched from the `WAKE_EN` registers to the `SLEEP_EN` registers. The intention is to reduce power consumed in the clock distribution networks when the chip is inactive. If the user has not configured the `WAKE_EN` and `SLEEP_EN` registers then system sleep will do nothing.

There is little value in using system sleep without taking other measures to reduce power before the cores are put to sleep. Things to consider include:

- stop unused clock sources such as the PLLs and Crystal Oscillator
- reduce the frequencies of generated clocks by increasing the clock divisors
- stop external clocks

For maximum power saving when the chip is inactive, the user should consider DORMANT mode in which clocks are sourced from the Crystal Oscillator and/or the Ring Oscillator and those clock sources are stopped. [TODO Terry: add a link to the DORMANT description](#)

2.14.4. Frequency Counter

The frequency counter measures the frequency of internal and external clocks by counting the clock edges seen over a test interval. The interval is defined by counting cycles of `clk_ref` which must be driven either from XOSC or from a stable external source of known frequency.

The user can pick between accuracy and test time using the `FC0_INTERVAL` register. [Table 199](#) shows the trade off.

Table 199. Frequency Counter Test Interval vs Accuracy

Interval Register	Test Interval	Accuracy
0	1 μ s	2048 kHz
1	2 μ s	1024 kHz
2	4 μ s	512 kHz
3	8 μ s	256 kHz
4	16 μ s	128 kHz
5	32 μ s	64 kHz
6	64 μ s	32 kHz
7	125 μ s	16 kHz
8	250 μ s	8 kHz
9	500 μ s	4 kHz
10	1 ms	2 kHz
11	2 ms	1 kHz
12	4 ms	500 Hz
13	8 ms	250 Hz
14	16 ms	125 Hz
15	32 ms	62.5 Hz

2.14.5. Resus

It is possible to write software that inadvertently stops `clk_sys`. This will normally cause an unrecoverable lock-up of the cores and the on-chip debugger, leaving the user unable to trace the problem. To mitigate against that, an automatic resuscitation circuit is provided which will switch `clk_sys` to a known good clock source if no edges are detected over a user-defined interval. The known good source is `clk_ref` which can be driven from the XOSC, ROSC or an external source.

The resus block counts edges on `clk_sys` during a timeout interval controlled by `clk_ref`, and forces `clk_sys` to be driven from `clk_ref` if no `clk_sys` edges are detected. The interval is programmable via `CLK_SYS_RESUS_CTRL`.

⊖ WARNING

There is no way for resus to revive the chip if `clk_ref` is also stopped.

To enable the resus, the programmer must set the timeout interval and then set the `ENABLE` bit in `CLK_SYS_RESUS_CTRL`. To detect a resus event, the `CLK_SYS_RESUS` interrupt must be enabled by setting the interrupt enable bit in `INTE`. The `CLOCKS_DEFAULT_IRQ` (see Section 2.3.2) must also be enabled at the processor.

Resus is intended as a debugging aid. The intention is for the user to trace the software error that triggered the resus, then correct the error and reboot. It is possible to continue running after a resus event by reconfiguring `clk_sys` then clearing the resus by writing the `CLEAR` bit in `CLK_SYS_RESUS_CTRL`. However, it should be noted that a resus can be triggered by `clk_sys` running more slowly than expected and that could result in a `clk_sys` glitch when resus is triggered. That glitch could corrupt the chip. This would be a rare event but is tolerable in a debugging scenario. However it is unacceptable in normal operation therefore it is recommended to only use resus for debug.

⊖ WARNING

Resus is a debugging aid and should not be used as a means of switching clocks in normal operation.

2.14.6. Programmer's Model

2.14.6.1. Configuring a clock generator

The Pico SDK defines an enum of clocks:

Pico SDK: https://github.com/raspberrypi/pico-sdk/tree/pre_release/src/rp2040/hardware_structs/include/hardware/structs/clocks.h Lines 18 - 30

```
18 enum clock_index {
19     clk_gpout0 = 0,    ///< GPIO Muxing 0
20     clk_gpout1,       ///< GPIO Muxing 1
21     clk_gpout2,       ///< GPIO Muxing 2
22     clk_gpout3,       ///< GPIO Muxing 3
23     clk_ref,          ///< Watchdog and timers reference clock
24     clk_sys,          ///< Processors, bus fabric, memory, memory mapped registers
25     clk_peri,         ///< Peripheral clock for UART and SPI
26     clk_usb,          ///< USB clock
27     clk_adc,          ///< ADC clock
28     clk_rtc,          ///< Real time clock
29     CLK_COUNT
30 };
```

And also a struct to describe the registers of a clock generator:

Pico SDK: https://github.com/raspberrypi/pico-sdk/tree/pre_release/src/rp2040/hardware_structs/include/hardware_structs/clocks.h Lines 34 - 38

```

34 typedef struct {
35     io_rw_32 ctrl;
36     io_rw_32 div;
37     io_rw_32 selected;
38 } clock_hw_t;

```

To configure a clock, we need to know the following pieces of information:

- The frequency of the clock source
- The mux / aux mux position of the clock source
- The desired output frequency

The Pico SDK provides `clock_configure` to configure a clock:

Pico SDK: https://github.com/raspberrypi/pico-sdk/tree/pre_release/src/rp2_common/hardware_clocks/clocks.c Lines 39 - 110

```

39 int clock_configure(enum clock_index clk_index, uint32_t src, uint32_t auxsrc, uint32_t
    src_freq, uint32_t freq) {
40     uint32_t div;
41
42     assert(src_freq >= freq);
43
44     if (freq > src_freq)
45         return -1;
46
47     // Div register is 24.8 int.frac divider so multiply by 2^8 (left shift by 8)
48     div = (uint32_t) (((uint64_t) src_freq << 8) / freq);
49
50     clock_hw_t *clock = &clocks_hw->clk[clk_index];
51
52     // If increasing divisor, set divisor before source. Otherwise set source
53     // before divisor. This avoids a momentary overspeed when e.g. switching
54     // to a faster source and increasing divisor to compensate.
55     if (div > clock->div)
56         clock->div = div;
57
58     // If switching a glitchless slice (ref or sys) to an aux source, switch
59     // away from aux *first* to avoid passing glitches when changing aux mux.
60     // Assume (!!!) glitchless source 0 is no faster than the aux source.
61     if (has_glitchless_mux(clk_index) && src ==
        CLOCKS_CLK_SYS_CTRL_SRC_VALUE_CLKSRC_CLK_SYS_AUX) {
62         hw_clear_bits(&clock->ctrl, CLOCKS_CLK_REF_CTRL_SRC_BITS);
63         while (!(clock->selected & 1u))
64             tight_loop_contents();
65     }
66     // If no glitchless mux, cleanly stop the clock to avoid glitches
67     // propagating when changing aux mux. Note it would be a really bad idea
68     // to do this on one of the glitchless clocks (clk_sys, clk_ref).
69     else {
70         hw_clear_bits(&clock->ctrl, CLOCKS_CLK_GPOUT0_CTRL_ENABLE_BITS);
71         if (configured_freq[clk_index] > 0) {
72             // Delay for 3 cycles of the target clock, for ENABLE propagation.
73             // Note XOSC_COUNT is not helpful here because XOSC is not
74             // necessarily running, nor is timer... so, 3 cycles per loop:
75             uint delay_cyc = configured_freq[clk_sys] / configured_freq[clk_index] + 1;
76             asm volatile (
77                 "1: \n\t"
78                 "sub %0, #1 \n\t"
79                 "bne 1b"

```

```

80         : "+r" (delay_cyc)
81     );
82     }
83 }
84
85 // Set aux mux first, and then glitchless mux if this clock has one
86 hw_write_masked(&clock->ctrl,
87     (auxsrc << CLOCKS_CLK_SYS_CTRL_AUXSRC_LSB),
88     CLOCKS_CLK_SYS_CTRL_AUXSRC_BITS
89 );
90
91 if (has_glitchless_mux(clk_index)) {
92     hw_write_masked(&clock->ctrl,
93         src << CLOCKS_CLK_REF_CTRL_SRC_LSB,
94         CLOCKS_CLK_REF_CTRL_SRC_BITS
95     );
96     while (!(clock->selected & (1u << src)))
97         tight_loop_contents();
98 }
99
100 hw_set_bits(&clock->ctrl, CLOCKS_CLK_GPOUT0_CTRL_ENABLE_BITS);
101
102 // Now that the source is configured, we can trust that the user-supplied
103 // divisor is a safe value.
104 clock->div = div;
105
106 // Store the configured frequency
107 configured_freq[clk_index] = freq;
108
109 return 0;
110 }

```

It is called in `clocks_init` for each clock. The following example shows the `clk_sys` configuration:

Pico SDK: https://github.com/raspberrypi/pico-sdk/tree/pre-release/src/rp2_common/hardware_clocks/clocks.c Lines 161 - 166

```

161 // CLK_SYS = PLL_SYS (125MHz) / 1 = 125MHz
162 clock_configure(clk_sys,
163     CLOCKS_CLK_SYS_CTRL_SRC_VALUE_CLKSRC_CLK_SYS_AUX,
164     CLOCKS_CLK_SYS_CTRL_AUXSRC_VALUE_CLKSRC_PLL_SYS,
165     125 * MHZ,
166     125 * MHZ);

```

Once a clock is configured, `clock_get_hz` can be called to get the output frequency in Hz.

Pico SDK: https://github.com/raspberrypi/pico-sdk/tree/pre-release/src/rp2_common/hardware_clocks/clocks.c Lines 200 - 202

```

200 uint32_t clock_get_hz(enum clock_index clk_index) {
201     return configured_freq[clk_index];
202 }

```

⊖ WARNING

It is assumed the source frequency the programmer provides is correct. If it is not then the frequency returned by `clock_get_hz` will be inaccurate.

2.14.6.2. Using the frequency counter

To use the frequency counter, the programmer must:

- Set the reference frequency: `clk_ref`
- Set the mux position of the source they want to measure. See `FC0_SRC`
- Wait for the `DONE` status bit in `FC0_STATUS` to be set
- Read the result

The Pico SDK defines a `frequency_count` function which takes the source as an argument and returns the frequency in kHz:

Pico SDK: https://github.com/raspberrypi/pico-sdk/tree/pre-release/src/rp2_common/hardware_clocks/clocks.c Lines 210 - 237

```

210 uint32_t frequency_count_khz(uint src) {
211     fc_hw_t *fc = &clocks_hw->fc0;
212
213     // If frequency counter is running need to wait for it. It runs even if the source is
    NULL
214     while(fc->status & CLOCKS_FC0_STATUS_RUNNING_BITS) {
215         tight_loop_contents();
216     }
217
218     // Set reference freq
219     fc->ref_khz = clock_get_hz(clk_ref) / 1000;
220
221     // FIXME: Don't pick random interval. Use best interval
222     fc->interval = 10;
223
224     // No min or max
225     fc->min_khz = 0;
226     fc->max_khz = 0xffffffff;
227
228     // Set SRC which automatically starts the measurement
229     fc->src = src;
230
231     while(!(fc->status & CLOCKS_FC0_STATUS_DONE_BITS)) {
232         tight_loop_contents();
233     }
234
235     // Return the result
236     return fc->result >> CLOCKS_FC0_RESULT_KHZ_LSB;
237 }

```

There is also a wrapper function to change the unit to MHz:

Pico SDK: https://github.com/raspberrypi/pico-sdk/tree/pre-release/src/rp2_common/hardware_clocks/include/hardware/clocks.h Lines 140 - 144

```

140 static inline float frequency_count_mhz(uint src) {
141     // FC result already in khz so only need to divide
142     // by 1000 to get mhz
143     return ((float) (frequency_count_khz(src))) / KHZ;
144 }

```

NOTE

The frequency counter can also be used in a test mode. This allows the hardware to check if the frequency is within a minimum frequency and a maximum frequency, set in `FC0_MIN_KHZ` and `FC0_MAX_KHZ`. In this mode, the `PASS` bit in `FC0_STATUS` will be set when `DONE` is set if the frequency is within the specified range. Otherwise, either the `FAST` or `SLOW` bit will be set.

If the programmer attempts to count a stopped clock, or the clock stops running then the `DIED` bit will be set. If any of `DIED`, `FAST`, or `SLOW` are set then `FAIL` will be set.

2.14.6.3. Configuring a GPCLK

TO DO: LIAM/TERRY: Missing content

2.14.6.4. Enabling resus

TO DO: LIAM/TERRY: Missing paragraph

2.14.6.5. Configuring sleep mode

TO DO: LIAM/TERRY: Missing paragraph

2.14.7. List of registers

Table 200. List of CLOCKS registers

Offset	Name	Info
0x00	<code>CLK_GPOUT0_CTRL</code>	Clock control, can be changed on-the-fly (except for auxsrc)
0x04	<code>CLK_GPOUT0_DIV</code>	Clock divisor, can be changed on-the-fly
0x08	<code>CLK_GPOUT0_SELECTED</code>	Indicates which src is currently selected (one-hot)
0x0c	<code>CLK_GPOUT1_CTRL</code>	Clock control, can be changed on-the-fly (except for auxsrc)
0x10	<code>CLK_GPOUT1_DIV</code>	Clock divisor, can be changed on-the-fly
0x14	<code>CLK_GPOUT1_SELECTED</code>	Indicates which src is currently selected (one-hot)
0x18	<code>CLK_GPOUT2_CTRL</code>	Clock control, can be changed on-the-fly (except for auxsrc)
0x1c	<code>CLK_GPOUT2_DIV</code>	Clock divisor, can be changed on-the-fly
0x20	<code>CLK_GPOUT2_SELECTED</code>	Indicates which src is currently selected (one-hot)
0x24	<code>CLK_GPOUT3_CTRL</code>	Clock control, can be changed on-the-fly (except for auxsrc)
0x28	<code>CLK_GPOUT3_DIV</code>	Clock divisor, can be changed on-the-fly
0x2c	<code>CLK_GPOUT3_SELECTED</code>	Indicates which src is currently selected (one-hot)
0x30	<code>CLK_REF_CTRL</code>	Clock control, can be changed on-the-fly (except for auxsrc)
0x34	<code>CLK_REF_DIV</code>	Clock divisor, can be changed on-the-fly
0x38	<code>CLK_REF_SELECTED</code>	Indicates which src is currently selected (one-hot)
0x3c	<code>CLK_SYS_CTRL</code>	Clock control, can be changed on-the-fly (except for auxsrc)
0x40	<code>CLK_SYS_DIV</code>	Clock divisor, can be changed on-the-fly
0x44	<code>CLK_SYS_SELECTED</code>	Indicates which src is currently selected (one-hot)

Offset	Name	Info
0x48	CLK_PERI_CTRL	Clock control, can be changed on-the-fly (except for auxsrc)
0x50	CLK_PERI_SELECTED	Indicates which src is currently selected (one-hot)
0x54	CLK_USB_CTRL	Clock control, can be changed on-the-fly (except for auxsrc)
0x58	CLK_USB_DIV	Clock divisor, can be changed on-the-fly
0x5c	CLK_USB_SELECTED	Indicates which src is currently selected (one-hot)
0x60	CLK_ADC_CTRL	Clock control, can be changed on-the-fly (except for auxsrc)
0x64	CLK_ADC_DIV	Clock divisor, can be changed on-the-fly
0x68	CLK_ADC_SELECTED	Indicates which src is currently selected (one-hot)
0x6c	CLK_RTC_CTRL	Clock control, can be changed on-the-fly (except for auxsrc)
0x70	CLK_RTC_DIV	Clock divisor, can be changed on-the-fly
0x74	CLK_RTC_SELECTED	Indicates which src is currently selected (one-hot)
0x78	CLK_SYS_RESUS_CTRL	
0x7c	CLK_SYS_RESUS_STATUS	
0x80	FC0_REF_KHZ	Reference clock frequency in kHz
0x84	FC0_MIN_KHZ	Minimum pass frequency in kHz. This is optional. Set to 0 if you are not using the pass/fail flags
0x88	FC0_MAX_KHZ	Maximum pass frequency in kHz. This is optional. Set to 0x1ffffff if you are not using the pass/fail flags
0x8c	FC0_DELAY	Delays the start of frequency counting to allow the mux to settle Delay is measured in multiples of the reference clock period
0x90	FC0_INTERVAL	The test interval is $0.98\mu\text{s} * 2^{\text{interval}}$, but let's call it $1\mu\text{s} * 2^{\text{interval}}$ The default gives a test interval of 250us
0x94	FC0_SRC	Clock sent to frequency counter, set to 0 when not required Writing to this register initiates the frequency count
0x98	FC0_STATUS	Frequency counter status
0x9c	FC0_RESULT	Result of frequency measurement, only valid when status_done=1
0xa0	WAKE_EN0	enable clock in wake mode
0xa4	WAKE_EN1	enable clock in wake mode
0xa8	SLEEP_EN0	enable clock in sleep mode
0xac	SLEEP_EN1	enable clock in sleep mode
0xb0	ENABLED0	indicates the state of the clock enable
0xb4	ENABLED1	indicates the state of the clock enable
0xb8	INTR	Raw Interrupts
0xbc	INTE	Interrupt Enable
0xc0	INTF	Interrupt Force
0xc4	INTS	Interrupt status after masking & forcing

CLK_GPOUT0_CTRL Register

Description

Clock control, can be changed on-the-fly (except for auxsrc)

Table 201.
CLK_GPOUT0_CTRL
Register

Bits	Name	Description	Type	Reset
31:21	Reserved.	-	-	-
20	NUDGE	An edge on this signal shifts the phase of the output by 1 cycle of the input clock This can be done at any time	RW	0x0
19:18	Reserved.	-	-	-
17:16	PHASE	This delays the enable signal by up to 3 cycles of the input clock This must be set before the clock is enabled to have any effect	RW	0x0
15:13	Reserved.	-	-	-
12	DC50	Enables duty cycle correction for odd divisors	RW	0x0
11	ENABLE	Starts and stops the clock generator cleanly	RW	0x0
10	KILL	Asynchronously kills the clock generator	RW	0x0
9	Reserved.	-	-	-
8:5	AUXSRC	Selects the auxiliary clock source, will glitch when switching 0x0 -> clksrc_pll_sys 0x1 -> clksrc_gpin0 0x2 -> clksrc_gpin1 0x3 -> clksrc_pll_usb 0x4 -> rosc_clksrc 0x5 -> xosc_clksrc 0x6 -> clk_sys 0x7 -> clk_usb 0x8 -> clk_adc 0x9 -> clk_rtc 0xa -> clk_ref	RW	0x0
4:0	Reserved.	-	-	-

CLK_GPOUT0_DIV Register

Description

Clock divisor, can be changed on-the-fly

Table 202.
CLK_GPOUT0_DIV
Register

Bits	Name	Description	Type	Reset
31:8	INT	Integer component of the divisor, 0 -> divide by 2 ¹⁶	RW	0x000001
7:0	FRAC	Fractional component of the divisor	RW	0x00

CLK_GPOUT0_SELECTED Register

Description

Indicates which src is currently selected (one-hot)

Table 203.
CLK_GPOUT0_SELECT
ED Register

Bits	Name	Description	Type	Reset
31:0	NONAME		RO	0x00000001

CLK_GPOUT1_CTRL Register

Description

Clock control, can be changed on-the-fly (except for auxsrc)

Table 204.
CLK_GPOUT1_CTRL
Register

Bits	Name	Description	Type	Reset
31:21	Reserved.	-	-	-
20	NUDGE	An edge on this signal shifts the phase of the output by 1 cycle of the input clock This can be done at any time	RW	0x0

Bits	Name	Description	Type	Reset
10	KILL	Asynchronously kills the clock generator	RW	0x0
9:8	Reserved.	-	-	-
7:5	AUXSRC	Selects the auxiliary clock source, will glitch when switching 0x0 -> clksrc_pll_usb 0x1 -> clksrc_pll_sys 0x2 -> rosc_clksrc_ph 0x3 -> xosc_clksrc 0x4 -> clksrc_gpin0 0x5 -> clksrc_gpin1	RW	0x0
4:0	Reserved.	-	-	-

CLK_RTC_DIV Register

Description

Clock divisor, can be changed on-the-fly

Table 228.
CLK_RTC_DIV Register

Bits	Name	Description	Type	Reset
31:8	INT	Integer component of the divisor, 0 -> divide by 2 ¹⁶	RW	0x000001
7:0	FRAC	Fractional component of the divisor	RW	0x00

CLK_RTC_SELECTED Register

Description

Indicates which src is currently selected (one-hot)

Table 229.
CLK_RTC_SELECTED Register

Bits	Name	Description	Type	Reset
31:0	NONAME		RO	0x00000001

CLK_SYS_RESUS_CTRL Register

Table 230.
CLK_SYS_RESUS_CTRL Register

Bits	Name	Description	Type	Reset
31:17	Reserved.	-	-	-
16	CLEAR	For clearing the resus after the fault that triggered it has been corrected	RW	0x0
15:13	Reserved.	-	-	-
12	FRCE	Force a resus, for test purposes only	RW	0x0
11:9	Reserved.	-	-	-
8	ENABLE	Enable resus	RW	0x0
7:0	TIMEOUT	This is expressed as a number of clk_ref cycles and must be >= 2x clk_ref_freq/min_clk_tst_freq	RW	0xff

CLK_SYS_RESUS_STATUS Register

Table 231.
CLK_SYS_RESUS_STA
TUS Register

Bits	Name	Description	Type	Reset
31:1	Reserved.	-	-	-
0	RESUSSED	Clock has been resuscitated, correct the error then send ctrl_clear=1	RO	0x0

FC0_REF_KHZ Register

Description

Reference clock frequency in kHz

Table 232.
FC0_REF_KHZ Register

Bits	Name	Description	Type	Reset
31:20	Reserved.	-	-	-
19:0	NONAME		RW	0x00000

FC0_MIN_KHZ Register

Description

Minimum pass frequency in kHz. This is optional. Set to 0 if you are not using the pass/fail flags

Table 233.
FC0_MIN_KHZ
Register

Bits	Name	Description	Type	Reset
31:25	Reserved.	-	-	-
24:0	NONAME		RW	0x0000000

FC0_MAX_KHZ Register

Description

Maximum pass frequency in kHz. This is optional. Set to 0x1ffffff if you are not using the pass/fail flags

Table 234.

2.15. Crystal Oscillator (XOSC)

2.15.1. Overview

The Crystal Oscillator (XOSC) uses an external crystal to produce an accurate reference clock. The RP2040 supports 1-15MHz crystals and the reference design uses a 12MHz crystal. The reference clock is distributed to the PLLs, which can be used to multiply the XOSC frequency (for example, to provide a 48MHz USB clock and a 133MHz system clock). The XOSC clock is also a clock source for the clock generators, so can be used directly if required. It is also possible to drive an external clock directly into the XIN pin, and disable the oscillator circuit.

Figure 31. XOSC overview

2.15.2. Usage

The XOSC is disabled on boot and RP2040 boots using the Ring Oscillator (ROSC). To start the XOSC, the programmer must set the enable bit then wait for the output clock to be stable. The XOSC is not immediately usable because it takes time for the oscillations to build to sufficient amplitude. This time will be dependent on the chosen crystal but will be of the order of a few milliseconds. The 12MHz crystal on the RP2040 reference design requires 1ms. On initial chip start-up the programmer can time this in software or configure the start-up delay which will set a flag when the XOSC clock is ready to use. If a software timer is used then the programmer must allow for the variation in frequency of the ROSC which is clocking the cores on power-up. If the DORMANT feature is used then the start-up delay must be configured.

2.15.3. Startup Delay

There is a startup delay register which specifies how many clock cycles must be seen from the crystal before it can be used. This is specified in multiples of 256. The Pico SDK `xosc_init` function sets this value. The 1ms default is sufficient for the RP2040 reference design.

The desired value can be calculated by:

$$(f_{Crystal} \times t_{Stable}) \div 256$$

So with a 12MHz crystal and a 1ms wait time, the calculation is:

$$(12 \times 10^6 \cdot 1 \times 10^{-3}) \div 256 \approx 47$$

NOTE

the value is rounded up to the nearest integer so the wait time will be just over 1ms

2.15.4. DORMANT mode

In DORMANT mode all of the on-chip clocks can be stopped to save power. This is particularly useful in battery-powered applications. The RP2040 is woken from DORMANT mode by an interrupt either from an external event such as an edge on a GPIO pin or from the on-chip RTC. If the RTC is being used to trigger wake-up then it must be clocked from an external source. To enter DORMANT mode the programmer must first switch all internal clocks to be driven from XOSC or ROSC then stop the PLLs. If XOSC is chosen then the frequency will be more precise but the restart time is longer (approximately 1ms on the reference design). If ROSC is chosen then the frequency is less precise but the start-up time is very short (approximately 1 usec). Then a specific 32-bit code must be written to the dormant register in the XOSC or

ROSC to stop the output clock.

i NOTE

the PLLs must be stopped before entering DORMANT mode

Pico SDK: https://github.com/raspberrypi/pico-sdk/tree/pre_release/src/rp2_common/hardware_xosc/xosc.c Lines 41 - 46

```
41 void xosc_dormant(void) {
42     // WARNING: This stops the xosc until woken up by an irq
43     xosc_hw->dormant = XOSC_DORMANT_VALUE_DORMANT;
44     // Wait for it to become stable once woken up
45     while(!(xosc_hw->status & XOSC_STATUS_STABLE_BITS));
46 }
```

⊖ WARNING

If no IRQ is configured before going into dormant mode the XOSC or ROSC will never restart.

See [Section 2.10.5.2](#) for a complete example of dormant mode using the XOSC.

2.15.5. XOSC COUNTER

The COUNT register provides a method of managing short software delays. Writing a value to the COUNT register automatically triggers it to start counting down to zero at the XOSC frequency. The programmer then simply polls the register until it reaches zero. This is preferable to using NOPs in software loops because it is independent of the core clock frequency, the compiler and the execution time of the compiled code.

2.15.6. Programmer's Model

Pico SDK: https://github.com/raspberrypi/pico-sdk/tree/pre_release/src/rp2040/hardware_structs/include/hardware/structs/xosc.h Lines 15 - 26

```
15 typedef struct {
16     io_rw_32 ctrl;
17     io_rw_32 status;
18     io_rw_32 dormant;
19     io_rw_32 startup;
20     io_rw_32 div2;
21     io_rw_32 padrefclk;
22     io_rw_32 clksrc;
23     io_rw_32 count;
24 } xosc_hw_t;
25
26 #define xosc_hw ((xosc_hw_t *const)XOSC_BASE)
```

Pico SDK: https://github.com/raspberrypi/pico-sdk/tree/pre_release/src/rp2_common/hardware_xosc/xosc.c Lines 16 - 30

```
16 void xosc_init(void) {
17     // Assumes 1-15 MHz input
18     assert(XOSC_MHZ <= 15);
19     xosc_hw->ctrl = XOSC_CTRL_FREQ_RANGE_VALUE_1_15MHZ;
20
21     // Set xosc startup delay
22     uint32_t startup_delay = (((12 * MHZ) * (MS) + 128) / 256); ①
```

① Adding 128 ensures the integer result is always rounded up

```

23  xosc_hw->startup = startup_delay;
24
25  // Set the enable bit now that we have set freq range and startup delay
26  hw_set_bits(&xosc_hw->ctrl, XOSC_CTRL_ENABLE_VALUE_ENABLE << XOSC_CTRL_ENABLE_LSB);
27
28  // Wait for XOSC to be stable
29  while(!(xosc_hw->status & XOSC_STATUS_STABLE_BITS));
30 }
    
```

2.15.7. List of registers

Table 250. List of XOSC registers

Offset	Name	Info
0x00	CTRL	Crystal Oscillator Control
0x04	STATUS	Crystal Oscillator Status
0x08	DORMANT	Crystal Oscillator Power down control
0x0c	STARTUP	Controls the startup delay
0x10	DIV2	Controls the optional div2 output
0x14	PADREFCLK	Selects the clock to be output to the reference clock pad
0x18	CLKSRC	Controls the general purpose clock outputs clksrc and clksrc_ph
0x1c	COUNT	A down counter running at the xosc frequency which counts to zero and stops.

CTRL Register

Description

Crystal Oscillator Control

Table 251. CTRL Register

Bits	Name	Description	Type	Reset
31:24	Reserved.	-	-	-
23:12	ENABLE	Think carefully before disabling. An invalid setting will enable the oscillator. 0xd1e -> DISABLE 0xfab -> ENABLE	RW	-
11:0	FREQ_RANGE	Frequency range. An invalid setting will retain the previous value. The actual value being used can be read from STATUS_FREQ_RANGE 0xaa0 -> 1_15MHZ 0xaa1 -> RESERVED_1 0xaa2 -> RESERVED_2 0xaa3 -> RESERVED_3	RW	-

STATUS Register

Description

Crystal Oscillator Status

Table 252. STATUS Register

Bits	Name	Description	Type	Reset
31	STABLE	Oscillator is running and stable	RO	0x0

Bits	Name	Description	Type	Reset
30:25	Reserved.	-	-	-
24	BADWRITE	An invalid value has been written to CTRL_ENABLE or CTRL_FREQ_RANGE or DORMANT	WC	0x0
23:13	Reserved.	-	-	-
12	ENABLED	Oscillator is enabled but not necessarily running and stable	RO	-
11:2	Reserved.	-	-	-
1:0	FREQ_RANGE	The current frequency range setting 0x0 -> 1_15MHZ 0x1 -> RESERVED_1 0x2 -> RESERVED_2 0x3 -> RESERVED_3	RO	-

DORMANT Register

Description

Crystal Oscillator Power down control

Table 253. DORMANT Register

Bits	Name	Description	Type	Reset
31:0	NONAME	Warning: stop the PLLs before selecting dormant mode Warning: setup the irq before selecting dormant mode An invalid setting will select WAKE mode 0x636f6d61 -> DORMANT 0x77616b65 -> WAKE	RW	-

STARTUP Register

Description

Controls the startup delay

Table 254. STARTUP Register

Bits	Name	Description	Type	Reset
31:21	Reserved.	-	-	-
20	X4	Multiplies the startup_delay by 4, just in case	RW	-
19:14	Reserved.	-	-	-
13:0	DELAY	in multiples of 256*xtal_period	RW	-

DIV2 Register

Description

The div2 clock can be sent to the reference clock pad or to the general purpose clock outputs clksrc and clksrc_ph
Note that div2 may not be implemented on this chip

Table 255. DIV2 Register

Bits	Name	Description	Type	Reset
31:1	Reserved.	-	-	-
0	ENABLE	starts and stops the div2 output cleanly	RW	0x0

PADREFCLK Register

Description

Note that div2 may not be implemented on this chip

Table 256. PADREFCLK Register

Bits	Name	Description	Type	Reset
31:1	Reserved.	-	-	-
0	SELECT	The output will glitch if this is changed on-the-fly 0x0 -> XOSC 0x1 -> XOSC_DIV2	RW	0x0

CLKSRC Register

Description

clksrc_ph is an optional phase shifted version of clksrc and may not be implemented on this chip

Table 257. CLKSRC Register

Bits	Name	Description	Type	Reset
31:6	Reserved.	-	-	-
5:4	PH_SELECT	selects the phase of clksrc_ph the output will glitch if this is changed on-the-fly for clksrc_select=XOSC: clksrc_ph_select=0 -> 0 degree phase shift for clksrc_select=XOSC: clksrc_ph_select=1 -> 0 degree phase shift for clksrc_select=XOSC: clksrc_ph_select=2 -> 180 degree phase shift for clksrc_select=XOSC: clksrc_ph_select=3 -> 180 degree phase shift for clksrc_select=XOSC_DIV2: clksrc_ph_select=0 -> 0 degree phase shift for clksrc_select=XOSC_DIV2: clksrc_ph_select=1 -> 90 degree phase shift for clksrc_select=XOSC_DIV2: clksrc_ph_select=2 -> 180 degree phase shift for clksrc_select=XOSC_DIV2: clksrc_ph_select=3 -> 270 degree phase shift	RW	0x0
3:1	Reserved.	-	-	-
0	SELECT	selects the source of clksrc & clksrc_ph the output will glitch if this is changed on-the-fly 0x0 -> XOSC 0x1 -> XOSC_DIV2	RW	0x0

COUNT Register

Description

Can be used for short software pauses when setting up time sensitive hardware.

2.16. Ring Oscillator (ROSC)

2.16.1. Overview

A Ring Oscillator is an on-chip oscillator that requires no external crystal. Instead, the output is generated from a series of inverters that are chained together to create a feedback loop. RP2040 boots from the ring oscillator initially, meaning the first stages of the bootrom, including booting from SPI flash, will be clocked by the ring oscillator.

You may choose to include a crystal oscillator in your design if you require a more accurate frequency than afforded by the ring oscillator.

Figure 32. ROSC overview.

2.16.2. Frequency Variation

The frequency of the Ring Oscillator can vary with temperature, voltage, and speed of the silicon itself. For example, the bootrom assumes a minimum boot frequency of 1.8MHz, with a typical boot frequency of 6.5MHz, and a maximum boot frequency of 12MHz.

2.16.3. Dormant mode

The ROSC supports dormant mode, which allows it to stop oscillating until woken up by an asynchronous interrupt. This can either come from the RTC, being clocked by an external clock, or a GPIO pin going high or low. To put the ROSC into dormant mode, a specific value has to be written to the dormant register. This means it is unlikely to be done by mistake.

NOTE

It is assumed all clocks will be running from the ROSC at this point, and PLLs will have been stopped.

Pico SDK: https://github.com/raspberrypi/pico-sdk/tree/pre_release/src/rp2_common/hardware_rosc/rosc.c Lines 60 - 65

```

60 void rosc_dormant(void) {
61     // WARNING: This stops the rosc until woken up by an irq
62     rosc_write(&rosc_hw->dormant, ROSC_DORMANT_VALUE_DORMANT);
63     // Wait for it to become stable once woken up
64     while(!(rosc_hw->status & ROSC_STATUS_STABLE_BITS));
65 }
    
```

⊖ WARNING

If no IRQ is configured before going into dormant mode the ROSC will never restart.

See [Section 2.10.5.2](#) for a some examples of dormant mode.

2.16.4. Programmer’s Model

TO DO: LIAM: Document ring osc code in the SDK

2.16.5. List of registers

Table 259. List of ROSC registers

Offset	Name	Info
0x00	CTRL	Ring Oscillator control
0x04	FREQA	Ring Oscillator frequency control A
0x08	FREQB	Ring Oscillator frequency control B
0x0c	DORMANT	Ring Oscillator Power control
0x10	DIV	Controls the output divider
0x14	PHASE	Controls the phase shifted output
0x18	STATUS	Ring Oscillator Status
0x1c	RANDOMBIT	Returns a 1 bit random value
0x20	COUNT	A down counter running at the rosc frequency which counts to zero and stops.

CTRL Register

Description

Ring Oscillator control

Table 260. CTRL Register

Bits	Name	Description	Type	Reset
31:24	Reserved.	-	-	-
23:12	ENABLE	Think carefully before disabling 0xd1e -> DISABLE 0xfab -> ENABLE	RW	-
11:0	FREQ_RANGE	Frequency range. Frequencies will vary with Process, Voltage & Temperature (PVT). Clock output will not glitch when changing the range up one step at a time. Clock output will glitch when changing the range down. 0xaa0 -> LOW 0xaa1 -> MEDIUM 0xaa3 -> HIGH 0xaa2 -> TOOHIGH	RW	0xaa0

FREQA Register

Description

freqa & freqb control the frequency by controlling the drive strength of each stage

The drive strength of each stage is given by:

$$ds_stage[n] = 1 + dsn[0] + dsn[1] + dsn[2]$$

To calculate the frequency to a first approximation:

$$\text{for range}=0: \quad \text{freq} = \text{fbase0} * \frac{4}{4} *$$

$$(8 + ds_stage[0] + ds_stage[1] + ds_stage[2] + ds_stage[3] + ds_stage[4] + ds_stage[5] + ds_stage[6] + ds_stage[7]) / 8$$

$$\text{for range}=1: \text{freq} = \text{fbase0} * \frac{4}{3} * (6 + ds_stage[0] + ds_stage[1] + ds_stage[2] + ds_stage[3] + ds_stage[4] + ds_stage[5]) / 6$$

$$\text{for range}=2: \text{freq} = \text{fbase0} * \frac{4}{2} * (4 + ds_stage[0] + ds_stage[1] + ds_stage[2] + ds_stage[3]) / 4$$

$$\text{for range}=3: \text{freq} = \text{fbase0} * \frac{4}{1} * (2 + ds_stage[0] + ds_stage[1]) / 2$$

where fbase0 is the frequency for range0 with no ds bits set

fbase0 will depend on temperature, voltage and process parameters.

fbase0 pre-layout estimate is 25-100MHz. This will be refined when final layout is available

If fbase0=50MHz then, to a first approximation:

for range=0: freq = 50 - 200 MHz in 32 unequal steps

for range=1: freq = 70 - 280 MHz in 24 unequal steps

for range=2: freq = 100 - 400 MHz in 16 unequal steps

for range=3: freq = 200 - 800 MHz in 8 unequal steps

In the higher ranges fewer stages contribute to the frequency but the generated clock propagates through the unused stages so their drive strengths should be set to the maximum.

2.17. PLL

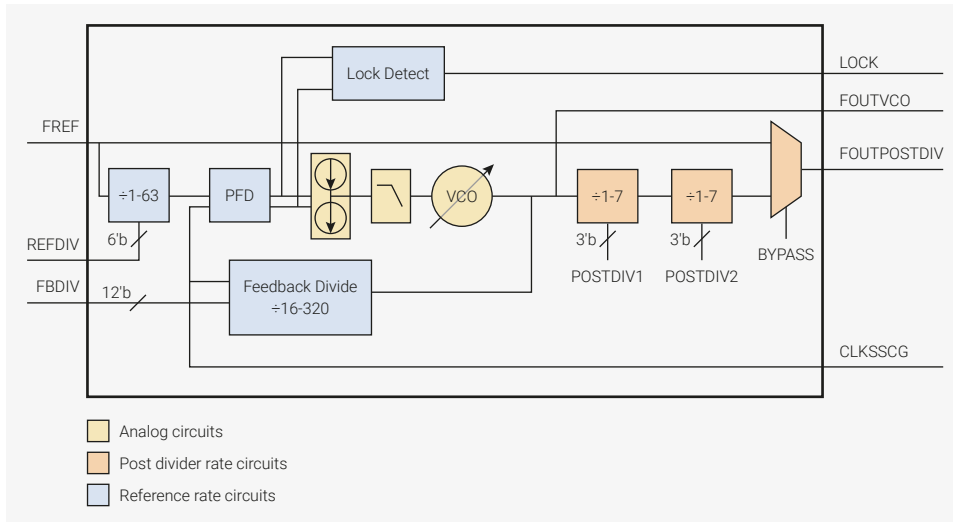

2.17.1. Overview

The PLL is designed to take a reference clock, and multiply it using a VCO (Voltage Controlled Oscillator) with a feedback loop. The VCO must run at high frequencies (between 400 and 1600 MHz), so there are two dividers, known as post dividers that can divide the VCO frequency before it is distributed to the clock generators on the chip.

There are two PLLs in RP2040. They are:

- `pll_sys` - Used to generate up to a 133 MHz system clock
- `pll_usb` - Used to generate a 48 MHz USB reference clock

Figure 33. On both PLLs, the FREF (reference) input is connected to the crystal oscillator's XI input. The PLL contains a VCO, which is locked to a constant ratio of the reference clock via the feedback loop (phase-frequency detector and loop filter). This can synthesise very high frequencies, which may be divided down by the post-dividers.

2.17.2. Calculating PLL parameters

To configure the PLL, you must know the frequency of the reference clock, which on RP2040 is routed directly from the crystal oscillator. This will often be a 12 MHz crystal, for compatibility with RP2040's USB bootrom. The PLL's final output frequency **FOUTPOSTDIV** can then be calculated as $(FREF / REFDIV) * FBDIV / (POSTDIV1 * POSTDIV2)$. With a desired output frequency in mind, you must select PLL parameters according to the following constraints of the PLL design:

- Minimum reference frequency (**FREF / REFDIV**) is 5 MHz
- Oscillator frequency (**FOUTVCO**) must be in the range 400 MHz -> 1600 MHz
- Feedback divider (**FBDIV**) must be in the range 16 -> 320
- The post dividers **POSTDIV1** and **POSTDIV2** must be in the range 1 -> 7
- Maximum input frequency (**FREF / REFDIV**) is VCO frequency divided by 16, due to minimum feedback divisor

Additionally, the maximum frequencies of the chip's clock generators (attached to **FOUTPOSTDIV**) must be respected. For the system PLL this is 133 MHz, and for the USB PLL, 48 MHz.

NOTE

The crystal oscillator on RP2040 is designed for crystals between 5 and 15 MHz, so typically **REFDIV** should be 1. If the application circuit drives a faster reference directly into the XI input, and a low VCO frequency is desired, the reference divisor can be increased to keep the PLL input within a suitable range.

TIP

When two different values are required for **POSTDIV1** and **POSTDIV2**, it's preferable to assign the higher value to **POSTDIV1**, for lower power consumption.

In the RP2040 reference design, which attaches a 12 MHz crystal to the crystal oscillator, this implies that the minimum achievable and legal VCO frequency is 12 MHz × 34 = 408 MHz, and the maximum VCO is 12 MHz × 133 = 1596 MHz, so **FBDIV** must remain in the range 34 -> 133. For example, setting **FBDIV** to 100 would synthesise a 1200 MHz VCO frequency. A **POSTDIV1** value of 6 and a **POSTDIV2** value of 2 would divide this by 12 in total, producing a clean 100 MHz at the PLL's final output.

2.17.2.1. Jitter vs Power Consumption

There are often several ways to get the desired output frequency, especially if you are willing to add some margin to the desired output frequency (124 MHz or 126 MHz instead of 125 MHz). It is up to the programmer to decide whether they optimise for low power consumption or low jitter. The lower the jitter, the lower the variation in the period of the clock. A clock optimised for low jitter will be more accurate than one optimised for low power consumption. A high accuracy clock is often needed for audio and video applications, or where data is being transmitted and received in accordance with a specification. For example, the USB specification defines a maximum amount of allowable jitter.

To achieve low jitter, the VCO frequency should be high and divided down. For example, $1500 \text{ MHz VCO} / 6 / 2 = 125 \text{ MHz}$. To reduce power consumption, the VCO frequency should be as low as possible. For example: $500 \text{ MHz VCO} / 4 / 1 = 125 \text{ MHz}$.

Pico SDK provides a Python script that shows various VCO and post divider options for a desired output frequency.

Pico SDK: https://github.com/raspberrypi/pico-sdk/tree/pre-release/src/rp2_common/hardware_clocks/scripts/vcocalc.py Lines 1 - 37

```

1  #!/usr/bin/env python3
2
3  import argparse
4
5  parser = argparse.ArgumentParser(description="PLL parameter calculator")
6  parser.add_argument("--input", "-i", default=12, help="Input (reference) frequency. Default
    12 MHz", type=float)
7  parser.add_argument("--vco-max", default=1600, help="Override maximum VCO frequency. Default
    1600 MHz", type=float)
8  parser.add_argument("--vco-min", default=400, help="Override minimum VCO frequency. Default
    400 MHz", type=float)
9  parser.add_argument("--low-vco", "-l", action="store_true", help="Use a lower VCO frequency
    when possible. This reduces power consumption, at the cost of increased jitter")
10 parser.add_argument("output", help="Output frequency in MHz.", type=float)
11 args = parser.parse_args()
12
13 # Fixed hardware parameters
14 fbdiv_range = range(16, 320 + 1)
15 postdiv_range = range(1, 7 + 1)
16
17 best = (0, 0, 0, 0)
18 best_margin = args.output
19
20 for fbdiv in (fbdiv_range if args.low_vco else reversed(fbdiv_range)):
21     vco = args.input * fbdiv
22     if vco < args.vco_min or vco > args.vco_max:
23         continue
24     # pd1 is inner loop so that we prefer higher ratios of pd1:pd2
25     for pd2 in postdiv_range:
26         for pd1 in postdiv_range:
27             out = vco / pd1 / pd2
28             margin = abs(out - args.output)
29             if margin < best_margin:
30                 best = (out, fbdiv, pd1, pd2)
31                 best_margin = margin
32
33 print("Requested: {} MHz".format(args.output))
34 print("Achieved: {} MHz".format(best[0]))
35 print("VCO: {} MHz".format(args.input * best[1]))
36 print("PD1: {}".format(best[2]))
37 print("PD2: {}".format(best[3]))

```

Given an input and output frequency, this script will find the best possible set of PLL parameters to get as close as possible. Where multiple equally good combinations are found, it returns the parameters which yield the highest VCO frequency, for best output stability. The `-l` or `--low-vco` flag will instead prefer lower frequencies, for reduced power

consumption.

Here a 48 MHz output is requested:

```
$ ./vcocalc.py 48
Requested: 48.0 MHz
Achieved: 48.0 MHz
VCO: 1440 MHz
PD1: 6
PD2: 5
```

Asking for a 48 MHz output with a lower VCO frequency, if possible:

```
$ ./vcocalc.py -l 48
Requested: 48.0 MHz
Achieved: 48.0 MHz
VCO: 432 MHz
PD1: 3
PD2: 3
```

For a 125 MHz system clock with a 12 MHz input, the minimum VCO frequency is quite high.

```
$ ./vcocalc.py -l 125
Requested: 125.0 MHz
Achieved: 125.0 MHz
VCO: 1500 MHz
PD1: 6
PD2: 2
```

We can restrict the search to lower VCO frequencies, so that the script will consider looser frequency matches. Note that, whilst a 500 MHz VCO would be ideal here, we can't achieve exactly 500 MHz by multiplying the 12 MHz input by an integer, which is why the previous invocation returned such a high VCO frequency.

```
$ ./vcocalc.py -l 125 --vco-max 600
Requested: 125.0 MHz
Achieved: 126.0 MHz
VCO: 504 MHz
PD1: 4
PD2: 1
```

2.17.3. Configuration

The Pico SDK uses the following PLL settings:

Pico SDK: https://github.com/raspberrypi/pico-sdk/tree/pre_release/src/rp2_common/hardware_clocks/clocks.c Lines 138 - 141

```
138 // Configure PLLs
139 //
140 // PLL SYS: 12 / 1 = 12MHz * 125 = 1500MHz / 6 / 2 = 125MHz
141 // PLL USB: 12 / 1 = 12MHz * 40 = 480 MHz / 5 / 2 = 48MHz
```

The `pll_init` function in the Pico SDK, which we will examine below, asserts that all of these conditions are true before attempting to configure the PLL.

The Pico SDK defines the PLL control registers as a struct. It then maps them into memory for each instance of the PLL.

Pico SDK: https://github.com/raspberrypi/pico-sdk/tree/pre-release/src/rp2040/hardware_structs/include/hardware/structs/pll.h Lines 14 - 22

```

14 typedef struct {
15     io_rw_32 cs;
16     io_rw_32 pwr;
17     io_rw_32 fbdiv_int;
18     io_rw_32 prim;
19 } pll_hw_t;
20
21 #define pll_sys_hw ((pll_hw_t *const)PLL_SYS_BASE)
22 #define pll_usb_hw ((pll_hw_t *const)PLL_USB_BASE)

```

The Pico SDK defines `pll_init` which is used to configure, or reconfigure a PLL. It starts by clearing any previous power state in the PLL, then calculates the appropriate feedback divider value. There are assertions to check these values satisfy the constraints above.

Pico SDK: https://github.com/raspberrypi/pico-sdk/tree/pre-release/src/rp2_common/hardware_pll/pll.c Lines 14 - 24

```

14 void pll_init(PLL pll, uint32_t refdiv, uint32_t vco_freq, uint32_t post_div1, uint8_t
    post_div2) {
15     // Turn off PLL in case it is already running
16     pll->pwr = 0xffffffff;
17     pll->fbdiv_int = 0;
18
19     uint32_t ref_mhz = XOSC_MHZ / refdiv;
20     pll->cs = refdiv;
21
22     // What are we multiplying the reference clock by to get the vco freq
23     // (The regs are called div, because you divide the vco output and compare it to the
    refclk)
24     uint32_t fbdiv = vco_freq / (ref_mhz * MHz);

```

The programming sequence for the PLL is as follows:

- Program the reference clock divider (is a divide by 1 in the RP2040 case)
- Program the feedback divider
- Turn on the main power and VCO
- Wait for the VCO to lock (i.e. keep its output frequency stable)
- Set up post dividers and turn them on

Pico SDK: https://github.com/raspberrypi/pico-sdk/tree/pre-release/src/rp2_common/hardware_pll/pll.c Lines 40 - 61

```

40     // Check that reference frequency is no greater than vco / 16
41     assert(ref_mhz <= (vco_freq / 16));
42
43     // Put calculated value into feedback divider
44     pll->fbdiv_int = fbdiv;
45
46     // Turn on PLL
47     uint32_t power = PLL_PWR_PD_BITS | // Main power
48                   PLL_PWR_VCOPD_BITS; // VCO Power
49

```

```

50 hw_clear_bits(&pll->pwr, power);
51
52 // Wait for PLL to lock
53 while (!(pll->cs & PLL_CS_LOCK_BITS)) tight_loop_contents();
54
55 // Set up post dividers - div1 feeds into div2 so if div1 is 5 and div2 is 2 then you get
  a divide by 10
56 uint32_t pdiv = (post_div1 << PLL_PRIM_POSTDIV1_LSB) |
57                 (post_div2 << PLL_PRIM_POSTDIV2_LSB);
58 pll->prim = pdiv;
59
60 // Turn on post divider
61 hw_clear_bits(&pll->pwr, PLL_PWR_POSTDIVPD_BITS);

```

Note the VCO is turned on first, followed by the post dividers so the PLL does not output a dirty clock while the VCO is locking.

2.17.4. List of registers

Table 269. List of PLL registers

Offset	Name	Info
0x0	CS	Control and Status

2.18. GPIO

2.18.1. Overview

RP2040 has 36 multi-functional General Purpose Input / Output (GPIO) pins, divided into two banks. In a typical use case, the pins in the QSPI bank (QSPL_SS, QSPL_SCLK and QSPL_SD0 to QSPL_SD3) are used to execute code from an external flash device, leaving the User bank (GPIO0 to GPIO29) for the programmer to use. All GPIOs support digital input and output, but GPIO26 to GPIO29 can also be used as inputs to the chip's Analogue to Digital Converter (ADC). Each GPIO can be controlled directly by software running on the processors, or by a number of other functional blocks.

The User GPIO bank supports the following functions:

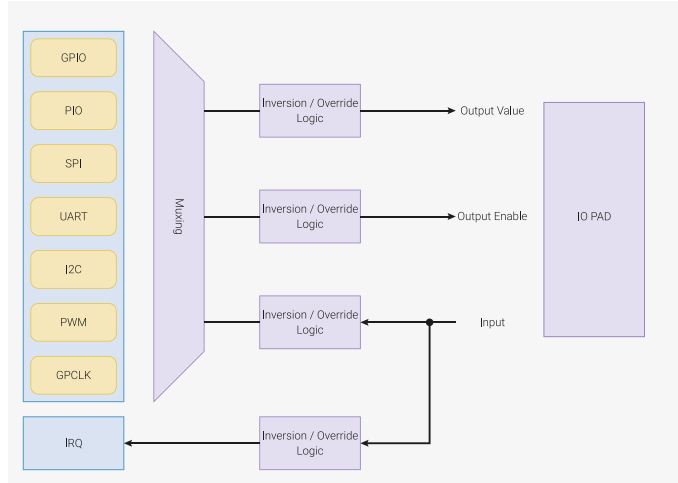

- processor controlled general purpose IO (GPIO) - [Section 2.3.1.2, "GPIO Control"](#)
- programmable IO (PIO) - [Chapter 3, PIO](#)
- 2 x SPI - [Section 4.5, "SPI"](#)
- 2 x UART - [Section 4.3, "UART"](#)
- 2 x I2C (two-wire serial interface) - [Section 4.4, "I2C"](#)
- 8 x two-channel PWM - [Section 4.6, "PWM"](#)
- 2 x external clock inputs - [Section 2.14.2.3, "External Clocks"](#)
- 4 x general purpose clock output - **TO DO: TERRY/LIAM: cross reference. Is there a section to cross reference to?**
- 4 x input to ADC - [Section 4.10, "ADC and Temperature Sensor"](#)
- USB VBUS management - [Section 4.1.2.8, "VBUS Control"](#)
- External interrupt requests, level or edge-sensitive

The QSPI bank supports the following functions:

- processor controlled General Purpose IO (GPIO) - [Section 2.3.1.2, "GPIO Control"](#)
- Flash execute in place (XIP) - [Execute-In-Place](#)

The logical structure of an example IO is shown in [Figure 34](#).

Figure 34. Logical structure of a GPIO. Each GPIO can be controlled by one of a number of peripherals, or by software control registers in the SIO. The function select (FSEL) selects which peripheral output is in control of the GPIO's direction and output level, and/or which peripheral input can see this GPIO's input level. These three signals (output level, output enable, input level) can also be inverted, or forced high or low, using the GPIO control registers.

2.18.2. Function Select

The function allocated to each GPIO is selected by writing to the **FUNCSEL** field in the GPIO's **CTRL** register. See [GPIO0_CTRL](#) as an example. The functions available on each IO are shown in [Table 274](#) and [Table 276](#).

Table 274. General Purpose Input/Output (GPIO) User Bank Functions

GPIO	Function								
	F1	F2	F3	F4	F5	F6	F7	F8	F9
0	SPI0 RX	UART0 TX	I2C0 SDA	PWM0 A	SIO	PIO0	PIO1		USB OVCUR DET
1	SPI0 CSn	UART0 RX	I2C0 SCL	PWM0 B	SIO	PIO0	PIO1		USB VBUS DET
2	SPI0 SCK	UART0 CTS	I2C1 SDA	PWM1 A	SIO	PIO0	PIO1		USB VBUS EN
3	SPI0 TX	UART0 RTS	I2C1 SCL	PWM1 B	SIO	PIO0	PIO1		USB OVCUR DET
4	SPI0 RX	UART1 TX	I2C0 SDA	PWM2 A	SIO	PIO0	PIO1		USB VBUS DET
5	SPI0 CSn	UART1 RX	I2C0 SCL	PWM2 B	SIO	PIO0	PIO1		USB VBUS EN
6	SPI0 SCK	UART1 CTS	I2C1 SDA	PWM3 A	SIO	PIO0	PIO1		USB OVCUR DET
7	SPI0 TX	UART1 RTS	I2C1 SCL	PWM3 B	SIO	PIO0	PIO1		USB VBUS DET
8	SPI1 RX	UART1 TX	I2C0 SDA	PWM4 A	SIO	PIO0	PIO1		USB VBUS EN
9	SPI1 CSn	UART1 RX	I2C0 SCL	PWM4 B	SIO	PIO0	PIO1		USB OVCUR DET
10	SPI1 SCK	UART1 CTS	I2C1 SDA	PWM5 A	SIO	PIO0	PIO1		USB VBUS DET
11	SPI1 TX	UART1 RTS	I2C1 SCL	PWM5 B	SIO	PIO0	PIO1		USB VBUS EN
12	SPI1 RX	UART0 TX	I2C0 SDA	PWM6 A	SIO	PIO0	PIO1		USB OVCUR DET
13	SPI1 CSn	UART0 RX	I2C0 SCL	PWM6 B	SIO	PIO0	PIO1		USB VBUS DET
14	SPI1 SCK	UART0 CTS	I2C1 SDA	PWM7 A	SIO	PIO0	PIO1		USB VBUS EN
15	SPI1 TX	UART0 RTS	I2C1 SCL	PWM7 B	SIO	PIO0	PIO1		USB OVCUR DET
16	SPI0 RX	UART0 TX	I2C0 SDA	PWM0 A	SIO	PIO0	PIO1		USB VBUS DET
17	SPI0 CSn	UART0 RX	I2C0 SCL	PWM0 B	SIO	PIO0	PIO1		USB VBUS EN
18	SPI0 SCK	UART0 CTS	I2C1 SDA	PWM1 A	SIO	PIO0	PIO1		USB OVCUR DET
19	SPI0 TX	UART0 RTS	I2C1 SCL	PWM1 B	SIO	PIO0	PIO1		USB VBUS DET
20	SPI0 RX	UART1 TX	I2C0 SDA	PWM2 A	SIO	PIO0	PIO1	CLOCK GPIN0	USB VBUS EN

Function									
21	SPI0 CSn	UART1 RX	I2C0 SCL	PWM2 B	SIO	PI00	PI01	CLOCK GPOUT0	USB OVCUR DET
22	SPI0 SCK	UART1 CTS	I2C1 SDA	PWM3 A	SIO	PI00	PI01	CLOCK GPIN1	USB VBUS DET
23	SPI0 TX	UART1 RTS	I2C1 SCL	PWM3 B	SIO	PI00	PI01	CLOCK GPOUT1	USB VBUS EN
24	SPI1 RX	UART1 TX	I2C0 SDA	PWM4 A	SIO	PI00	PI01	CLOCK GPOUT2	USB OVCUR DET
25	SPI1 CSn	UART1 RX	I2C0 SCL	PWM4 B	SIO	PI00	PI01	CLOCK GPOUT3	USB VBUS DET
26	SPI1 SCK	UART1 CTS	I2C1 SDA	PWM5 A	SIO	PI00	PI01		USB VBUS EN
27	SPI1 TX	UART1 RTS	I2C1 SCL	PWM5 B	SIO	PI00	PI01		USB OVCUR DET
28	SPI1 RX	UART0 TX	I2C0 SDA	PWM6 A	SIO	PI00	PI01		USB VBUS DET
29	SPI1 CSn	UART0 RX	I2C0 SCL	PWM6 B	SIO	PI00	PI01		USB VBUS EN

Each GPIO can have one function selected at a time. Likewise, each peripheral input (e.g. UART0 RX) should only be selected on one *GPIO* at a time. If the same peripheral input is connected to multiple GPIOs, the peripheral sees the logical OR of these GPIO inputs.

Table 275. GPIO User Bank function descriptions

Function Name	Description
SPIx	Connect one of the internal PL022 SPI peripherals to GPIO
UARTx	Connect one of the internal PL011 UART peripherals to GPIO
I2Cx	Connect one of the internal DW I2C peripherals to GPIO
PWMx A/B	Connect a PWM slice to GPIO. There are eight PWM slices, each with two output channels (A/B). The B pin can also be used as an input, for frequency and duty cycle measurement.
SIO	Software control of GPIO, from the single-cycle IO (SIO) block. The SIO function (F5) must be selected for the processors to <i>drive</i> a GPIO, but the input is always connected, so software can check the state of GPIOs at any time.
PIOx	Connect one of the programmable IO blocks (PIO) to GPIO. PIO can implement a <i>wide</i> variety of interfaces, and has its own internal pin mapping hardware, allowing flexible placement of digital interfaces on user bank GPIOs. The PIO function (F6, F7) must be selected for PIO to <i>drive</i> a GPIO, but the input is always connected, so the PIOs can always see the state of all pins.
CLOCK GPINx	General purpose clock inputs. Can be routed to a number of internal clock domains on RP2040, e.g. to provide a 1 Hz clock for the RTC, or can be connected to an internal frequency counter.
CLOCK GPOUTx	General purpose clock outputs. Can drive a number of internal clocks onto GPIOs, with optional integer divide.
USB OVCUR DET/VBUS DET/VBUS EN	USB power control signals to/from the internal USB controller

Table 276. General Purpose Input/Output (GPIO) QSPI Bank Functions

IO	Function									
	F0	F1	F2	F3	F4	F5	F6	F7	F8	F9
QSPI SCK	XIP SCK					SIO				
QSPI CSn	XIP CSn					SIO				
QSPI SD0	XIP SD0					SIO				
QSPI SD1	XIP SD1					SIO				

		Function									
QSPI SD2	XIP SD2						SIO				
QSPI SD3	XIP SD3						SIO				

Table 277. GPIO QSPI Bank function descriptions

Function Name	Description
XIP	Connection to the synchronous serial interface (SSI) inside the flash execute in place (XIP) subsystem. This allows processors to execute code directly from an external SPI, Dual-SPI or Quad-SPI flash
SIO	Software control of GPIO, from the single-cycle IO (SIO) block. The SIO function (F5) must be selected for the processors to <i>drive</i> a GPIO, but the input is always connected, so software can check the state of GPIOs at any time. The QSPI IOs are controlled via the <code>SIO_GPIO_HI_x</code> registers, and are mapped to register bits in the order SCK, CSn, SD0, SD1, SD2, SD3, starting at the LSB.

The six QSPI Bank GPIO pins are typically used by the XIP peripheral to communicate with an external flash device. However, there are two scenarios where the pins can be used as software-controlled GPIOs:

- If a SPI or Dual-SPI flash device is used for execute-in-place, then the SD2 and SD3 pins are not used for flash access, and can be used for other GPIO functions on the circuit board.
- If RP2040 is used in a flashless configuration (USB boot only), then all six pins can be used for software-controlled GPIO functions

2.18.3. Interrupts

An interrupt can be generated for every GPIO pin in four scenarios:

- Level High: the GPIO pin is a logical 1
- Level Low: the GPIO pin is a logical 0
- Edge High: the GPIO has transitioned from a logical 0 to a logical 1
- Edge Low: the GPIO has transitioned from a logical 1 to a logical 0

The level interrupts are not latched. This means that if the pin is a logical 1 and the level high interrupt is active, it will become inactive as soon as the pin changes to a logical 0. The edge interrupts are stored in the `INTR` register and can be cleared by writing to the `INTR` register.

There are enable (`PROC0_INTE0`), status (`PROC0_INTS0`), and force (`PROC0_INTF0`) registers for three interrupt destinations: core 0, core 1, and dormant_wake. Dormant wake is used to wake the ROSC or XOSC up from dormant mode. See Section 2.10.5.2 for more information on dormant mode.

All interrupts are ORed together per-bank per-destination resulting in a total of six GPIO interrupts:

- `io_bank0_to_dormant_wake`
- `io_bank0_to_proc0`
- `io_bank0_to_proc1`
- `io_bank1_to_dormant_wake`
- `io_bank1_to_proc0`
- `io_bank1_to_proc1`

This means the user can watch for several GPIO events at once.

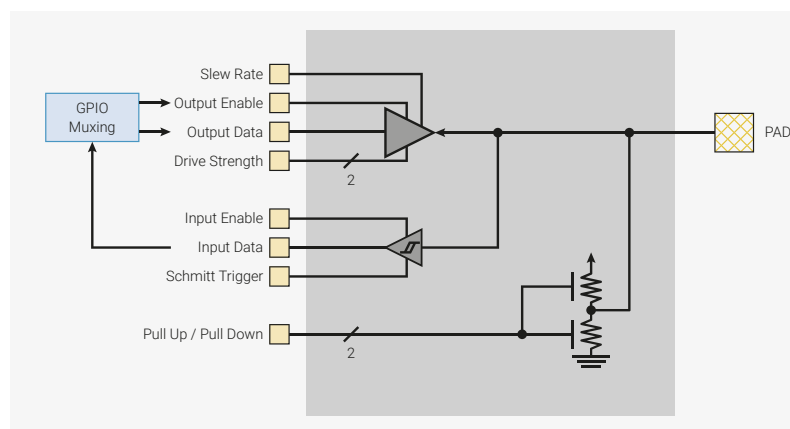

2.18.4. Pads

Each GPIO is connected to the off-chip world via a "pad". Pads are the electrical interface between the chip's internal logic and external circuitry. They translate signal voltage levels, support higher currents and offer some protection against electrostatic discharge (ESD) events. Pad electrical behaviour can be adjusted to meet the requirements of the external circuitry. The following adjustments are available:

- Output drive strength can be set to 2mA, 4mA, 8mA or 12mA
- Output slew rate can be set to slow or fast
- Input hysteresis (schmitt trigger mode) can be enabled
- A pull-up or pull-down can be enabled, to set the output signal level when the output driver is disabled
- The input buffer can be disabled, to reduce current consumption when the pad is unused, unconnected or connected to an analogue signal.

An example pad is shown in [Figure 35](#).

Figure 35. Diagram of a single IO pad.

The pad's Output Enable, Output Data and Input Data ports are connected, via the IO mux, to the function controlling the pad. All other ports are controlled from the pad control register. The register also allows the pad's output driver to be disabled, by overriding the Output Enable signal from the function controlling the pad. See [GPIO0](#) for an example of a pad control register.

Both the output signal level and acceptable input signal level at the pad are determined by the digital IO supply (IOVDD). IOVDD can be any nominal voltage between 1.8V and 3.3V, but to meet specification when powered at 1.8V, the pad input thresholds must be adjusted by writing a 1 to the pad `VOLTAGE_SELECT` registers. By default the pad input thresholds are valid for an IOVDD voltage between 2.5V and 3.3V. Using a voltage of 1.8V with the default input thresholds is a safe operating mode, though it will result in input thresholds that don't meet specification.

⚠ WARNING

Using IOVDD voltages greater than 1.8V, with the input thresholds set for 1.8V may result in damage to the chip.

Pad input threshold are adjusted on a per bank basis, with separate `VOLTAGE_SELECT` registers for the pads associated with the User IO bank (IO Bank 0) and the QSPI IO bank. However, both banks share the same digital IO supply (IOVDD), so both register should always be set to the same value.

Pad register details are available in [Section 2.18.6.3, "Pad Control - User Bank"](#) and [Section 2.18.6.4, "Pad Control - QSPI Bank"](#).

2.18.5. Software Examples

2.18.5.1. Select an IO function

An IO pin can perform many different functions and must be configured before use. For example, you may want it to be a `UART_TX` pin, or a `PWM` output. The Pico SDK provides `gpio_set_function` for this purpose. Many Pico SDK examples will call `gpio_set_function` at the beginning so that it can print to a UART.

The Pico SDK starts by defining a structure to represent the registers of IO bank 0, the User IO bank. Each IO has a status register, followed by a control register. There are 30 IOs, so the structure containing a status and control register is instantiated as `io[30]` to repeat it 30 times.

Pico SDK: https://github.com/raspberrypi/pico-sdk/tree/pre-release/src/rp2040/hardware_structs/include/hardware/structs/iobank0.h Lines 21 - 30

```
21 typedef struct {
22     struct {
23         io_rw_32 status;
24         io_rw_32 ctrl;
25     } io[30];
26     io_rw_32 intr[4];
27     io_irq_ctrl_hw_t proc0_irq_ctrl;
28     io_irq_ctrl_hw_t proc1_irq_ctrl;
29     io_irq_ctrl_hw_t dormant_wake_irq_ctrl;
30 } iobank0_hw_t;
```

A similar structure is defined for the pad control registers for IO bank 1. By default, all pads come out of reset ready to use, with their input enabled and output disable set to 0. Regardless, `gpio_set_function` in the Pico SDK sets these to make sure the pad is ready to use by the selected function. Finally, the desired function select is written to the IO control register (see `GPIO0_CTRL` for an example of an IO control register).

Pico SDK: https://github.com/raspberrypi/pico-sdk/tree/pre-release/src/rp2_common/hardware_gpio/gpio.c Lines 27 - 40

```
27 // Select function for this GPIO, and ensure input/output are enabled at the pad.
28 // This also clears the input/output/irq override bits.
29 void gpio_set_function(uint gpio, enum gpio_function fn) {
30     invalid_params_if(GPIO, gpio >= N_GPIOES);
31     invalid_params_if(GPIO, fn << IO_BANK0_GPIO0_CTRL_FUNCSEL_LSB &
~IO_BANK0_GPIO0_CTRL_FUNCSEL_BITS);
32     // Set input enable on, output disable off
33     hw_write_masked(&padsbank0_hw->io[gpio],
34                    PADS_BANK0_GPIO0_IE_BITS,
35                    PADS_BANK0_GPIO0_IE_BITS | PADS_BANK0_GPIO0_OD_BITS
36     );
37     // Zero all fields apart from fsel; we want this IO to do what the peripheral tells it.
38     // This doesn't affect e.g. pullup/pulldown, as these are in pad controls.
39     iobank0_hw->io[gpio].ctrl = fn << IO_BANK0_GPIO0_CTRL_FUNCSEL_LSB;
40 }
```

2.18.5.2. Enable a GPIO interrupt

The SDK provides a method of being interrupted when a GPIO pin changes state:

Pico SDK: https://github.com/raspberrypi/pico-sdk/tree/pre-release/src/rp2_common/hardware_gpio/gpio.c Lines 114 - 120

```
114 void gpio_set_irq_enabled(uint gpio, uint32_t events, bool enable) {
115     // Separate mask/force/status per-core, so check which core called, and
116     // set the relevant IRQ controls.
117     io_irq_ctrl_hw_t *irq_ctrl_base = get_core_num() ?
118                                     &iobank0_hw->proc1_irq_ctrl : &iobank0_hw-
>proc0_irq_ctrl;
```

```

119     _gpio_set_irq_enabled(gpio, events, enable, irq_ctrl_base);
120 }

```

`gpio_set_irq_enabled` uses a lower level function `_gpio_set_irq_enabled`:

Pico SDK: https://github.com/raspberrypi/pico-sdk/tree/pre-release/src/rp2_common/hardware_gpio/gpio.c Lines 101 - 112

```

101 void _gpio_set_irq_enabled(uint gpio, uint32_t events, bool enable, io_irq_ctrl_hw_t
    *irq_ctrl_base) {
102     // Clear stale events which might cause immediate spurious handler entry
103     gpio_acknowledge_irq(gpio, events);
104
105     io_rw_32 *en_reg = &irq_ctrl_base->inte[gpio / 8];
106     events <<= 4 * (gpio % 8);
107
108     if (enable)
109         hw_set_bits(en_reg, events);
110     else
111         hw_clear_bits(en_reg, events);
112 }

```

The user provides a pointer to a callback function that is called when the GPIO event happens. An example application that uses this system is `hello_gpio_irq`:

Pico Examples: https://github.com/raspberrypi/pico-examples/tree/pre-release/gpio/hello_gpio_irq/hello_gpio_irq.c Lines 1 - 61

```

2.20. Syscfg

2.20.1. Overview

The system config block controls miscellaneous chip settings including:

- NMI (Non-Maskable-Interrupt) mask to pick sources that generate the NMI
- Processor config
 - DAP Instance ID (to change the address that the SWD uses to communicate with the core in debug)
 - Processor status (If the processor is halted, which may be useful in debug)
- Processor IO config
 - Input synchroniser control (to allow input synchronisers to be bypassed to reduce latency where clocks are synchronous)
- Debug control
 - Provides the ability to control the SWD interface from inside the chip. This means Core 0 could debug Core 1, which may make debug connectivity easier.
- Memory power down (each memory can be powered down if not being used to save a small amount of extra power).

2.20.2. List of registers

Table 348. List of
SYSCFG registers

Offset	Name	Info
0x00	PROC0_NMI_MASK	Processor core 0 NMI source mask

Chapter 3. PIO

3.1. Overview

Figure 36. PIO block-level diagram. There are two PIO blocks with four state machines each. The four state machines simultaneously execute programs from a shared instruction memory. FIFO data queues buffer data transferred between PIO and the system. GPIO mapping logic allows each state machine to observe and manipulate up to 30 GPIOs.

The programmable input/output block (PIO) is a versatile hardware interface. It can support a variety of IO standards, including:

- 8080 and 6800 parallel bus
- I2C
- 3-pin I2S
- SDIO
- SPI, DSPI, QSPI
- UART
- DPI or VGA (via resistor DAC)

PIO is programmable in the same sense as a processor. There are two PIO blocks with four state machines each, that can independently execute sequential programs to manipulate GPIOs and transfer data. Unlike a general purpose processor, PIO state machines are highly specialised for IO, with a focus on determinism, precise timing, and close integration with fixed-function hardware. Each state machine is equipped with:

- Two 32-bit shift registers – either direction, any shift count
- Two 32-bit scratch registers
- 4x32 bit bus FIFO in each direction (TX/RX), reconfigurable as 8x32 in a single direction
- Fractional clock divider (16 integer, 8 fractional bits)
- Flexible GPIO mapping
- DMA interface, sustained throughput up to 1 word per clock from system DMA

- IRQ flag set/clear/status

Each state machine, along with its supporting hardware, occupies approximately the same silicon area as a standard serial interface block, such as an SPI or I2C controller. However, PIO state machines can be configured and reconfigured dynamically to implement numerous different interfaces.

Making state machines programmable in a software-like manner, rather than a fully configurable logic fabric like a CPLD, allows more hardware interfaces to be offered in the same cost and power envelope. This also presents a more familiar programming model, and simpler tool flow, to those who wish to exploit PIO’s full flexibility by programming it directly, rather than using a premade interface from the PIO library.

PIO is highly performant as well as flexible, thanks to a carefully selected set of fixed-function hardware inside each state machine. The DPI examples output 360 Mb/s during the active scanline period when running from a 48 MHz system clock. In this example, one state machine is handling frame/scanline timing and generating the pixel clock, while another is handling the pixel data, and unpacking run-length-encoded scanlines.

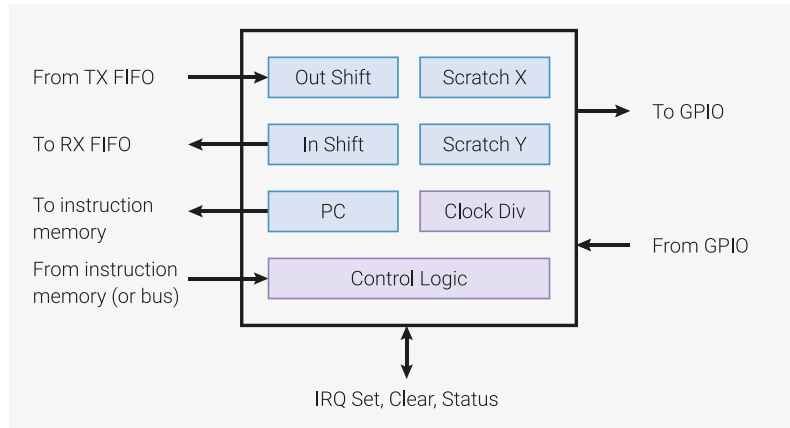

State machines’ inputs and outputs are mapped to up to 32 GPIOs (limited to 30 GPIOs for RP2040), and all state machines have independent, simultaneous access to any GPIO. For example, the standard UART code allows TX, RX, CTS and RTS to be any four arbitrary GPIOs, and I2C permits the same for SDA and SCL. The amount of freedom available depends on how exactly a given PIO program chooses to use PIO’s pin mapping resources, but at the minimum, an interface can be freely shifted up or down by some number of GPIOs.

3.2. Programmer’s Model

The four state machines execute from a shared instruction memory. System software loads programs into this memory, configures the state machines and IO mapping, and then sets the state machines running. PIO programs come from various sources: assembled directly by the user, drawn from the PIO library, or generated programmatically by user software.

From this point on, state machines are generally autonomous, and system software interacts through DMA, interrupts and control registers, as with other peripherals on RP2040. For more complex interfaces, PIO provides a small but flexible set of primitives which allow system software to be more hands-on with state machine control flow.

Figure 37. State machine overview. Data flows in and out through a pair of FIFOs. The state machine executes a program which transfers data between these FIFOs, a set of internal registers, and the pins. The clock divider can reduce the state machine’s execution speed by a constant factor.

3.2.1. PIO Programs

PIO state machines execute short, binary programs.

Programs for common interfaces, such as UART, SPI, or I2C, are available in the PIO library, so in many cases, it is not necessary to write PIO programs. However, the PIO is much more flexible when programmed directly, supporting a wide variety of interfaces which may not have been foreseen by its designers.

The PIO has a total of nine instructions: **JMP**, **WAIT**, **IN**, **OUT**, **PUSH**, **PULL**, **MOV**, **IRQ**, and **SET**. See Section 3.4 for details on these instructions.

Though the PIO only has a total of nine instructions, it would be difficult to edit PIO program binaries by hand. PIO assembly is a textual format, describing a PIO program, where each command corresponds to one instruction in the output binary. Below is an example program in PIO assembly:

```
1 .program squarewave
2 again:
3   set pins, 1 [1] ; Drive pin high and then delay for one cycle
4   set pins, 0     ; Drive pin low
5   jmp again      ; Set PC to label `again`
```

The PIO assembler is included with the Pico SDK, and is called `pioasm`. This program processes a PIO assembly input text file, which may contain multiple programs, and writes out the assembled programs ready for use. For the Pico SDK these assembled programs are emitted in form of C headers, containing constant arrays: For more information see [Section 3.3](#)

3.2.2. Control Flow

On every system clock cycle, each state machine fetches, decodes and executes one instruction. Each instruction takes precisely one cycle, unless it explicitly stalls (such as the `WAIT` instruction). Instructions may also insert a delay of up to 31 cycles before the next instruction is executed to aid the writing of cycle-exact programs.

The program counter, or `PC`, points to the location in the instruction memory being executed on this cycle. Generally, `PC` increments by one each cycle, wrapping at the end of the instruction memory. Jump instructions are an exception and explicitly provide the next value that `PC` will take.

```
1 .program squarewave
2
3 again:
4   set pins, 1 [1] ; Drive pin high, then delay for one cycle
5   set pins, 0     ; Drive pin low
6   jmp again      ; Set PC to label `again`
```

Our example assembly program shows both of these concepts in practice. It drives a 50/50 duty cycle square wave onto a GPIO, with a period of four cycles. Using some other features (e.g. side-set, [section 3.5.1](#)) this can be made as low as two cycles. The system has write-only access to the instruction memory, which is used to load programs:

```
1 // Load the assembled program into the PIO's instruction memory
2 for (int i = 0; i < count_of(squarewave_program_instructions); ++i)
3   pio->instr_mem[i] = squarewave_program_instructions[i];
```

The clock divider slows the state machine's execution by a constant factor, represented as a 16.8 fixed-point fractional number. Using the above example, if a clock division of `2.5` were programmed, the square wave would have a period of $4 \times 2.5 = 10$ cycles. This is useful for setting a precise baud rate for a serial interface, such as a UART.

```
1 // Configure state machine 0 to run at sysclk / 2.5
2 pio->sm[0].clkdiv = (int)(2.5f * 256);
```

The system can start and stop each state machine at any time, via the CTRL register. Multiple state machines can be started simultaneously, and the deterministic nature of PIO means they can stay perfectly synchronised.

```

1 // Set the state machine running
2 hw_set_bits(&pio->ctrl, 1 << (PIO_CTRL_SM_ENABLE_LSB + 0));

```

The above code fragments are part of a complete application which drives a 12 MHz square wave out of GPIO 0. **TO DO: LIAM/GRAHAM: link to SDK**

Most instructions are executed from the instruction memory, but there are other sources, which can be freely mixed:

- Instructions written to a special configuration register (**SMx INSTR**) are immediately executed, momentarily interrupting other execution. For example, a **JMP** instruction written to **SMx INSTR** will cause the state machine to start executing from a different location.
- Instructions can be executed from a register, using the **MOV EXEC** instruction.
- Instructions can be executed from the output shifter, using the **OUT EXEC** instruction

The last of these is particularly versatile: instructions can be embedded in the stream of data passing through the FIFO. The I2C example uses this to embed e.g. **STOP** and **RESTART** line conditions alongside normal data. In the case of **MOV** and **OUT EXEC**, the **MOV/OUT** itself executes in one cycle, and the executee on the next.

3.2.3. Registers

Each state machine possesses a small number of internal registers. These hold input or output data, and temporary values such as loop counter variables.

3.2.3.1. Output Shift Register (OSR)

Figure 38. Output Shift Register (OSR). Data is parcelled out 1...32 bits at a time, and unused data is recycled by a bidirectional shifter. Once empty, the OSR is reloaded from the TX FIFO.

The Output Shift Register (OSR) holds and shifts output data, between the TX FIFO and the pins (or other destinations, such as the scratch registers).

- **PULL** instructions pop a 32-bit word from the TX FIFO into the OSR.
- **OUT** instructions shift data from the OSR to other destinations, 1...32 bits at a time.
- The OSR fills with zeroes as data is shifted out
- The state machine will automatically refill the OSR from the FIFO on an **OUT** instruction, once some total shift count threshold is reached, if autopull is enabled
- Shift direction can be left/right, configurable by the processor via configuration registers

For example, to stream data through the FIFO and output to the pins at a rate of one byte per two clocks:

```

1 .program pull_example1
2 loop:
3   out pins, 8
4 .extern entry_point
5   pull
6   out pins, 8 [1]
7   out pins, 8 [1]
8   out pins, 8
9   jmp loop

```

Autopull (see [Section 3.5.4](#)) allows the hardware to automatically refill the OSR in the majority of cases, with the state machine stalling if it tries to **OUT** from an empty OSR. This has two benefits:

- No instructions spent on explicitly pulling from FIFO at the right time
- Higher throughput: can output up to 32 bits on every single clock cycle, if the FIFO stays topped up

After configuring autopull, the above program can be simplified to the following, which behaves identically:

```
1 .program pull_example2
2
3 loop:
4   out pins, 8
5 .extern entry_point
6   jmp loop
```

Program wrapping (section [Section 3.5.2](#)) allows further simplification and, if desired, an output of 1 byte every system clock cycle.

```
1 .program pull_example3
2
3 .extern entry_point
4 .wrap_target
5   out pins, 8 [1]
6 .wrap
```

3.2.3.2. Input Shift Register (ISR)

Figure 39. Input Shift Register (ISR). Data enters 1...32 bits at a time, and current contents is shifted left or right to make room. Once full, contents is written to the RX FIFO.

- **IN** instructions shift 1...32 bits at a time into the register.
- **PUSH** instructions write the ISR contents to the RX FIFO.
- The ISR is cleared to all-zeroes when pushed.
- The state machine will automatically push the ISR on an **IN** instruction, once some shift threshold is reached, if autopush is enabled.
- Shift direction is configurable by the processor via configuration registers

Some peripherals, like UARTs, must shift in from the left to get correct bit order, since the wire order is LSB-first; however, the processor may expect the resulting byte to be right-aligned. This is solved by the special **null** input source, which allows the programmer to shift some number of zeroes into the ISR, following the data.

3.2.3.3. Shift Counters

State machines remember how many bits, in total, have been shifted out of the OSR via **OUT** instructions, and into the **ISR** via **IN** instructions. This information is tracked at all times by a pair of hardware counters, capable of holding values from 0 to 32 inclusive (the width of a shift register). The state machine can be configured to perform certain actions when the **IN** or **OUT** count reaches a configurable threshold:

- The OSR can be automatically refilled once some number of bits have been shifted out. See [Section 3.5.4](#)

- The ISR can be automatically emptied once some number of bits have been shifted in. See [Section 3.5.4](#)
- **PUSH** or **PULL** instructions can be conditioned on the input or output shift counter, respectively

On PIO reset, or the assertion of **CTRL_SM_RESTART**, the ISR shift counter is cleared to 0 (nothing yet shifted in), and the OSR shift counter is initialised to 32 (nothing remaining to be shifted out). Some other instructions affect the shift counters:

- **PULL** clears the output shift counter
- **PUSH** clears the input shift counter
- **MOV OSR, x** clears the output shift counter
- **MOV ISR, x** clears the input shift counter
- **OUT ISR, count** sets the input shift counter to **count**

3.2.3.4. Scratch Registers

Each state machine has two 32-bit internal scratch registers, called **X** and **Y**.

They are used as:

- Source/destination for **IN/OUT/SET/MOV**
- Source for branch conditions

For example, suppose we wanted to produce a long pulse for "1" data bits, and a short pulse for "0" data bits:

```

1 .program ws2812_led
2
3 .extern entry_point
4     pull
5     set x, 23        ; Loop over 24 bits
6 bitloop:
7     set pins, 1     ; Drive pin high
8     out y, 1 [5]    ; Shift 1 bit out, and write it to y
9     jmp !y skip     ; Skip the extra delay if the bit was 0
10    nop [5]
11 skip:
12    set pins, 0 [5]
13    jmp x-- bitloop ; Jump if x nonzero, and decrement x
14    jmp entry_point

```

Here **X** is used as a loop counter, and **Y** is used as a temporary variable for branching on single bits from the OSR. This program can be used to drive a WS2812 LED interface, although more compact implementations are possible (as few as 3 instructions).

MOV allows the use of the scratch registers to save/restore the shift registers if, for example, you would like to repeatedly shift out the same sequence.

3.2.3.5. FIFOs

Each state machine has a pair of 4-word deep FIFOs, one for data transfer from system to state machine (TX), and the other for state machine to system (RX). The TX FIFO is written to by system busmasters, such as a processor or DMA controller, and the RX FIFO is written to by the state machine. FIFOs decouple the timing of the PIO state machines and the system bus, allowing state machines to go for longer periods without processor intervention.

FIFOs also generate data request (DREQ) signals, which allow a system DMA controller to pace its reads/writes based on the presence of data in an RX FIFO, or space for new data in a TX FIFO. This allows a processor to set up a long transaction, potentially involving many kilobytes of data, which will proceed with no further processor intervention.

Often, a state machine is only transferring data in one direction. In this case the `SHIFTCTRL_FJOIN` option can merge the two FIFOs into a single 8-entry FIFO going in one direction only. This is useful for high-bandwidth interfaces such as DPI.

3.2.4. Stalling

State machines may momentarily pause execution for a number of reasons:

- A `WAIT` instruction's condition is not yet met
- A blocking `PULL` when the TX FIFO is empty, or a blocking `PUSH` when the RX FIFO is full
- An `IRQ WAIT` instruction which has set an IRQ flag, and is waiting for it to clear
- An `OUT` instruction when autopull is enabled, OSR has reached its shift threshold, and the TX FIFO is empty
- An `IN` instruction when autopush is enabled, ISR reaches its shift threshold, and the RX FIFO is full

In this case, the program counter does not advance, and the state machine will continue executing this instruction on the next cycle. If the instruction specifies some number of delay cycles before the next instruction starts, these do not begin until **after** the stall clears.

i NOTE

Side-set ([Section 3.5.1](#)) is not affected by stalls, and always takes place on the first cycle of the attached instruction.

3.2.5. Pin Mapping

PIO controls the output level and direction of up to 32 GPIOs, and can observe their input levels. On every system clock cycle, each state machine may do none, one, or both of the following:

- Change the level or direction of some GPIOs via an `OUT` or `SET` instruction, or read some GPIOs via an `IN` instruction
- Change the level or direction of some GPIOs via a side-set operation

Each of these operations is on some contiguous range of GPIOs, with the base and count configured via each state machine's `PINCTRL` register. `OUT`, `SET`, `IN` and side-set have their own independent mappings, which are allowed to overlap.

For each individual GPIO output (level and direction separately), PIO considers all 8 writes that may have occurred on that cycle, and applies the write from the highest-numbered state machine. If the same state machine performs a `SET/OUT` and a side-set on the same GPIO simultaneously, the side-set is used. If no state machine writes to this GPIO output, its value does not change from the previous cycle.

Generally each state machine's outputs are mapped to a distinct group of GPIOs, implementing some peripheral interface.

3.2.6. IRQ Flags

IRQ flags are state bits which can be set or cleared by state machines or the system. There are 8 in total: all 8 are visible to all state machines, and the lower 4 can also be masked into one of PIO's interrupt request lines, via the `IRQ0_INTE` and `IRQ1_INTE` control registers.

They have two main uses:

- Asserting system level interrupts from a state machine program, and optionally waiting for the interrupt to be acknowledged
- Synchronising execution between two state machines

State machines interact with the flags via the `IRQ` and `WAIT` instructions.

3.2.7. Interactions Between State Machines

The instruction memory is implemented as a 1-write 4-read register file, so all four state machines can read an instruction on the same cycle, without stalling.

There are three ways to apply the multiple state machines:

- Pointing multiple state machines at the same program
- Pointing multiple state machines at different programs
- Using multiple state machines to run different parts of the same interface, e.g. TX and RX side of a UART, or clock/hsync and pixel data on a DPI display

State machines can not communicate data, but they can synchronise with one another by using the IRQ flags. There are 8 flags total (the lower four of which can be masked for use as system IRQs), and each state machine can set or clear any flag using the `IRQ` instruction, and can wait for a flag to go high or low using the `WAIT IRQ` instruction. This allows cycle-accurate synchronisation between state machines.

3.3. PIO Assembler (pioasm)

The PIO Assembler parses a PIO source file and outputs the assembled version ready for inclusion in a program.

pioasm currently supports output for the Pico SDK and MicroPython. See [Section 3.3.9](#) for more details on the different output generators.

3.3.1. Usage

A description of the command line arguments can be obtained by running:

```
pioasm -?
```

giving:

```
usage: pioasm <options> <input> (<output>)

Assemble file of PIO program(s) for use in applications.
<input>           the input filename
<output>         the output filename (or filename prefix if the output
                  format produces multiple outputs).
                  if not specified, a single output will be written to stdout

options:
-o <output_format>  select output_format (default 'c-sdk'); available options are:
                    c-sdk
                    C header suitable for use with the Pico SDK
                    python
                    Python file suitable for use with MicroPython
                    hex
                    Raw hex output (only valid for single program inputs)
-p <output_param>  add a parameter to be passed to the outputter
-?, --help         print this help and exit
```

i NOTE

Within the Pico SDK you do not need to invoke pioasm directly, as the CMake function `pico_generate_pio_header(TARGET PIO_FILE)` takes care of invoking pioasm and adding the generated header to the include path of the target TARGET for you.

3.3.2. Directives

The following directives control the assembly of PIO programs:

Table 356. pioasm directives

<code>.define (PUBLIC) <symbol> <value></code>	Define an integer symbol named <symbol> with the value <value> (see Section 3.3.3). If this <code>.define</code> appears before the first program in the input file, then the define is global to all programs, otherwise it is local to the program in which it occurs. If <code>PUBLIC</code> is specified the symbol will be emitted into the assembled output for use by user code. For the Pico SDK this takes the form of: <code>#define <program_name>_<symbol> value</code> for program symbols or <code>#define <symbol> value</code> for global symbols
<code>.program <name></code>	Start a new program with the name <name>. Note that that name is used in code so should be alphanumeric/underscore not starting with a digit. The program lasts until another <code>.program</code> directive or the end of the source file. PIO instructions are only allowed within a program
<code>.origin <offset></code>	Optional directive to specify the PIO instruction memory offset at which the program <i>must</i> load. Most commonly this is used for programs that must load at offset 0, because they use data based JMPs with the (absolute) jmp target being stored in only a few bits. This directive is invalid outside of a program
<code>.side_set <count> (opt) (pindirs)</code>	If this directive is present, <count> indicates the number of side set bits to be used. Additionally <code>opt</code> may be specified to indicate that a <code>side <value></code> is optional for instructions (not using this requires stealing an extra bit - in addition to the <count> bits - from those available for the instruction delay). Finally, <code>pindirs</code> may be specified to indicate that the side set values should be applied to the PINDIRs and not the PINs. This directive is only valid within a program before the first instruction
<code>.wrap_target</code>	Place prior to an instruction, this directive specifies the instruction where execution continues due to program wrapping. This directive is invalid outside of a program, may only be used once within a program, and if not specified defaults to the start of the program
<code>.wrap</code>	Placed after an instruction, this directive specifies the instruction after which, in normal control flow, the program wraps (to <code>.wrap_target</code> instruction). This directive is invalid outside of a program, may only be used once within a program, and if not specified defaults to after the last program instruction.
<code>.lang_opt <lang> <name> <option></code>	Specifies an option for the program related to a particular language generator. (See Section 3.3.9). This directive is invalid outside of a program
<code>.word <value></code>	Stores a raw 16 bit value as an instruction in the program. This directive is invalid outside of a program.

3.3.3. Values

The following types of values can be used to define integer numbers or branch targets

Table 357. Values in pioasm, i.e. <value>

<i>integer</i>	An integer value e.g. 3 or -7
<i>hex</i>	A hexadecimal value e.g. 0xf
<i>binary</i>	A binary value e.g. 0b1001
<i>symbol</i>	A value defined by a .define (see [pioasm_define])
<label>	The instruction offset of the label within the program. This makes most sense when used with a JMP instruction (see Section 3.4.2)
(<expression>)	An expression to be evaluated; see expressions. Note that the parentheses are necessary.

3.3.4. Expressions

Expressions may be freely (boldly?) used within pioasm values.

Table 358. Expressions in pioasm i.e. <expression>

<expression> + <expression>	The sum of two expressions
<expression> - <expression>	The difference of two expressions
<expression> * <expression>	The multiplication of two expressions
<expression> / <expression>	The integer division of two expressions
- <expression>	The negation of another expression
:: <expression>	The bit reverse of another expression
<value>	Any value (see Section 3.3.3)

3.3.5. Comments

Line comments are supported with **//** or **;**

C-style block comments are supported via **/*** and ***/**

3.3.6. Labels

Labels are of the form:

<symbol>:

or

PUBLIC <symbol>:

at the start of a line.

TIP

A label is really just an automatic **.define** with a value set to the current program instruction offset. A **PUBLIC** label is exposed to the user code in the same way as a **PUBLIC .define**.

3.3.7. Instructions

All pioasm instructions follow a common pattern:

`<instruction> (side <side_set_value>) ([<delay_value>])`

where:

<code><instruction></code>	Is an assembly instruction detailed in the following sections. (See Section 3.4)
<code><side_set_value></code>	Is a value (see Section 3.3.3) to apply to the side_set pins at the start of the instruction. Note that the rules for a side set value via <code>side <side_set_value></code> are dependent on the <code>.side_set</code> (see [pioasm_side_set]) directive for the program. If no <code>.side_set</code> is specified then the <code>side <side_set_value></code> is invalid, if an optional number of sideset pins is specified then <code>side <side_set_value></code> may be present, and if a non-optional number of sideset pins is specified, then <code>side <side_set_value></code> is required. The <code><side_set_value></code> must fit within the number of side set bits specified in the <code>.side_set</code> directive.
<code><delay_value></code>	Specifies the number of cycles to delay after the instruction completes. The <code>delay_value</code> is specified as a value (see Section 3.3.3), and in general is between 0 and 31 inclusive (a 5 bit value), however the number of bits is reduced when sideset is enabled via the <code>.side_set</code> (see [pioasm_side_set]) directive. If the <code><delay_value></code> is not present, then the instruction has no delay

i NOTE

pioasm instruction names, keywords and directives are case insensitive; lower case is used in the *Assembly Syntax* sections below as this is the style used in the Pico SDK.

i NOTE

Commas appear in some *Assembly Syntax* sections below, but are entirely optional, e.g. `out pins, 3` may be written `out pins 3`, and `jmp x-- label` may be written as `jmp x--, label`. The *Assembly Syntax* sections below uses the first style in each case as this is the style used in the Pico SDK.

3.3.8. Output pass through

Text in the PIO file may be passed, unmodified, to the output based on the language generator being used.

For example the following (comment and function) would be included in the generated header when the default `c-sdk` language generator is used.

```
% c-sdk {

// an inline function (since this is going in a header file)
static inline int some_c_code() {
    return 0;
}
%}
```

The general format is

```
% target {
pass thru contents
%}
```

with `targets` being recognized by a particular language generator (see [Section 3.3.9](#); note that `target` is usually the language generator name e.g. `c-sdk`, but could potentially be `some_language.some_group` if the language generator supports different classes of pass thru with different output locations.

This facility allows you to encapsulate both the PIO program and the associated setup required in the same source file. See [Section 3.3.9](#) for a more complete example.

3.3.9. Language generators

The following example shows a multi program source file (with multiple programs) which we will use to highlight c-sdk and python output features

```

3.3.9.1. c-sdk

The c-sdk language generator produces a single header file with all the programs in the PIO source file:

The pass thru sections (`% c-sdk {`) are embedded in the output, and the `PUBLIC` defines are available via `#define`

TIP

A method is created for each program (e.g. `ws2812_program_get_default_config()`) which sets up a `pio_sm_config` based on the `.side_set`, `.wrap` and `.wrap_target` settings of the program, which you can then use as a basis for configuration the PIO state machine.

3.3.9.2. python

The python language generator produces a single python file with all the programs in the PIO source file:

The pass thru sections (% python {) would be embedded in the output, and the PUBLIC defines are available as python variables.

Also note the use of .lang_opt python to pass initializers for the @pico.asm_pio decorator

 TIP

The python language output is provided as a utility. MicroPython supports programming with the PIO natively, so you may only want to use pioasm when sharing PIO code between the Pico SDK and MicroPython. No effort is currently made to preserve label names, symbols or comments, as it is assumed you are either using the PIO file as a source or python; not both. The python language output can of course be used to bootstrap your MicroPython PIO development based on an existing PIO file.

Pico Examples: https://github.com/raspberrypi/pico-examples/tree/pre_release/pio/ws2812/generated/ws2812.py Lines 1 - 45

3.4. Instruction Set

3.4.1. Summary

PIO instructions are 16 bits long, and have the following encoding:

Table 359. PIO instruction encoding

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
JMP	0	0	0	Delay/side-set			Condition			Address						
WAIT	0	0	1	Delay/side-set			Pol	Source		Index						
IN	0	1	0	Delay/side-set			Source			Bit count						
OUT	0	1	1	Delay/side-set			Destination			Bit count						
PUSH	1	0	0	Delay/side-set			0	IfF	Blk	0	0	0	0	0	0	0
PULL	1	0	0	Delay/side-set			1	IfE	Blk	0	0	0	0	0	0	0
MOV	1	0	1	Delay/side-set			Destination			Op		Source				
IRQ	1	1	0	Delay/side-set			0	Clr	Wait	Index						
SET	1	1	1	Delay/side-set			Destination			Data						

All PIO instructions execute in one clock cycle.

The **Delay/side-set** field is present in all instructions. Its exact use is configured for each state machine by **PINCTRL_SIDESET_COUNT**:

- Up to 5 MSBs encode a side-set operation (section [Section 3.5.1](#)), which optionally asserts a constant value onto some GPIOs, concurrently with main instruction execution logic
- Remaining LSBs (up to 5) encode the number of idle cycles inserted between this instruction and the next

3.4.2. JMP

3.4.2.1. Encoding

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
JMP	0	0	0	Delay/side-set				Condition			Address					

3.4.2.2. Operation

Set program counter to **Address** if **Condition** is true, otherwise no operation.

Delay cycles on a **JMP** always take effect, whether **Condition** is true or false, and they take place *after* **Condition** is evaluated and the program counter is updated.

- Condition:
 - 000: *(no condition)*: Always
 - 001: **!X**: scratch X zero
 - 010: **X--**: scratch X non-zero, post-decrement
 - 011: **!Y**: scratch Y zero
 - 100: **Y--**: scratch Y non-zero, post-decrement
 - 101: **X!=Y**: scratch X not equal scratch Y
 - 110: **PIN**: branch on input pin
 - 111: **!OSRE**: output shift register not empty
- Address: Instruction address to jump to. In the instruction encoding this is an absolute address within the PIO instruction memory.

JMP PIN branches on the GPIO selected by **EXECCTRL_JMP_PIN**. The branch is taken if the GPIO is high.

!OSRE compares the bits shifted out since the last **PULL** with the shift count threshold configured by **SHIFTCTRL_PULL_THRESH**. This is the same threshold used by autopull (section [Section 3.5.4](#)).

3.4.2.3. Assembler Syntax

```
jmp (<cond>) <target>
```

where:

<cond> Is an optional condition listed above (e.g. **!x** for scratch X zero). If a condition code is not specified, the branch is always taken

<target> Is a program label or value (see [Section 3.3.3](#)) representing instruction offset within the program (the first instruction being offset 0). Note that because the PIO JMP instruction uses absolute addresses in the PIO instruction memory, Jumps need to be adjusted based on the program load offset at runtime. This is handled for you when loading a program with the Pico SDK, but care should be taken when encoding JMP instructions for use by **OUT EXEC**

3.4.3. WAIT

3.4.3.1. Encoding

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
WAIT	0	0	1	Delay/side-set				Pol	Source		Index					

3.4.3.2. Operation

Stall until some condition is met.

Like all stalling instructions ([Section 3.2.4](#)), delay cycles begin after the instruction *completes*. That is, if any delay cycles are present, they do not begin counting until *after* the wait condition is met.

- Polarity:
 - 1: wait for a 1.
 - 0: wait for a 0.
- Source: what to wait on. Values are:
 - 00: **GPIO**: System GPIO input selected by **Index**. This is an absolute GPIO index, and is not affected by the state machine's input IO mapping.
 - 01: **PIN**: Input pin selected by **Index**. This state machine's input IO mapping is applied first, and then **Index** selects which of the mapped bits to wait on.
 - 10: **IRQ**: PIO IRQ flag selected by **Index**
 - 11: Reserved
- Index: which pin or bit to check.

WAIT x IRQ behaves slightly differently from other **WAIT** sources:

- If **Polarity** is 1, the selected IRQ flag is cleared by the state machine upon the wait condition being met.
- The flag index is decoded in the same way as the **IRQ** index field: if the MSB is set, the state machine ID (0...3) is added to the IRQ index, by way of modulo-4 addition on the two LSBs. For example, state machine 2 with a flag value of '0x11' will wait on flag 3, and a flag value of '0x13' will wait on flag 1. This allows multiple state machines running the same program to synchronise with each other.

CAUTION

WAIT 1 IRQ x should not be used with IRQ flags presented to the interrupt controller, to avoid a race condition with a system interrupt handler

3.4.3.3. Assembler Syntax

`wait <polarity> gpio <gpio_num>`

`wait <polarity> pin <pin_num>`

`wait <polarity> irq <irq_num> (rel)`

where:

- `<polarity>` Is a value (see [Section 3.3.3](#)) specifying the polarity (either 0 or 1)
- `<pin_num>` Is a value (see [Section 3.3.3](#)) specifying the input pin number (as mapped by the SM input pin mapping)
- `<gpio_num>` Is a value (see [Section 3.3.3](#)) specifying the actual GPIO pin number
- `<irq_num> (rel)` Is a value (see [Section 3.3.3](#)) specifying The irq number to wait on (0-7). If `rel` is present, then the actual irq number used is calculating by replacing the low two bits of the irq number (irq_num_{10}) with the low two bits of the sum ($irq_num_{10} + sm_num_{10}$) where sm_num_{10} is the state machine number

3.4.4. IN

3.4.4.1. Encoding

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
IN	0	1	0	Delay/side-set				Source			Bit count					

3.4.4.2. Operation

Shift **Bit count** bits from **Source** into the Input Shift Register (ISR). Shift direction is configured for each state machine by **SHIFTCTRL_IN_SHIFTDIR**. Additionally, increase the input shift count by **Bit count**, saturating at 32.

- Source:
 - 000: **PINS**
 - 001: **X** (scratch register X)
 - 010: **Y** (scratch register Y)
 - 011: **NULL** (all zeroes)
 - 100: Reserved
 - 101: Reserved
 - 110: **ISR**
 - 111: **OSR**
- Bit count: How many bits to shift into the ISR. 1...32 bits, 32 is encoded as **00000**.

If automatic push is enabled, **IN** will also push the ISR contents to the RX FIFO if the push threshold is reached

(`SHIFTCTRL_PUSH_THRESH`). `IN` still executes in one cycle, whether an automatic push takes place or not. The state machine will stall if the RX FIFO is full when an automatic push occurs. An automatic push clears the ISR contents to all-zeroes, and clears the input shift count. See section [Section 3.5.4](#).

`IN` always uses the least significant `Bit count` bits of the source data. For example, if `PINCTRL_IN_BASE` is set to 5, the instruction `IN 3, PINS` will take the values of pins 5, 6 and 7, and shift these into the ISR. First the ISR is shifted to the left or right to make room for the new input data, then the input data is copied into the gap this leaves. The bit order of the input data is not dependent on the shift direction.

`NULL` can be used for shifting the ISR's contents. For example, UARTs receive the LSB first, so must shift to the right. After 8 `IN PINS, 1` instructions, the input serial data will occupy bits 31..24 of the ISR. An `IN NULL, 24` instruction will shift in 24 zero bits, aligning the input data at ISR bits 7..0. Alternatively, the processor or DMA could perform a byte read from FIFO address + 3, which would take bits 31...24 of the FIFO contents.

3.4.4.3. Assembler Syntax

`in <source>, <bit_count>`

where:

- `<source>` Is one of the sources specified above.
- `<bit_count>` Is a value (see [Section 3.3.3](#)) specifying the number of bits to shift (valid range 1-32)

3.4.5. OUT

3.4.5.1. Encoding

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
OUT	0	1	1	Delay/side-set				Destination			Bit count					

3.4.5.2. Operation

Shift `Bit count` bits out of the Output Shift Register (OSR), and write those bits to `Destination`. Additionally, increase the output shift count by `Bit count`, saturating at 32.

- Destination:
 - 000: `PINS`
 - 001: `X` (scratch register X)
 - 010: `Y` (scratch register Y)
 - 011: `NULL` (discard data)
 - 100: `PINDIRS`
 - 101: `PC`
 - 110: `ISR` (also sets ISR shift counter to `Bit count`)
 - 111: `EXEC` (Execute OSR shift data as instruction)
- Bit count: how many bits to shift out of the OSR. 1..32 bits, 32 is encoded as `00000`.

A 32-bit value is written to `Destination`: the lower `Bit count` bits come from the OSR, and the remainder are zeroes. This value is the least significant `Bit count` bits of the OSR if `SHIFTCTRL_OUT_SHIFTDIR` is to the right, otherwise it is the most significant bits.

PINS and **PINDIRS** use the **OUT** pin mapping, as described in section [Section 3.5.6](#).

If automatic pull is enabled, the OSR is automatically refilled from the TX FIFO if the pull threshold, **SHIFTCTRL_PULL_THRESH**, is reached. The output shift count is simultaneously cleared to 0. In this case, the **OUT** will stall if the TX FIFO is empty, but otherwise still executes in one cycle. The specifics are given in section [Section 3.5.4](#).

OUT EXEC allows instructions to be included inline in the FIFO datastream. The **OUT** itself executes on one cycle, and the instruction from the OSR is executed on the next cycle. There are no restrictions on the types of instructions which can be executed by this mechanism. Delay cycles on the initial **OUT** are ignored, but the executee may insert delay cycles as normal.

OUT PC behaves as an unconditional jump to an address shifted out from the OSR.

3.4.5.3. Assembler Syntax

out <destination>, <bit_count>

where:

<destination> Is one of the destinations specified above.

<bit_count> Is a value (see [Section 3.3.3](#)) specifying the number of bits to shift (valid range 1-32)

3.4.6. PUSH

3.4.6.1. Encoding

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PUSH	1	0	0	Delay/side-set				0	IfF	Blk	0	0	0	0	0	0

3.4.6.2. Operation

Push the contents of the ISR into the RX FIFO, as a single 32-bit word. Clear ISR to all-zeroes.

- **IfFull**: If 1, do nothing unless the total input shift count has reached its threshold, **SHIFTCTRL_PUSH_THRESH** (the same as for autopush; see section [Section 3.5.4](#)).
- **Block**: If 1, stall execution if RX FIFO is full.

PUSH IFFULL helps to make programs more compact, like autopush. It is useful in cases where the **IN** would stall at an inappropriate time if autopush were enabled, e.g. if the state machine is asserting some external control signal at this point.

3.4.6.3. Assembler Syntax

push (*iffull*)

push (*iffull*) block

push (*iffull*) noblock

where:

iffull Is equivalent to **IfFull == 1** above. i.e. the default if this is not specified is **IfFull == 0**

block Is equivalent to **Block == 1** above. This is the default if neither *block* nor *noblock* are specified

noblock Is equivalent to **Block == 0** above.

3.4.7. PULL

3.4.7.1. Encoding

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PULL	1	0	0	Delay/side-set				1	IfE	Blk	0	0	0	0	0	0

3.4.7.2. Operation

Load a 32-bit word from the TX FIFO into the OSR.

- **IfEmpty**: If 1, do nothing unless the total output shift count has reached its threshold, **SHIFTCTRL_PULL_THRESH** (the same as for autopull; see section [Section 3.5.4](#)).
- **Block**: If 1, stall if TX FIFO is empty. If 0, pulling from an empty FIFO copies scratch X to OSR.

Some peripherals (UART, SPI...) should halt when no data is available, and pick it up as it comes in; others (I2S) should clock continuously, and it is better to output placeholder or repeated data than to stop clocking. This can be achieved with the **Block** parameter.

A nonblocking **PULL** on an empty FIFO has the same effect as **MOV OSR, X**. The program can either preload scratch register X with a suitable default, or execute a **MOV X, OSR** after each **PULL NOBLOCK**, so that the last valid FIFO word will be recycled until new data is available.

PULL IFEMPTY is useful if an **OUT** with autopull would stall in an inappropriate location when the TX FIFO is empty. For example, a UART transmitter should not stall immediately after asserting the start bit. **IfEmpty** permits some of the same program simplifications as autopull, but the stall occurs at a controlled point in the program.

3.4.7.3. Assembler Syntax

pull (ifempty)

pull (ifempty) block

pull (ifempty) noblock

where:

ifempty Is equivalent to **IfEmpty == 1** above. i.e. the default if this is not specified is **IfEmpty == 0**

block Is equivalent to **Block == 1** above. This is the default if neither *block* nor *noblock* are specified

noblock Is equivalent to **Block == 0** above.

3.4.8. MOV

3.4.8.1. Encoding

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MOV	1	0	1	Delay/side-set				Destination			Op		Source			

3.4.8.2. Operation

Copy data from **Source** to **Destination**.

- Destination:
 - 000: **PINS** (Uses same pin mapping as **OUT**)
 - 001: **X** (Scratch register X)
 - 010: **Y** (Scratch register Y)
 - 011: Reserved
 - 100: **EXEC** (Execute data as instruction)
 - 101: **PC**
 - 110: **ISR** (Input shift counter is reset to 0 by this operation, i.e. empty)
 - 111: **OSR** (Output shift counter is reset to 0 by this operation, i.e. full)
- Operation:
 - 00: None
 - 01: Invert (bitwise complement)
 - 10: Bit-reverse
 - 11: Reserved
- Source:
 - 000: **PINS** (Uses same pin mapping as **IN**)
 - 001: **X**
 - 010: **Y**
 - 011: **NULL**
 - 100: Reserved
 - 101: **STATUS**
 - 110: **ISR**
 - 111: **OSR**

MOV PC causes an unconditional jump. **MOV EXEC** has the same behaviour as **OUT EXEC** (section [Section 3.4.5](#)), and allows register contents to be executed as an instruction. The **MOV** itself executes in 1 cycle, and the instruction in **Source** on the next cycle. Delay cycles on **MOV EXEC** are ignored, but the executee may insert delay cycles as normal.

The **STATUS** source has a value of all-ones or all-zeroes, depending on some state machine status such as FIFO full/empty, configured by **EXECCTRL_STATUS_SEL**.

MOV can manipulate the transferred data in limited ways, specified by the **Operation** argument. Invert sets each bit in **Destination** to the logical NOT of the corresponding bit in **Source**, i.e. 1 bits become 0 bits, and vice versa. Bit reverse sets each bit n in **Destination** to bit $31 - n$ in **Source**, assuming the bits are numbered 0 to 31.

3.4.8.3. Assembler Syntax

```
mov <destination>, ( op ) <source>
```

where:

<destination> Is one of the destinations specified above.

<op> If present, is:

- ! or ~ for NOT (Note: this is always a bitwise NOT)
- :: for bit reverse

<source> Is one of the sources specified above.

3.4.9. IRQ

3.4.9.1. Encoding

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
IRQ	1	1	0	Delay/side-set				0	Clr	Wait	Index					

3.4.9.2. Operation

Set or clear the IRQ flag selected by **Index** argument.

- Clear: if 1, clear the flag selected by **Index**, instead of raising it. If **Clear** is set, the **Wait** bit has no effect.
- Wait: if 1, halt until the raised flag is lowered again, e.g. if a system interrupt handler has acknowledged the flag.
- Index:
 - The 3 LSBs specify an IRQ index from 0-7. This IRQ flag will be set/cleared depending on the Clear bit.
 - If the MSB is set, the state machine ID (0...3) is added to the IRQ index, by way of modulo-4 addition on the two LSBs. For example, state machine 2 with a flag value of 0x11 will raise flag 3, and a flag value of 0x13 will raise flag 1.

IRQ flags 4-7 are visible only to the state machines; IRQ flags 0-3 can be routed out to system level interrupts, on either of the PIO's two external interrupt request lines, configured by **IRQ0_INTE** and **IRQ1_INTE**.

The modulo addition bit allows relative addressing of 'IRQ' and 'WAIT' instructions, for synchronising state machines which are running the same program. Bit 2 (the third LSB) is unaffected by this addition.

If **Wait** is set, **Delay** cycles do not begin until after the wait period elapses.

3.4.9.3. Assembler Syntax

irq <irq_num> (_rel)

irq set <irq_num> (_rel)

irq nowait <irq_num> (_rel)

irq wait <irq_num> (_rel)

irq clear <irq_num> (_rel)

where:

<irq_num> (rel) Is a value (see [Section 3.3.3](#)) specifying The irq number to wait on (0-7). If *rel* is present, then the actual irq number used is calculating by replacing the low two bits of the irq number (irq_num_{10}) with the low two bits of the sum ($irq_num_{10} + sm_num_{10}$) where sm_num_{10} is the state machine number

irq Means set the IRQ without waiting

<i>irq set</i>	Also means set the IRQ without waiting
<i>irq nowait</i>	Again, means set the IRQ without waiting
<i>irq wait</i>	Means set the IRQ and wait for it to be cleared before proceeding
<i>irq clear</i>	Means clear the IRQ

3.4.10. SET

3.4.10.1. Encoding

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SET	1	1	1	Delay/side-set					Destination			Data				

3.4.10.2. Operation

Write immediate value **Data** to **Destination**.

- Destination:
- 000: **PINS**
- 001: **X** (scratch register X) 5 LSBs are set to **Data**, all others cleared to 0.
- 010: **Y** (scratch register Y) 5 LSBs are set to **Data**, all others cleared to 0.
- 011: Reserved
- 100: **PINDIRS**
- 101: Reserved
- 110: Reserved
- 111: Reserved
- Data: 5-bit immediate value to drive to pins or register.

This can be used to assert control signals such as a clock or chip select, or to initialise loop counters. As **Data** is 5 bits in size, scratch registers can be **SET** to values from 0-31, which is sufficient for a 32-iteration loop.

The mapping of **SET** and **OUT** onto pins is configured independently. They may be mapped to distinct locations, for example if one pin is to be used as a clock signal, and another for data. They may also be overlapping ranges of pins: a UART transmitter might use **SET** to assert start and stop bits, and **OUT** instructions to shift out FIFO data to the same pins.

3.4.10.3. Assembler Syntax

```
set <destination>, <value>
```

where:

- <destination> Is one of the destinations specified above.
- <value> The value (see [Section 3.3.3](#)) to set (valid range 0-31)

3.5. Functional Details

3.5.1. Side-set

Side-set is a feature that allows state machines to change the level or direction of up to 5 pins, concurrently with the main execution of the instruction.

One example where this is necessary is a fast SPI interface: here a clock transition (toggling 1->0 or 0->1) must be simultaneous with a data transition, where a new data bit is shifted from the OSR to a GPIO. In this case an **OUT** with a side-set would achieve both of these at once.

This makes the timing of the interface more precise, reduces the overall program size (as a separate **SET** instruction is not needed to toggle the clock pin), and also increases the maximum frequency the SPI can run at.

Side-set also makes GPIO mapping much more flexible, as its mapping is independent from **SET**. The example I2C code allows SDA and SCL to be mapped to any two arbitrary pins. Normally, SCL toggles to synchronise data transfer, and SDA contains the data bits being shifted out. However, some particular I2C sequences such as **Start** and **Stop** line conditions, need a fixed pattern to be driven on SDA as well as SCL. The mapping I2C uses to achieve this is:

- Side-set -> SCL
- **OUT** -> SDA
- **SET** -> SDA

This lets the state machine serve the two use cases of data on SDA and clock on SCL, or fixed transitions on both SDA and SCL, while still allowing SDA and SCL to be mapped to any two GPIOs of choice.

The side-set data is encoded in the **Delay/side-set** field of each instruction. Any instruction can be combined with side-set, including instructions which write to the pins, such as **OUT PINS** or **SET PINS**. Side-set's pin mapping is independent from **OUT** and **SET** mappings, though it may overlap. If side-set and an **OUT** or **SET** write to the same pin simultaneously, the side-set data is used.

i NOTE

If an instruction stalls, the side-set still takes effect immediately.

```

1 .program spi_tx_fast
2 .side_set 1
3
4 loop:
5     out pins, 1 side 0
6     jmp loop     side 1

```

The **spi_tx_fast** example shows two benefits of this: data and clock transitions can be more precisely co-aligned, and programs can be made faster overall, with an output of one bit per two system clock cycles in this case. Programs can also be made smaller.

There are four things to configure when using side-set:

1. The number of MSBs of the **Delay/side-set** field to use for side-set rather than delay. This is configured by **PINCTRL_SIDESET_COUNT**. If this is set to 5, delay cycles are not available. If set to 0, no side-set will take place.
2. Whether to use the most significant of these bits as an enable. Side-set takes place on instructions where the enable is high. If there is no enable bit, **every** instruction on that state machine will perform a side-set, if **SIDESET_COUNT** is nonzero. This is configured by **EXECCTRL_SIDE_EN**.
3. The GPIO number to map the least-significant side-set bit to. Configured by **PINCTRL_SIDESET_BASE**.

- Whether side-set writes to GPIO levels or GPIO directions. Configured by `EXECCTRL_SIDE_PINDIR`

In the above example, we have only one side-set data bit, and every instruction performs a side-set, so no enable bit is required. `SIDASET_COUNT` would be 1, `SIDE_EN` would be false. `SIDE_PINDIR` would also be false, as we want to drive the clock high and low, not high- and low-impedance. `SIDASET_BASE` would select the GPIO the clock is driven from.

3.5.2. Program Wrapping

PIO programs often have an "outer loop": they perform the same sequence of steps, repetitively, as they transfer a stream of data between the FIFOs and the outside world. The square wave program from the introduction is a minimal example of this:

```
1 .program squarewave
2 again:
3     set pins, 1 [1] ; Drive pin high and then delay for one cycle
4     set pins, 0     ; Drive pin low
5     jmp again      ; Set PC to label `again`
```

The main body of the program drives a pin high, and then low, producing one period of a square wave. The entire program then loops, driving a periodic output. The jump itself takes one cycle, as does each `set` instruction, so to keep the high and low periods of the same duration, the `set pins, 1` has a single delay cycle added, which makes the state machine idle for one cycle before executing the `set pins, 0` instruction. In total, each loop takes four cycles. There are two frustrations here:

- The `JMP` takes up space in the instruction memory that could be used for other programs
- The extra cycle taken to execute the `JMP` ends up *halving* the maximum output rate

As the Program Counter (`PC`) naturally wraps to 0 when incremented past 31, we could solve the second of these by filling the entire instruction memory with a repeating pattern of `set pins, 1` and `set pins, 0`, but this is wasteful. State machines have a hardware feature, configured via their `EXECCTRL` control register, which solves this common case.

```
1 .program squarewave_wrap
2
3 .wrap_target
4     set pins, 1 [1] ; Drive pin high and then delay for one cycle
5     set pins, 0 [1] ; Drive pin low and then delay for one cycle
6 .wrap
```

After executing an instruction from the program memory, state machines use the following logic to update `PC`:

- If the current instruction is a `JMP`, and the `Condition` is true, set `PC` to the `Target`
- Otherwise, if `PC` matches `EXECCTRL_WRAP_TOP`, set `PC` to `EXECCTRL_WRAP_BOTTOM`
- Otherwise, increment `PC`, or set to 0 if the current value is 31.

The `.wrap_target` and `.wrap` assembly directives are essentially labels. They export constants which can be written to the `WRAP_BOTTOM` and `WRAP_TOP` control fields, respectively:

```
1 // --- squarewave_wrap ---
2
3 static const uint16_t squarewave_wrap_program[] = {
4     0xe101, // 00
5     0xe100, // 01
6 };
7
```

```

8 #define squarewave_wrap_wrap_target 0u
9 #define squarewave_wrap_wrap 1u

```

The `squarewave_wrap` example has delay cycles inserted, so that it behaves identically to the original `squarewave` program. Thanks to program wrapping, these can be removed, so that the output toggles twice as fast, while maintaining an even balance of high and low periods.

```

1 .program squarewave_fast
2
3 .wrap_target
4     set pins, 1      ; Drive pin high
5     set pins, 0      ; Drive pin low
6 .wrap

```

3.5.3. FIFO Joining

By default, each state machine possesses a 4-entry FIFO in each direction: one for data transfer from system to state machine (TX), the other for the reverse direction (RX). However, many applications do not require bidirectional data transfer between the system and an individual state machine, but may benefit from deeper FIFOs: in particular, high-bandwidth interfaces such as DPI. For these cases, `SHIFTCTRL_FJOIN` can merge the two 4-entry FIFOs into a single 8-entry FIFO.

Figure 40. Joinable dual FIFO. A pair of four-entry FIFOs, implemented with four data registers, a 1:4 decoder and a 4:1 multiplexer. Additional multiplexing allows write data and read data to cross between the TX and RX lanes, so that all 8 entries are accessible from both ports

Another example is a UART: because the TX/CTS and RX/RTS parts of a UART are asynchronous, they are implemented on two separate state machines. It would be wasteful to leave half of each state machine's FIFO resources idle. The ability to join the two halves into just a TX FIFO for the TX/CTS state machine, or just an RX FIFO in the case of the RX/RTS state machine, allows full utilisation. A UART equipped with an 8-deep FIFO can be left alone for twice as long between interrupts as one with only a 4-deep FIFO.

The area and power footprint of this whole FIFO arrangement is nearly identical to a single 8-deep FIFO, but this design covers many more use cases.

When one FIFO is increased in size (from 4 to 8), the other FIFO on that state machine is reduced to zero. For example, if joining to TX, the RX FIFO is unavailable, and any `PUSH` instruction will stall. The RX FIFO will appear both `RXFULL` and `RXEMPTY` in the `FSTAT` register. The converse is true if joining to RX: the TX FIFO is unavailable, and the `TXFULL` and `TXEMPTY` bits for this state machine will both be set in `FSTAT`.

8 FIFO entries is sufficient for 1 word per clock through the RP2040 system DMA, provided the DMA is not slowed by contention with other masters.

CAUTION

Changing **FJOIN** discards any data present in the state machine's FIFOs. If this data is irreplaceable, it must be drained beforehand.

3.5.4. Autopush and Autopull

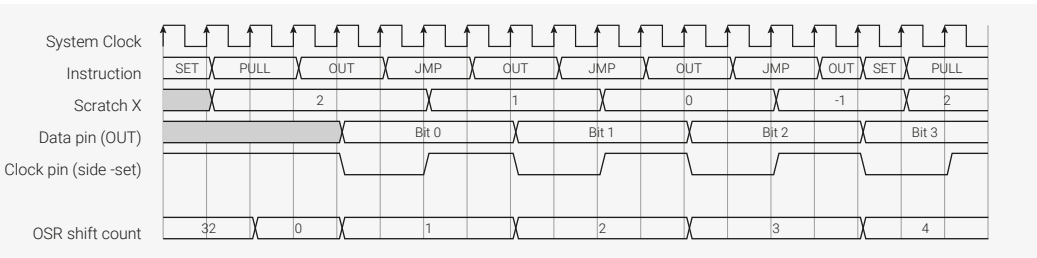

With each **OUT** instruction, the OSR gradually empties, as data is shifted out. Once empty, it must be refilled: for example, a **PULL** transfers one word of data from the TX FIFO to the OSR. Similarly, the ISR must be emptied once full. One approach to this is a loop which performs a **PULL** after an appropriate amount of data has been shifted:

```

1 .program manual_pull
2 .side_set 1 opt
3
4 .wrap_target
5     set x, 2                ; X = bit count - 2
6     pull                    side 1 [1] ; Stall here if no TX data
7 bitloop:
8     out pins, 1            side 0 [1] ; Shift out data bit and toggle clock low
9     jmp x-- bitloop side 1 [1] ; Loop runs 3 times
10    out pins, 1            side 0     ; Shift out last bit before reloading X
11 .wrap
    
```

This program shifts out 4 bits from each FIFO word, with an accompanying bit clock, at a constant rate of 1 bit per 4 cycles. When the TX FIFO is empty, it stalls with the clock high (noting that side-set still takes place on cycles where the instruction stalls). [Figure 41](#) shows how a state machine would execute this program.

Figure 41. Execution of manual_pull program. X is used as a loop counter. On each iteration, one data bit is shifted out, and the clock is asserted low, then high. A delay cycle on each instruction brings the total up to four cycles per iteration. After the third loop, a fourth bit is shifted out, and the state machine immediately returns to the start of the program to reload the loop counter and pull fresh data, while maintaining the 4 cycles/bit cadence.

This program has some limitations:

- It occupies 5 instruction slots, but only 2 of these are immediately useful (**out pins, 1 set 0** and **... set 1**), for outputting serial data and a clock.
- Its throughput is limited to system clock over 4, due to the extra cycles required to pull in new data, and reload the loop counter

This is a common type of problem for PIO, so each state machine has some extra hardware to handle it. State machines keep track of the total shift count **OUT** of the OSR and **IN** to the ISR, and trigger certain actions once these counters reach a programmable threshold.

- On an **OUT** instruction which reaches or exceeds the pull threshold, the state machine can simultaneously refill the OSR from the TX FIFO, if data is available.
- On an **IN** instruction which reaches or exceeds the push threshold, the state machine can write the shift result directly to the RX FIFO, and clear the ISR.

The `manual_pull` example can be rewritten to take advantage of automatic pull (autopull):

```

1 .program autopull
2 .side_set 1
3
4 .wrap_target
5   out pins, 1   side 0   [1]
6   nop          side 1   [1]
7 .wrap

```

This is shorter and simpler than the original, and can run *twice* as fast, if the delay cycles are removed, since the hardware refills the OSR "for free". Note that the program does not determine the total number of bits to be shifted before the next pull; the hardware automatically pulls once the programmable threshold, `SHIFCTRL_PULL_THRESH`, is reached, so the same program could also shift out e.g. 16 or 32 bits from each FIFO word.

Finally, note that the above program is not *exactly* the same as the original, since it stalls with the clock output low, rather than high. We can change the location of the stall, using the `PULL_IFEMPTY` instruction, which uses the same configurable threshold as autopull:

```

1 .program somewhat_manual_pull
2 .side_set 1
3
4 .wrap_target
5   out pins, 1   side 0   [1]
6   pull ifempty side 1   [1]
7 .wrap

```

Below is a complete example (PIO program, plus a C program to load and run it) which illustrates autopull and autopush both enabled on the same state machine. It programs state machine 0 to loopback data from the TX FIFO to the RX FIFO, with a throughput of one word per two clocks. It also demonstrates how the state machine will stall if it tries to `OUT` when both the OSR and TX FIFO are empty.

```

1 .program auto_push_pull
2
3 .wrap_target
4   out x, 32
5   in x, 32
6 .wrap

```

```

1 #include "tb.h" // TODO this is built against existing sw tree, so that we get printf etc
2
3 #include "platform.h"
4 #include "pio_regs.h"
5 #include "system.h"
6 #include "hardware.h"
7
8 #include "auto_push_pull.pio.h"
9
10 int main()
11 {
12     tb_init();
13
14     // Load program and configure state machine 0 for autopush/pull with
15     // threshold of 32, and wrapping on program boundary. A threshold of 32 is
16     // encoded by a register value of 00000.
17     for (int i = 0; i < count_of(auto_push_pull_program); ++i)

```

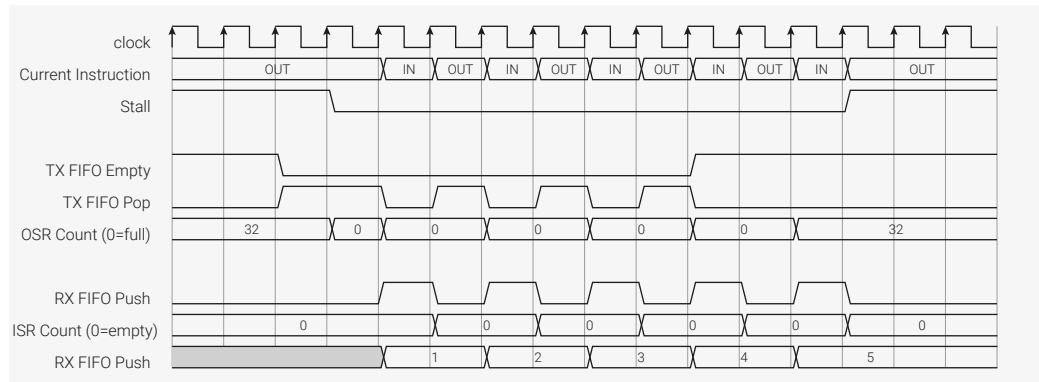

```

18     mm_pio->instr_mem[i] = auto_push_pull_program[i];
19     mm_pio->sm[0].shiftctrl =
20         (1u << PIO_SM0_SHIFTCTRL_AUTOPUSH_LSB) |
21         (1u << PIO_SM0_SHIFTCTRL_AUTOPULL_LSB) |
22         (0u << PIO_SM0_SHIFTCTRL_PUSH_THRESH_LSB) |
23         (0u << PIO_SM0_SHIFTCTRL_PULL_THRESH_LSB);
24     mm_pio->sm[0].execctrl =
25         (auto_push_pull_wrap_target << PIO_SM0_EXECCTRL_WRAP_BOTTOM_LSB) |
26         (auto_push_pull_wrap << PIO_SM0_EXECCTRL_WRAP_TOP_LSB);
27
28     // Start state machine 0
29     hw_set_bits(&mm_pio->ctrl1, 1u << (PIO_CTRL_SM_ENABLE_LSB + 0));
30
31     // Push data into TX FIFO, and pop from RX FIFO
32     for (int i = 0; i < 5; ++i)
33         mm_pio->txf[0] = i;
34     for (int i = 0; i < 5; ++i)
35         printf("%d\n", mm_pio->rx[0]);
36
37     return 0;
38 }

```

Figure 42 shows how the state machine executes the example program. Initially the OSR is empty, so the state machine stalls on the first OUT instruction. Once data is available in the TX FIFO, the state machine transfers this into the OSR. On the next cycle, the OUT can execute using the data in the OSR (in this case, transferring this data to the X scratch register), and the state machine simultaneously refills the OSR with fresh data from the FIFO. Since every IN instruction immediately fills the ISR, the ISR remains empty, and IN transfers data directly from scratch X to the RX FIFO.

Figure 42. Execution of auto_push_pull program. The state machine stalls on an OUT until data has travelled through the TX FIFO into the OSR. Subsequently, the OSR is refilled simultaneously with each OUT operation (due to bit count of 32), and IN data bypasses the ISR and goes straight to the RX FIFO. The state machine stalls again when the FIFO has drained, and the OSR is once again empty.

To trigger automatic push or pull at the correct time, the state machine tracks the total shift count of the ISR and OSR, using a pair of saturating 6 bit counters.

- At reset, or upon **CTRL_SM_RESTART** assertion, ISR shift counter is set to 0 (nothing shifted in), and OSR to 32 (nothing left to be shifted out)
- An **OUT** instruction increases the OSR shift counter by **Bit count**
- An **IN** instruction increases the ISR shift counter by **Bit count**
- A **PULL** instruction or autopull clears the OSR counter to 0
- A **PUSH** instruction or autopush clears the ISR counter to 0
- A **MOV OSR, x** or **MOV ISR, x** clears the OSR or ISR shift counter to 0, respectively
- A **OUT ISR, n** instruction sets the ISR shift counter to **n**

On any **OUT** or **IN** instruction, the state machine compares the shift counters to the values of **SHIFTCTRL_PULL_THRESH** and **SHIFTCTRL_PUSH_THRESH** to decide whether action is required. Autopull and autopush are individually enabled by the **SHIFTCTRL_AUTOPULL** and **SHIFTCTRL_AUTOPUSH** fields.

3.5.4.1. Autopush Details

Pseudocode for an 'IN' with autopush enabled:

```

1 isr = shift_in(isr, input())
2 isr count = saturate(isr count + in count)
3
4 if rx count >= threshold:
5     if rx fifo is full:
6         stall
7     else:
8         push(isr)
9         isr = 0
10        isr count = 0

```

Note that the hardware performs the above steps in a single machine clock cycle (unless there is a stall).

Threshold is configurable from 1 to 32.

3.5.4.2. Autopull Details

On non-'OUT' cycles, the hardware performs the equivalent of the following pseudocode:

```

1 if MOV or PULL:
2     osr count = 0
3
4 if osr count >= threshold:
5     if tx fifo not empty:
6         osr = pull()
7         osr count = 0

```

An autopull can therefore occur at any point between two 'OUT' s, depending on when the data arrives in the FIFO.

On 'OUT' cycles, the sequence is a little different:

```

1 if osr count >= threshold:
2     if tx fifo not empty:
3         osr = pull()
4         osr count = 0
5     stall
6 else:
7     output(osr)
8     osr = shift(osr, out count)
9     osr count = saturate(osr count + out count)
10
11 if osr count >= threshold:
12     if tx fifo not empty:
13         osr = pull()
14         osr count = 0

```

The hardware is capable of refilling the OSR simultaneously with shifting out the last of the shift data, as these two operations can proceed in parallel. However, it cannot fill an empty OSR and 'OUT' it on the same cycle, due to the long logic path this would create.

The refill is somewhat asynchronous to your program, but an 'OUT' behaves as a data fence, and the state machine will never 'OUT' data which you didn't write into the FIFO.

Note that a 'MOV' from the OSR is undefined whilst autopull is enabled; you will read either any residual data that has not been shifted out, or a fresh word from the FIFO, depending on a race against system DMA. Likewise, a 'MOV' to the OSR may overwrite data which has just been autopulled. However, data which you 'MOV' into the OSR will never be overwritten, since 'MOV' updates the shift counter.

If you **do** need to read the OSR contents, you should perform an explicit 'PULL' of some kind. The nondeterminism described above is the cost of the hardware managing pulls automatically. When autopull is enabled, the behaviour of 'PULL' is altered: it becomes a no-op if the OSR is full. This is to avoid a race condition against the system DMA. It behaves as a fence: either an autopull has already taken place, in which case the 'PULL' has no effect, or the program will stall on the 'PULL' until data becomes available in the FIFO.

'PUSH' does not need a similar behaviour, because autopush does not have the same nondeterminism.

3.5.5. Clock Dividers

PIO runs off the system clock, but this is simply too fast for many interfaces, and the number of Delay cycles which can be inserted is limited. Some devices, such as UART, require the signalling rate to be precisely controlled and varied, and ideally multiple state machines can be varied independently while running identical programs. Each state machine is equipped with a clock divider, for this purpose.

Rather than slowing the system clock itself, the clock divider redefines how many system clock periods are considered to be "one cycle", for execution purposes. It does this by generating a clock enable signal, which can pause and resume execution on a per-system-clock-cycle basis. The clock divider generates clock enable pulses at regular intervals, so that the state machine runs at some steady pace, potentially much slower than the system clock.

Implementing the clock dividers in this way allows interfacing between the state machines and the system to be simpler, lower-latency, and with a smaller footprint. The state machine is completely idle on cycles where clock enable is low, though the system can still access the state machine's FIFOs and change its configuration.

The clock dividers are 16-bit integer, 8-bit fractional, with first-order delta-sigma for the fractional divider. The clock divisor can vary between 1 and 65536, in increments of $1 / 256$.

If the clock divisor is set to 1, the state machine runs on every cycle, i.e. full speed:

Figure 43. State machine operation with a clock divisor of 1. Once the state machine is enabled via the CTRL register, its clock enable is asserted on every cycle.

In general, an integer clock divisor of n will cause the state machine to run 1 cycle in every n , giving an effective clock speed of f_{sys} / n .

Figure 44. Integer clock divisors yield a periodic clock enable. The clock divider repeatedly counts down from n , and emits an enable pulse when it reaches 1.

Fractional division will maintain a steady state division rate of $n + f / 256$, where n and f are the integer and fractional fields of this state machine's CLKDIV register. It does this by selectively extending some division periods from n cycles to $n + 1$.

Figure 45. Fractional clock division with an average divisor of 2.5. The clock divider maintains a running total of the fractional value from each division period, and every time this value wraps through 1, the integer divisor is increased by one for the next division period.

For small n , the jitter introduced by a fractional divider may be unacceptable. However, for larger values, this effect is much less apparent.

NOTE

For fast asynchronous serial, it is recommended to use even divisions or multiples of 1 Mbaud where possible, rather than the traditional multiples of 300, to avoid unnecessary jitter.

3.5.6. GPIO Mapping

Internally, PIO has a 32-bit register for the output levels of each GPIO it can drive, and another register for the output enables (Hi/Lo-Z). On every system clock cycle, each state machine can write to some or all of the GPIOs in each of these registers.

Figure 46. The state machine has two independent output channels, one shared by OUT/SET, and another used by side-set (which can happen at any time). Three independent mappings (first GPIO, number of GPIOs) control which GPIOs OUT, SET and side-set are directed to. Input data is rotated according to which GPIO is mapped to the LSB of the IN data.

The write data and write masks for the output level and output enable registers come from the following sources:

- An **OUT** instruction writes to up to 32 bits. Depending on the instruction's **Destination** field, this is applied to either pins or pindirs. The least-significant bit of **OUT** data is mapped to **PINCTRL_OUT_BASE**, and this mapping continues for **PINCTRL_OUT_COUNT** bits, wrapping after GPIO31.
- A **SET** instruction writes up to 5 bits. Depending on the instruction's **Destination** field, this is applied to either pins or pindirs. The least-significant bit of **SET** data is mapped to **PINCTRL_SET_BASE**, and this mapping continues for **PINCTRL_SET_COUNT** bits, wrapping after GPIO31.
- A side-set operation writes up to 5 bits. Depending on the register field **EXECCTRL_SIDE_PINDIR**, this is applied to either pins or pindirs. The least-significant bit of side-set data is mapped to **PINCTRL_SIDESET_BASE**, continuing for **PINCTRL_SIDESET_COUNT** pins, minus one if **EXECCTRL_SIDE_EN** is set.

Each **OUT/SET/side-set** operation writes to a contiguous range of pins, but each of these ranges is independently sized and positioned in the 32-bit GPIO space. This is sufficiently flexible for many applications. For example, if one state machine is implementing some interface such as an SPI on a group of pins, another state machine can run the same program, mapped to a different group of pins, and provide a second SPI interface.

On any given clock cycle, the state machine may perform an **OUT** or a **SET**, and may simultaneously perform a side-set. The pin mapping logic generates a 32-bit write mask and write data bus for the output level and output enable registers, based

on this request, and the pin mapping configuration.

If a side-set overlaps with an **OUT/SET** performed by that state machine on the same cycle, the side-set takes precedence in the overlapping region.

3.5.6.1. Output Priority

Figure 47. Per-GPIO priority select of write masks from each state machine. Each GPIO considers level and direction writes from each of the four state machines, and applies the value from the highest-numbered state machine.

Each state machine may assert an **OUT/SET** and a side-set through its pin mapping hardware on each cycle. This generates 32 bits of write data and write mask for the GPIO output level and output enable registers, from each state machine.

For each GPIO, PIO collates the writes from all four state machines, and applies the write from the highest-numbered state machine. This occurs separately for output levels and output values – it is possible for a state machine to change both the level and direction of the same pin on the same cycle (e.g. via simultaneous **SET** and side-set), or for one state machine to change a GPIO’s direction while another changes that GPIO’s level. If no state machine asserts a write to a GPIO’s level or direction, the value does not change.

3.5.6.2. Input Mapping

The data observed by **IN** instructions is mapped such that the LSB is the GPIO selected by **PINCTRL_IN_BASE**, and successively more-significant bits come from successively higher-numbered GPIOs, wrapping after 31.

In other words, the **IN** bus is a right-rotate of the GPIO input values, by **PINCTRL_IN_BASE**. If fewer than 32 GPIOs are present, the PIO input is padded with zeroes up to 32 bits.

Some instructions, such as **WAIT GPIO**, use an absolute GPIO number, rather than an index into the **IN** data bus. In this case, the right-rotate is not applied.

3.5.6.3. Input Synchronisers

To protect PIO from metastabilities, each GPIO input is equipped with a standard 2-flipflop synchroniser. This adds two cycles of latency to input sampling, but the benefit is that state machines can perform an **IN PINS** at any point, and will see only a clean high or low level, not some intermediate value that could disturb the state machine circuitry. This is absolutely necessary for asynchronous interfaces such as UART RX.

It is possible to bypass these synchronisers, on a per-GPIO basis. This reduces input latency, but it is then up to the user to guarantee that the state machine does not sample its inputs at inappropriate times. Generally this is only possible for synchronous interfaces such as SPI. Synchronisers are bypassed by setting the corresponding bit in **INPUT_SYNC_BYPASS**.

⊖ WARNING

Sampling a metastable input can lead to unpredictable state machine behaviour. This should be avoided.

3.5.7. Forced and EXEC'd Instructions

Besides the instruction memory, state machines can execute instructions from 3 other sources:

- **MOV EXEC** which executes an instruction from some register *Source*
- **OUT EXEC** which executes data shifted out from the OSR
- The **SM_x_INSTR** control registers, to which the system can write instructions for immediate execution

```

1 .program exec_example
2
3 hang:
4     jmp hang
5 execute:
6     out exec, 32
7     jmp execute
8
9 .program instructions_to_push
10
11     out x, 32
12     in x, 32
13     push

```

```

1 #include "tb.h" // TODO this is built against existing sw tree, so that we get printf etc
2
3 #include "platform.h"
4 #include "pio_regs.h"
5 #include "system.h"
6 #include "hardware.h"
7
8 #include "exec_example.pio.h"
9
10 int main()
11 {
12     tb_init();
13
14     for (int i = 0; i < count_of(exec_example_program); ++i)
15         mm_pio->instr_mem[i] = exec_example_program[i];
16
17     // Enable autopull, threshold of 32
18     mm_pio->sm[0].shiftctrl = (1u << PIO_SM0_SHIFTCTRL_AUTOPULL_LSB);
19
20     // Start state machine 0 -- will sit in "hang" loop
21     hw_set_bits(&mm_pio->ctrl1, 1u << (PIO_CTRL_SM_ENABLE_LSB + 0));
22
23     // Force a jump to program location 1
24     mm_pio->sm[0].instr = 0x0000 | 0x1; // jmp execute
25
26     // Feed a mixture of instructions and data into FIFO
27     mm_pio->txf[0] = instructions_to_push_program[0]; // out x, 32
28     mm_pio->txf[0] = 12345678; // data to be OUTed
29     mm_pio->txf[0] = instructions_to_push_program[1]; // in x, 32

```

```

30     mm_pio->txf[0] = instructions_to_push_program[2]; // push
31
32     // The program pushed into TX FIFO will return some data in RX FIFO
33     while (mm_pio->fstat & (1u << PIO_FSTAT_RXEMPTY_LSB))
34         ;
35
36     printf("%d\n", mm_pio->rxr[0]);
37
38     return 0;
39 }

```

Here we load an example program into the state machine, which does two things:

- Enters an infinite loop
- Enters a loop which repeatedly pops 32 bits of data from the TX FIFO, and executes the lower 16 bits as an instruction

The C program sets the state machine running, at which point it enters the **hang** loop. While the state machine is still running, the C program forces in a **jmp** instruction, which causes the state machine to break out of the loop.

When an instruction is written to the **INSTR** register, the state machine immediately decodes and executes that instruction, rather than the instruction it would have fetched from the PIO's instruction memory. The program counter does not advance, so on the next cycle (assuming the instruction forced into the **INSTR** interface did not stall) the state machine continues to execute its current program from the point where it left off, unless the written instruction itself manipulated **PC**.

Delay cycles are ignored on instructions written to the **INSTR** register, and execute immediately, ignoring the state machine clock divider. This interface is provided for performing initial setup and effecting control flow changes, so it executes instructions in a timely manner, no matter how the state machine is configured.

Instructions written to the **INSTR** register are permitted to stall, in which case the state machine will latch this instruction internally until it completes. This is signified by the **EXECCTRL_EXEC_STALLED** flag. This can be cleared by restarting the state machine, or writing a **NOP** to **INSTR**.

In the second phase of the example state machine program, the **OUT EXEC** instruction is used. The **OUT** itself occupies one execution cycle, and the instruction which the **OUT** executes is on the next execution cycle. Note that one of the instructions we execute is also an **OUT** – the state machine is only capable of executing one **OUT** instruction on any given cycle.

OUT EXEC works by writing the **OUT** shift data to an internal instruction latch. On the next cycle, the state machine remembers it must execute from this latch rather than the instruction memory, and also knows to not advance **PC** on this second cycle.

This program will print "12345678" when run.

⚠ CAUTION

If an instruction written to **INSTR** stalls, it is stored in the same instruction latch used by **OUT EXEC** and **MOV EXEC**, and will overwrite an in-progress instruction there. If **EXEC** instructions are used, instructions written to **INSTR** must not stall.

3.6. Examples

3.6.1. Duplex SPI

Figure 48. In SPI, a host and device exchange data over a bidirectional pair of serial data lines, synchronous with a clock (SCK). Two flags, CPOL and CPHA, specify the clock's behaviour. CPOL is the idle state of the clock: 0 for low, 1 for high. The clock pulses a number of times, transferring one bit in each direction per pulse, but always returns to its idle state. CPHA determines on which edge of the clock data is captured: 0 for leading edge, and 1 for trailing edge. The arrows in the figure show the clock edge where data is captured by both the host and device.

SPI is a common serial interface with a twisty history. The following program implements full-duplex (i.e. transferring data in both directions simultaneously) SPI, with a CPHA parameter of 0.

Pico Examples: https://github.com/raspberrypi/pico-examples/tree/pre_release/pio/spi/spi.pio Lines 14 - 32

```

14 .program spi_cpha0
15 .side_set 1
16
17 ; Pin assignments:
18 ; - SCK is side-set pin 0
19 ; - MOSI is OUT pin 0
20 ; - MISO is IN pin 0
21 ;
22 ; Autopush and autopull must be enabled, and the serial frame size is set by
23 ; configuring the push/pull threshold. Shift left/right is fine, but you must
24 ; justify the data yourself. This is done most conveniently for frame sizes of
25 ; 8 or 16 bits by using the narrow store replication and narrow load byte
26 ; picking behaviour of RP2040's IO fabric.
27
28 ; Clock phase = 0: data is captured on the leading edge of each SCK pulse, and
29 ; transitions on the trailing edge, or some time before the first leading edge.
30
31     out pins, 1 side 0 [1] ; Stall here on empty (sideset proceeds even if
32     in pins, 1 side 1 [1] ; instruction stalls, so we stall with SCK low)
    
```

This code uses autopush and autopull to continuously stream data from the FIFOs. The entire program runs once for every bit that is transferred, and then loops. The state machine tracks how many bits have been shifted in/out, and automatically pushes/pops the FIFOs at the correct point. A similar program handles the CPHA=1 case:

Pico Examples: https://github.com/raspberrypi/pico-examples/tree/pre_release/pio/spi/spi.pio Lines 34 - 42

```

34 .program spi_cpha1
35 .side_set 1
36
37 ; Clock phase = 1: data transitions on the leading edge of each SCK pulse, and
38 ; is captured on the trailing edge.
39
40     out x, 1 side 0 ; Stall here on empty (keep SCK deasserted)
41     mov pins, x side 1 [1] ; Output data, assert SCK (mov pins uses OUT mapping)
42     in pins, 1 side 0 ; Input data, deassert SCK
    
```

NOTE

These programs do not control the chip select line; chip select is often implemented as a software-controlled GPIO, due to wildly different behaviour between different SPI hardware. The full `spi.pio` source linked above contains some examples how PIO can implement a hardware chip select line.

A C helper function configures the state machine, connects the GPIOs, and sets the state machine running. Note that the SPI frame size – that is, the number of bits transferred for each FIFO record – can be programmed to any value from 1 to 32, without modifying the program. Once configured, the state machine is set running.

Pico Examples: https://github.com/raspberrypi/pico-examples/tree/pre_release/pio/spi/spi.pio Lines 46 - 72

```

46 static inline void pio_spi_init(PIO pio, uint sm, uint prog_offs, uint n_bits,
47     float clkdiv, bool cpha, bool cpol, uint pin_sck, uint pin_mosi, uint pin_miso) {
48     pio_sm_config c = cpha ? spi_cpha1_program_get_default_config(prog_offs) :
    spi_cpha0_program_get_default_config(prog_offs);
49     sm_config_set_out_pins(&c, pin_mosi, 1);
50     sm_config_set_in_pins(&c, pin_miso);
51     sm_config_set_sideset_pins(&c, pin_sck);
52     // Only support MSB-first in this example code (shift to left, auto push/pull,
    threshold=nbits)
53     sm_config_set_out_shift(&c, false, true, n_bits);
54     sm_config_set_in_shift(&c, false, true, n_bits);
55     sm_config_set_clkdiv(&c, clkdiv);
56
57     // MOSI, SCK output are low, MISO is input
58     pio_sm_set_pins_with_mask(pio, sm, 0, (1u << pin_sck) | (1u << pin_mosi));
59     pio_sm_set_pindirs_with_mask(pio, sm, (1u << pin_sck) | (1u << pin_mosi), (1u <<
    pin_sck) | (1u << pin_mosi) | (1u << pin_miso));
60     pio_gpio_select(pio, pin_mosi);
61     pio_gpio_select(pio, pin_miso);
62     pio_gpio_select(pio, pin_sck);
63
64     // The pin muxes can be configured to invert the output (among other things,
65     // thank you Terry) and this is a cheesy way to get CPOL=1
66     gpio_set_outover(pin_sck, cpol ? GPIO_OVERRIDE_INVERT : GPIO_OVERRIDE_NORMAL);
67     // SPI is synchronous, so bypass input synchroniser to reduce input delay.
68     hw_set_bits(&pio->input_sync_bypass, 1u << pin_miso);
69
70     pio_sm_init(pio, sm, prog_offs, &c);
71     pio_sm_enable(pio, sm, true);
72 }

```

The state machine will now immediately begin to shift out any data appearing in the TX FIFO, and push received data into the RX FIFO.

Pico Examples: https://github.com/raspberrypi/pico-examples/tree/pre_release/pio/spi/pio_spi.c Lines 18 - 34

```

18 void __time_critical_func(pio_spi_write8_blocking)(const pio_spi_inst_t *spi, const uint8_t
    *src, size_t len) {
19     size_t tx_remain = len, rx_remain = len;
20     // Do 8 bit accesses on FIFO, so that write data is byte-replicated. This
21     // gets us the left-justification for free (for MSB-first shift-out)
22     io_rw_8 *txfifo = (io_rw_8 *) &spi->pio->txf[spi->sm];
23     io_rw_8 *rxfifo = (io_rw_8 *) &spi->pio->rxr[spi->sm];
24     while (tx_remain || rx_remain) {
25         if (tx_remain && !pio_sm_is_tx_full(spi->pio, spi->sm)) {
26             *txfifo = *src++;
27             --tx_remain;

```

```

28     }
29     if (rx_remain && !pio_sm_is_rx_empty(spi->pio, spi->sm)) {
30         (void) *rxfifo;
31         --rx_remain;
32     }
33 }
34 }

```

Putting this all together, this complete C program will loop back some data through a PIO SPI at 1 MHz, with all four CPOL/CPHA combinations:

Pico Examples: https://github.com/raspberrypi/pico-examples/tree/pre_release/pio/spi/spi_loopback.c Lines 1 - 77

71                      PIN_MISO
72          );
73          test(&spi);
74          sleep_ms(10);
75      }
76  }
77 }

```

3.6.2. WS2812 LEDs

WS2812 LEDs are driven by a proprietary pulse-width serial format, with a wide positive pulse representing a "1" bit, and narrow positive pulse a "0". Each LED has a serial input and a serial output; LEDs are connected in a chain, with each serial input connected to the previous LED's serial output.

Figure 49. WS2812 line format. Wide positive pulse for 1, narrow positive pulse for 0, very long negative pulse for latch enable

LEDs consume 24 bits of pixel data, then pass any additional input data on to their output. In this way a single serial burst can individually program the colour of each LED in a chain. A long negative pulse latches the pixel data into the LEDs.

[TODO link to examples](#)

```

1  .program ws2812
2  .side_set 1
3
4  .wrap_target
5  bitloop:
6      out x, 1      [3] set 0 ; Side-set still takes place when instruction stalls
7      jmp !x do_zero [2] set 1 ; Branch on the bit we shifted out. Positive pulse
8  do_one:
9      jmp bitloop  [3] set 1 ; Continue driving high, for a long pulse
10 do_zero:
11     nop          [3] set 0 ; Or drive low, for a short pulse
12 .wrap

```

This program shifts bits from the OSR into X, and produces a wide or narrow pulse on side-set pin 0, based on the value of

each data bit. Autopull must be configured, with a threshold of 24. Software can then write 24-bit pixel values into the FIFO, and these will be serialised to a chain of WS2812 LEDs.

```

99 }

```

A C program configures the state machine to execute this program correctly, and sends some test patterns to a string of 150 LEDs. This program transmits on GPIO 0, but any pin can be selected, by changing the constant `PIN_TX`.

The state machine's clock divider is configured to slow execution to around 10 MIPS. If system clock speed is 120 MHz, this is a clock divisor of 12.

Note it is possible to make this program as short as 3 instructions, at the cost of making transmission time dependent on data content:

```

1 .program ws2812_mini
2 .side_set 1
3
4 .wrap_target
5 bitloop:
6     out x, 1          [5] set 0
7     jmp !x bitloop [2] set 1
8     nop              [3] set 1
9 .wrap

```

3.6.3. UART TX

Figure 50. UART serial format. The line is high when idle. The transmitter pulls the line down for one bit period to signify the start of a serial frame (the "start bit"), and a small, fixed number of data bits follows. The line returns to the idle state for at least one bit period (the "stop bit") before the next serial frame can begin.

This program implements the transmit component of a universal asynchronous receive/transmit (UART) serial peripheral. Perhaps it would be more correct to refer to this as a UAT.

Pico Examples: https://github.com/raspberrypi/pico-examples/tree/pre_release/pio/uart_tx/uart_tx.pio Lines 7 - 17

```

7 .program uart_tx
8 .side_set 1 opt
9
10 ; An 8n1 UART transmit program.
11 ; OUT pin 0 and side-set pin 0 are both mapped to UART TX pin.
12
13     pull        side 1 [7] ; Assert stop bit, or stall with line in idle state
14     set x, 7    side 0 [7] ; Preload bit counter, assert start bit for 8 clocks
15 bitloop:
16     out pins, 1          ; Shift 1 bit from OSR to the first OUT pin
17     jmp x-- bitloop    [6] ; Each loop iteration is 8 cycles.
```

As written, it will:

- Stall with the pin driven high until data appears (noting that side-set takes effect even when the state machine is stalled)
- Assert a start bit, for 8 SM execution cycles
- Shift out 8 data bits, each lasting for 8 cycles
- Return to the idle line state for at least 8 cycles before asserting the next start bit

If the state machine's clock divider is configured to run at 8 times the desired baud rate, this program will transmit well-formed UART serial frames, whenever data is pushed to the TX FIFO either by software or the system DMA. To extend the program to cover different frame sizes (different numbers of data bits), the `set x, 7` could be replaced with `mov x, y`, so that the `y` scratch register becomes a per-SM configuration register for UART frame size.

The `.pio` file in the SDK also contains this function, for configuring the pins and the state machine, once the program has been loaded into the PIO instruction memory:

Pico Examples: https://github.com/raspberrypi/pico-examples/tree/pre_release/pio/uart_tx/uart_tx.pio Lines 23 - 50

```

23 static inline void uart_tx_program_init(PIO pio, uint sm, uint offset, uint pin_tx, uint
    baud) {
24     // Tell PIO to initially drive output-high on the selected pin, then map PIO
25     // onto that pin with the IO muxes.
26     pio_sm_set_pins_with_mask(pio, sm, 1u << pin_tx, 1u << pin_tx);
27     pio_sm_set_pindirs_with_mask(pio, sm, 1u << pin_tx, 1u << pin_tx);
28     pio_gpio_select(pio, pin_tx);
29
30     pio_sm_config c = uart_tx_program_get_default_config(offset);
31
32     // OUT shifts to right, no autopull
33     sm_config_set_out_shift(&c, true, false, 32);
34
35     // We are mapping both OUT and side-set to the same pin, because sometimes
36     // we need to assert user data onto the pin (with OUT) and sometimes
37     // assert constant values (start/stop bit)
38     sm_config_set_out_pins(&c, pin_tx, 1);
```

```

39     sm_config_set_sideset_pins(&c, pin_tx);
40
41     // We only need TX, so get an 8-deep FIFO!
42     sm_config_set_fifo_join(&c, PIO_FIFO_JOIN_TX);
43
44     // SM transmits 1 bit per 8 execution cycles.
45     float div = (float)clock_get_hz(clk_sys) / (8 * baud);
46     sm_config_set_clkdiv(&c, div);
47
48     pio_sm_init(pio, sm, offset, &c);
49     pio_sm_enable(pio, sm, true);
50 }

```

The state machine is configured to shift right in `out` instructions, because UARTs typically send data LSB-first. Once configured, the state machine will print any characters pushed to the TX FIFO.

Pico Examples: https://github.com/raspberrypi/pico-examples/tree/pre_release/pio/uart_tx/uart_tx.pio Lines 52 - 54

```

52 static inline void uart_tx_program_putc(PIO pio, uint sm, char c) {
53     pio_sm_put_blocking(pio, sm, (uint32_t)c);
54 }

```

Pico Examples: https://github.com/raspberrypi/pico-examples/tree/pre_release/pio/uart_tx/uart_tx.pio Lines 56 - 59

```

56 static inline void uart_tx_program_puts(PIO pio, uint sm, const char *s) {
57     while (*s)
58         uart_tx_program_putc(pio, sm, *s++);
59 }

```

The example program in the SDK will configure one PIO state machine as a UART TX peripheral, and use it to print a message on GPIO 0 at 115200 baud once per second.

Pico Examples: https://github.com/raspberrypi/pico-examples/tree/pre_release/pio/uart_tx/uart_tx.c Lines 1 - 27

```

5   */
6
7  #include "pico/stdlib.h"
8  #include "hardware/pio.h"
9  #include "uart_tx.pio.h"
10
11 int main() {
12     // We're going to use PIO to print "Hello, world!" on the same GPIO which we
13     // normally attach UART0 to.
14     const uint PIN_TX = 0;
15     // This is the same as the default UART baud rate on Pico
16     const uint SERIAL_BAUD = 115200;
17
18     PIO pio = pio0;
19     uint sm = 0;
20     uint offset = pio_add_program(pio, &uart_tx_program);
21     uart_tx_program_init(pio, sm, offset, PIN_TX, SERIAL_BAUD);
22
23     while (true) {
24         uart_tx_program_puts(pio, sm, "Hello, world! (from PIO!)\n");

```

```

25     sleep_ms(1000);
26     }
27 }

```

With the two PIO instances on RP2040, this could be extended to 8 additional UART TX interfaces, on 8 different pins, with 8 different baud rates.

3.6.4. UART RX

Recalling figure [Figure 50](#) showing the format of an 8n1 UART:

We can recover the data by waiting for the start bit, sampling 8 times with the correct timing, and pushing the result to the RX FIFO. Below is possibly the shortest program which can do this:

Pico Examples: https://github.com/raspberrypi/pico-examples/tree/pre_release/pio/uart_rx/uart_rx.pio Lines 7 - 18

```

7 .program uart_rx_mini
8
9 ; Minimum viable 8n1 UART receiver. Wait for the start bit, then sample 8 bits
10 ; with the correct timing.
11 ; IN pin 0 is mapped to the GPIO used as UART RX.
12 ; Autopush must be enabled, with a threshold of 8.
13
14     wait 0 pin 0           ; Wait for start bit
15     set x, 7 [10]         ; Preload bit counter, delay until eye of first data bit
16 bitloop:                 ; Loop 8 times
17     in pins, 1           ; Sample data
18     jmp x-- bitloop [6] ; Each iteration is 8 cycles

```

This works, but it has some annoying characteristics, like repeatedly outputting **NUL** characters if the line is stuck low. Ideally, we would want to drop data that is not correctly framed by a start and stop bit (and set some sticky flag to indicate this has happened), and pause receiving when the line is stuck low for long periods. We can add these to our program, at the cost of a few more instructions.

Pico Examples: https://github.com/raspberrypi/pico-examples/tree/pre_release/pio/uart_rx/uart_rx.pio Lines 43 - 62

```

43 .program uart_rx
44
45 ; Slightly more fleshed-out 8n1 UART receiver which handles framing errors and
46 ; break conditions more gracefully.
47 ; IN pin 0 and JMP pin are both mapped to the GPIO used as UART RX.
48
49 start:
50     wait 0 pin 0           ; Stall until start bit is asserted
51     set x, 7 [10]         ; Preload bit counter, then delay until halfway through
52 bitloop:                 ; the first data bit (12 cycles incl wait, set).
53     in pins, 1           ; Shift data bit into ISR
54     jmp x-- bitloop [6] ; Loop 8 times, each loop iteration is 8 cycles
55     jmp pin good_stop    ; Check stop bit (should be high)
56
57     irq 4 rel            ; Either a framing error or a break. Set a sticky flag,
58     wait 1 pin 0         ; and wait for line to return to idle state.
59     jmp start           ; Don't push data if we didn't see good framing.

```

```

60
61 good_stop:           ; No delay before returning to start; a little slack is
62   push                ; important in case the TX clock is slightly too fast.

```

The second example does not use `autopush` (Section 3.5.4), preferring instead to use an explicit `push` instruction, so that it can condition the push on whether a correct stop bit is seen. The `.pio` file includes a helper function which configures the state machine and connects it to a GPIO with the pullup enabled:

Pico Examples: https://github.com/raspberrypi/pico-examples/tree/pre_release/pio/uart_rx/uart_rx.pio Lines 66 - 84

```

66 static inline void uart_rx_program_init(PIO pio, uint sm, uint offset, uint pin, uint baud)
67 {
68     pio_sm_set_consecutive_pindirs(pio, sm, pin, 1, false);
69     pio_gpio_select(pio, pin);
70     gpio_pull_up(pin);
71     pio_sm_config c = uart_rx_program_get_default_config(offset);
72     sm_config_set_in_pins(&c, pin); // for WAIT, IN
73     sm_config_set_jmp_pin(&c, pin); // for JMP
74     // Shift to right, autopull disabled
75     sm_config_set_in_shift(&c, true, false, 32);
76     // Deeper FIFO as we're not doing any TX
77     sm_config_set_fifo_join(&c, PIO_FIFO_JOIN_RX);
78     // SM transmits 1 bit per 8 execution cycles.
79     float div = (float)clock_get_hz(clk_sys) / (8 * baud);
80     sm_config_set_clkdiv(&c, div);
81
82     pio_sm_init(pio, sm, offset, &c);
83     pio_sm_enable(pio, sm, true);
84 }

```

To correctly receive data which is sent LSB-first, the ISR is configured to shift to the right. After shifting in 8 bits, this unfortunately leaves our 8 data bits in bits 31:24 of the ISR, with 24 zeroes in the LSBs. One option here is an `in null, 24` instruction to shuffle the ISR contents down to 7:0. Another is to read from the FIFO at an offset of 3 bytes, with an 8 bit read, so that the processor's bus hardware (or the DMA's) picks out the relevant byte for free:

Pico Examples: https://github.com/raspberrypi/pico-examples/tree/pre_release/pio/uart_rx/uart_rx.pio Lines 86 - 92

```

86 static inline char uart_rx_program_getc(PIO pio, uint sm) {
87     // 8-bit read from the uppermost byte of the FIFO, as data is left-justified
88     io_rw_8 *rxfifo_shift = (io_rw_8*)&pio->rxfr[sm] + 3;
89     while (pio_sm_is_rx_empty(pio, sm))
90         tight_loop_contents();
91     return (char)*rxfifo_shift;
92 }

```

An example program shows how this UART RX program can be used to receive characters sent by one of the hardware UARTs on RP2040. A wire must be connected from GPIO4 to GPIO3 for this program to function. To make the wrangling of 3 different serial ports a little easier, this program uses core 1 to print out a string on the test UART (UART 1), and the code running on core 0 will pull out characters from the PIO state machine, and pass them along to the UART used for the debug console (UART 0). Another approach here would be interrupt-based IO, using PIO's FIFO IRQs. If the `SM0_RXNEMPTY` bit is set in the `IRQ0_INTE` register, then PIO will raise its first interrupt request line whenever there is a character in state machine 0's RX FIFO.

Pico Examples: https://github.com/raspberrypi/pico-examples/tree/pre_release/pio/uart_rx/uart_rx.c Lines 1 - 60

```

55
56     // Echo characters received from PIO to the console
57     while (true) {
58         char c = uart_rx_program_getc(pio, sm);
59         putchar(c);
60     }

```

3.6.5. Manchester Serial TX and RX

Figure 51. Manchester serial line code. Each data bit is represented by either a high pulse followed by a low pulse (representing a '0' bit) or a low pulse followed by a high pulse (a '1' bit).

Pico Examples: https://github.com/raspberrypi/pico-examples/tree/pre_release/pio/manchester_encoding/manchester_encoding.pio Lines 7 - 29

```

7 .program manchester_tx
8 .side_set 1 opt
9
10 ; Transmit one bit every 12 cycles. a '0' is encoded as a high-low sequence
11 ; (each part lasting half a bit period, or 6 cycles) and a '1' is encoded as a
12 ; low-high sequence.
13 ;
14 ; Side-set bit 0 must be mapped to the GPIO used for TX.
15 ; Autopull must be enabled -- this program does not care about the threshold.
16 ; The program starts at the public label 'start'.
17
18 .wrap_target
19 do_1:
20     nop            side 0 [5] ; Low for 6 cycles (5 delay, +1 for nop)
21     jmp get_bit side 1 [3] ; High for 4 cycles. 'get_bit' takes another 2 cycles
22 do_0:
23     nop            side 1 [5] ; Output high for 6 cycles
24     nop            side 0 [3] ; Output low for 4 cycles
25 public start:
26 get_bit:
27     out x, 1        ; Always shift out one bit from OSR to X, so we can
28     jmp !x do_0     ; branch on it. Autopull refills the OSR when empty.
29 .wrap

```

Starting from the label called `start`, this program shifts one data bit at a time into the X register, so that it can branch on the value. Depending on the outcome, it uses side-set to drive either a 1-0 or 0-1 sequence onto the chosen GPIO. This program uses autopull (Section 3.5.4.2) to automatically replenish the OSR from the TX FIFO once a certain amount of data has been shifted out, without interrupting program control flow or timing. This feature is enabled by a helper function in the `.pio` file which configures and starts the state machine:

Pico Examples: https://github.com/raspberrypi/pico-examples/tree/pre_release/pio/manchester_encoding/manchester_encoding.pio Lines 32 - 45

```

32 static inline void manchester_tx_program_init(PIO pio, uint sm, uint offset, uint pin, float
    div) {
33     pio_sm_set_pins_with_mask(pio, sm, 0, 1u << pin);
34     pio_sm_set_consecutive_pindirs(pio, sm, pin, 1, true);
35     pio_gpio_select(pio, pin);
36
37     pio_sm_config c = manchester_tx_program_get_default_config(offset);
38     sm_config_set_sideset_pins(&c, pin);
39     sm_config_set_out_shift(&c, true, true, 32);
40     sm_config_set_fifo_join(&c, PIO_FIFO_JOIN_TX);
41     sm_config_set_clkdiv(&c, div);
42     pio_sm_init(pio, sm, offset + manchester_tx_offset_start, &c);
43
44     pio_sm_enable(pio, sm, true);
45 }

```

Another state machine can be programmed to recover the original data from the transmitted signal:

Pico Examples: https://github.com/raspberrypi/pico-examples/tree/pre_release/pio/manchester_encoding/manchester_encoding.pio Lines 48 - 70

```

48 .program manchester_rx
49
50 ; Assumes line is idle low, first bit is 0
51 ; One bit is 12 cycles
52 ; a '0' is encoded as 10
53 ; a '1' is encoded as 01
54 ;
55 ; Both the IN base and the JMP pin mapping must be pointed at the GPIO used for RX.
56 ; Autopush must be enabled.
57 ; Before enabling the SM, it should be placed in a 'wait 1, pin' state, so that
58 ; it will not start sampling until the initial line idle state ends.
59
60 start_of_0:          ; We are 0.25 bits into a 0 - signal is high
61   wait 0 pin 0      ; Wait for the 1->0 transition - at this point we are 0.5 into the
   bit
62   in y, 1 [8]       ; Emit a 0, sleep 3/4 of a bit
63   jmp pin start_of_0 ; If signal is 1 again, it's another 0 bit, otherwise it's a 1
64
65 .wrap_target
66 start_of_1:          ; We are 0.25 bits into a 1 - signal is 1
67   wait 1 pin 0      ; Wait for the 0->1 transition - at this point we are 0.5 into the
   bit
68   in x, 1 [8]       ; Emit a 1, sleep 3/4 of a bit
69   jmp pin start_of_0 ; If signal is 0 again, it's another 1 bit otherwise it's a 0
70 .wrap

```

The main complication here is staying aligned to the input transitions, as the transmitter's and receiver's clocks may drift relative to one another. In Manchester code there is always a transition in the centre of the symbol, and based on the initial line state (high or low) we know the direction of this transition, so we can use a `wait` instruction to resynchronise to the line transitions on every data bit.

This program expects the X and Y registers to be initialised with the values 1 and 0 respectively, so that a constant 1 or 0 can be provided to the `in` instruction. The code that configures the state machine initialises these registers by executing some `set` instructions before setting the program running.

Pico Examples: https://github.com/raspberrypi/pico-examples/tree/pre_release/pio/manchester_encoding/manchester_encoding.pio Lines 73 - 93

```

73 static inline void manchester_rx_program_init(PIO pio, uint sm, uint offset, uint pin, float
   div) {
74   pio_sm_set_consecutive_pindirs(pio, sm, pin, 1, false);
75   pio_gpio_select(pio, pin);
76
77   pio_sm_config c = manchester_rx_program_get_default_config(offset);
78   sm_config_set_in_pins(&c, pin); // for WAIT
79   sm_config_set_jmp_pin(&c, pin); // for JMP
80   sm_config_set_in_shift(&c, true, true, 32);
81   sm_config_set_fifo_join(&c, PIO_FIFO_JOIN_RX);
82   sm_config_set_clkdiv(&c, div);
83   pio_sm_init(pio, sm, offset, &c);
84
85   // X and Y are set to 0 and 1, to conveniently emit these to ISR/FIFO.
86   pio_sm_exec(pio, sm, pio_encode_set(pio_x, 1));
87   pio_sm_exec(pio, sm, pio_encode_set(pio_y, 0));
88   // Assume line is idle low, and first transmitted bit is 0. Put SM in a
89   // wait state before enabling. RX will begin once the first 0 symbol is
90   // detected.
91   pio_sm_exec(pio, sm, pio_encode_wait_pin(1, 0) | pio_encode_delay(2));
92   pio_sm_enable(pio, sm, true);
93 }

```

The example C program in the SDK will transmit Manchester serial data from GPIO2 to GPIO3 at approximately 10 Mbps (assuming a system clock of 125 MHz).

Pico Examples: https://github.com/raspberrypi/pico-examples/tree/pre_release/pio/manchester_encoding/manchester_encoding.c Lines 20 - 43

```

20 int main() {
21     setup_default_uart();
22
23     PIO pio = pio0;
24     uint sm_tx = 0;
25     uint sm_rx = 1;
26
27     uint offset_tx = pio_add_program(pio, &manchester_tx_program);
28     uint offset_rx = pio_add_program(pio, &manchester_rx_program);
29     printf("Transmit program loaded at %d\n", offset_tx);
30     printf("Receive program loaded at %d\n", offset_rx);
31
32     manchester_tx_program_init(pio, sm_tx, offset_tx, pin_tx, 1.f);
33     manchester_rx_program_init(pio, sm_rx, offset_rx, pin_rx, 1.f);
34
35     pio_sm_enable(pio, sm_tx, false);
36     pio_sm_put_blocking(pio, sm_tx, 0);
37     pio_sm_put_blocking(pio, sm_tx, 0xff0a55a);
38     pio_sm_put_blocking(pio, sm_tx, 0x12345678);
39     pio_sm_enable(pio, sm_tx, true);
40
41     for (int i = 0; i < 3; ++i)
42         printf("%08x\n", pio_sm_get_blocking(pio, sm_rx));
43 }

```

3.6.6. Differential Manchester (BMC) TX and RX

Figure 52. Differential Manchester serial line code, also known as biphase mark code (BMC). The line transitions at the start of every bit period. The presence of a transition in the centre of the bit period signifies a 1 data bit, and the absence, a 0 bit. These encoding rules are the same whether the line has an initial high or low state.

The transmit program is similar to the Manchester example: it repeatedly shifts a bit from the OSR into X (relying on autopull to refill the OSR in the background), branches, and drives a GPIO up and down based on the value of this bit. The added complication is that the pattern we drive onto the pin depends not just on the value of the data bit, as with vanilla Manchester encoding, but also on the state the line was left in at the end of the last bit period. This is illustrated in Figure 52, where the pattern is inverted if the line is initially high. To cope with this, there are two copies of the test-and-drive code, one for each initial line state, and these are linked together in the correct order by a sequence of jumps.

Pico Examples: https://github.com/raspberrypi/pico-examples/tree/pre_release/pio/differential_manchester/differential_manchester.pio Lines 7 - 32

```

7 .program differential_manchester_tx
8 .side_set 1 opt
9
10 ; Transmit one bit every cycles. In each bit period:
11 ; - A '0' is encoded as a transition at the start of the bit period
12 ; - A '1' is encoded as a transition at the start *and* in the middle
13 ;
14 ; Side-set bit 0 must be mapped to the data output pin.
15 ; Autopull must be enabled.
16
17 public start:
18 initial_high:
19     out x, 1             side 1             ; Start of bit period: always assert transition

```

```

20     jmp !x high_0           [6] ; Test the data bit we just shifted out of OSR
21 high_1:
22     jmp initial_high   side 0 [7] ; For `1` bits, also transition in the middle
23 high_0:
24     jmp initial_low     [7] ; Otherwise, the line is stable in the middle
25
26 initial_low:
27     out x, 1           side 0 ; Always shift 1 bit from OSR to X so we can
28     jmp !x low_0       [6] ; branch on it. Autopull refills OSR for us.
29 low_1:
30     jmp initial_low   side 1 [7] ; If there are two transitions, return to
31 low_0:                ; initial_low on the next bit. If just one,
32     jmp initial_high   [7] ; the initial line state is flipped!

```

The `.pio` file also includes a helper function to initialise a state machine for differential Manchester TX, and connect it to a chosen GPIO. We arbitrarily choose a 32-bit frame size and LSB-first serialisation (`shift_to_right` is true in `sm_config_set_out_shift`), but as the program operates on one bit at a time, we could change this by reconfiguring the state machine.

Pico Examples: https://github.com/raspberrypi/pico-examples/tree/pre_release/pio/differential_manchester/differential_manchester.pio Lines 35 - 50

```

35 static inline void differential_manchester_tx_program_init(PIO pio, uint sm, uint offset,
    uint pin, float div) {
36     pio_sm_set_pins_with_mask(pio, sm, 0, 1u << pin);
37     pio_sm_set_consecutive_pindirs(pio, sm, pin, 1, true);
38     pio_gpio_select(pio, pin);
39
40     pio_sm_config c = differential_manchester_tx_program_get_default_config(offset);
41     sm_config_set_sideset_pins(&c, pin);
42     sm_config_set_out_shift(&c, true, true, 32);
43     sm_config_set_fifo_join(&c, PIO_FIFO_JOIN_TX);
44     sm_config_set_clkdiv(&c, div);
45     pio_sm_init(pio, sm, offset + differential_manchester_tx_offset_start, &c);
46
47     // Execute a blocking pull so that we maintain the initial line state until data is
    available
48     pio_sm_exec(pio, sm, pio_encode_pull(false, true));
49     pio_sm_enable(pio, sm, true);
50 }

```

The RX program uses the following strategy:

- Wait until the initial transition at the start of the bit period, so we stay aligned to the transmit clock
- Then wait 3/4 of the configured bit period, so that we are centred on the second half-bit-period (see [Figure 52](#))
- Sample the line at this point to determine whether there are one or two transitions in this bit period
- Repeat

Pico Examples: https://github.com/raspberrypi/pico-examples/tree/pre_release/pio/differential_manchester/differential_manchester.pio Lines 52 - 82

```

52 .program differential_manchester_rx
53
54 ; Assumes line is idle low
55 ; One bit is 16 cycles. In each bit period:
56 ; - A '0' is encoded as a transition at time 0
57 ; - A '1' is encoded as a transition at time 0 and a transition at time T/2
58 ;
59 ; The IN mapping and the JMP pin select must both be mapped to the GPIO used for
60 ; RX data. Autopush must be enabled.

```

```

61
62 public start:
63   initial_high:           ; Find rising edge at start of bit period
64     wait 1 pin, 0 [11] ; Delay to eye of second half-period (i.e 3/4 of way
65     jmp pin high_0       ; through bit) and branch on RX pin high/low.
66 high_1:
67   in x, 1                ; Second transition detected (a `1` data symbol)
68   jmp initial_high
69 high_0:
70   in y, 1 [1]           ; Line still high, no centre transition (data is `0`)
71   ; Fall-through
72
73 .wrap_target
74 initial_low:            ; Find falling edge at start of bit period
75   wait 0 pin, 0 [11] ; Delay to eye of second half-period
76   jmp pin low_1
77 low_0:
78   in y, 1                ; Line still low, no centre transition (data is `0`)
79   jmp initial_high
80 low_1:
81   in x, 1 [1]           ; Second transition detected (data is `1`)
82 .wrap

```

This code assumes that X and Y have the values 1 and 0, respectively. This is arranged for by the included C helper function:

Pico Examples: https://github.com/raspberrypi/pico-examples/tree/pre_release/pio/differential_manchester/differential_manchester.pio Lines 85 - 101

```

85 static inline void differential_manchester_rx_program_init(PIO pio, uint sm, uint offset,
86   uint pin, float div) {
87   pio_sm_set_consecutive_pindirs(pio, sm, pin, 1, false);
88   pio_gpio_select(pio, pin);
89
90   pio_sm_config c = differential_manchester_rx_program_get_default_config(offset);
91   sm_config_set_in_pins(&c, pin); // for WAIT
92   sm_config_set_jmp_pin(&c, pin); // for JMP
93   sm_config_set_in_shift(&c, true, true, 32);
94   sm_config_set_fifo_join(&c, PIO_FIFO_JOIN_RX);
95   sm_config_set_clkdiv(&c, div);
96   pio_sm_init(pio, sm, offset, &c);
97
98   // X and Y are set to 0 and 1, to conveniently emit these to ISR/FIFO.
99   pio_sm_exec(pio, sm, pio_encode_set(pio_x, 1));
100  pio_sm_exec(pio, sm, pio_encode_set(pio_y, 0));
101  pio_sm_enable(pio, sm, true);

```

All the pieces now exist to loopback some serial data over a wire between two GPIOs.

Pico Examples: https://github.com/raspberrypi/pico-examples/tree/pre_release/pio/differential_manchester/differential_manchester.c Lines 1 - 43

12
13 // Differential serial transmit/receive example
14 // Need to connect a wire from GPIO2 -> GPIO3
15
16 const uint pin_tx = 2;
17 const uint pin_rx = 3;
18
19 int main() {
20     setup_default_uart();
21
22     PIO pio = pio0;
23     uint sm_tx = 0;
24     uint sm_rx = 1;
25
26     uint offset_tx = pio_add_program(pio, &differential_manchester_tx_program);
27     uint offset_rx = pio_add_program(pio, &differential_manchester_rx_program);
28     printf("Transmit program loaded at %d\n", offset_tx);
29     printf("Receive program loaded at %d\n", offset_rx);
30
31     // Configure state machines, set bit rate at 5 Mbps
32     differential_manchester_tx_program_init(pio, sm_tx, offset_tx, pin_tx, 125.f / (16 *
33     5));
34     differential_manchester_rx_program_init(pio, sm_rx, offset_rx, pin_rx, 125.f / (16 *
35     5));
36
37     pio_sm_enable(pio, sm_tx, false);
38     pio_sm_put_blocking(pio, sm_tx, 0);
39     pio_sm_put_blocking(pio, sm_tx, 0xff0a55a);
40     pio_sm_put_blocking(pio, sm_tx, 0x12345678);
41     pio_sm_enable(pio, sm_tx, true);
42
43     for (int i = 0; i < 3; ++i)
44         printf("%08x\n", pio_sm_get_blocking(pio, sm_rx));
45 }

```

3.6.7. Addition

Although not designed for computation, PIO is quite likely Turing-complete, and it is conjectured that it could run DOOM, given a sufficiently high clock speed.

Pico Examples: https://github.com/raspberrypi/pico-examples/tree/pre_release/pio/addition/addition.pio Lines 1 - 19

```

1 .program addition
2
3 ; Pop two 32 bit integers from the TX FIFO, add them together, and push the
4 ; result to the TX FIFO. Autopush/pull should be disabled as we're using
5 ; explicit push and pull instructions.
6 ;
7 ; This program uses the two's complement identity  $x + y == \sim(\sim x - y)$ 
8
9     pull
10    mov x, ~osr
11    pull
12    mov y, osr
13    jmp test      ; this loop is equivalent to the following C code:
14 incr:          ; while (y--)
15    jmp x-- test ;   x--;
16 test:         ; This has the effect of subtracting y from x, eventually.

```

```

17     jmp y-- incr
18     mov isr, ~x
19     push

```

A full 32-bit addition takes only around one minute at 125 MHz. The program pops two numbers from the TX FIFO and pushes their sum to the RX FIFO, which is perfect for use either with the system DMA, or directly by the processor:

Pico Examples: https://github.com/raspberrypi/pico-examples/tree/pre_release/pio/addition/addition.c Lines 1 - 35

```

1  /**

5  */
6
7  #include <stdlib.h>
8  #include <stdio.h>
9
10 #include "pico/stdlib.h"
11 #include "hardware/pio.h"
12 #include "addition.pio.h"
13
14 // Pop quiz: how many additions does the processor do when calling this function
15 uint32_t do_addition(PIO pio, uint sm, uint32_t a, uint32_t b) {
16     pio_sm_put_blocking(pio, sm, a);
17     pio_sm_put_blocking(pio, sm, b);
18     return pio_sm_get_blocking(pio, sm);
19 }
20
21 int main() {
22     setup_default_uart();
23
24     PIO pio = pio0;
25     uint sm = 0;
26     uint offset = pio_add_program(pio, &addition_program);
27     addition_program_init(pio, sm, offset);
28
29     printf("Doing some random additions:\n");
30     for (int i = 0; i < 10; ++i) {
31         uint a = rand() % 100;
32         uint b = rand() % 100;
33         printf("%u + %u = %u\n", a, b, do_addition(pio, sm, a, b));
34     }
35 }

```

3.7. Outdated Examples

⊖ WARNING

These examples are outdated, and may not reflect best practices, or even assemble under the latest `picoasm` — you are much better off looking at the code in `pico-examples`! This section will shrink with time and the "Examples" section will grow to replace it.

TODO delete this section once each of these is replaced with a documented SDK example

3.7.1. UART with CTSn and RTSn

```

1 .program uart_tx_cts
2 .side_set 1 opt
3
4 .wrap_target
5     ; Block until data is available
6     pull
7     ; Wait for CTSn to assert
8     wait 0 pin, 0
9     ; Initialise loop counter, assert start bit, delay for further 7 cycles
10    set x, 7        set 0 [7]
11    ; Shift out 8 bits, at 8 cycles per loop
12 bitloop:
13    out pins, 1
14    jmp x-- bitloop    [6]
15 .extern entry_point
16     ; Assert stop bit. 5 cycle delay, plus 2 cycles for pull & wait
17    nop                set 1 [5]
18 .wrap
19
20
21 .program uart_rx_rts
22
23 .extern entry_point
24 .wrap_target
25     ; Continue to update RTSn until we see a start bit
26 update_rts:
27    mov pins, !status ; low if RX FIFO less than threshold
28    jmp pin update_rts
29
30    set x, 7        [11]
31 bitloop:
32    in pins, 1 [6]
33    jmp x-- bitloop
34    push
35 .wrap

```

3.7.2. PWM (4 varieties)

In the first example, the processor initialises 'isr' to the counter top value, using the exec interface. Counter periods of up to $2^{32} - 1$ clocks are therefore possible. The initial PULL is used to prime the sample register (will only have to do this once, since autopull will be enabled), and can also be performed over the exec interface to save program space.

This example uses 8-bit PWM values, but anything in the range 1...32 bits is possible by tweaking the OUT parameter.

```

1 .side_set 1 opt          ; 1-bit wide side set, with an enable bit.
2
3 .wrap_target
4   out x, 8              ; pin will go high when we count down through this value
5   mov y, isr side 0 ; preload counter to max value, and set pin low (simultaneous)
6 pwm_loop:
7   jmp x!=y skip
8   nop                  side 1 ; nop with side-set (could also use set, if mapping configured)
9 skip:
10  jmp y-- pwm_loop [14]
11 .wrap

```

For an autopull threshold of 8, this program will consume one FIFO word per sample; a threshold of 32 will consume one FIFO word per **4** samples.

'nop' (no operation) is a pseudo-instruction which is assembled as 'mov x, x'.

The above program will stop running the PWM counter when the TX FIFO runs empty. For many applications this would not be the desired behaviour; we would rather recycle the most recently written value indefinitely. This can be done using a nonblocking 'pull', which executes as 'mov osr, x' when the TX FIFO is empty:

```

1 .side_set 1 opt
2
3 .wrap_target
4   pull noblock
5   out x, 8
6   mov y, isr side 0
7 pwm_loop:
8   jmp x!=y skip
9   nop                  side 1
10 skip:
11  jmp y-- inner_loop [14]
12 .wrap

```

A third type of PWM is one where the FIFO data is formatted as (high duration, low duration). This is ideal for e.g. a servo controller:

```

1 .side_set 1 opt
2
3 .wrap_target
4   out x, 16 side 1
5 loop1:
6   jmp x-- loop1
7   out x, 16 side 0
8 loop0:
9   jmp x-- loop0
10 .wrap_target

```

Finally, an interesting PWM with a compressed dithering format, which can be used in conjunction with noise shaping on the processor for relatively high-fidelity audio. It will repeat the same sample a variable number of times, each time adding either 0 or 1 to the duty value.

```

1 .side_set 1 opt
2
3 ; FIFO Format:

```

```

4 ; | high len | low len | (dither, continue) * n |
5
6 start:
7  out y, 7          ; Stash the two base pulse lengths
8  mov isr, y        ; (ab)use ISR as 3rd scratch register
9  out y, 7
10 .wrap_target
11  out pins, 1      ; Dither is prepended to next 1, or appended to prev 0
12  mov x, isr      side 1
13 loop1:
14  jmp x-- loop1
15  mov x, y        side 0
16 loop0:
17  jmp x-- loop0
18  out x, 1
19  jmp !x start    ; Branch on continue bit
20  nop [2]         ; Ensure carrier freq is constant
21 .wrap

```

Alternatively, if variable length is not required, the "output shift register not empty" condition can be used. This allows twice as many dithering bits to be packed into the FIFO words. The number of dithering bits is still configurable by setting the autopull threshold. Note that, in this case, autopull must be disabled, since the refilling of the OSR will affect 'jmp losre'.

```

1 .side_set 1 opt
2
3 ; FIFO Format:
4 ; | high len | low len | dither * n |
5
6 start:
7  pull
8  out y, 7          ; Stash the two base pulse lengths
9  mov isr, y        ; (ab)use ISR as 3rd scratch register
10 out y, 7
11 .wrap_target
12  out pins, 1      ; Dither is prepended to next 1, or appended to prev 0
13  mov x, isr      side 1
14 loop1:
15  jmp x-- loop1
16  mov x, y        side 0
17 loop0:
18  jmp x-- loop0
19  jmp !osre start
20  nop [2]         ; Ensure carrier freq is constant
21 .wrap

```

3.7.3. I2C

```

1 ; TX Encoding:
2 ; | 15:10 | 9      | 8:1 | 0 |
3 ; | Instr | Final | Data | NAK |
4 ;
5 ; If Instr has a value n > 0, then this FIFO word has no
6 ; data payload, and the next n + 1 words will be executed as instructions.
7 ; Otherwise, shift out the 8 data bits, followed by the ACK bit.
8 ;

```

```

 9 ; The Instr mechanism allows stop/start/repstart sequences to be programmed
10 ; by the processor, and then carried out by the state machine at defined points
11 ; in the datastream.
12 ;
13 ; The "Final" field should be set for the final byte in a transfer.
14 ; This tells the state machine to ignore a NAK: if this field is not
15 ; set, then any NAK will cause the state machine to halt and interrupt.
16 ;
17 ; Autopull should be enabled, with a threshold of 16.
18 ; Autopush should be enabled, with a threshold of 8.
19 ; The TX FIFO should be accessed with halfword writes, to ensure
20 ; the data is immediately available in the OSR.
21 ;
22 ; Pin mapping:
23 ; - Input pin 0 is SDA, 1 is SCL (if clock stretching used)
24 ; - Jump pin is SDA
25 ; - Side-set pin 0 is SCL
26 ; - Set pin 0 is SDA
27 ; - OUT pin 0 is SDA
28 ;
29 ; The OE outputs should be inverted in the system IO controls!
30 ; (It's possible for the inversion to be done in this program,
31 ; but costs 2 instructions: 1 for inversion, and one to cope
32 ; with the side effect of the MOV on TX shift counter.)
33
34 .program i2c
35 .side_set 1 opt
36
37 do_nack:
38     ; Check if NAK was expected; if so, continue
39     jmp y-- entry_point
40     ; Stop and ask processor to come help us :(
41     irq wait 0 rel
42
43 do_byte:
44     set x, 7
45 bitloop:
46     out pindirs, 1          [7]
47     nop                    side 1 [2] ; SCL rising edge
48     wait 1 pin, 1          [4] ; Allow clock to be stretched
49     in pins, 1             [7]
50     jmp x-- bitloop side 0 [7] ; SCL falling edge
51
52     ; Handle ACK pulse
53     out pindirs, 1          [7]
54     nop                    side 1 [7] ; SCL rising edge
55     wait 1 pin, 1          [7] ; Allow clock to be stretched
56     jmp pin do_nack side 0 [2]
57
58 .extern entry_point
59 .wrap_target
60     out x, 6
61     out y, 1
62     jmp !x do_byte
63     out null, 32
64 do_exec:
65     out exec, 16
66     jmp x-- do_exec
67 .wrap

```

3.7.4. I2S

```

1 .program i2s_2x16
2 .side_set 2
3
4 ; Transmit a stereo I2S audio stream.
5 ; This is 16 bits per sample; can be altered by modifying the "set" params,
6 ; or made programmable by replacing "set x" with "mov x, y" and using Y as a config
   register.
7 ;
8 ; Autopull must be enabled, with threshold set to 32.
9 ; Since I2S is MSB-first, shift direction should be to left.
10 ; Hence the format of the FIFO word is:
11 ;
12 ; | 31   : 16 | 15   :  0 |
13 ; | sample ws=0 | sample ws=1 |
14 ;
15 ; Data is output at 1 bit per 2 clocks. Use clock divider to adjust frequency.
16 ; Fractional divider will probably be needed to get correct bit clock period,
17 ; but for common sysclk freqs this should still give a constant word select period.
18 ;
19 ; One output pin is used for the data output.
20 ; Two side-set pins are used. Bit 0 is clock, bit 1 is word select.
21
22 .wrap_target
23     ; Loops are partially unrolled so that set delay can replace a jump delay
24     ; Note that word select toggles for final bit of each word, *not* first of next
25 bitloop0:
26     out pins, 1         set 0x0
27     jmp x-- bitloop0   set 0x1
28
29     out pins, 1         set 0x2
30     set x, 14          set 0x3
31 bitloop1:
32     out pins, 1         set 0x2
33     jmp x-- bitloop1   set 0x3
34     out pins, 1         set 0x0
35 .extern entry_point
36     set x, 14          set 0x1
37 .wrap

```

3.7.5. IRDA Receiver

TO DO: LUKE/GRAHAM/LIAM: I think more detail is needed here - wiring etc?

Wait for the start bit, capture a programmable number of bit samples, then interrupt the processor to scan through it. Thanks to WIC on Cortex-M0, the processor can stay in sleep during this time. This has a huge impact on power consumption.

```

1 .wrap
2     pull
3     out x, 32           ; Get a sample count from the processor
4     wait 0 pin 0       ; Wait for start bit on the mapped input pin
5 sample_loop:
6     in pins, 1
7     jmp x-- sample_loop
8     irq wait 0 rel     ; Tell the processor the capture buffer is ready, and wait for

```

```
acknowledgement
9 .wrap_top
```

Note the use of relative IRQ addressing. Up to 4 of these interfaces could be instantiated on different pins, using the same instructions, and the processor would receive a separate interrupt from each.

3.7.6. APA102 LEDs

APA102s have a 32-bit command syntax containing some constant bits, a global brightness config, and 24 bits of colour data.

This program takes RGB555 pixels packed 2 per FIFO word, and serialises them to the LEDs, with colour padded to RGB888. The global brightness is configured by initialising the Y register.

Start of frame and end of frame commands are transmitted by initialising the OSR correctly.

```
1 .program apa102
2
3 ; OSR: shift to right
4 ; ISR: shift to right
5

3.8. List of Registers

Table 360. List of PIO registers

Offset	Name	Info
0x000	CTRL	PIO control register
0x004	FSTAT	FIFO status register
0x008	FDEBUG	FIFO debug register
0x00c	FLEVEL	FIFO levels
0x010	TXF0	Direct write access to the TX FIFO for this state machine. Each write pushes one word to the FIFO.
0x014	TXF1	Direct write access to the TX FIFO for this state machine. Each write pushes one word to the FIFO.
0x018	TXF2	Direct write access to the TX FIFO for this state machine. Each write pushes one word to the FIFO.
0x01c	TXF3	Direct write access to the TX FIFO for this state machine. Each write pushes one word to the FIFO.
0x020	RXF0	Direct read access to the RX FIFO for this state machine. Each read pops one word from the FIFO.
0x024	RXF1	Direct read access to the RX FIFO for this state machine. Each read pops one word from the FIFO.
0x028	RXF2	Direct read access to the RX FIFO for this state machine. Each read pops one word from the FIFO.
0x02c	RXF3	Direct read access to the RX FIFO for this state machine. Each read pops one word from the FIFO.
0x030	IRQ	Interrupt request register. Write 1 to clear
0x034	IRQ_FORCE	Writing a 1 to each of these bits will forcibly assert the corresponding IRQ. Note this is different to the INTF register: writing here affects PIO internal state. INTF just asserts the processor-facing IRQ signal for testing ISRs, and is not visible to the state machines.
0x038	INPUT_SYNC_BYPASS	There is a 2-flipflop synchronizer on each GPIO input, which protects PIO logic from metastabilities. This increases input delay, and for fast synchronous IO (e.g. SPI) these synchronizers may need to be bypassed. Each bit in this register corresponds to one GPIO. 0 -> input is synchronized (default) 1 -> synchronizer is bypassed If in doubt, leave this register as all zeroes.
0x03c	DBG_PADOUT	
0x040	DBG_PADOE	

Offset	Name	Info
0x044	DBG_CFGINFO	The PIO hardware has some free parameters that may vary between chip products. These should be provided in the chip datasheet, but are also exposed here.
0x048	INSTR_MEM0

0x0b0	INSTR_MEM26	
0x0b4	INSTR_MEM27	
0x0b8	INSTR_MEM28	
0x0bc	INSTR_MEM29	
0x0c0	INSTR_MEM30	
0x0c4	INSTR_MEM31	

Offset	Name	Info
0x0c8	SM0_CLKDIV	Clock divider register for state machine 0 Frequency = clock freq / (CLKDIV_INT + CLKDIV_FRAC / 256)
0x0cc	SM0_EXECCTRL	Execution/behavioural settings for state machine 0
0x0d0	SM0_SHIFTCTRL	Control behaviour of the input/output shift registers for state machine 0
0x0d4	SM0_ADDR	Current instruction address of state machine 0
0x0d8	SM0_INSTR	Instruction currently being executed by state machine 0 Write to execute an instruction immediately (including jumps) and then resume execution.
0x0dc	SM0_PINCTRL	
0x0e0	SM1_CLKDIV	Clock divider register for state machine 1 Frequency = clock freq / (CLKDIV_INT + CLKDIV_FRAC / 256)
0x0e4	SM1_EXECCTRL	Execution/behavioural settings for state machine 1
0x0e8	SM1_SHIFTCTRL	Control behaviour of the input/output shift registers for state machine 1
0x0ec	SM1_ADDR	Current instruction address of state machine 1
0x0f0	SM1_INSTR	Instruction currently being executed by state machine 1 Write to execute an instruction immediately (including jumps) and then resume execution.
0x0f4	SM1_PINCTRL	
0x0f8	SM2_CLKDIV	Clock divider register for state machine 2 Frequency = clock freq / (CLKDIV_INT + CLKDIV_FRAC / 256)
0x0fc	SM2_EXECCTRL	Execution/behavioural settings for state machine 2
0x100	SM2_SHIFTCTRL	Control behaviour of the input/output shift registers for state machine 2
0x104	SM2_ADDR	Current instruction address of state machine 2
0x108	SM2_INSTR	Instruction currently being executed by state machine 2 Write to execute an instruction immediately (including jumps) and then resume execution.
0x10c	SM2_PINCTRL	
0x110	SM3_CLKDIV	Clock divider register for state machine 3 Frequency = clock freq / (CLKDIV_INT + CLKDIV_FRAC / 256)
0x114	SM3_EXECCTRL	Execution/behavioural settings for state machine 3
0x118	SM3_SHIFTCTRL	Control behaviour of the input/output shift registers for state machine 3
0x11c	SM3_ADDR	Current instruction address of state machine 3
0x120	SM3_INSTR	Instruction currently being executed by state machine 3 Write to execute an instruction immediately (including jumps) and then resume execution.
0x124	SM3_PINCTRL	
0x128	INTR	Raw Interrupts

Offset	Name	Info
0x12c	IRQ0_INTE	Interrupt Enable for irq0
0x130	IRQ0_INTF	Interrupt Force for irq0
0x134	IRQ0_INTS	Interrupt status after masking & forcing for irq0
0x138	IRQ1_INTE	Interrupt Enable for irq1
0x13c	IRQ1_INTF	Interrupt Force for irq1
0x140	IRQ1_INTS	Interrupt status after masking & forcing for irq1

CTRL Register

Description

PIO control register

Table 361. CTRL Register

Bits	Name	Description	Type	Reset
31:12	Reserved.	-	-	-
11:8	CLKDIV_RESTART	Force clock dividers to restart their count and clear fractional accumulators. Restart multiple dividers to synchronise them.	SC	0x0
7:4	SM_RESTART	Clear internal SM state which is otherwise difficult to access (e.g. shift counters). Self-clearing.	SC	0x0
3:0	SM_ENABLE	Enable state machine	RW	0x0

FSTAT Register

Description

FIFO status register

Table 362. FSTAT Register

Bits	Name	Description	Type	Reset
31:28	Reserved.	-	-	-
27:24	TXEMPTY	State machine TX FIFO is empty	RO	0xf
23:20	Reserved.	-	-	-
19:16	TXFULL	State machine TX FIFO is full	RO	0x0
15:12	Reserved.	-	-	-
11:8	RXEMPTY	State machine RX FIFO is empty	RO	0xf
7:4	Reserved.	-	-	-
3:0	RXFULL	State machine RX FIFO is full	RO	0x0

FDEBUG Register

Description

FIFO debug register

Table 363. FDEBUG Register

Bits	Name	Description	Type	Reset
31:28	Reserved.	-	-	-

Bits	Name	Description	Type	Reset
27:24	TXSTALL	State machine has stalled on empty TX FIFO. Write 1 to clear.	WC	0x0
23:20	Reserved.	-	-	-
19:16	TXOVER	TX FIFO overflow has occurred. Write 1 to clear.	WC	0x0
15:12	Reserved.	-	-	-
11:8	RXUNDER	RX FIFO underflow has occurred. Write 1 to clear.	WC	0x0
7:4	Reserved.	-	-	-
3:0	RXSTALL	State machine has stalled on full RX FIFO. Write 1 to clear.	WC	0x0

FLEVEL Register

Description

FIFO levels

Table 364. FLEVEL Register

Bits	Name	Description	Type	Reset
31:28	RX3		RO	0x0
27:24	TX3		RO	0x0
23:20	RX2		RO	0x0
19:16	TX2		RO	0x0
15:12	RX1		RO	0x0
11:8	TX1		RO	0x0
7:4	RX0		RO	0x0
3:0	TX0		RO	0x0

TXF0, TXF1, TXF2, TXF3 Registers

Description

Direct write access to the TX FIFO for this state machine. Each write pushes one word to the FIFO.

Table 365. TXF0, TXF1, TXF2, TXF3 Registers

Bits	Name	Description	Type	Reset
31:0	NONAME		WF	0x00000000

RXF0, RXF1, RXF2, RXF3 Registers

Description

Direct read access to the RX FIFO for this state machine. Each read pops one word from the FIFO.

Table 366. RXF0, RXF1, RXF2, RXF3 Registers

Bits	Name	Description	Type	Reset
31:0	NONAME		RF	-

IRQ Register

Description

Interrupt request register. Write 1 to clear

Table 367. IRQ Register

Bits	Name	Description	Type	Reset
31:8	Reserved.	-	-	-
7:0	NONAME		WC	0x00

IRQ_FORCE Register

Description

Writing a 1 to each of these bits will forcibly assert the corresponding IRQ. Note this is different to the INTF register: writing here affects PIO internal state. INTF just asserts the processor-facing IRQ signal for testing ISRs, and is not visible to the state machines.

Table 368. IRQ_FORCE Register

Bits	Name	Description	Type	Reset
31:8	Reserved.	-	-	-
7:0	NONAME		WF	0x00

INPUT_SYNC_BYPASS Register

Description

There is a 2-flipflop synchronizer on each GPIO input, which protects PIO logic from metastabilities. This increases input delay, and for fast synchronous IO (e.g. SPI) these synchronizers may need to be bypassed. Each bit in this register corresponds to one GPIO.
 0 -> input is synchronized (default)
 1 -> synchronizer is bypassed
 If in doubt, leave this register as all zeroes.

Table 369. INPUT_SYNC_BYPASS Register

Bits	Name	Description	Type	Reset
31:0	NONAME		RW	0x00000000

DBG_PADOUT Register

Table 370. DBG_PADOUT Register

Bits	Name	Description	Type	Reset
31:0	NONAME	Read to sample the pad output values PIO is currently driving to the GPIOs.	RO	0x00000000

DBG_PADOE Register

Table 371. DBG_PADOE Register

Bits	Name	Description	Type	Reset
31:0	NONAME	Read to sample the pad output enables (direction) PIO is currently driving to the GPIOs.	RO	0x00000000

DBG_CFGINFO Register

Description

The PIO hardware has some free parameters that may vary between chip products. These should be provided in the chip datasheet, but are also exposed here.

Table 372. DBG_CFGINFO Register

Bits	Name	Description	Type	Reset
31:22	Reserved.	-	-	-

Bits	Name	Description	Type	Reset
21:16	IMEM_SIZE	The size of the instruction memory, measured in units of one instruction	RO	-
15:12	Reserved.	-	-	-
11:8	SM_COUNT	The number of state machines this PIO instance is equipped with.	RO	-
7:6	Reserved.	-	-	-
5:0	FIFO_DEPTH	The depth of the state machine TX/RX FIFOs, measured in words. Joining fifos via SHIFTCTRL_FJOIN gives one FIFO with double this depth.	RO	-

INSTR_MEM0, INSTR_MEM1, ..., INSTR_MEM30, INSTR_MEM31 Registers

Table 373.
INSTR_MEM0,
INSTR_MEM1, ...,
INSTR_MEM30,
INSTR_MEM31
Registers

Bits	Name	Description	Type	Reset
31:16	Reserved.	-	-	-
15:0	NONAME	Write-only access to instruction memory location <i>N</i>	WO	0x0000

SM0_CLKDIV, SM1_CLKDIV, SM2_CLKDIV, SM3_CLKDIV Registers

Description

Clock divider register for state machine *N*
 Frequency = clock freq / (CLKDIV_INT + CLKDIV_FRAC / 256)

Table 374.
SM0_CLKDIV,
SM1_CLKDIV,
SM2_CLKDIV,
SM3_CLKDIV
Registers

Bits	Name	Description	Type	Reset
31:16	INT	Effective frequency is sysclk/int. Value of 0 is interpreted as max possible value	RW	0x0001
15:8	FRAC	Fractional part of clock divider	RW	0x00
7:0	Reserved.	-	-	-

SM0_EXECCTRL, SM1_EXECCTRL, SM2_EXECCTRL, SM3_EXECCTRL Registers

Description

Execution/behavioural settings for state machine *N*

Table 375.
SM0_EXECCTRL,
SM1_EXECCTRL,
SM2_EXECCTRL,
SM3_EXECCTRL
Registers

Bits	Name	Description	Type	Reset
31	EXEC_STALLED	An instruction written to SMx_INSTR is stalled, and latched by the state machine. Will clear once the instruction completes.	RO	0x0
30	SIDE_EN	If 1, the delay MSB is used as side-set enable, rather than a side-set data bit. This allows instructions to perform side-set optionally, rather than on every instruction.	RW	0x0
29	SIDE_PINDIR	Side-set data is asserted to pin OEs instead of pin values	RW	0x0

Bits	Name	Description	Type	Reset
28:24	JMP_PIN	The GPIO number to use as condition for JMP PIN. Unaffected by input mapping.	RW	0x00
23:19	OUT_EN_SEL	Which data bit to use for inline OUT enable	RW	0x00
18	INLINE_OUT_EN	If 1, use a bit of OUT data as an auxiliary write enable When used in conjunction with OUT_STICKY, writes with an enable of 0 will deassert the latest pin write. This can create useful masking/override behaviour due to the priority ordering of state machine pin writes (SM0 < SM1 < ...)	RW	0x0
17	OUT_STICKY	Continuously assert the most recent OUT/SET to the pins	RW	0x0
16:12	WRAP_TOP	After reaching this address, execution is wrapped to wrap_bottom. If the instruction is a jump, and the jump condition is true, the jump takes priority.	RW	0x1f
11:7	WRAP_BOTTOM	After reaching wrap_top, execution is wrapped to this address.	RW	0x00
6:5	Reserved.	-	-	-
4	STATUS_SEL	Comparison used for the MOV x, STATUS instruction. 0x0 -> All-ones if TX FIFO level < N, otherwise all-zeroes 0x1 -> All-ones if RX FIFO level < N, otherwise all-zeroes	RW	0x0
3:0	STATUS_N	Comparison level for the MOV x, STATUS instruction	RW	0x0

SM0_SHIFTCTRL, SM1_SHIFTCTRL, SM2_SHIFTCTRL, SM3_SHIFTCTRL Registers

Description

Control behaviour of the input/output shift registers for state machine *N*

Table 376.
SM0_SHIFTCTRL,
SM1_SHIFTCTRL,
SM2_SHIFTCTRL,
SM3_SHIFTCTRL
Registers

Bits	Name	Description	Type	Reset
31	FJOIN_RX	When 1, RX FIFO steals the TX FIFO's storage, and becomes twice as deep. TX FIFO is disabled as a result (always reads as both full and empty). FIFOs are flushed when this bit is changed.	RW	0x0
30	FJOIN_TX	When 1, TX FIFO steals the RX FIFO's storage, and becomes twice as deep. RX FIFO is disabled as a result (always reads as both full and empty). FIFOs are flushed when this bit is changed.	RW	0x0
29:25	PULL_THRESH	Number of bits shifted out of TXSR before autopull or conditional pull. Write 0 for value of 32.	RW	0x00
24:20	PUSH_THRESH	Number of bits shifted into RXSR before autopush or conditional push. Write 0 for value of 32.	RW	0x00
19	OUT_SHIFTDIR	1 = shift out of output shift register to right. 0 = to left.	RW	0x1

Bits	Name	Description	Type	Reset
18	IN_SHIFTDIR	1 = shift input shift register to right (data enters from left). 0 = to left.	RW	0x1
17	AUTOPULL	Pull automatically when the output shift register is emptied	RW	0x0
16	AUTOPUSH	Push automatically when the input shift register is filled	RW	0x0
15:0	Reserved.	-	-	-

SM0_ADDR, SM1_ADDR, SM2_ADDR, SM3_ADDR Registers

Description

Current instruction address of state machine *N*

Table 377. SM0_ADDR, SM1_ADDR, SM2_ADDR, SM3_ADDR Registers

Bits	Name	Description	Type	Reset
31:5	Reserved.	-	-	-
4:0	NONAME		RO	0x00

SM0_INSTR, SM1_INSTR, SM2_INSTR, SM3_INSTR Registers

Description

Instruction currently being executed by state machine *N*.

Write to execute an instruction immediately (including jumps) and then resume execution.

Table 378. SM0_INSTR, SM1_INSTR, SM2_INSTR, SM3_INSTR Registers

Bits	Name	Description	Type	Reset
31:16	Reserved.	-	-	-
15:0	NONAME		RW	-

SM0_PINCTRL, SM1_PINCTRL, SM2_PINCTRL, SM3_PINCTRL Registers

Table 379. SM0_PINCTRL, SM1_PINCTRL, SM2_PINCTRL, SM3_PINCTRL Registers

Bits	Name	Description	Type	Reset
31:29	SIDASET_COUNT	The number of delay bits co-opted for side-set. Inclusive of the enable bit, if present.	RW	0x0
28:26	SET_COUNT	The number of pins asserted by a SET. Max of 5	RW	0x5
25:20	OUT_COUNT	The number of pins asserted by an OUT. Value of 0 -> 32 pins	RW	0x00
19:15	IN_BASE	The virtual pin corresponding to IN bit 0	RW	0x00
14:10	SIDASET_BASE	The virtual pin corresponding to delay field bit 0	RW	0x00
9:5	SET_BASE	The virtual pin corresponding to SET bit 0	RW	0x00
4:0	OUT_BASE	The virtual pin corresponding to OUT bit 0	RW	0x00

INTR Register

Description

Raw Interrupts

Table 380. INTR Register

Bits	Name	Description	Type	Reset
31:12	Reserved.	-	-	-

Bits	Name	Description	Type	Reset

Chapter 4. Peripherals

4.1. USB

4.1.1. Overview

Prerequisite Knowledge Required

This section requires knowledge of the USB protocol. We recommend [\[usbmadesimple\]](#) if you are unclear on the terminology used in this section (see [References](#)).

RP2040 contains a USB 2.0 controller that can operate as either:

- a Full Speed device (12 Mbit/s)
- a host that can communicate with both Low Speed (1.5 Mbit/s) and Full Speed devices. This includes multiple downstream devices connected to a USB hub.

There is an integrated USB 1.1 PHY which interfaces the USB controller with the **DP** and **DM** pins of the chip.

4.1.1.1. Features

The USB controller hardware handles the low level USB protocol, meaning the main job of the programmer is to configure the controller and then provide / consume data buffers in response to events on the bus. The controller interrupts the processor when it needs attention. The USB controller has 4K of DPSRAM which is used for configuration and data buffers.

4.1.1.1.1. Device Mode

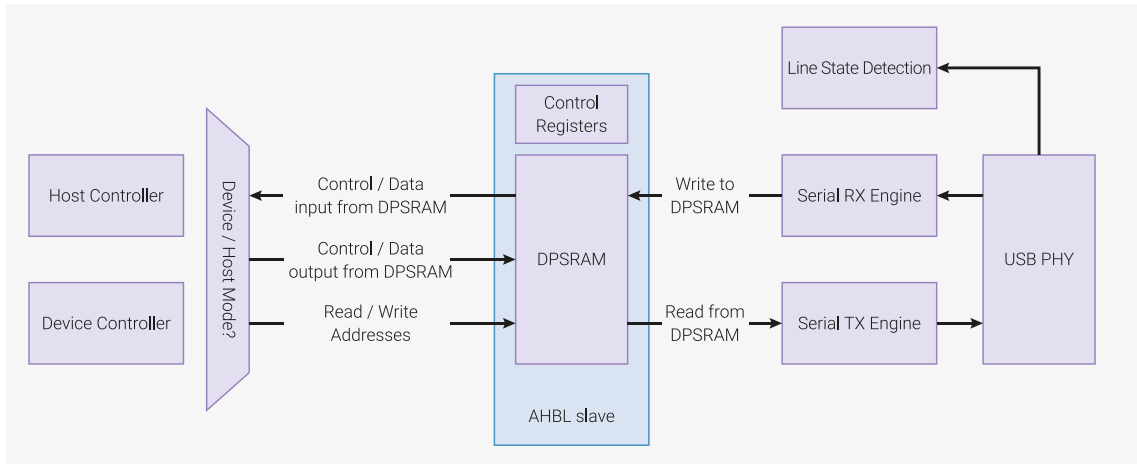

- USB 2.0 compatible Full Speed device (12 Mbps)
- Supports up to 32 endpoints (Endpoints 0 -> 15 in both in and out directions)
- Supports **Control**, **Isochronous**, **Bulk**, and **Interrupt** endpoint types
- Supports double buffering
- 3840 bytes of usable buffer space in DPSRAM. This is equivalent to 60 × 64-byte buffers.

4.1.1.1.2. Host Mode

- Can communicate with Full Speed (12 Mbps) devices and Low Speed devices (1.5 Mbps)
- Can communicate with multiple devices via a USB hub, including Low Speed devices connected to a Full Speed hub
- Can poll up to 15 interrupt endpoints in hardware. (Interrupt endpoints are used by hubs to notify the host of connect/disconnect events, mice to notify the host of movement etc.)

4.1.2. Architecture

Figure 53. A simplified overview of the USB controller architecture.

The USB controller is an area efficient design that muxes a device controller or host controller onto a common set of components. Each component is detailed below.

4.1.2.1. USB PHY

The USB PHY provides the electrical interface between the USB **DP** and **DM** pins and the digital logic of the controller. The **DP** and **DM** pins are a differential pair, meaning the values are always the inverse of each other, except to encode a specific line state (**SE0**, etc). The USB PHY drives the **DP** and **DM** pins to transmit data, as well as performing a differential receive of any incoming data. The USB PHY provides both single-ended and differential receive data to the line state detection module.

The USB PHY has built in pull-up and pull-down resistors. If the controller is acting as a Full Speed device then the **DP** pin is pulled up to indicate to the host that a Full Speed device has been connected. In host mode, a weak pull down is applied to **DP** and **DM** so that the lines are pulled to a logical zero until the device pulls up **DP** for Full Speed or **DM** for Low Speed.

4.1.2.2. Line state detection

The [usb^{spec}] defines several line states (Bus Reset, Connected, Suspend, Resume, Data 1, Data 0, etc) that need to be detected. The line state detection module has several state machines to detect these states and signal events to the other hardware components. There is no shared clock signal in USB, so the RX data must be sampled by an internal clock. The maximum data rate of USB Full Speed is 12 Mbps. The RX data is sampled at 48MHz, giving 4 clock cycles to capture and filter the bus state. The line state detection module distributes the filtered RX data to the Serial RX Engine.

4.1.2.3. Serial RX Engine

The serial receive engine decodes receive data captured by the line state detection module. It produces the following information:

- The **PID** of the incoming data packet
- The device address for the incoming data
- The device endpoint for the incoming data
- Data bytes

The serial receive engine also detects errors in RX data by performing a CRC check on the incoming data. Any errors are signalled to the other hardware blocks and can raise an interrupt.

NOTE

If you disconnect the USB cable during a packet in either host or device mode you will see errors raised by the hardware. Your software will need to take this scenario into account if you enable error interrupts.

4.1.2.4. Serial TX Engine

The serial transmit engine is a mirror of the serial receive engine. It is connected to the currently active controller (either device or host). It creates **TOKEN** and **DATA** packets, including calculating the CRC, and transmits them on the bus.

4.1.2.5. DPSRAM

The USB controller has 4K (4096 bytes) of DPSRAM (Dual Port SRAM). The DPSRAM is used to store control registers and data buffers. From the AHB-Lite bus this is 32-bit wide memory with DWORD, WORD and BYTES accesses supported.

Data Buffers are typically 64 bytes long as this is the max normal packet size for most FS packets. For Isochronous endpoints a maximum buffer size of 1023 bytes is supported. For other packet types the maximum size is 64 bytes per buffer.

4.1.2.5.1. Layout

Addresses **0x0-0xff** are used for control registers containing configuration data. The remaining space, addresses **0x100-0xffff** (3840 bytes) can be used for data buffers. The controller has control registers that start at address **0x10000**.

The memory layout is different depending on if the controller is in Device or Host mode. In device mode, there are multiple endpoints a host can access so there must be endpoint control and buffer control registers for each endpoint. In host mode, the host software running on the processor is deciding which endpoints and which devices to access, so there only needs to be one set of endpoint control and buffer control registers. As well as software driven transfers, the host controller can poll up to 15 interrupt endpoints and has a register for each of these interrupt endpoints.

Table 387. DPSRAM layout

Offset	Device Function	Host Function
0x0	Setup packet (8 bytes)	
0x8	EP1 in control	Interrupt endpoint control 1
0xc	EP1 out control	Spare
0x10	EP2 in control	Interrupt endpoint control 2
0x14	EP2 out control	Spare
0x18	EP3 in control	Interrupt endpoint control 3
0x1c	EP3 out control	Spare
0x20	EP4 in control	Interrupt endpoint control 4
0x24	EP4 out control	Spare
0x28	EP5 in control	Interrupt endpoint control 5
0x2c	EP5 out control	Spare
0x30	EP6 in control	Interrupt endpoint control 6
0x34	EP6 out control	Spare
0x38	EP7 in control	Interrupt endpoint control 7
0x3c	EP7 out control	Spare

Offset	Device Function	Host Function
0x40	EP8 in control	Interrupt endpoint control 8
0x44	EP8 out control	Spare
0x48	EP9 in control	Interrupt endpoint control 9
0x4c	EP9 out control	Spare
0x50	EP10 in control	Interrupt endpoint control 10
0x54	EP10 out control	Spare
0x58	EP11 in control	Interrupt endpoint control 11
0x5c	EP11 out control	Spare
0x60	EP12 in control	Interrupt endpoint control 12
0x64	EP12 out control	Spare
0x68	EP13 in control	Interrupt endpoint control 13
0x6c	EP13 out control	Spare
0x70	EP14 in control	Interrupt endpoint control 14
0x74	EP14 out control	Spare
0x78	EP15 in control	Interrupt endpoint control 15
0x7c	EP15 out control	Spare
0x80	EP0 in buffer control	EPx buffer control
0x84	EP0 out buffer control	Spare
0x88	EP1 in buffer control	Interrupt endpoint buffer control 1
0x8c	EP1 out buffer control	Spare
0x90	EP2 in buffer control	Interrupt endpoint buffer control 2
0x94	EP2 out buffer control	Spare
0x98	EP3 in buffer control	Interrupt endpoint buffer control 3
0x9c	EP3 out buffer control	Spare
0xa0	EP4 in buffer control	Interrupt endpoint buffer control 4
0xa4	EP4 out buffer control	Spare
0xa8	EP5 in buffer control	Interrupt endpoint buffer control 5
0xac	EP5 out buffer control	Spare
0xb0	EP6 in buffer control	Interrupt endpoint buffer control 6
0xb4	EP6 out buffer control	Spare
0xb8	EP7 in buffer control	Interrupt endpoint buffer control 7
0xbc	EP7 out buffer control	Spare
0xc0	EP8 in buffer control	Interrupt endpoint buffer control 8
0xc4	EP8 out buffer control	Spare
0xc8	EP9 in buffer control	Interrupt endpoint buffer control 9
0xcc	EP9 out buffer control	Spare

Offset	Device Function	Host Function
0xd0	EP10 in buffer control	Interrupt endpoint buffer control 10
0xd4	EP10 out buffer control	Spare
0xd8	EP11 in buffer control	Interrupt endpoint buffer control 11
0xdc	EP11 out buffer control	Spare
0xe0	EP12 in buffer control	Interrupt endpoint buffer control 12
0xe4	EP12 out buffer control	Spare
0xe8	EP13 in buffer control	Interrupt endpoint buffer control 13
0xec	EP13 out buffer control	Spare
0xf0	EP14 in buffer control	Interrupt endpoint buffer control 14
0xf4	EP14 out buffer control	Spare
0xf8	EP15 in buffer control	Interrupt endpoint buffer control 15
0xfc	EP15 out buffer control	Spare
0x100	EP0 buffer 0 (shared between in and out)	EPx control
0x140	Optional EP0 buffer 1	Spare
0x180	Data buffers	

4.1.2.5.2. Endpoint control register

The endpoint control register is used to configure an endpoint. It contains:

- The endpoint type
- The base address of its data buffer, or data buffers if double buffered
- Interrupts events on the endpoint should trigger

A device must support Endpoint 0 so that it can reply to SETUP packets and be enumerated. As a result, there is no endpoint control register for EP0. Its buffers begin at **0x100**. All other endpoints can have either single or dual buffers and are mapped at the base address programmed. As EP0 has no endpoint control register, the interrupt enable controls for EP0 come from [SIE_CTRL](#).

Table 388. Endpoint control register layout

Bit(s)	Device Function	Host Function
31	Endpoint Enable	
30	Single buffered (64 bytes) = 0, Double buffered (64 bytes x 2) = 1	
29	Enable Interrupt for every transferred buffer	
28	Enable Interrupt for every 2 transferred buffers (valid for double buffered only)	
27:26	Endpoint Type: Control = 0, ISO = 1, Bulk = 2, Interrupt = 3	
25:18	N/A	The interval the host controller should poll this endpoint. Only applicable for interrupt endpoints. Specified in ms - 1. For example: a value of 9 would poll the endpoint every 10ms.
17	Interrupt on Stall	
16	Interrupt on NAK	
15:6	Address base offset in DPSRAM of data buffer(s)	

NOTE

The data buffer base address must be 64-byte aligned as bits 0-5 are ignored

4.1.2.5.3. Buffer control register

The buffer control register contains information about the state of the data buffers for that endpoint. It is shared between the processor and the controller. If the endpoint is configured to be single buffered, only the first half (bits 0-15) of the buffer are used.

If double buffering, the buffer select starts at buffer 0. From then on, the buffer select flips between buffer 0 and 1 unless the "reset buffer select" bit is set.

For host interrupt and isochronous packets on EPx, the buffer full bit will be set on completion even if the transfer was unsuccessful. The error bits in the [SIE_STATUS](#) register can be read to determine the error.

Table 389. Buffer control register layout

Bit(s)	Function
31	Buffer 1 full - only valid for double buffered
30	Last buffer of transfer for buffer 1 - only valid for double buffered
29	Data PID for buffer 1 - DATA0 = 0, DATA1 = 1 - only valid for double buffered
27:28	Double buffer offset for Ichronous mode (0 = 128, 1 = 256, 2 = 512, 3 = 1024)
26	Available - can I be used for a transfer. 1 is yes, 0 is status from controller
25:16	Transfer length buffer 1 - only valid for double buffered
15	Buffer 0 full
14	Last buffer of transfer for buffer 0
13	Data PID for buffer 0 - DATA0 = 0, DATA1 = 1
12	Reset buffer select to buffer 0 - cleared at end of transfer. For DEVICE ONLY
11	Send STALL for device, STALL received for host
10	Available - can I be used for a transfer. 1 is yes, 0 is status from controller
9:0	Transfer length buffer 0

WARNING

If running `clk_sys` and `clk_usb` at different speeds, the available and stall bits should be set after the other data in the buffer control register. Otherwise the controller may initiate a transaction with data from a previous packet. That is to say, the controller could see the available bit set but get the data pid or length from the previous packet.

4.1.2.6. Device Controller

This section details how the device controller operates when it receives various packet types from the host.

4.1.2.6.1. SETUP

The device controller **MUST** always accept a setup packet from the host. That is why the first 8 bytes of the DPSRAM has dedicated space for the setup packet.

The [usbspec] states that receiving a setup packet also clears any stall bits on EP0. For this reason, the stall bits for EP0 are gated with two bits in the `EP_STALL_ARM` register. These bits are cleared when a setup packet is received. This means that to send a stall on EP0, you have to set both the stall bit in the buffer control register, and the appropriate bit in `EP_STALL_ARM`.

Barring any errors, the setup packet will be put into the setup packet buffer at DPSRAM offset `0x0`. The device controller will then reply with an ACK.

Finally, `SIE_STATUS.SETUP_REC` is set to indicate that a setup packet has been received. This will trigger an interrupt if the programmer has enabled the `SETUP_REC` interrupt (see `INTE`).

4.1.2.6.2. IN

From the device's point of view, an **IN** transfer means transferring data **INTO** the host. When an **IN** token is received from the host the request is handled as follows:

TOKEN phase:

- If **STALL** is set in the buffer control register (and if EP0, the appropriate `EP_STALL_ARM` bit is set) then send a **STALL** response and go back to idle.
- If **AVAILABLE** and **FULL** bits are set in buffer control move to the phase
- Otherwise send **NAK** unless this is an Isochronous endpoint, in which case go to idle.

DATA phase:

- Send **DATA**. If Isochronous go to idle. Otherwise move to ACK phase.

ACK phase:

- Wait for **ACK** packet from host. If there is a timeout then raise a timeout error. If **ACK** is received then the packet is done, so move to status phase.

STATUS phase:

- If this was the last buffer in the transfer (i.e. if the **LAST_BUFFER** bit in the buffer control register was set), set `SIE_STATUS.TRANS_COMPLETE`.
- If the endpoint is double buffered, flip the buffer select to the other buffer.
- Set a bit in `BUFF_STATUS` to indicate the buffer is done. When handling this event, the programmer should read `BUFF_CPU_SHOULD_HANDLE` to see if it is buffer 0 or buffer 1 that is finished. If the endpoint is double buffered it is possible to have both buffers done. The cleared `BUFF_STATUS` bit will be set again, and `BUFF_CPU_SHOULD_HANDLE` will change in this instance.
- Update status in the appropriate half of the buffer control register: length, pid, and last_buff are set. Everything else is written to zero.

If a **NAK** gets sent to the host the host will retry again later.

4.1.2.6.3. OUT

When an **OUT** token is received from the host, the request is handled as follows:

TOKEN phase:

- Is the **DATA** pid what is specified in the buffer control register? If not raise `SIE_STATUS.DATA_SEQ_ERROR`. (The data pid for an Isochronous endpoint is not checked because Isochronous data is always sent with a **DATA0** pid.)

- Is the **AVAILABLE** bit set and the **FULL** bit unset. If so go to the data phase, unless the **STALL** bit is set in which case the device controller will reply with a **STALL**.

DATA phase:

- Store received data in buffer. If Isochronous go to STATUS phase. Otherwise go to ACK phase.

ACK phase:

- Send ACK. Go to STATUS phase.

STATUS phase:

See status phase from [Section 4.1.2.6.2](#). The only difference is that the **FULL** bit is set in the buffer control register to indicate that data has been received whereas in the **IN** case the **FULL** bit is cleared to indicate that data has been sent.

4.1.2.6.4. Suspend and Resume

The USB device controller supports both suspend and resume, as well as remote resume (triggered with [SIE_CTRL.RESUME](#)), where the device initiates the resume. There is an interrupt / status bit in [SIE_STATUS](#). It is not necessary to enable the suspend and resume interrupts, as most devices do not need to care about suspend and resume.

The device goes into suspend when it does not see any start of frame packets (transmitted every 1ms) from the host.

i NOTE

If you enable the suspend interrupt, it is likely you will see a suspend interrupt when the device is first connected but the bus is idle. The bus can be idle for a few ms before the host begins sending start of frame packets. You will also see a suspend interrupt when the device is disconnected if you do not have a VBUS detect circuit connected. This is because without VBUS detection, it is impossible to tell the difference between being disconnected and suspended.

4.1.2.6.5. Errata

There are two hardware issues with the device controller, both of which have software workarounds. See [and RP2040-E2](#) and [RP2040-E5](#) for more information.

4.1.2.7. Host Controller

The host controller design is similar to the device controller. All transactions are started by the host, so the host is always dealing with transactions it has started. For this reason there is only one set of endpoint control / endpoint buffer control registers. There is also additional hardware to poll interrupt endpoints in the background when there are no software controlled transactions taking place.

The host needs to send keep-alive packets to the device every 1ms to keep the device from suspending. In Full Speed mode this is done by sending a **SOF** (start of frame) packet. In Low Speed mode, an **EOP** (end of packet) is sent. When setting up the controller, [SIE_CTRL.KEEP_ALIVE](#) and [SIE_CTRL.SOF_ENABLE`](#) should be set to enable these packets.

Several bits in [SIE_CTRL](#) are used to begin a host transaction:

- **SEND_SETUP** - Send a setup packet. This is typically used in conjunction with **RECEIVE_TRANS** so the setup packet will be sent followed by the additional data transaction expected from the device.
- **SEND_TRANS** - This transfer is **OUT** from the host
- **RECEIVE_TRANS** - This transfer is **IN** to the host
- **START_TRANS** - Start the transfer - non latching
- **STOP_TRANS** - Stop the current transfer - non latching
- **PREAMBLE_ENABLE** - Use this to send a packet to a Low Speed device on a Full Speed hub. This will send a **PRE** token packet before every packet the host sends (i.e. pre, token, pre, data, pre, ack).

- **SOF_SYNC** - The SOF Sync bit is used to delay the transaction until after the next SOF. This is useful for interrupt and isochronous endpoints. The Host controller prevents a transaction of 64bytes from clashing with the SOF packets. For longer Isochronous packet the software is responsible for preventing a collision by using the SOF Sync bit and limiting the number of packets sent in one frame. If a transaction is set up with multiple packets the SOF Sync bit only applies to the first packet.

4.1.2.7.1. SETUP

The **SETUP** packet sent from the host always comes from the dedicated 8 bytes of space at offset **0x0** of the DPSRAM. Like the device controller, there are no control registers associated with the setup packet. The parameters are hard coded and loaded into the hardware when you write to **START_TRANS** with the **SEND_SETUP** bit set. Once the setup packet has been sent, the host state machine will wait for an **ACK** from the device. If there is a timeout then an **RX_TIMEOUT** error will be raised. If the **SEND_TRANS** bit is set then the host state machine will move to the **OUT** phase. Most commonly the **SEND_SETUP** packet is used in conjunction with the **RECEIVE_TRANS** bit and will therefore move to the **IN** phase after sending a setup packet.

4.1.2.7.2. IN

An **IN** transfer is triggered with the **RECEIVE_TRANS** bit set when the **START_TRANS** bit is set. This may be preceded by a **SETUP** packet being sent if the **SEND_SETUP** bit was set.

CONTROL phase:

- Read *EPx control* register located at **0x80** to get the endpoint information:
 - Are we double buffered?
 - What interrupts to enable
 - Base address of the data buffer, or data buffers if in double buffered mode
 - Endpoint type
- Read *EPx buffer control* register at **0x100** to get the endpoint buffer information such as transfer length and data pid. The host state machine still checks for the presence of the **AVAILABLE** bit, so this needs to be set and **FULL** needs to be unset. The transaction will not happen until this is the case.

TOKEN phase:

- Send the **IN** token packet to the device. The target device address and endpoint come from the **ADDR_ENDP** register.

DATA phase:

- Receive the first data packet from the device. Raise RX timeout error if the device doesn't reply. Raise DATA SEQ ERROR if the data packet has wrong DATA PID.

ACK phase:

- Send ACK to device

STATUS phase:

- Set **BUFF_STATUS** bit and update buffer control register. Will set **FULL**, **LAST_BUFF** if applicable, **DATA_PID**, **WR_LEN**. **TRANS_COMPLETE** will be set if this is the last buffer in the transfer.

CONTROL phase (pt 2):

- The host state machine will keep performing **IN** transactions until **LAST_BUFF** is seen in the buffer_control register. If the host is in double buffered mode then the host controller will toggle between **BUF0** and **BUF1** sections of the buffer control register. Otherwise it will keep reading the buffer control register for buffer 0 and wait for the **FULL** to be unset and **AVAILABLE** to be set before starting the next **IN** transaction (i.e. wait in the control phase). The device can send a zero length packet to the host to indicate that it has no more data. In which case the host state machine will stop listening for more data regardless of if the **LAST_BUFF** flag was set or not. The host software can tell this has happened because **BUFF_DONE** will be set with a data length of 0 in the buffer control register.

⊖ WARNING

The USB host controller has a bug (RP2040-E4) that means the status written back to the buffer control register can appear in the wrong half of the register. Bits 0-15 are for buffer 0, and bits 16-31 are for buffer 1. The host controller has a buffer selector that is flipped after each transfer is complete. This buffer selector is incorrectly used when writing status information back to the buffer control register even in single buffered mode. The buffer selector is not used when reading the buffer control register. The implication of this is that host software needs to keep track of the buffer selector and shift the buffer control register to the right by 16 bits if the buffer selector is 1.

For more information, see [RP2040-E4](#).

Also see our TinyUSB host code: https://github.com/raspberrypi/tinyusb/tree/pico/src/portable/raspberrypi/rp2040/rp2040_usb.c Lines 177 - 183.

4.1.2.7.3. OUT

An **OUT** transfer is triggered with the **SEND_TRANS** bit set when the **START_TRANS** bit is set. This may be preceded by a **SETUP** packet being sent if the **SEND_SETUP** bit was set.

CONTROL phase:

- Read *EPx control* to get endpoint information (same as [Section 4.1.2.7.2](#))
- Read *EPx buffer control* to get the transfer length, data pid. **AVAILABLE** and **FULL** must be set for the transfer to start.

TOKEN phase

- Send **OUT** packet to the device. The target device address and endpoint come from the **ADDR_ENDP** register.

DATA phase:

- Send the first data packet to the device. If the endpoint type is Isoochronous then there is no ACK phase so the host controller will go straight to status phase. If **ACK** received then go to status phase. Otherwise:
 - If no reply is received than raise **SIE_STATUS.RX_TIMEOUT**.
 - If **NAK** received raise **SIE_STATUS.NAK_REC** and send the data packet again.
 - If **STALL** received then raise **SIE_STATUS.STALL_REC** and go to idle.

STATUS phase:

- Set **BUFF_STATUS** bit and update buffer control register. **FULL** will be set to 0. **TRANS_COMPLETE** will be set if this is the last buffer in the transfer.

⊖ WARNING

The bug mentioned above (RP2040-E4) in the IN section also applies to the OUT section.

CONTROL phase (pt 2):

If this isn't the last buffer in the transfer then wait for **FULL** and **AVAILABLE** to be set in the *EPx buffer control* register again.

4.1.2.7.4. Interrupt Endpoints

The host controller can poll interrupt endpoints on many devices (up to a maximum of 15 endpoints). To enable these, the programmer must:

- Pick the next free interrupt endpoint slot on the host controller (starting at 1, to a maximum of 15)
- Program the appropriate endpoint control register and buffer control register like you would with a normal **IN** or **OUT** transfer. Note that interrupt endpoints are only single buffered so the **BUF1** part of the buffer control register is invalid.

- Set the address and endpoint of the device in the appropriate **ADDR_ENDP** register (**ADDR_ENDP1** to **ADDR_ENDP15**). The preamble bit should be set if the device is Low Speed but attached to a Full Speed hub. The endpoint direction bit should also be set.
- Set the interrupt endpoint active bit in **INT_EP_CTRL** (i.e. set bit 1 to 15 of that register)

Typically an interrupt endpoint will be an **IN** transfer. For example, a USB hub would be polled to see if the state of any of its ports have changed. If there is no change the hub will reply with a **NAK** to the controller and nothing will happen. Similarly, a mouse will reply with a **NAK** unless the mouse has been moved since the last time the interrupt endpoint was polled.

Interrupt endpoints are polled by the controller once a **SOF** packet has been sent by the host controller.

The controller loops from 1 to 15 and will attempt to poll any interrupt endpoint with the **EP_ACTIVE** bit set to 1 in **INT_EP_CTRL**. The controller will then read the endpoint control register, and buffer control register to see if there is an available buffer (i.e. **FULL + AVAILABLE** if an **OUT** transfer and **NOT FULL + AVAILABLE** for an **IN** transfer). If not, the controller will move onto the next interrupt endpoint slot.

If there is an available buffer, then the transfer is dealt with the same as a normal **IN** or **OUT** transfer and the **BUFF_DONE** flag in **BUFF_STATUS** will be set when the interrupt endpoint has a valid buffer. **BUFF_CPU_SHOULD_HANDLE** is invalid for interrupt endpoints as there is only a single buffer that can ever be done (**RP2040-E3**).

4.1.2.8. VBUS Control

The USB controller can be connected up to GPIO pins (see [Section 2.18](#)) for the purpose of VBUS control:

- VBUS enable, used to enable VBUS in host mode. VBUS enable is set in **SIE_CTRL**
- VBUS detect, used to detect that VBUS is present in device mode. VBUS detect is a bit in **SIE_STATUS** and can also raise a **VBUS_DETECT** interrupt (enabled in **INTE**)
- VBUS overcurrent, used to detect an overcurrent event. Applicable to both device and host. VBUS overcurrent is a bit in **SIE_STATUS**.

It is not necessary to connect up any of these pins to GPIO. The host can permanently supply VBUS and detect a device being connected when either the DP or DM pin is pulled high. VBUS detect can be forced in **USB_PWR**.

4.1.3. Programmer's Model

4.1.3.1. TinyUSB

The RP2040 TinyUSB port should be considered as the reference implementation for this USB controller. This port can be found in:

https://github.com/raspberrypi/tinyusb/tree/pico/src/portable/raspberrypi/rp2040/dcd_rp2040.c

https://github.com/raspberrypi/tinyusb/tree/pico/src/portable/raspberrypi/rp2040/hcd_rp2040.c

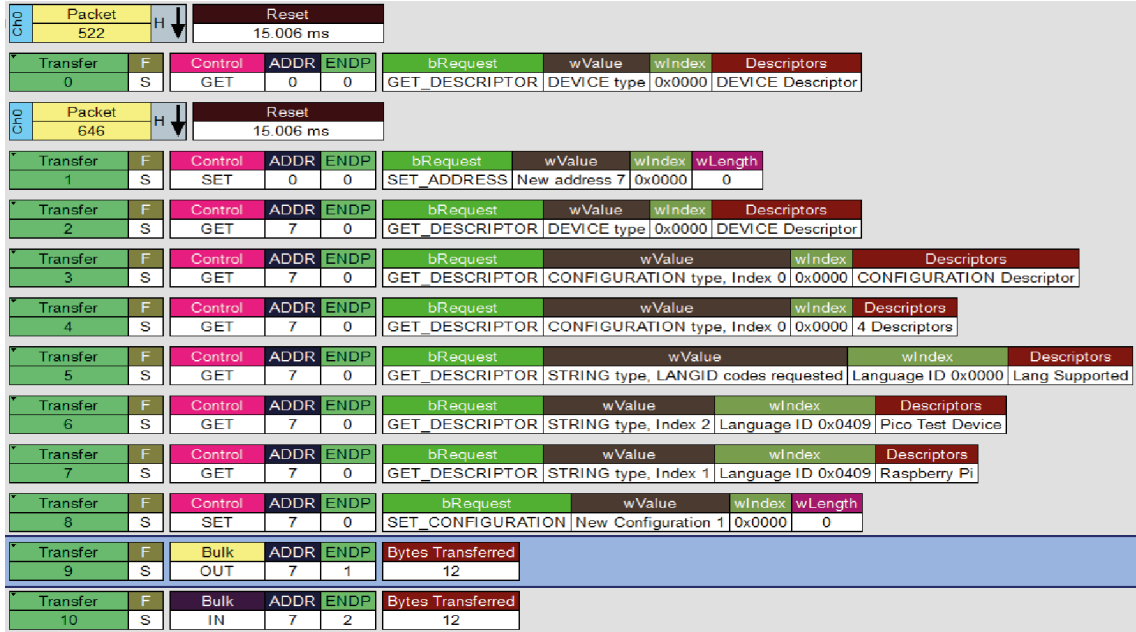

https://github.com/raspberrypi/tinyusb/tree/pico/src/portable/raspberrypi/rp2040/rp2040_usb.h

4.1.3.2. Standalone device example

A standalone USB device example, `dev_lowlevel`, makes it easier to understand how to interact with the USB controller without needing to understand the TinyUSB abstractions. In addition to endpoint 0, the standalone device has two bulk endpoints: EP1 OUT and EP2 IN. The device is designed to send whatever data it receives on EP1 to EP2. The example comes with a small Python script that writes "Hello World" into EP1 and checks that it is correctly received on EP2.

The code included in this section will walk you through setting up to the USB device controller to receive a setup packet, and then respond to the setup packet.

Figure 54. USB analyser trace of the dev_lowlevel USB device example. The control transfers are the device enumeration. The first bulk OUT (out from the host) transfer, highlighted in blue, is the host sending "Hello World" to the device. The second bulk transfer IN (in to the host), is the device returning "Hello World" to the host.

4.1.3.2.1. Device controller initialisation

The following code initialises the USB device.

Pico Examples: https://github.com/raspberrypi/pico-examples/tree/pre_release/usb/device/dev_lowlevel/dev_lowlevel.c Lines 183 - 218

```

183 void usb_device_init() {
184     // Reset usb controller
185     reset_block(RESETS_RESET_USBCTRL_BITS);
186     unreset_block_wait(RESETS_RESET_USBCTRL_BITS);
187
188     // Clear any previous state in dpram just in case
189     memset(usb_dpram, 0, sizeof(*usb_dpram)); ①
190
191     // Enable USB interrupt at processor
192     irq_enable(USBCTRL_IRQ, true);
193
194     // Mux the controller to the onboard usb phy

196
197     // Force VBUS detect so the device thinks it is plugged into a host
198     usb_hw->pwr = USB_USB_PWR_VBUS_DETECT_BITS | USB_USB_PWR_VBUS_DETECT_OVERRIDE_EN_BITS;
199
200     // Enable the USB controller in device mode.
201     usb_hw->main_ctrl = USB_MAIN_CTRL_CONTROLLER_EN_BITS;
202
203     // Enable an interrupt per EP0 transaction
204     usb_hw->sie_ctrl = USB_SIE_CTRL_EP0_INT_1BUF_BITS; ②
205
206     // Enable interrupts for when a buffer is done, when the bus is reset,
207     // and when a setup packet is recieved
208     usb_hw->inte = USB_INTS_BUFF_STATUS_BITS |
209                 USB_INTS_BUS_RESET_BITS |
210                 USB_INTS_SETUP_REQ_BITS;
211
212     // Set up endpoints (endpoint control registers)
213     // described by device configuration
214     usb_setup_endpoints();
215

```

```

216 // Present full speed device by enabling pull up on DP
217 usb_hw_set->sie_ctrl = USB_SIE_CTRL_PULLUP_EN_BITS;
218 }

```

4.1.3.2.2. Configuring the endpoint control registers for EP1 and EP2

The function `usb_configure_endpoints` loops through each endpoint defined in the device configuration (including EP0 in and EP0 out, which don't have an endpoint control register defined) and calls the `usb_configure_endpoint` function. This sets up the endpoint control register for that endpoint:

Pico Examples: https://github.com/raspberrypi/pico-examples/tree/pre_release/usb/device/dev_lowlevel/dev_lowlevel.c Lines 149 - 164

```

149 void usb_setup_endpoint(const struct usb_endpoint_configuration *ep) {
150     printf("Set up endpoint 0x%x with buffer address 0x%p\n", ep->descriptor-
        >bEndpointAddress, ep->data_buffer);
151
152     // EP0 doesn't have one so return if that is the case
153     if (!ep->endpoint_control) {
154         return;
155     }
156
157     // Get the data buffer as an offset of the USB controller's DPRAM
158     uint32_t dpram_offset = usb_buffer_offset(ep->data_buffer);
159     uint32_t reg = EP_CTRL_ENABLE_BITS
160                 | EP_CTRL_INTERRUPT_PER_BUFFER
161                 | (ep->descriptor->bmAttributes << EP_CTRL_BUFFER_TYPE_LSB)
162                 | dpram_offset;
163     *ep->endpoint_control = reg;
164 }

```

4.1.3.2.3. Receiving a setup packet

An interrupt is raised when a setup packet is received, so the interrupt handler must handle this event:

Pico Examples: https://github.com/raspberrypi/pico-examples/tree/pre_release/usb/device/dev_lowlevel/dev_lowlevel.c Lines 484 - 494

```

484 void isr_usbctrl(void) {
485     // USB interrupt handler
486     uint32_t status = usb_hw->ints;
487     uint32_t handled = 0;
488
489     // Setup packet received
490     if (status & USB_INTS_SETUP_REQ_BITS) {
491         handled |= USB_INTS_SETUP_REQ_BITS;
492         usb_hw_clear->sie_status = USB_SIE_STATUS_SETUP_REC_BITS;
493         usb_handle_setup_packet();
494     }

```

The setup packet gets written to the first 8 bytes of the USB ram, so the setup packet handler casts that area of memory to `struct usb_setup_packet *`.

Pico Examples: https://github.com/raspberrypi/pico-examples/tree/pre_release/usb/device/dev_lowlevel/dev_lowlevel.c Lines 377 - 420

```

377 void usb_handle_setup_packet(void) {
378     volatile struct usb_setup_packet *pkt = (volatile struct usb_setup_packet *) &usb_dpram
        ->setup_packet;

```

```

379     uint8_t req_direction = pkt->bmRequestType;
380     uint8_t req = pkt->bRequest;
381
382     // Reset PID to 1 for EP0 IN
383     usb_get_endpoint_configuration(EP0_IN_ADDR)->next_pid = 1u;
384
385     if (req_direction == USB_DIR_OUT) {
386         if (req == USB_REQUEST_SET_ADDRESS) {
387             usb_set_device_address(pkt);
388         } else if (req == USB_REQUEST_SET_CONFIGURATION) {
389             usb_set_device_configuration(pkt);
390         } else {
391             printf("Other OUT request (0x%x)\r\n", pkt->bRequest);
392         }
393     } else if (req_direction == USB_DIR_IN) {
394         if (req == USB_REQUEST_GET_DESCRIPTOR) {
395             uint16_t descriptor_type = pkt->wValue >> 8;
396
397             switch (descriptor_type) {
398                 case USB_DT_DEVICE:
399                     usb_handle_device_descriptor();
400                     printf("GET DEVICE DESCRIPTOR\r\n");
401                     break;
402
403                 case USB_DT_CONFIG:
404                     usb_handle_config_descriptor(pkt);
405                     printf("GET CONFIG DESCRIPTOR\r\n");
406                     break;
407
408                 case USB_DT_STRING:
409                     usb_handle_string_descriptor(pkt);
410                     printf("GET STRING DESCRIPTOR\r\n");
411                     break;
412
413                 default:
414                     printf("Unhandled GET_DESCRIPTOR type 0x%x\r\n", descriptor_type);
415             }
416         } else {
417             printf("Other IN request (0x%x)\r\n", pkt->bRequest);
418         }
419     }
420 }

```

4.1.3.2.4. Replying to a setup packet on EP0 IN

The first thing a host will request is the device descriptor, the following code handles that setup request.

Pico Examples: https://github.com/raspberrypi/pico-examples/tree/pre_release/usb/device/dev_lowlevel/dev_lowlevel.c Lines 267 - 274

```

267 void usb_handle_device_descriptor(void) {
268     const struct usb_device_descriptor *d = dev_config.device_descriptor;
269     // EP0 in
270     struct usb_endpoint_configuration *ep = usb_get_endpoint_configuration(EP0_IN_ADDR);
271     // Always respond with pid 1
272     ep->next_pid = 1;
273     usb_start_transfer(ep, (uint8_t *) d, sizeof(struct usb_device_descriptor));
274 }

```

The `usb_start_transfer` function copies the data to send into the appropriate hardware buffer, and configures the buffer

control register. Once the buffer control register has been written to, the device controller will respond to the host with the data. Before this point, the device will reply with a **NAK**.

Pico Examples: https://github.com/raspberrypi/pico-examples/tree/pre_release/usb/device/dev_lowlevel/dev_lowlevel.c Lines 239 - 261

```

239 void usb_start_transfer(struct usb_endpoint_configuration *ep, uint8_t *buf, uint16_t len)
    {
240     // We are asserting that the length is <= 64 bytes for simplicity of the example.
241     // For multi packet transfers see the tinyusb port.
242     assert(len <= 64);
243
244     printf("Start transfer of len %d on ep addr 0x%x\n", len, ep->descriptor-
    >bEndpointAddress);
245
246     // Prepare buffer control register value
247     uint32_t val = len | USB_BUF_CTRL_AVAIL;
248
249     if (ep_is_tx(ep)) {
250         // Need to copy the data from the user buffer to the usb memory
251         memcpy((void *) ep->data_buffer, (void *) buf, len);
252         // Mark as full
253         val |= USB_BUF_CTRL_FULL;
254     }
255
256     // Set pid and flip for next transfer
257     val |= ep->next_pid ? USB_BUF_CTRL_DATA1_PID : USB_BUF_CTRL_DATA0_PID;
258     ep->next_pid ^= 1u;
259
260     *ep->buffer_control = val;
261 }

```

4.1.4. List of Registers

Table 390. List of USB registers

Offset	Name	Info
0x00	ADDR_ENDP	Device address and endpoint control
0x04	ADDR_ENDP1	Interrupt endpoint 1. Only valid for HOST mode.
0x08	ADDR_ENDP2	Interrupt endpoint 2. Only valid for HOST mode.
0x0c	ADDR_ENDP3	Interrupt endpoint 3. Only valid for HOST mode.
0x10	ADDR_ENDP4	Interrupt endpoint 4. Only valid for HOST mode.
0x14	ADDR_ENDP5	Interrupt endpoint 5. Only valid for HOST mode.
0x18	ADDR_ENDP6	Interrupt endpoint 6. Only valid for HOST mode.
0x1c	ADDR_ENDP7	Interrupt endpoint 7. Only valid for HOST mode.
0x20	ADDR_ENDP8	Interrupt endpoint 8. Only valid for HOST mode.
0x24	ADDR_ENDP9	Interrupt endpoint 9. Only valid for HOST mode.
0x28	ADDR_ENDP10	Interrupt endpoint 10. Only valid for HOST mode.
0x2c	ADDR_ENDP11	Interrupt endpoint 11. Only valid for HOST mode.
0x30	ADDR_ENDP12	Interrupt endpoint 12. Only valid for HOST mode.
0x34	ADDR_ENDP13	Interrupt endpoint 13. Only valid for HOST mode.
0x38	ADDR_ENDP14	Interrupt endpoint 14. Only valid for HOST mode.

Offset	Name	Info
0x3c	ADDR_ENDP15	Interrupt endpoint 15. Only valid for HOST mode.
0x40	MAIN_CTRL	Main control register
0x44	SOF_WR	Set the SOF (Start of Frame) frame number in the host controller. The SOF packet is sent every 1ms and the host will increment the frame number by 1 each time.
0x48	SOF_RD	Read the last SOF (Start of Frame) frame number seen. In device mode the last SOF received from the host. In host mode the last SOF sent by the host.
0x4c	SIE_CTRL	SIE control register
0x50	SIE_STATUS	SIE status register
0x54	INT_EP_CTRL	interrupt endpoint control register
0x58	BUFF_STATUS	Buffer status register. A bit set here indicates that a buffer has completed on the endpoint (if the buffer interrupt is enabled). It is possible for 2 buffers to be completed, so clearing the buffer status bit may instantly re set it on the next clock cycle.
0x5c	BUFF_CPU_SHOULD_HANDLE	Which of the double buffers should be handled. Only valid if using an interrupt per buffer (i.e. not per 2 buffers). Not valid for host interrupt endpoint polling because they are only single buffered.
0x60	EP_ABORT	Device only: Can be set to ignore the buffer control register for this endpoint in case you would like to revoke a buffer. A NAK will be sent for every access to the endpoint until this bit is cleared. A corresponding bit in EP_ABORT_DONE is set when it is safe to modify the buffer control register.
0x64	EP_ABORT_DONE	Device only: Used in conjunction with EP_ABORT . Set once an endpoint is idle so the programmer knows it is safe to modify the buffer control register.
0x68	EP_STALL_ARM	Device: this bit must be set in conjunction with the STALL bit in the buffer control register to send a STALL on EP0. The device controller clears these bits when a SETUP packet is received because the USB spec requires that a STALL condition is cleared when a SETUP packet is received.
0x6c	NAK_POLL	Used by the host controller. Sets the wait time in microseconds before trying again if the device replies with a NAK.
0x70	EP_STATUS_STALL_NAK	Device: bits are set when the IRQ_ON_NAK or IRQ_ON_STALL bits are set. For EP0 this comes from SIE_CTRL . For all other endpoints it comes from the endpoint control register.
0x74	USB_MUXING	Where to connect the USB controller. Should be to_phy by default.
0x78	USB_PWR	Overrides for the power signals in the event that the VBUS signals are not hooked up to GPIO. Set the value of the override and then the override enable to switch over to the override value.
0x7c	USBPHY_DIRECT	This register allows for direct control of the USB phy. Use in conjunction with usbphy_direct_override register to enable each override bit.
0x80	USBPHY_DIRECT_OVERRIDE	Override enable for each control in usbphy_direct
0x84	USBPHY_TRIM	Used to adjust trim values of USB phy pull down resistors.

Offset	Name	Info
0x8c	INTR	Raw Interrupts
0x90	INTE	Interrupt Enable
0x94	INTF	Interrupt Force
0x98	INTS	Interrupt status after masking & forcing

ADDR_ENDP Register

Description

Device address and endpoint control

Table 391.
ADDR_ENDP Register

Bits	Name	Description	Type	Reset
31:20	Reserved.	-	-	-
19:16	ENDPOINT	Device endpoint to send data to. Only valid for HOST mode.	RW	0x0
15:7	Reserved.	-	-	-
6:0	ADDRESS	In device mode, the address that the device should respond to. Set in response to a SET_ADDR setup packet from the host. In host mode set to the address of the device to communicate with.	RW	0x00

ADDR_ENDP1, ADDR_ENDP2, ..., ADDR_ENDP14, ADDR_ENDP15 Registers

Description

Interrupt endpoint *N*. Only valid for HOST mode.

17	RPU_OPT	Device: Pull-up strength (0=1K2, 1=2k3)	RW	0x0
16	PULLUP_EN	Device: Enable pull up resistor	RW	0x0
15	PULLDOWN_EN	Host: Enable pull down resistors	RW	0x0
14	Reserved.	-	-	-
13	RESET_BUS	Host: Reset bus	SC	0x0

Bits	Name	Description	Type	Reset
12	RESUME	Device: Remote wakeup. Device can initiate its own resume after suspend.	SC	0x0
11	VBUS_EN	Host: Enable VBUS	RW	0x0
10	KEEP_ALIVE_EN	Host: Enable keep alive packet (for low speed bus)	RW	0x0
9	SOF_EN	Host: Enable SOF generation (for full speed bus)	RW	0x0
8	SOF_SYNC	Host: Delay packet(s) until after SOF	RW	0x0
7	Reserved.	-	-	-
6	PREAMBLE_EN	Host: Preamble enable for LS device on FS hub	RW	0x0
5	Reserved.	-	-	-
4	STOP_TRANS	Host: Stop transaction	SC	0x0
3	RECEIVE_DATA	Host: Receive transaction (IN to host)	RW	0x0
2	SEND_DATA	Host: Send transaction (OUT from host)	RW	0x0
1	SEND_SETUP	Host: Send Setup packet	RW	0x0
0	START_TRANS	Host: Start transaction	SC	0x0

SIE_STATUS Register

Description

SIE status register

Table 397.
SIE_STATUS Register

Bits	Name	Description	Type	Reset
31	DATA_SEQ_ERROR	Data Sequence Error. The device can raise a sequence error in the following conditions: * A SETUP packet is received followed by a DATA1 packet (data phase should always be DATA0) * An OUT packet is received from the host but doesn't match the data pid in the buffer control register read from DPSRAM The host can raise a data sequence error in the following conditions: * An IN packet from the device has the wrong data PID	WC	0x0
30	ACK_REC	ACK received. Raised by both host and device.	WC	0x0
29	STALL_REC	Host: STALL received	WC	0x0
28	NAK_REC	Host: NAK received	WC	0x0
27	RX_TIMEOUT	RX timeout is raised by both the host and device if an ACK is not received in the maximum time specified by the USB spec.	WC	0x0
26	RX_OVERFLOW	RX overflow is raised by the Serial RX engine if the incoming data is too fast.	WC	0x0

Bits	Name	Description	Type	Reset
25	BIT_STUFF_ERROR	Bit Stuff Error. Raised by the Serial RX engine.	WC	0x0
24	CRC_ERROR	CRC Error. Raised by the Serial RX engine.	WC	0x0
23:20	Reserved.	-	-	-
19	BUS_RESET	Device: bus reset received	WC	0x0
18	TRANS_COMPLETE	Transaction complete. Raised by device if: * An IN or OUT packet is sent with the LAST_BUFF bit set in the buffer control register Raised by host if: * A setup packet is sent when no data in or data out transaction follows * An IN packet is received and the LAST_BUFF bit is set in the buffer control register * An IN packet is received with zero length * An OUT packet is sent and the LAST_BUFF bit is set	WC	0x0
17	SETUP_REC	Device: Setup packet received	WC	0x0
16	CONNECTED	Device: connected	RO	0x0
15:12	Reserved.	-	-	-
11	RESUME	Host: Device has initiated a remote resume. Device: host has initiated a resume.	WC	0x0
10	VBUS_OVER_CURRENT	VBUS over current detected	RO	0x0
9:8	SPEED	Host: device speed. Disconnected = 00, LS = 01, FS = 10	RO	0x0
7:5	Reserved.	-	-	-
4	SUSPENDED	Bus in suspended state. Valid for device and host. Host and device will go into suspend if neither Keep Alive / SOF frames are enabled.	RO	0x0
3:2	LINE_STATE	USB bus line state	RO	0x0
1	Reserved.	-	-	-
0	VBUS_DETECTED	Device: VBUS Detected	RO	0x0

INT_EP_CTRL Register

Description

interrupt endpoint control register

Table 398.
INT_EP_CTRL Register

Bits	Name	Description	Type	Reset
31:16	Reserved.	-	-	-
15:1	INT_EP_ACTIVE	Host: Enable interrupt endpoint 1 -> 15	RW	0x0000
0	Reserved.	-	-	-

BUFF_STATUS Register

Description

Buffer status register. A bit set here indicates that a buffer has completed on the endpoint (if the buffer interrupt is enabled). It is possible for 2 buffers to be completed, so clearing the buffer status bit may instantly re set it on the next clock cycle.

Table 399.

0	EP0_IN		RO	0x0

EP_ABORT Register

Description

Device only: Can be set to ignore the buffer control register for this endpoint in case you would like to revoke a buffer. A NAK will be sent for every access to the endpoint until this bit is cleared. A corresponding bit in **EP_ABORT_DONE** is set when it is safe to modify the buffer control register.

Table 401. EP_ABORT Register

Bits	Name	Description	Type	Reset

0	EP0_IN		WC	0x0

EP_STALL_ARM Register

Description

Device: this bit must be set in conjunction with the **STALL** bit in the buffer control register to send a STALL on EP0. The device controller clears these bits when a SETUP packet is received because the USB spec requires that a STALL condition is cleared when a SETUP packet is received.

Table 403. EP_STALL_ARM Register

Bits	Name	Description	Type	Reset
31:2	Reserved.	-	-	-
1	EP0_OUT		RW	0x0
0	EP0_IN		RW	0x0

NAK_POLL Register

Description

Used by the host controller. Sets the wait time in microseconds before trying again if the device replies with a NAK.

Table 404. NAK_POLL Register

Bits	Name	Description	Type	Reset
31:26	Reserved.	-	-	-
25:16	DELAY_FS	NAK polling interval for a full speed device	RW	0x010
15:10	Reserved.	-	-	-
9:0	DELAY_LS	NAK polling interval for a low speed device	RW	0x010

EP_STATUS_STALL_NAK Register

Description

Device: bits are set when the **IRQ_ON_NAK** or **IRQ_ON_STALL** bits are set. For EP0 this comes from **SIE_CTRL**. For all other endpoints it comes from the endpoint control register.

Table 405. EP_STATUS_STALL_NAK Register

4.2. DMA

The RP2040 Direct Memory Access (DMA) master performs bulk data transfers on a processor's behalf. This leaves processors free to attend to other tasks, or enter low-power sleep states. The data throughput of the DMA is also significantly higher than one of RP2040's processors.

Figure 55. DMA Architecture Overview.
 The read master can read data from some address every clock cycle. Likewise, the write master can write to another address. The address generator produces matched pairs of read and write addresses, which the masters consume through the address FIFOs. Up to 12 transfer sequences may be in progress simultaneously, supervised by software via the control and status registers.

The DMA can perform one read access and one write access, up to 32 bits in size, every clock cycle. There are 12 independent channels, each which supervise a sequence of bus transfers, usually in one of the following scenarios:

- *Memory-to-peripheral*: a peripheral signals the DMA when it needs more data to transmit. The DMA reads data from an array in RAM or flash, and writes to the peripheral's data FIFO.
- *Peripheral-to-memory*: a peripheral signals the DMA when it has received data. The DMA reads this data from the peripheral's data FIFO, and writes it to an array in RAM.
- *Memory-to-memory*: the DMA transfers data between two buffers in RAM, as fast as possible.

Each channel has its own control and status registers (CSRs), with which software can program and monitor the channel's progress. When multiple channels are active at the same time, the DMA shares bandwidth evenly between the channels, with round-robin over all channels which are currently requesting data transfers.

The transfer size can be either 32, 16, or 8 bits. This is configured once per channel: source transfer size and destination transfer size are the same. The DMA performs standard byte lane replication on narrow writes, so byte data is available in all 4 bytes of the databus, and halfword data in both halfwords.

Channels can be combined in varied ways for more sophisticated behaviour and greater autonomy. For example, one channel can configure another, loading configuration data from a sequence of control blocks in memory, and the second can then call back to the first via the `CHAIN_TO` option, when it needs to be reconfigured.

Making the DMA more autonomous means that much less processor supervision is required: overall this allows the system to do more at once, or to dissipate less power.

4.2.1. Configuring Channels

Each channel has four control/status registers:

- `READ_ADDR` is a pointer to the next address to be read from
- `WRITE_ADDR` is a pointer to the next address to be written to
- `TRANS_COUNT` shows the number of transfers remaining in the current transfer sequence, and is used to program the number of transfers in the next transfer sequence (see [Section 4.2.1.2](#)).
- `CTRL` is used to configure all other aspects of the channel's behaviour, to enable/disable it, and to check for completion.

These are live registers: they update continuously as the channel progresses.

4.2.1.1. Read and Write Addresses

`READ_ADDR` and `WRITE_ADDR` contain the address the channel will next read from, and write to, respectively. These registers update automatically after each read/write access. They increment by 1, 2 or 4 bytes at a time, depending on the transfer size configured in `CTRL`.

Software should generally program these registers with new start addresses each time a new transfer sequence starts. If `READ_ADDR` and `WRITE_ADDR` are not reprogrammed, the DMA will use the current values as start addresses for the next

transfer. For example:

- If the address does not increment (e.g. it is the address of a peripheral FIFO), and the next transfer sequence is to/from that *same* address, there is no need to write to the register again.
- When transferring to/from a consecutive series of buffers in memory (e.g. scattering and gathering), an address register will already have incremented to the start of the next buffer at the completion of a transfer.

By not programming all four CSRs for each transfer sequence, software can use shorter interrupt handlers, and more compact control block formats when used with channel chaining (see register aliases in [Section 4.2.2.1](#), chaining in [Section 4.2.2.2](#)).

CAUTION

`READ_ADDR` and `WRITE_ADDR` must always be aligned to the current transfer size, as specified in `CTRL.DATA_SIZE`. It is up to software to ensure the initial values are correctly aligned.

4.2.1.2. Transfer Count

Reading from `TRANS_COUNT` yields the number of transfers remaining in the current transfer sequence. This value updates continuously as the channel progresses. Writing to `TRANS_COUNT` sets the length of the *next* transfer sequence. Up to $2^{32} - 1$ transfers can be performed in one sequence.

Each time the channel starts a new transfer sequence, the most recent value written to `TRANS_COUNT` is copied to the live transfer counter, which will then start to decrement again as the new transfer sequence makes progress. For debugging purposes, the last value written can be read from the `DBG_TCR` (`TRANS_COUNT` reload value) register.

If the channel is triggered multiple times without intervening writes to `TRANS_COUNT`, it performs the same number of transfers each time. For example, when chained to, one channel might load a fixed-size control block into another channel's CSRs. `TRANS_COUNT` would be programmed once by software, and then reload automatically every time.

Alternatively, `TRANS_COUNT` can be written with a new value before starting each transfer sequence. If `TRANS_COUNT` is the channel trigger (see [Section 4.2.2.1](#)), the channel will start immediately, and the value just written will be used, *not* the value currently in the reload register.

NOTE

the `TRANS_COUNT` is the number of *transfers* to be performed. The total number of bytes transferred is `TRANS_COUNT` times the size of each transfer in bytes, given by `CTRL.DATA_SIZE`.

4.2.1.3. Control/Status

The `CTRL` register has more, smaller fields than the other 3 registers, and full details of these are given in the `CTRL` register listings. Among other things, `CTRL` is used to:

- Configure the size of this channel's data transfers, via `CTRL.DATA_SIZE`. Reads and writes are the same size.
- Configure if and how `READ_ADDR` and `WRITE_ADDR` increment after each read or write, via `CTRL.INCR_WRITE`, `CTRL.INCR_READ`, `CTRL.RING_SEL`, `CTRL.RING_SIZE`. Ring transfers are available, where one of the address pointers wraps at some power-of-2 boundary.
- Select another channel (or none) to be triggered when this channel completes, via `CTRL.CHAIN_TO`.
- Select a peripheral data request (DREQ) signal to pace this channel's transfers, via `CTRL.TREQ_SEL`.
- See when the channel is idle, via `CTRL.BUSY`.
- See if the channel has encountered a bus error, e.g. due to a faulty address being accessed, via `CTRL.AHB_ERROR`, `CTRL.READ_ERROR`, or `CTRL.WRITE_ERROR`.

4.2.2. Starting Channels

There are three ways to start a channel:

- Writing to a channel trigger register
- A chain trigger from another channel which has just completed, and has its **CHAIN_TO** field configured
- The **MULTI_CHAN_TRIGGER** register, which can start multiple channels at once

Each of these covers different use cases. For example, trigger registers are simple and efficient when configuring and starting a channel in an interrupt service routine, and **CHAIN_TO** allows one channel to callback to another channel, which can then reconfigure the first channel.

NOTE

Triggering a channel which is already running has no effect.

4.2.2.1. Aliases and Triggers

Table 415. Control register aliases. Each channel has four control/status registers. Each register can be accessed at multiple different addresses. In each naturally-aligned group of four, all four registers appear, in different orders.

Offset	+0x0	+0x4	+0x8	+0xC (Trigger)
0x00 (Alias 0)	READ_ADDR	WRITE_ADDR	TRANS_COUNT	CTRL_TRIG
0x10 (Alias 1)	CTRL	READ_ADDR	WRITE_ADDR	TRANS_COUNT_TRIG
0x20 (Alias 2)	CTRL	TRANS_COUNT	READ_ADDR	WRITE_ADDR_TRIG
0x30 (Alias 3)	CTRL	WRITE_ADDR	TRANS_COUNT	READ_ADDR_TRIG

The four CSRs are aliased multiple times in memory. Each alias – of which there are four – exposes the same four physical registers, but in a different order. The final register in each alias (at offset **+0xC**, highlighted) is a trigger register. Writing to the trigger register starts the channel.

Often, only alias 0 is used, and aliases 1-3 can be ignored. The channel is configured *and* started by writing **READ_ADDR**, **WRITE_ADDR**, **TRANS_COUNT** and finally **CTRL**. Since **CTRL** is the trigger register in alias 0, this starts the channel.

The other aliases allow more compact control block lists when using one channel to configure another, and more efficient reconfiguration and launch in interrupt handlers:

- Each CSR is a trigger register in one of the aliases:
 - When gathering fixed-size buffers into a peripheral, the DMA channel can be configured and launched by writing only **READ_ADDR_TRIG**.
 - When scattering from a peripheral to fixed-size buffers, the channel can be configured and launched by writing only **WRITE_ADDR_TRIG**.
- Useful combinations of registers appear as naturally-aligned tuples which contain a trigger register. In conjunction with channel chaining and address wrapping, these implement compressed control block formats, e.g.:
 - (**WRITE_ADDR**, **TRANS_COUNT_TRIG**) for peripheral scatter operations
 - (**TRANS_COUNT**, **READ_ADDR_TRIG**) for peripheral gather operations, or calculating CRCs on a list of buffers
 - (**READ_ADDR**, **WRITE_ADDR_TRIG**) for manipulating fixed-size buffers in memory

Trigger registers do not start the channel if:

- The channel is disabled via **CTRL.EN**. (If the trigger is **CTRL**, the just-written value of **EN** is used, *not* the value currently in the **CTRL** register.)
- The channel is already running

- The value 0 is written to the trigger register. (This is useful for ending control block chains. See null triggers, [Section 4.2.2.3](#))

4.2.2.2. Chaining

When a channel completes, it can name a different channel to immediately be triggered. This can be used as a callback for the second channel to reconfigure and restart the first.

This feature is configured through the `CHAIN_TO` field in the channel `CTRL` register. This 4-bit value selects a channel that will start when this one finishes. A channel can not chain to itself. Setting `CHAIN_TO` to a channel's own index means no chaining will take place.

Chain triggers behave the same as triggers from other sources, such as trigger registers. For example, they cause `TRANS_COUNT` to reload, and they are ignored if the targeted channel is already running.

TO DO: GRAHAM/LIAM: this next paragraph should be a code sample:

One application is for a channel to request reconfiguration by another channel, from a sequence of control blocks in memory. Channel A is configured to perform a wrapped transfer from memory to channel B's control registers (including a trigger register), and channel B is configured to chain back to channel A when it completes each transfer sequence.

Use of the register aliases (section [Section 4.2.2.1](#)) enables compact formats for DMA control blocks: as little as one word in some cases.

Another use of chaining is a "ping-pong" configuration, where two channels each trigger one another. The processor can respond to the channel completion interrupts, and reconfigure each channel after it completes; however, the chained channel, which has already been configured, starts immediately. In other words, channel configuration and channel operation are pipelined. Performance can improve dramatically where many short transfer sequences are required.

Section [Section 4.2.6](#) goes into more detail on the possibilities of chain triggers, in the real world.

4.2.2.3. Null Triggers and Chain Interrupts

As mentioned in [Section 4.2.2.1](#), writing all-zeroes to a trigger register does *not* start the channel. This is called a null trigger, and it has two purposes:

- Cause a halt at the end of an array of control blocks, by appending an all-zeroes block
- Reduce the number of interrupts generated when control blocks are used

By default, a channel will generate an interrupt each time it finishes a transfer sequence, unless that channel's IRQ is masked in `INTE0` or `INTE1`. The rate of interrupts can be excessive, particularly as processor attention is generally not required while a sequence of control blocks are in progress; however, processor attention is required at the end of a chain.

The channel `CTRL` register has a field called `IRQ_QUIET`. Its default value is 0. When this set to 1, channels generate an interrupt when they receive a null trigger, and at no other time. The interrupt is generated by the channel which receives the trigger.

4.2.3. Data Request (DREQ)

Peripherals produce or consume data at their own pace. If the DMA simply transferred data as fast as possible, loss or corruption of data would ensue. DREQs are a communication channel between peripherals and the DMA, which enables the DMA to pace transfers according to the needs of the peripheral.

The `CTRL.TREQ_SEL` (transfer request) field selects an external DREQ. It can also be used to select one of the internal pacing timers, or select no TREQ at all (the transfer proceeds as fast as possible), e.g. for memory-to-memory transfers.

4.2.3.1. System DREQ Table

There is a global assignment of DREQ numbers to peripheral DREQ channels.

Table 416. DREQs

DREQ	DREQ Channel	DREQ	DREQ Channel	DREQ	DREQ Channel	DREQ	DREQ Channel
0	DREQ_PIO0_TX0	10	DREQ_PIO1_TX2	20	DREQ_UART0_TX	30	DREQ_PWM_WRAP6
1	DREQ_PIO0_TX1	11	DREQ_PIO1_TX3	21	DREQ_UART0_RX	31	DREQ_PWM_WRAP7
2	DREQ_PIO0_TX2	12	DREQ_PIO1_RX0	22	DREQ_UART1_TX	32	DREQ_I2C0_TX
3	DREQ_PIO0_TX3	13	DREQ_PIO1_RX1	23	DREQ_UART1_RX	33	DREQ_I2C0_RX
4	DREQ_PIO0_RX0	14	DREQ_PIO1_RX2	24	DREQ_PWM_WRAP0	34	DREQ_I2C1_TX
5	DREQ_PIO0_RX1	15	DREQ_PIO1_RX3	25	DREQ_PWM_WRAP1	35	DREQ_I2C1_RX
6	DREQ_PIO0_RX2	16	DREQ_SPI0_TX	26	DREQ_PWM_WRAP2	36	DREQ_ADC
7	DREQ_PIO0_RX3	17	DREQ_SPI0_RX	27	DREQ_PWM_WRAP3	37	DREQ_XIP_STREAM
8	DREQ_PIO1_TX0	18	DREQ_SPI1_TX	28	DREQ_PWM_WRAP4	38	DREQ_XIP_SSITX
9	DREQ_PIO1_TX1	19	DREQ_SPI1_RX	29	DREQ_PWM_WRAP5	39	DREQ_XIP_SSIRX

4.2.3.2. Credit-based DREQ Scheme

The RP2040 DMA is designed for systems where:

- The area and power cost of large peripheral data FIFOs is prohibitive
- The bandwidth demands of individual peripherals may be high, e.g. >50% bus injection rate for short periods
- Bus latency is low, but multiple masters may be competing for bus access

In addition, the DMA's transfer FIFOs and dual-master structure permit multiple accesses to the same peripheral to be in flight at once, to improve gross throughput. Choice of DREQ mechanism is therefore critical:

- The traditional "turn on the tap" method can cause overflow if multiple writes are backed up in the TDF. Some systems solve this by overprovisioning peripheral FIFOs and setting the DREQ threshold below the full level, but this wastes precious area and power
- The ARM-style single and burst handshake does not permit additional requests to be registered while the current request is being served. This limits performance when FIFOs are very shallow.

The RP2040 DMA uses a credit-based DREQ mechanism. For each peripheral, the DMA attempts to keep as many transfers in flight as the peripheral has capacity for. This enables full bus throughput (1 word per clock) through an 8-deep peripheral FIFO with no possibility of overflow or underflow, in the absence of fabric latency or contention.

For each channel, the DMA maintains a counter. Each 1-clock pulse on the `dreq` signal will increment this counter (saturating). When nonzero, the channel requests a transfer from the DMA's internal arbiter, and the counter is decremented when the transfer is issued to the address FIFOs. At this point the transfer is in flight, but has not yet necessarily completed.

Figure 56. DREQ counting

The effect is to upper bound the number of in-flight transfers based on the amount of room or data available in the peripheral FIFO. In the steady state, this gives maximum throughput, but can't underflow or underflow.

One caveat is that the user *must not* access a FIFO which is currently being serviced by the DMA. This causes the channel

and peripheral to become desynchronised, and can cause corruption or loss of data.

Another caveat is that multiple channels should not be connected to the same DREQ.

4.2.4. Interrupts

Each channel can generate interrupts; these can be masked on a per-channel basis using the `INTE0` or `INTE1` registers. There are two circumstances where a channel raises an interrupt request:

- On the completion of each transfer sequence, if `CTRL.IRQ_QUIET` is disabled
- On receiving a null trigger, if `CTRL.IRQ_QUIET` is enabled

The masked interrupt status is visible in the `INTS` registers; there is one bit for each channel. Interrupts are cleared by writing a bit mask to `INTS`. One idiom for acknowledging interrupts is to read `INTS` and then write the same value back, so only enabled interrupts are cleared.

The RP2040 DMA provides two system IRQs, with independent masking and status registers (e.g. `INTE0`, `INTE1`). Any combination of channel interrupt requests can be routed to either system IRQ. For example:

- Some channels can be given a higher priority in the system interrupt controller, if they have particularly tight timing requirements
- In multiprocessor systems, different channel interrupts can be routed independently to different cores

For debugging purposes, the `INTF` registers can force either IRQ to be asserted.

4.2.5. Additional Features

4.2.5.1. Pacing Timers

These allow transfer of data roughly once every n `clk_sys` clocks instead of using external peripheral DREQ to trigger transfers. A fractional (X/Y) divider is used, and will generate a maximum of 1 request per `clk_sys` cycle.

There are 4 timers available in RP2040. Each DMA is able to select any of these in `CTRL.TREQ_SEL`.

4.2.5.2. CRC Calculation

The DMA can watch data from a given channel passing through the data FIFO, and calculate checksums based on this data. This is a purely passive affair: the data is not altered by this hardware, only observed.

The feature is controlled via the `SNIFF_CTRL` and `SNIFF_DATA` registers, and can be enabled/disabled per DMA transfer via the `CTRL.SNIFF_EN` field.

As this hardware cannot place backpressure on the FIFO, it must keep up with the DMA's maximum transfer rate of 32 bits per clock.

The supported checksums are:

- CRC-32, MSB-first and LSB-first
- CRC-16-CCITT, MSB-first and LSB-first
- Simple summation (add to 32 bit accumulator)
- Even parity

The result register is both readable and writable, so that the initial seed value can be set.

Bit/byte manipulations are available on the result which may aid specific use cases:

- Bit inversion

- Bit reversal
- Byte swap

These manipulations do not affect the CRC calculation, just how the data is presented in the result register.

4.2.5.3. Channel Abort

It is possible for a channel to get into an irrecoverable state: e.g. if commanded to transfer more data than a peripheral will ever request, it will never complete. Clearing the **CTRL.EN** bit merely pauses the channel, and does not solve the problem. This should not occur under normal circumstances, but it is important that there is a mechanism to recover without simply hard-resetting the entire DMA block.

The **CHAN_ABORT** register forces channels to complete early. There is one bit for each channel, and writing a 1 terminates that channel. This clears the transfer counter and forces the channel into an inactive state. Channels do not generate a normal completion interrupt when they are aborted.

Warning: the channel may already have a bus transfer in flight between the read and write master, and this transfer cannot be revoked. Starting the channel again while old transfers are still in flight can cause loss of data. The channel bit in the **CHAN_ABORT** register will stay high until the channel has reached a safe state; generally this takes only a few cycles.

The correct procedure is to write a bitmap into **CHAN_ABORT** of the channels you wish to terminate, and then poll the register until it reads all-zeroes.

4.2.5.4. Debug

Debug registers are available for each DMA channel to show the dreq counter **DBG_CTDREQ** and next transfer count **DBG_TCR**. These can also be used to reset a DMA channel if required.

4.2.6. Example Use Cases

TO DO: GRAHAM/LIAM: Show to do channel pingponging, with some diagrams.

TO DO: GRAHAM/LIAM: Show a simple example of how to do control blocks.

TO DO: GRAHAM/LIAM: Show a peripheral gather operation, with (**READ_ADDR** , **TRANS_COUNT**) control blocks.

4.2.7. List of Registers

Table 417. List of DMA registers

Offset	Name	Info
0x000	CH0_READ_ADDR	DMA Channel 0 Read Address pointer
0x004	CH0_WRITE_ADDR	DMA Channel 0 Write Address pointer
0x008	CH0_TRANS_COUNT	DMA Channel 0 Transfer Count
0x00c	CH0_CTRL_TRIG	DMA Channel 0 Control and Status
0x010	CH0_AL1_CTRL	Alias for channel 0 CTRL register
0x014	CH0_AL1_READ_ADDR	Alias for channel 0 READ_ADDR register
0x018	CH0_AL1_WRITE_ADDR	Alias for channel 0 WRITE_ADDR register
0x01c	CH0_AL1_TRANS_COUNT_TRIG	Alias for channel 0 TRANS_COUNT register This is a trigger register (0xc). Writing a nonzero value will reload the channel counter and start the channel.
0x020	CH0_AL2_CTRL	Alias for channel 0 CTRL register

Offset	Name	Info
0x024	CH0_AL2_TRANS_COUNT	Alias for channel 0 TRANS_COUNT register
0x028	CH0_AL2_READ_ADDR	Alias for channel 0 READ_ADDR register
0x02c	CH0_AL2_WRITE_ADDR_TRIG	Alias for channel 0 WRITE_ADDR register This is a trigger register (0xc). Writing a nonzero value will reload the channel counter and start the channel.
0x030	CH0_AL3_CTRL	Alias for channel 0 CTRL register
0x034	CH0_AL3_WRITE_ADDR	Alias for channel 0 WRITE_ADDR register
0x038	CH0_AL3_TRANS_COUNT	Alias for channel 0 TRANS_COUNT register
0x03c	CH0_AL3_READ_ADDR_TRIG	Alias for channel 0 READ_ADDR register This is a trigger register (0xc). Writing a nonzero value will reload the channel counter and start the channel.
0x040	CH1_READ_ADDR	DMA Channel 1 Read Address pointer
0x044	CH1_WRITE_ADDR	DMA Channel 1 Write Address pointer
0x048	CH1_TRANS_COUNT	DMA Channel 1 Transfer Count
0x04c	CH1_CTRL_TRIG	DMA Channel 1 Control and Status
0x050	CH1_AL1_CTRL	Alias for channel 1 CTRL register
0x054	CH1_AL1_READ_ADDR	Alias for channel 1 READ_ADDR register
0x058	CH1_AL1_WRITE_ADDR	Alias for channel 1 WRITE_ADDR register
0x05c	CH1_AL1_TRANS_COUNT_TRIG	Alias for channel 1 TRANS_COUNT register This is a trigger register (0xc). Writing a nonzero value will reload the channel counter and start the channel.
0x060	CH1_AL2_CTRL	Alias for channel 1 CTRL register
0x064	CH1_AL2_TRANS_COUNT	Alias for channel 1 TRANS_COUNT register
0x068	CH1_AL2_READ_ADDR	Alias for channel 1 READ_ADDR register
0x06c	CH1_AL2_WRITE_ADDR_TRIG	Alias for channel 1 WRITE_ADDR register This is a trigger register (0xc). Writing a nonzero value will reload the channel counter and start the channel.
0x070	CH1_AL3_CTRL	Alias for channel 1 CTRL register
0x074	CH1_AL3_WRITE_ADDR	Alias for channel 1 WRITE_ADDR register
0x078	CH1_AL3_TRANS_COUNT	Alias for channel 1 TRANS_COUNT register
0x07c	CH1_AL3_READ_ADDR_TRIG	Alias for channel 1 READ_ADDR register This is a trigger register (0xc). Writing a nonzero value will reload the channel counter and start the channel.
0x080	CH2_READ_ADDR	DMA Channel 2 Read Address pointer
0x084	CH2_WRITE_ADDR	DMA Channel 2 Write Address pointer
0x088	CH2_TRANS_COUNT	DMA Channel 2 Transfer Count
0x08c	CH2_CTRL_TRIG	DMA Channel 2 Control and Status
0x090	CH2_AL1_CTRL	Alias for channel 2 CTRL register
0x094	CH2_AL1_READ_ADDR	Alias for channel 2 READ_ADDR register

Offset	Name	Info
0x098	CH2_AL1_WRITE_ADDR	Alias for channel 2 WRITE_ADDR register
0x09c	CH2_AL1_TRANS_COUNT_TRIG	Alias for channel 2 TRANS_COUNT register This is a trigger register (0xc). Writing a nonzero value will reload the channel counter and start the channel.
0x0a0	CH2_AL2_CTRL	Alias for channel 2 CTRL register
0x0a4	CH2_AL2_TRANS_COUNT	Alias for channel 2 TRANS_COUNT register
0x0a8	CH2_AL2_READ_ADDR	Alias for channel 2 READ_ADDR register
0x0ac	CH2_AL2_WRITE_ADDR_TRIG	Alias for channel 2 WRITE_ADDR register This is a trigger register (0xc). Writing a nonzero value will reload the channel counter and start the channel.
0x0b0	CH2_AL3_CTRL	Alias for channel 2 CTRL register
0x0b4	CH2_AL3_WRITE_ADDR	Alias for channel 2 WRITE_ADDR register
0x0b8	CH2_AL3_TRANS_COUNT	Alias for channel 2 TRANS_COUNT register
0x0bc	CH2_AL3_READ_ADDR_TRIG	Alias for channel 2 READ_ADDR register This is a trigger register (0xc). Writing a nonzero value will reload the channel counter and start the channel.
0x0c0	CH3_READ_ADDR	DMA Channel 3 Read Address pointer
0x0c4	CH3_WRITE_ADDR	DMA Channel 3 Write Address pointer
0x0c8	CH3_TRANS_COUNT	DMA Channel 3 Transfer Count
0x0cc	CH3_CTRL_TRIG	DMA Channel 3 Control and Status
0x0d0	CH3_AL1_CTRL	Alias for channel 3 CTRL register
0x0d4	CH3_AL1_READ_ADDR	Alias for channel 3 READ_ADDR register
0x0d8	CH3_AL1_WRITE_ADDR	Alias for channel 3 WRITE_ADDR register
0x0dc	CH3_AL1_TRANS_COUNT_TRIG	Alias for channel 3 TRANS_COUNT register This is a trigger register (0xc). Writing a nonzero value will reload the channel counter and start the channel.
0x0e0	CH3_AL2_CTRL	Alias for channel 3 CTRL register
0x0e4	CH3_AL2_TRANS_COUNT	Alias for channel 3 TRANS_COUNT register
0x0e8	CH3_AL2_READ_ADDR	Alias for channel 3 READ_ADDR register
0x0ec	CH3_AL2_WRITE_ADDR_TRIG	Alias for channel 3 WRITE_ADDR register This is a trigger register (0xc). Writing a nonzero value will reload the channel counter and start the channel.
0x0f0	CH3_AL3_CTRL	Alias for channel 3 CTRL register
0x0f4	CH3_AL3_WRITE_ADDR	Alias for channel 3 WRITE_ADDR register
0x0f8	CH3_AL3_TRANS_COUNT	Alias for channel 3 TRANS_COUNT register
0x0fc	CH3_AL3_READ_ADDR_TRIG	Alias for channel 3 READ_ADDR register This is a trigger register (0xc). Writing a nonzero value will reload the channel counter and start the channel.
0x100	CH4_READ_ADDR	DMA Channel 4 Read Address pointer
0x104	CH4_WRITE_ADDR	DMA Channel 4 Write Address pointer

Offset	Name	Info
0x108	CH4_TRANS_COUNT	DMA Channel 4 Transfer Count
0x10c	CH4_CTRL_TRIG	DMA Channel 4 Control and Status
0x110	CH4_AL1_CTRL	Alias for channel 4 CTRL register
0x114	CH4_AL1_READ_ADDR	Alias for channel 4 READ_ADDR register
0x118	CH4_AL1_WRITE_ADDR	Alias for channel 4 WRITE_ADDR register
0x11c	CH4_AL1_TRANS_COUNT_TRIG	Alias for channel 4 TRANS_COUNT register This is a trigger register (0xc). Writing a nonzero value will reload the channel counter and start the channel.
0x120	CH4_AL2_CTRL	Alias for channel 4 CTRL register
0x124	CH4_AL2_TRANS_COUNT	Alias for channel 4 TRANS_COUNT register
0x128	CH4_AL2_READ_ADDR	Alias for channel 4 READ_ADDR register
0x12c	CH4_AL2_WRITE_ADDR_TRIG	Alias for channel 4 WRITE_ADDR register This is a trigger register (0xc). Writing a nonzero value will reload the channel counter and start the channel.
0x130	CH4_AL3_CTRL	Alias for channel 4 CTRL register
0x134	CH4_AL3_WRITE_ADDR	Alias for channel 4 WRITE_ADDR register
0x138	CH4_AL3_TRANS_COUNT	Alias for channel 4 TRANS_COUNT register
0x13c	CH4_AL3_READ_ADDR_TRIG	Alias for channel 4 READ_ADDR register This is a trigger register (0xc). Writing a nonzero value will reload the channel counter and start the channel.
0x140	CH5_READ_ADDR	DMA Channel 5 Read Address pointer
0x144	CH5_WRITE_ADDR	DMA Channel 5 Write Address pointer
0x148	CH5_TRANS_COUNT	DMA Channel 5 Transfer Count
0x14c	CH5_CTRL_TRIG	DMA Channel 5 Control and Status
0x150	CH5_AL1_CTRL	Alias for channel 5 CTRL register
0x154	CH5_AL1_READ_ADDR	Alias for channel 5 READ_ADDR register
0x158	CH5_AL1_WRITE_ADDR	Alias for channel 5 WRITE_ADDR register
0x15c	CH5_AL1_TRANS_COUNT_TRIG	Alias for channel 5 TRANS_COUNT register This is a trigger register (0xc). Writing a nonzero value will reload the channel counter and start the channel.
0x160	CH5_AL2_CTRL	Alias for channel 5 CTRL register
0x164	CH5_AL2_TRANS_COUNT	Alias for channel 5 TRANS_COUNT register
0x168	CH5_AL2_READ_ADDR	Alias for channel 5 READ_ADDR register
0x16c	CH5_AL2_WRITE_ADDR_TRIG	Alias for channel 5 WRITE_ADDR register This is a trigger register (0xc). Writing a nonzero value will reload the channel counter and start the channel.
0x170	CH5_AL3_CTRL	Alias for channel 5 CTRL register
0x174	CH5_AL3_WRITE_ADDR	Alias for channel 5 WRITE_ADDR register
0x178	CH5_AL3_TRANS_COUNT	Alias for channel 5 TRANS_COUNT register

Offset	Name	Info
0x17c	CH5_AL3_READ_ADDR_TRIG	Alias for channel 5 READ_ADDR register This is a trigger register (0xc). Writing a nonzero value will reload the channel counter and start the channel.
0x180	CH6_READ_ADDR	DMA Channel 6 Read Address pointer
0x184	CH6_WRITE_ADDR	DMA Channel 6 Write Address pointer
0x188	CH6_TRANS_COUNT	DMA Channel 6 Transfer Count
0x18c	CH6_CTRL_TRIG	DMA Channel 6 Control and Status
0x190	CH6_AL1_CTRL	Alias for channel 6 CTRL register
0x194	CH6_AL1_READ_ADDR	Alias for channel 6 READ_ADDR register
0x198	CH6_AL1_WRITE_ADDR	Alias for channel 6 WRITE_ADDR register
0x19c	CH6_AL1_TRANS_COUNT_TRIG	Alias for channel 6 TRANS_COUNT register This is a trigger register (0xc). Writing a nonzero value will reload the channel counter and start the channel.
0x1a0	CH6_AL2_CTRL	Alias for channel 6 CTRL register
0x1a4	CH6_AL2_TRANS_COUNT	Alias for channel 6 TRANS_COUNT register
0x1a8	CH6_AL2_READ_ADDR	Alias for channel 6 READ_ADDR register
0x1ac	CH6_AL2_WRITE_ADDR_TRIG	Alias for channel 6 WRITE_ADDR register This is a trigger register (0xc). Writing a nonzero value will reload the channel counter and start the channel.
0x1b0	CH6_AL3_CTRL	Alias for channel 6 CTRL register
0x1b4	CH6_AL3_WRITE_ADDR	Alias for channel 6 WRITE_ADDR register
0x1b8	CH6_AL3_TRANS_COUNT	Alias for channel 6 TRANS_COUNT register
0x1bc	CH6_AL3_READ_ADDR_TRIG	Alias for channel 6 READ_ADDR register This is a trigger register (0xc). Writing a nonzero value will reload the channel counter and start the channel.
0x1c0	CH7_READ_ADDR	DMA Channel 7 Read Address pointer
0x1c4	CH7_WRITE_ADDR	DMA Channel 7 Write Address pointer
0x1c8	CH7_TRANS_COUNT	DMA Channel 7 Transfer Count
0x1cc	CH7_CTRL_TRIG	DMA Channel 7 Control and Status
0x1d0	CH7_AL1_CTRL	Alias for channel 7 CTRL register
0x1d4	CH7_AL1_READ_ADDR	Alias for channel 7 READ_ADDR register
0x1d8	CH7_AL1_WRITE_ADDR	Alias for channel 7 WRITE_ADDR register
0x1dc	CH7_AL1_TRANS_COUNT_TRIG	Alias for channel 7 TRANS_COUNT register This is a trigger register (0xc). Writing a nonzero value will reload the channel counter and start the channel.
0x1e0	CH7_AL2_CTRL	Alias for channel 7 CTRL register

CH0_READ_ADDR, CH1_READ_ADDR, ..., CH10_READ_ADDR, CH11_READ_ADDR Registers

Description

DMA Channel N Read Address pointer

Table 418.
CH0_READ_ADDR,
CH1_READ_ADDR, ...,
CH10_READ_ADDR,
CH11_READ_ADDR
Registers

Bits	Name	Description	Type	Reset
31:0	NONAME	This register updates automatically each time a read completes. The current value is the next address to be read by this channel.	RW	0x00000000

CH0_WRITE_ADDR, CH1_WRITE_ADDR, ..., CH10_WRITE_ADDR, CH11_WRITE_ADDR Registers

Description

DMA Channel N Write Address pointer

Table 419.
CH0_WRITE_ADDR,
CH1_WRITE_ADDR, ...,
CH10_WRITE_ADDR,
CH11_WRITE_ADDR
Registers

Bits	Name	Description	Type	Reset
31:0	NONAME	This register updates automatically each time a write completes. The current value is the next address to be written by this channel.	RW	0x00000000

CH0_TRANS_COUNT, CH1_TRANS_COUNT, ..., CH10_TRANS_COUNT, CH11_TRANS_COUNT Registers

Description

DMA Channel N Transfer Count

Table 420.
CH0_TRANS_COUNT,
CH1_TRANS_COUNT,
...,
CH10_TRANS_COUNT,
CH11_TRANS_COUNT
Registers

Bits	Name	Description	Type	Reset
31:0	NONAME	<p>Program the number of bus transfers a channel will perform before halting. Note that, if transfers are larger than one byte in size, this is not equal to the number of bytes transferred (see CTRL_DATA_SIZE).</p> <p>When the channel is active, reading this register shows the number of transfers remaining, updating automatically each time a write transfer completes.</p> <p>Writing this register sets the RELOAD value for the transfer counter. Each time this channel is triggered, the RELOAD value is copied into the live transfer counter. The channel can be started multiple times, and will perform the same number of transfers each time, as programmed by most recent write.</p> <p>The RELOAD value can be observed at CHx_DBG_TCR. If TRANS_COUNT is used as a trigger, the written value is used immediately as the length of the new transfer sequence, as well as being written to RELOAD.</p>	RW	0x00000000

CH0_CTRL_TRIG, CH1_CTRL_TRIG, ..., CH10_CTRL_TRIG, CH11_CTRL_TRIG Registers

Description

DMA Channel N Control and Status

Table 421.
 CH0_CTRL_TRIG,
 CH1_CTRL_TRIG, ...,
 CH10_CTRL_TRIG,
 CH11_CTRL_TRIG
 Registers

Bits	Name	Description	Type	Reset
31	AHB_ERROR	Logical OR of the READ_ERROR and WRITE_ERROR flags. The channel halts when it encounters any bus error, and always raises its channel IRQ flag.	RO	0x0
30	READ_ERROR	If 1, the channel received a read bus error. Write one to clear. READ_ADDR shows the approximate address where the bus error was encountered (will not to be earlier, or more than 3 transfers later)	WC	0x0
29	WRITE_ERROR	If 1, the channel received a write bus error. Write one to clear. WRITE_ADDR shows the approximate address where the bus error was encountered (will not to be earlier, or more than 5 transfers later)	WC	0x0
28:25	Reserved.	-	-	-
24	BUSY	This flag goes high when the channel starts a new transfer sequence, and low when the last transfer of that sequence completes. Clearing EN while BUSY is high pauses the channel, and BUSY will stay high while paused. To terminate a sequence early (and clear the BUSY flag), see CHAN_ABORT.	RO	0x0
23	SNIFF_EN	If 1, this channel's data transfers are visible to the sniff hardware, and each transfer will advance the state of the checksum. This only applies if the sniff hardware is enabled, and has this channel selected. This allows checksum to be enabled or disabled on a per-control- block basis.	RW	0x0
22	BSWAP	Apply byte-swap transformation to DMA data. For byte data, this has no effect. For halfword data, the two bytes of each halfword are swapped. For word data, the four bytes of each word are swapped to reverse order.	RW	0x0
21	IRQ_QUIET	In QUIET mode, the channel does not generate IRQs at the end of every transfer block. Instead, an IRQ is raised when NULL is written to a trigger register, indicating the end of a control block chain. This reduces the number of interrupts to be serviced by the CPU when transferring a DMA chain of many small control blocks.	RW	0x0

Bits	Name	Description	Type	Reset
20:15	TREQ_SEL	Select a Transfer Request signal. The channel uses the transfer request signal to pace its data transfer rate. Sources for TREQ signals are internal (TIMERS) or external (DREQ, a Data Request from the system). 0x0 to 0x3a -> select DREQ n as TREQ 0x3b -> Select Timer 0 as TREQ 0x3c -> Select Timer 1 as TREQ 0x3d -> Select Timer 2 as TREQ (Optional) 0x3e -> Select Timer 3 as TREQ (Optional) 0x3f -> Permanent request, for unpaced transfers.	RW	0x00
14:11	CHAIN_TO	When this channel completes, it will trigger the channel indicated by CHAIN_TO. Disable by setting CHAIN_TO = <i>(this channel)</i> . Reset value is equal to channel number (so CHAIN_TO disabled by default).	RW	varies
10	RING_SEL	Select whether RING_SIZE applies to read or write addresses. If 0, read addresses are wrapped on a (1 << RING_SIZE) boundary. If 1, write addresses are wrapped.	RW	0x0
9:6	RING_SIZE	Size of address wrap region. If 0, don't wrap. For values n > 0, only the lower n bits of the address will change. This wraps the address on a (1 << n) byte boundary, facilitating access to naturally-aligned ring buffers. Ring sizes between 2 and 32768 bytes are possible. This can apply to either read or write addresses, based on value of RING_SEL. 0x0 -> RING_NONE	RW	0x0
5	INCR_WRITE	If 1, the write address increments with each transfer. If 0, each write is directed to the same, initial address. Generally this should be disabled for memory-to-peripheral transfers.	RW	0x0
4	INCR_READ	If 1, the read address increments with each transfer. If 0, each read is directed to the same, initial address. Generally this should be disabled for peripheral-to-memory transfers.	RW	0x0
3:2	DATA_SIZE	Set the size of each bus transfer (byte/halfword/word). READ_ADDR and WRITE_ADDR advance by this amount (1/2/4 bytes) with each transfer. 0x0 -> SIZE_BYTE 0x1 -> SIZE_HALFWORD 0x2 -> SIZE_WORD	RW	0x0

Bits	Name	Description	Type	Reset
1	HIGH_PRIORITY	HIGH_PRIORITY gives a channel preferential treatment in issue scheduling: in each scheduling round, all high priority channels are considered first, and then only a single low priority channel, before returning to the high priority channels. This only affects the order in which the DMA schedules channels. The DMA's bus priority is not changed. If the DMA is not saturated then a low priority channel will see no loss of throughput.	RW	0x0
0	EN	DMA Channel Enable. When 1, the channel will respond to triggering events, which will cause it to become BUSY and start transferring data. When 0, the channel will ignore triggers, stop issuing transfers, and pause the current transfer sequence (i.e. BUSY will remain high if already high)	RW	0x0

CH0_AL1_CTRL, CH1_AL1_CTRL, ..., CH10_AL1_CTRL, CH11_AL1_CTRL Registers

TIMER0, TIMER1 Registers

Description

Pacing (X/Y) Fractional Timer

The pacing timer produces TREQ assertions at a rate set by $((X/Y) * \text{sys_clk})$. This equation is evaluated every sys_clk cycles and therefore can only generate TREQs at a rate of 1 per sys_clk (i.e. permanent TREQ) or less.

Table 441. TIMER0, TIMER1 Registers

Bits	Name	Description	Type	Reset
31:16	X	Pacing Timer Dividend. Specifies the X value for the (X/Y) fractional timer.	RW	0x0000
15:0	Y	Pacing Timer Divisor. Specifies the Y value for the (X/Y) fractional timer.	RW	0x0000

MULTI_CHAN_TRIGGER Register

Description

Trigger one or more channels simultaneously

Table 442. MULTI_CHAN_TRIGGER Register

Bits	Name	Description	Type	Reset
31:16	Reserved.	-	-	-
15:0	NONAME	Each bit in this register corresponds to a DMA channel. Writing a 1 to the relevant bit is the same as writing to that channel's trigger register; the channel will start if it is currently enabled and not already busy.	SC	0x0000

SNIFF_CTRL Register

Description

Sniffer Control

Table 443. SNIFF_CTRL Register

Bits	Name	Description	Type	Reset
31:12	Reserved.	-	-	-
11	OUT_INV	If set, the result appears inverted (bitwise complement) when read. This does not affect the way the checksum is calculated; the result is transformed on-the-fly between the result register and the bus.	RW	0x0
10	OUT_REV	If set, the result appears bit-reversed when read. This does not affect the way the checksum is calculated; the result is transformed on-the-fly between the result register and the bus.	RW	0x0
9	BSWAP	Locally perform a byte reverse on the sniffed data, before feeding into checksum. Note that the sniff hardware is downstream of the DMA channel byteswap performed in the read master: if channel CTRL_BSWAP and SNIFF_CTRL_BSWAP are both enabled, their effects cancel from the sniffer's point of view.	RW	0x0
8:5	CALC	0x0 -> Calculate a CRC-32 (IEEE802.3 polynomial) 0x1 -> Calculate a CRC-32 (IEEE802.3 polynomial) with bit reversed data 0x2 -> Calculate a CRC-16-CCITT 0x3 -> Calculate a CRC-16-CCITT with bit reversed data 0xe -> XOR reduction over all data. == 1 if the total 1 population count is odd. 0xf -> Calculate a simple 32-bit checksum (addition with a 32 bit accumulator)	RW	0x0
4:1	DMACH	DMA channel for Sniffer to observe	RW	0x0

Bits	Name	Description	Type	Reset
0	EN	Enable sniffer	RW	0x0

SNIFF_DATA Register

Description

Data accumulator for sniff hardware

Table 444.
SNIFF_DATA Register

Bits	Name	Description	Type	Reset
31:0	NONAME	Write an initial seed value here before starting a DMA transfer on the channel indicated by SNIFF_CTRL_DMACH. The hardware will update this register each time it observes a read from the indicated channel. Once the channel completes, the final result can be read from this register.	RW	0x00000000

FIFO_LEVELS Register

Description

Debug RAF, WAF, TDF levels

Table 445.
FIFO_LEVELS Register

Bits	Name	Description	Type	Reset
31:24	Reserved.	-	-	-
23:16	RAF_LVL	Current Read-Address-FIFO fill level	RO	0x00
15:8	WAF_LVL	Current Write-Address-FIFO fill level	RO	0x00
7:0	TDF_LVL	Current Transfer-Data-FIFO fill level	RO	0x00

CHAN_ABORT Register

Description

Abort an in-progress transfer sequence on one or more channels

Table 446.
CHAN_ABORT Register

Bits	Name	Description	Type	Reset
31:16	Reserved.	-	-	-
15:0	NONAME	Each bit corresponds to a channel. Writing a 1 aborts whatever transfer sequence is in progress on that channel. The bit will remain high until any in-flight transfers have been flushed through the address and data FIFOs. After writing, this register must be polled until it returns all-zero. Until this point, it is unsafe to restart the channel.	SC	0x0000

N_CHANNELS Register

Table 447.
N_CHANNELS Register

Bits	Name	Description	Type	Reset
31:5	Reserved.	-	-	-
4:0	NONAME	The number of channels this DMA instance is equipped with. This DMA supports up to 16 hardware channels, but can be configured with as few as one, to minimise silicon area.	RO	-

CH0_DBG_CTDREQ, CH1_DBG_CTDREQ, ..., CH10_DBG_CTDREQ, CH11_DBG_CTDREQ Registers

4.3. UART

ARM Documentation

Excerpted from the [PrimeCell UART \(PL011\) Technical Reference Manual](#). Used with permission.

RP2040 has 2 identical instances of a UART peripheral, based on the ARM Primecell UART (PL011) (Revision r1p5).

Each instance supports the following features:

- Separate 32x8 Tx and 32x12 Rx FIFOs
- Programmable baud rate generator, clocked by `clk_peri` (see [Figure 26](#))
- Standard asynchronous communication bits (start, stop, parity) added on transmit and removed on receive
- line break detection
- programmable serial interface (5, 6, 7, or 8 bits)
- 1 or 2 stop bits
- programmable hardware flow control

Each UART can be connected to a number of GPIO pins as defined in the GPIO muxing [table](#) in [Section 2.18.2](#). Connections to the GPIO muxing are prefixed with the UART instance name `uart0_` or `uart1_`, and include the following:

- Transmit data `tx` (referred to as UARTTXD in the following sections)

- Received data `rx` (referred to as UARTRXD in the following sections)
- Output flow control `rts` (referred to as nUARTRTS in the following sections)
- Input flow control `cts` (referred to as nUARTCTS in the following sections)

The modem mode and IrDA mode of the PL011 are not supported.

The `UARTCLK` is driven from `clk_peri`, and `PCLK` is driven from the system clock `clk_sys` (see [Figure 26](#)).

4.3.1. Overview

The UART performs:

- serial-to-parallel conversion on data received from a peripheral device
- parallel-to-serial conversion on data transmitted to the peripheral device.

The CPU reads and writes data and control/status information through the AMBA APB interface. The transmit and receive paths are buffered with internal FIFO memories enabling up to 32-bytes to be stored independently in both transmit and receive modes.

The UART:

- includes a programmable baud rate generator that generates a common transmit and receive internal clock from the UART internal reference clock input, `UARTCLK`
- offers similar functionality to the industry-standard 16C650 UART device
- supports the a maximum baud rates of 921600 bps in UART mode

The UART operation and baud rate values are controlled by the Line Control Register, [UARTLCR_H](#) and the baud rate divisor registers (Integer Baud Rate Register, [UARTIBRD](#) and Fractional Baud Rate Register, [UARTFBRD](#)).

The UART can generate:

- individually-maskable interrupts from the receive (including timeout), transmit, modem status and error conditions
- a single combined interrupt so that the output is asserted if any of the individual interrupts are asserted, and unmasked
- DMA request signals for interfacing with a Direct Memory Access (DMA) controller.

If a framing, parity, or break error occurs during reception, the appropriate error bit is set, and is stored in the FIFO. If an overrun condition occurs, the overrun register bit is set immediately and FIFO data is prevented from being overwritten.

You can program the FIFOs to be 1-byte deep providing a conventional double-buffered UART interface.

There is a programmable hardware flow control feature that uses the `nUARTCTS` input and the `nUARTRTS` output to automatically control the serial data flow.

4.3.2. Functional description

Figure 57. UART block diagram. Test logic is not shown for clarity.

4.3.2.1. AMBA APB interface

The AMBA APB interface generates read and write decodes for accesses to status/control registers, and the transmit and receive FIFOs.

4.3.2.2. Register block

The register block stores data written, or to be read across the AMBA APB interface.

4.3.2.3. Baud rate generator

The baud rate generator contains free-running counters that generate the internal clocks: Baud16 and IrLPBaud16 signals. Baud16 provides timing information for UART transmit and receive control. Baud16 is a stream of pulses with a width of one UARTCLK clock period and a frequency of 16 times the baud rate.

4.3.2.4. Transmit FIFO

The transmit FIFO is an 8-bit wide, 32 location deep, FIFO memory buffer. CPU data written across the APB interface is stored in the FIFO until read out by the transmit logic. You can disable the transmit FIFO to act like a one-byte holding register.

4.3.2.5. Receive FIFO

The receive FIFO is a 12-bit wide, 32 location deep, FIFO memory buffer. Received data and corresponding error bits, are stored in the receive FIFO by the receive logic until read out by the CPU across the APB interface. The receive FIFO can be disabled to act like a one-byte holding register.

4.3.2.6. Transmit logic

The transmit logic performs parallel-to-serial conversion on the data read from the transmit FIFO. Control logic outputs the serial bit stream beginning with a start bit, data bits with the Least Significant Bit (LSB) first, followed by the parity bit, and then the stop bits according to the programmed configuration in control registers.

4.3.2.7. Receive logic

The receive logic performs serial-to-parallel conversion on the received bit stream after a valid start pulse has been detected. Overrun, parity, frame error checking, and line break detection are also performed, and their status accompanies the data that is written to the receive FIFO.

4.3.2.8. Interrupt generation logic

Individual maskable active HIGH interrupts are generated by the UART. A combined interrupt output is generated as an OR function of the individual interrupt requests and is connected to the processor interrupt controllers.

See [Section 4.3.6](#) for more information.

4.3.2.9. DMA interface

The UART provides an interface to connect to the DMA controller as UART DMA interface in [Section 4.3.5](#) describes.

4.3.2.10. Synchronizing registers and logic

The UART supports both asynchronous and synchronous operation of the clocks, PCLK and UARTCLK. Synchronization registers and handshaking logic have been implemented, and are active at all times. This has a minimal impact on performance or area. Synchronization of control signals is performed on both directions of data flow, that is from the PCLK to the UARTCLK domain, and from the UARTCLK to the PCLK domain.

4.3.3. Operation

4.3.3.1. Clock signals

The frequency selected for UARTCLK must accommodate the required range of baud rates:

- $F_{UARTCLK}(\min) \geq 16 \times \text{baud_rate}(\max)$
- $F_{UARTCLK}(\max) \leq 16 \times 65535 \times \text{baud_rate}(\min)$

For example, for a range of baud rates from 110 baud to 460800 baud the UARTCLK frequency must be between 7.3728MHz to 115.34MHz.

The frequency of UARTCLK must also be within the required error limits for all baud rates to be used.

There is also a constraint on the ratio of clock frequencies for PCLK to UARTCLK. The frequency of UARTCLK must be no more than 5/3 times faster than the frequency of PCLK:

- $F_{UARTCLK} \leq 5/3 \times F_{PCLK}$

For example, in UART mode, to generate 921600 baud when UARTCLK is 14.7456MHz then PCLK must be greater than or equal to 8.85276MHz. This ensures that the UART has sufficient time to write the received data to the receive FIFO.

4.3.3.2. UART operation

Control data is written to the UART Line Control Register, UARTLCR. This register is 30-bits wide internally, but is externally accessed through the APB interface by writes to the following registers:

The `UARTLCR_H` register defines the:

- transmission parameters
- word length
- buffer mode
- number of transmitted stop bits
- parity mode
- break generation.

The `UARTIBRD` register defines the integer baud rate divider, and the `UARTFBRD` register defines the fractional baud rate divider.

4.3.3.2.1. Fractional baud rate divider

The baud rate divisor is a 22-bit number consisting of a 16-bit integer and a 6-bit fractional part. This is used by the baud rate generator to determine the bit period. The fractional baud rate divider enables the use of any clock with a frequency >3.6864MHz to act as UARTCLK, while it is still possible to generate all the standard baud rates.

The 16-bit integer is written to the Integer Baud Rate Register, `UARTIBRD`. The 6-bit fractional part is written to the Fractional Baud Rate Register, `UARTFBRD`. The Baud Rate Divisor has the following relationship to UARTCLK:

Baud Rate Divisor = $\text{UARTCLK}/(16 \times \text{Baud Rate}) = \mathbf{BRD}_I + \mathbf{BRD}_F$ where \mathbf{BRD}_I is the integer part and \mathbf{BRD}_F is the fractional part separated by a decimal point as [Figure 58](#).

Figure 58. Baud rate divisor.

You can calculate the 6-bit number (m) by taking the fractional part of the required baud rate divisor and multiplying it by 64 (that is, 2^n , where n is the width of the `UARTFBRD` Register) and adding 0.5 to account for rounding errors:

$$m = \text{integer}(\mathbf{BRD}_F \times 2n + 0.5)$$

An internal clock enable signal, Baud16, is generated, and is a stream of one UARTCLK wide pulses with an average frequency of 16 times the required baud rate. This signal is then divided by 16 to give the transmit clock. A low number in the baud rate divisor gives a short bit period, and a high number in the baud rate divisor gives a long bit period.

4.3.3.2.2. Data transmission or reception

Data received or transmitted is stored in two 32-byte FIFOs, though the receive FIFO has an extra four bits per character for status information. For transmission, data is written into the transmit FIFO. If the UART is enabled, it causes a data frame to start transmitting with the parameters indicated in the Line Control Register, `UARTLCR_H`. Data continues to be transmitted until there is no data left in the transmit FIFO. The BUSY signal goes HIGH as soon as data is written to the transmit FIFO (that is, the FIFO is non-empty) and remains asserted HIGH while data is being transmitted. BUSY is negated only when the transmit FIFO is empty, and the last character has been transmitted from the shift register, including the stop bits. BUSY can be asserted HIGH even though the UART might no longer be enabled.

For each sample of data, three readings are taken and the majority value is kept. In the following paragraphs the middle sampling point is defined, and one sample is taken either side of it.

When the receiver is idle (`UARTRXD` continuously 1, in the marking state) and a LOW is detected on the data input (a start bit has been received), the receive counter, with the clock enabled by Baud16, begins running and data is sampled on the eighth cycle of that counter in UART mode, or the fourth cycle of the counter in SIR mode to allow for the shorter logic 0

pulses (half way through a bit period).

The start bit is valid if UARTRXD is still LOW on the eighth cycle of Baud16, otherwise a false start bit is detected and it is ignored.

If the start bit was valid, successive data bits are sampled on every 16th cycle of Baud16 (that is, one bit period later) according to the programmed length of the data characters. The parity bit is then checked if parity mode was enabled.

Lastly, a valid stop bit is confirmed if UARTRXD is HIGH, otherwise a framing error has occurred. When a full word is received, the data is stored in the receive FIFO, with any error bits associated with that word

4.3.3.2.3. Error bits

Three error bits are stored in bits [10:8] of the receive FIFO, and are associated with a particular character. There is an additional error that indicates an overrun error and this is stored in bit 11 of the receive FIFO.

4.3.3.2.4. Overrun bit

The overrun bit is not associated with the character in the receive FIFO. The overrun error is set when the FIFO is full, and the next character is completely received in the shift register. The data in the shift register is overwritten, but it is not written into the FIFO. When an empty location is available in the receive FIFO, and another character is received, the state of the overrun bit is copied into the receive FIFO along with the received character. The overrun state is then cleared. [Table 450](#) lists the bit functions of the receive FIFO.

Table 450. Receive FIFO bit functions

FIFO bit	Function
11	Overrun indicator
10	Break error
9	Parity error
8	Framing error
7:0	Received data

4.3.3.2.5. Disabling the FIFOs

Additionally, you can disable the FIFOs. In this case, the transmit and receive sides of the UART have 1-byte holding registers (the bottom entry of the FIFOs). The overrun bit is set when a word has been received, and the previous one was not yet read. In this implementation, the FIFOs are not physically disabled, but the flags are manipulated to give the illusion of a 1-byte register. When the FIFOs are disabled, a write to the data register bypasses the holding register unless the transmit shift register is already in use.

4.3.3.2.6. System and diagnostic loopback testing

You can perform loopback testing for UART data by setting the Loop Back Enable (LBE) bit to 1 in the Control Register, [UARTCR](#).

Data transmitted on UARTTXD is received on the UARTRXD input.

4.3.3.3. UART character frame

Figure 59. UART character frame.

4.3.4. UART hardware flow control

The hardware flow control feature is fully selectable, and enables you to control the serial data flow by using the nUARTRTS output and nUARTCTS input signals. Figure 60 shows how two devices can communicate with each other using hardware flow control.

Figure 60. Hardware flow control between two similar devices.

When the RTS flow control is enabled, nUARTRTS is asserted until the receive FIFO is filled up to the programmed watermark level. When the CTS flow control is enabled, the transmitter can only transmit data when nUARTCTS is asserted.

The hardware flow control is selectable using the RTSEn and CTSEn bits in the Control Register, UARTCR. Table 451 lists how you must set the bits to enable RTS and CTS flow control both simultaneously, and independently.

Table 451. Control bits to enable and disable hardware flow control.

UARTCR Register bits		
CTSEn	RTSEn	Description
1	1	Both RTS and CTS flow control enabled
1	0	Only CTS flow control enabled
0	1	Only RTS flow control enabled
0	0	Both RTS and CTS flow control disabled

NOTE

When RTS flow control is enabled, the software cannot use the RTSEn bit in the Control Register, UARTCR, to control the status of nUARTRTS.

4.3.4.1. RTS flow control

The RTS flow control logic is linked to the programmable receive FIFO watermark levels. When RTS flow control is enabled, the nUARTRTS is asserted until the receive FIFO is filled up to the watermark level. When the receive FIFO watermark level is reached, the nUARTRTS signal is deasserted, indicating that there is no more room to receive any more data. The transmission of data is expected to cease after the current character has been transmitted.

The nUARTRTS signal is reasserted when data has been read out of the receive FIFO so that it is filled to less than the watermark level. If RTS flow control is disabled and the UART is still enabled, then data is received until the receive FIFO is full, or no more data is transmitted to it.

4.3.4.2. CTS flow control

If CTS flow control is enabled, then the transmitter checks the nUARTCTS signal before transmitting the next byte. If the nUARTCTS signal is asserted, it transmits the byte otherwise transmission does not occur.

The data continues to be transmitted while nUARTCTS is asserted, and the transmit FIFO is not empty. If the transmit FIFO is empty and the nUARTCTS signal is asserted no data is transmitted.

If the nUARTCTS signal is deasserted and CTS flow control is enabled, then the current character transmission is completed before stopping. If CTS flow control is disabled and the UART is enabled, then the data continues to be transmitted until the transmit FIFO is empty.

4.3.5. UART DMA Interface

The UART provides an interface to connect to a DMA controller. The DMA operation of the UART is controlled using the DMA Control Register, [UARTDMACR](#). The DMA interface includes the following signals:

For receive:

UARTRXDMASREQ

Single character DMA transfer request, asserted by the UART. For receive, one character consists of up to 12 bits. This signal is asserted when the receive FIFO contains at least one character.

UARTRXDMABREQ

Burst DMA transfer request, asserted by the UART. This signal is asserted when the receive FIFO contains more characters than the programmed watermark level. You can program the watermark level for each FIFO using the Interrupt FIFO Level Select Register, [UARTIFLS](#).

UARTRXDMACLR

DMA request clear, asserted by a DMA controller to clear the receive request signals. If DMA burst transfer is requested, the clear signal is asserted during the transfer of the last data in the burst.

For transmit:

UARTTXDMASREQ

Single character DMA transfer request, asserted by the UART. For transmit one character consists of up to eight bits. This signal is asserted when there is at least one empty location in the transmit FIFO.

UARTTXDMABREQ

Burst DMA transfer request, asserted by the UART. This signal is asserted when the transmit FIFO contains less characters than the watermark level. You can program the watermark level for each FIFO using the Interrupt FIFO Level Select Register, [UARTIFLS](#).

UARTTXDMACLR

DMA request clear, asserted by a DMA controller to clear the transmit request signals. If DMA burst transfer is requested, the clear signal is asserted during the transfer of the last data in the burst.

The burst transfer and single transfer request signals are not mutually exclusive, they can both be asserted at the same time. For example, when there is more data than the watermark level in the receive FIFO, the burst transfer request and the single transfer request are asserted. When the amount of data left in the receive FIFO is less than the watermark level, the single request only is asserted. This is useful for situations where the number of characters left to be received in the stream is less than a burst.

For example, if 19 characters have to be received and the watermark level is programmed to be four. The DMA controller then transfers four bursts of four characters and three single transfers to complete the stream.

NOTE

For the remaining three characters the UART cannot assert the burst request.

Each request signal remains asserted until the relevant DMACLR signal is asserted. After the request clear signal is deasserted, a request signal can become active again, depending on the conditions described previously. All request signals are deasserted if the UART is disabled or the relevant DMA enable bit, TXDMAE or RXDMAE, in the DMA Control Register, [UARTDMACR](#), is cleared.

If you disable the FIFOs in the UART then it operates in character mode and only the DMA single transfer mode can operate, because only one character can be transferred to, or from the FIFOs at any time. UARTRXDMASREQ and UARTRXDMASREQ are the only request signals that can be asserted. See the Line Control Register, [UARTLCR_H](#), for information about disabling the FIFOs.

When the UART is in the FIFO enabled mode, data transfers can be made by either single or burst transfers depending on the programmed watermark level and the amount of data in the FIFO. [Table 452](#) lists the trigger points for UARTRXDMABREQ and UARTRXDMABREQ depending on the watermark level, for the transmit and receive FIFOs.

Table 452. DMA trigger points for the transmit and receive FIFOs.

Watermark level	Burst length	
	Transmit (number of empty locations)	Receive (number of filled locations)
1/8	28	4
1/4	24	8
1/2	16	16
3/4	8	24
7/8	4	28

In addition, the DMAONERR bit in the DMA Control Register, [UARTDMACR](#), supports the use of the receive error interrupt, UARTEINTR. It enables the DMA receive request outputs, UARTRXDMASREQ or UARTRXDMABREQ, to be masked out when the UART error interrupt, UARTEINTR, is asserted. The DMA receive request outputs remain inactive until the UARTEINTR is cleared. The DMA transmit request outputs are unaffected.

Figure 61. DMA transfer waveforms.

[Figure 61](#) shows the timing diagram for both a single transfer request and a burst transfer request with the appropriate DMACLR signal. The signals are all synchronous to PCLK. For the sake of clarity it is assumed that there is no synchronization of the request signals in the DMA controller.

4.3.6. Interrupts

There are eleven maskable interrupts generated in the UART. On RP2040, only the combined interrupt output, [UARTINTR](#), is connected.

You can enable or disable the individual interrupts by changing the mask bits in the Interrupt Mask Set/Clear Register, [UARTIMSC](#). Setting the appropriate mask bit HIGH enables the interrupt.

Provision of individual outputs and the combined interrupt output, enables you to use either a global interrupt service routine, or modular device drivers to handle interrupts.

The transmit and receive dataflow interrupts UARTRXINTR and UARTRXINTR have been separated from the status interrupts. This enables you to use UARTRXINTR and UARTRXINTR so that data can be read or written in response to the

FIFO trigger levels.

The error interrupt, `UARTEINTR`, can be triggered when there is an error in the reception of data. A number of error conditions are possible.

The modem status interrupt, `UARTMSINTR`, is a combined interrupt of all the individual modem status signals.

The status of the individual interrupt sources can be read either from the Raw Interrupt Status Register, `UARTRIS`, or from the Masked Interrupt Status Register, `UARTMIS`.

4.3.6.1. UARTMSINTR

The modem status interrupt is asserted if any of the modem status signals (`nUARTCTS`, `nUARTDCD`, `nUARTDSR`, and `nUARTRI`) change. It is cleared by writing a 1 to the corresponding bit(s) in the Interrupt Clear Register, `UARTICR`, depending on the modem status signals that generated the interrupt.

4.3.6.2. UARTRXINTR

The receive interrupt changes state when one of the following events occurs:

- If the FIFOs are enabled and the receive FIFO reaches the programmed trigger level. When this happens, the receive interrupt is asserted HIGH. The receive interrupt is cleared by reading data from the receive FIFO until it becomes less than the trigger level, or by clearing the interrupt.
- If the FIFOs are disabled (have a depth of one location) and data is received thereby filling the location, the receive interrupt is asserted HIGH. The receive interrupt is cleared by performing a single read of the receive FIFO, or by clearing the interrupt.

4.3.6.3. UARTRXINTR

The transmit interrupt changes state when one of the following events occurs:

- If the FIFOs are enabled and the transmit FIFO is equal to or lower than the programmed trigger level then the transmit interrupt is asserted HIGH. The transmit interrupt is cleared by writing data to the transmit FIFO until it becomes greater than the trigger level, or by clearing the interrupt.
- If the FIFOs are disabled (have a depth of one location) and there is no data present in the transmitters single location, the transmit interrupt is asserted HIGH. It is cleared by performing a single write to the transmit FIFO, or by clearing the interrupt.

To update the transmit FIFO you must:

- Write data to the transmit FIFO, either prior to enabling the UART and the interrupts, or after enabling the UART and interrupts.

NOTE

The transmit interrupt is based on a transition through a level, rather than on the level itself. When the interrupt and the UART is enabled before any data is written to the transmit FIFO the interrupt is not set. The interrupt is only set, after written data leaves the single location of the transmit FIFO and it becomes empty.

4.3.6.4. UARTRTINTR

The receive timeout interrupt is asserted when the receive FIFO is not empty, and no more data is received during a 32-bit period. The receive timeout interrupt is cleared either when the FIFO becomes empty through reading all the data (or by reading the holding register), or when a 1 is written to the corresponding bit of the Interrupt Clear Register, `UARTICR`.

4.3.6.5. UARTEINTR

The error interrupt is asserted when an error occurs in the reception of data by the UART. The interrupt can be caused by a number of different error conditions:

- framing
- parity
- break
- overrun.

You can determine the cause of the interrupt by reading the Raw Interrupt Status Register, [UARTRIS](#), or the Masked Interrupt Status Register, [UARTMIS](#). It can be cleared by writing to the relevant bits of the Interrupt Clear Register, [UARTICR](#) (bits 7 to 10 are the error clear bits).

4.3.6.6. UARTINTR

The interrupts are also combined into a single output, that is an OR function of the individual masked sources. You can connect this output to a system interrupt controller to provide another level of masking on a individual peripheral basis.

The combined UART interrupt is asserted if any of the individual interrupts are asserted and enabled.

4.3.7. Programmer's Model

The Pico SDK provides a `uart_init` function to configure the UART with a particular baud rate. Once the UART is initialised, the user must configure a GPIO pin as `UART_TX` and `UART_RX`. This can be seen in the following example:

Pico SDK: https://github.com/raspberrypi/pico-sdk/tree/pre_release/src/rp2_common/pico_stdlib/stdlib.c Lines 13 - 19

```
13 void setup_default_uart() {
14     uart_init(uart_default, PICO_DEFAULT_UART_BAUD_RATE);
15     gpio_set_function(PICO_DEFAULT_UART_TX_PIN, GPIO_FUNC_UART);
16     gpio_set_function(PICO_DEFAULT_UART_RX_PIN, GPIO_FUNC_UART);
17     bi_decl_if_func_used(bi_2pins_with_func(PICO_DEFAULT_UART_RX_PIN,
18     PICO_DEFAULT_UART_TX_PIN, GPIO_FUNC_UART));
19     bi_decl_if_func_used(bi_program_feature("stdout to UART"));
19 }
```

To initialise the UART, the `uart_init` function takes the following steps:

- Deassert the reset
- Enable `clk_peri`
- Set enable bits in the control register
- Enable the FIFOs
- Set the baud rate divisors
- Set the format

59     uart_set_baudrate(uart, baudrate);
60     uart_set_format(uart, 8, 1, UART_PARITY_NONE);
61
62     // Enable the UART, both TX and RX
63     uart_hw(uart)->cr = UART_UARTCR_UARTEN_BITS | UART_UARTCR_TXE_BITS |
        UART_UARTCR_RXE_BITS;
64     // Enable FIFOs
65     hw_set_bits(&uart_hw(uart)->lcr_h, UART_UARTLCR_H_FEN_BITS);
66     // Always enable DREQ signals -- no harm in this if DMA is not listening
67     uart_hw(uart)->dmacr = UART_UARTDMACR_TXDMAE_BITS | UART_UARTDMACR_RXDMAE_BITS;
68 }

```

4.3.7.1. Baud Rate Calculation

The uart baud rate is derived from dividing `clk_peri`.

If the required baud rate is 115200 and UARTCLK = 125MHz then:

Baud Rate Divisor = $(125 * 10^6) / (16 * 115200) \approx 67.817$

Therefore, BRDI = 67 and BRDF = 0.817,

Therefore, fractional part, m = integer((0.817 * 64) + 0.5) = 52

Generated baud rate divider = 67 + 52/64 = 67.8125

Generated baud rate = $(125 * 10^6) / (16 * 67.8125) \approx 115207$

Error = $(\text{abs}(115200 - 115207) / 115200) * 100 \approx 0.006\%$

Pico SDK: https://github.com/raspberrypi/pico-sdk/tree/pre_release/src/rp2_common/hardware_uart/uart.c Lines 77 - 97

```

77 uint uart_set_baudrate(uart_inst_t *uart, uint baudrate) {
78     invalid_params_if(UART, baudrate == 0);
79     uint32_t baud_rate_div = (8 * clock_get_hz(clk_peri) / baudrate);
80     uint32_t baud_ibrd = baud_rate_div >> 7;
81     uint32_t baud_fbrd = ((baud_rate_div & 0x7f) + 1) / 2;
82     invalid_params_if(UART, (baud_ibrd > 65535) || (baud_ibrd == 0));
83
84     // Load PL011's baud divisor registers
85     uart_hw(uart)->ibrd = baud_ibrd;
86     if (baud_ibrd == 65535) {
87         uart_hw(uart)->fbrd = 0;
88     } else {
89         uart_hw(uart)->fbrd = baud_fbrd;
90     }
91
92     // PL011 needs a (dummy) line control register write to latch in the
93     // divisors. We don't want to actually change LCR contents here.
94     hw_set_bits(&uart_hw(uart)->lcr_h, 0);
95     // todo what is supposed to be returned here?
96     return 0;

```

97 }

4.3.8. List of Registers

Table 453. List of UART registers

Offset	Name	Info
0x000	UARTDR	Data Register, UARTDR
0x004	UARTRSR	Receive Status Register/Error Clear Register, UARTRSR/UARTECR
0x018	UARTFR	Flag Register, UARTFR
0x020	UARTILPR	IrDA Low-Power Counter Register, UARTILPR
0x024	UARTIBRD	Integer Baud Rate Register, UARTIBRD
0x028	UARTFBRD	Fractional Baud Rate Register, UARTFBRD
0x02c	UARTLCR_H	Line Control Register, UARTLCR_H
0x030	UARTCR	Control Register, UARTCR
0x034	UARTIFLS	Interrupt FIFO Level Select Register, UARTIFLS
0x038	UARTIMSC	Interrupt Mask Set/Clear Register, UARTIMSC
0x03c	UARTRIS	Raw Interrupt Status Register, UARTRIS
0x040	UARTMIS	Masked Interrupt Status Register, UARTMIS
0x044	UARTICR	Interrupt Clear Register, UARTICR

0xffc	UARTPCELLID3	UARTPCellID3 Register

UARTDR Register

Description

Data Register, UARTDR

Table 454. UARTDR Register

Bits	Name	Description	Type	Reset
31:12	Reserved.	-	-	-
11	OE	Overrun error. This bit is set to 1 if data is received and the receive FIFO is already full. This is cleared to 0 once there is an empty space in the FIFO and a new character can be written to it.	RO	-

Bits	Name	Description	Type	Reset
10	BE	Break error. This bit is set to 1 if a break condition was detected, indicating that the received data input was held LOW for longer than a full-word transmission time (defined as start, data, parity and stop bits). In FIFO mode, this error is associated with the character at the top of the FIFO. When a break occurs, only one 0 character is loaded into the FIFO. The next character is only enabled after the receive data input goes to a 1 (marking state), and the next valid start bit is received.	RO	-
9	PE	Parity error. When set to 1, it indicates that the parity of the received data character does not match the parity that the EPS and SPS bits in the Line Control Register, UARTLCR_H. In FIFO mode, this error is associated with the character at the top of the FIFO.	RO	-
8	FE	Framing error. When set to 1, it indicates that the received character did not have a valid stop bit (a valid stop bit is 1). In FIFO mode, this error is associated with the character at the top of the FIFO.	RO	-
7:0	DATA	Receive (read) data character. Transmit (write) data character.	RWF	-

UARTSR Register

Description

Receive Status Register/Error Clear Register, UARTSR/UARTECR

Table 455. UARTSR Register

Bits	Name	Description	Type	Reset
31:4	Reserved.	-	-	-
3	OE	Overrun error. This bit is set to 1 if data is received and the FIFO is already full. This bit is cleared to 0 by a write to UARTECR. The FIFO contents remain valid because no more data is written when the FIFO is full, only the contents of the shift register are overwritten. The CPU must now read the data, to empty the FIFO.	WC	0x0
2	BE	Break error. This bit is set to 1 if a break condition was detected, indicating that the received data input was held LOW for longer than a full-word transmission time (defined as start, data, parity, and stop bits). This bit is cleared to 0 after a write to UARTECR. In FIFO mode, this error is associated with the character at the top of the FIFO. When a break occurs, only one 0 character is loaded into the FIFO. The next character is only enabled after the receive data input goes to a 1 (marking state) and the next valid start bit is received.	WC	0x0
1	PE	Parity error. When set to 1, it indicates that the parity of the received data character does not match the parity that the EPS and SPS bits in the Line Control Register, UARTLCR_H. This bit is cleared to 0 by a write to UARTECR. In FIFO mode, this error is associated with the character at the top of the FIFO.	WC	0x0

Bits	Name	Description	Type	Reset
0	FE	Framing error. When set to 1, it indicates that the received character did not have a valid stop bit (a valid stop bit is 1). This bit is cleared to 0 by a write to UARTECR. In FIFO mode, this error is associated with the character at the top of the FIFO.	WC	0x0

UARTFR Register

Description

Flag Register, UARTFR

Table 456. UARTFR Register

Bits	Name	Description	Type	Reset
31:9	Reserved.	-	-	-
8	RI	Ring indicator. This bit is the complement of the UART ring indicator, nUARTRI, modem status input. That is, the bit is 1 when nUARTRI is LOW.	RO	-
7	TXFE	Transmit FIFO empty. The meaning of this bit depends on the state of the FEN bit in the Line Control Register, UARTECR_H. If the FIFO is disabled, this bit is set when the transmit holding register is empty. If the FIFO is enabled, the TXFE bit is set when the transmit FIFO is empty. This bit does not indicate if there is data in the transmit shift register.	RO	0x1
6	RXFF	Receive FIFO full. The meaning of this bit depends on the state of the FEN bit in the UARTECR_H Register. If the FIFO is disabled, this bit is set when the receive holding register is full. If the FIFO is enabled, the RXFF bit is set when the receive FIFO is full.	RO	0x0
5	TXFF	Transmit FIFO full. The meaning of this bit depends on the state of the FEN bit in the UARTECR_H Register. If the FIFO is disabled, this bit is set when the transmit holding register is full. If the FIFO is enabled, the TXFF bit is set when the transmit FIFO is full.	RO	0x0
4	RXFE	Receive FIFO empty. The meaning of this bit depends on the state of the FEN bit in the UARTECR_H Register. If the FIFO is disabled, this bit is set when the receive holding register is empty. If the FIFO is enabled, the RXFE bit is set when the receive FIFO is empty.	RO	0x1
3	BUSY	UART busy. If this bit is set to 1, the UART is busy transmitting data. This bit remains set until the complete byte, including all the stop bits, has been sent from the shift register. This bit is set as soon as the transmit FIFO becomes non-empty, regardless of whether the UART is enabled or not.	RO	0x0
2	DCD	Data carrier detect. This bit is the complement of the UART data carrier detect, nUARTDCD, modem status input. That is, the bit is 1 when nUARTDCD is LOW.	RO	-

Bits	Name	Description	Type	Reset
1	DSR	Data set ready. This bit is the complement of the UART data set ready, nUARTDSR, modem status input. That is, the bit is 1 when nUARTDSR is LOW.	RO	-
0	CTS	Clear to send. This bit is the complement of the UART clear to send, nUARTCTS, modem status input. That is, the bit is 1 when nUARTCTS is LOW.	RO	-

UARTILPR Register

Description

IrDA Low-Power Counter Register, UARTILPR

Table 457. UARTILPR Register

Bits	Name	Description	Type	Reset
31:8	Reserved.	-	-	-
7:0	ILPDVSR	8-bit low-power divisor value. These bits are cleared to 0 at reset.	RW	0x00

UARTIBRD Register

Description

Integer Baud Rate Register, UARTIBRD

Table 458. UARTIBRD Register

Bits	Name	Description	Type	Reset
31:16	Reserved.	-	-	-
15:0	BAUD_DIVINT	The integer baud rate divisor. These bits are cleared to 0 on reset.	RW	0x0000

UARTFBRD Register

Description

Fractional Baud Rate Register, UARTFBRD

Table 459. UARTFBRD Register

Bits	Name	Description	Type	Reset
31:6	Reserved.	-	-	-
5:0	BAUD_DIVFRAC	The fractional baud rate divisor. These bits are cleared to 0 on reset.	RW	0x00

UARTLCR_H Register

Description

Line Control Register, UARTLCR_H

Table 460. UARTLCR_H Register

Bits	Name	Description	Type	Reset
31:8	Reserved.	-	-	-
7	SPS	Stick parity select. 0 = stick parity is disabled 1 = either: * if the EPS bit is 0 then the parity bit is transmitted and checked as a 1 * if the EPS bit is 1 then the parity bit is transmitted and checked as a 0. This bit has no effect when the PEN bit disables parity checking and generation.	RW	0x0

Bits	Name	Description	Type	Reset
6:5	WLEN	Word length. These bits indicate the number of data bits transmitted or received in a frame as follows: b11 = 8 bits b10 = 7 bits b01 = 6 bits b00 = 5 bits.	RW	0x0
4	FEN	Enable FIFOs: 0 = FIFOs are disabled (character mode) that is, the FIFOs become 1-byte-deep holding registers 1 = transmit and receive FIFO buffers are enabled (FIFO mode).	RW	0x0
3	STP2	Two stop bits select. If this bit is set to 1, two stop bits are transmitted at the end of the frame. The receive logic does not check for two stop bits being received.	RW	0x0
2	EPS	Even parity select. Controls the type of parity the UART uses during transmission and reception: 0 = odd parity. The UART generates or checks for an odd number of 1s in the data and parity bits. 1 = even parity. The UART generates or checks for an even number of 1s in the data and parity bits. This bit has no effect when the PEN bit disables parity checking and generation.	RW	0x0
1	PEN	Parity enable: 0 = parity is disabled and no parity bit added to the data frame 1 = parity checking and generation is enabled.	RW	0x0
0	BRK	Send break. If this bit is set to 1, a low-level is continually output on the UARTTXD output, after completing transmission of the current character. For the proper execution of the break command, the software must set this bit for at least two complete frames. For normal use, this bit must be cleared to 0.	RW	0x0

UARTCR Register

Description

Control Register, UARTCR

Table 461. UARTCR Register

Bits	Name	Description	Type	Reset
31:16	Reserved.	-	-	-
15	CTSEN	CTS hardware flow control enable. If this bit is set to 1, CTS hardware flow control is enabled. Data is only transmitted when the nUARTCTS signal is asserted.	RW	0x0
14	RTSEN	RTS hardware flow control enable. If this bit is set to 1, RTS hardware flow control is enabled. Data is only requested when there is space in the receive FIFO for it to be received.	RW	0x0
13	OUT2	This bit is the complement of the UART Out2 (nUARTOut2) modem status output. That is, when the bit is programmed to a 1, the output is 0. For DTE this can be used as Ring Indicator (RI).	RW	0x0
12	OUT1	This bit is the complement of the UART Out1 (nUARTOut1) modem status output. That is, when the bit is programmed to a 1 the output is 0. For DTE this can be used as Data Carrier Detect (DCD).	RW	0x0

Bits	Name	Description	Type	Reset
11	RTS	Request to send. This bit is the complement of the UART request to send, nUARTRTS, modem status output. That is, when the bit is programmed to a 1 then nUARTRTS is LOW.	RW	0x0
10	DTR	Data transmit ready. This bit is the complement of the UART data transmit ready, nUARTDTR, modem status output. That is, when the bit is programmed to a 1 then nUARTDTR is LOW.	RW	0x0
9	RXE	Receive enable. If this bit is set to 1, the receive section of the UART is enabled. Data reception occurs for either UART signals or SIR signals depending on the setting of the SIREN bit. When the UART is disabled in the middle of reception, it completes the current character before stopping.	RW	0x1
8	TXE	Transmit enable. If this bit is set to 1, the transmit section of the UART is enabled. Data transmission occurs for either UART signals, or SIR signals depending on the setting of the SIREN bit. When the UART is disabled in the middle of transmission, it completes the current character before stopping.	RW	0x1
7	LBE	Loopback enable. If this bit is set to 1 and the SIREN bit is set to 1 and the SIRTEST bit in the Test Control Register, UARTTCR is set to 1, then the nSIROUT path is inverted, and fed through to the SIRIN path. The SIRTEST bit in the test register must be set to 1 to override the normal half-duplex SIR operation. This must be the requirement for accessing the test registers during normal operation, and SIRTEST must be cleared to 0 when loopback testing is finished. This feature reduces the amount of external coupling required during system test. If this bit is set to 1, and the SIRTEST bit is set to 0, the UARTTXD path is fed through to the UARTRXD path. In either SIR mode or UART mode, when this bit is set, the modem outputs are also fed through to the modem inputs. This bit is cleared to 0 on reset, to disable loopback.	RW	0x0
6:3	Reserved.	-	-	-
2	SIRLP	SIR low-power IrDA mode. This bit selects the IrDA encoding mode. If this bit is cleared to 0, low-level bits are transmitted as an active high pulse with a width of 3 / 16th of the bit period. If this bit is set to 1, low-level bits are transmitted with a pulse width that is 3 times the period of the IrLPBaud16 input signal, regardless of the selected bit rate. Setting this bit uses less power, but might reduce transmission distances.	RW	0x0

Bits	Name	Description	Type	Reset
1	SIREN	SIR enable: 0 = IrDA SIR ENDEC is disabled. nSIRROUT remains LOW (no light pulse generated), and signal transitions on SIRIN have no effect. 1 = IrDA SIR ENDEC is enabled. Data is transmitted and received on nSIRROUT and SIRIN. UARTRXD remains HIGH, in the marking state. Signal transitions on UARTRXD or modem status inputs have no effect. This bit has no effect if the UARTEN bit disables the UART.	RW	0x0
0	UARTEN	UART enable: 0 = UART is disabled. If the UART is disabled in the middle of transmission or reception, it completes the current character before stopping. 1 = the UART is enabled. Data transmission and reception occurs for either UART signals or SIR signals depending on the setting of the SIREN bit.	RW	0x0

UARTIFLS Register

Description

Interrupt FIFO Level Select Register, UARTIFLS

Table 462. UARTIFLS Register

Bits	Name	Description	Type	Reset
31:6	Reserved.	-	-	-
5:3	RXIFLSEL	Receive interrupt FIFO level select. The trigger points for the receive interrupt are as follows: b000 = Receive FIFO becomes $\geq 1/8$ full b001 = Receive FIFO becomes $\geq 1/4$ full b010 = Receive FIFO becomes $\geq 1/2$ full b011 = Receive FIFO becomes $\geq 3/4$ full b100 = Receive FIFO becomes $\geq 7/8$ full b101-b111 = reserved.	RW	0x2
2:0	TXIFLSEL	Transmit interrupt FIFO level select. The trigger points for the transmit interrupt are as follows: b000 = Transmit FIFO becomes $\leq 1/8$ full b001 = Transmit FIFO becomes $\leq 1/4$ full b010 = Transmit FIFO becomes $\leq 1/2$ full b011 = Transmit FIFO becomes $\leq 3/4$ full b100 = Transmit FIFO becomes $\leq 7/8$ full b101-b111 = reserved.	RW	0x2

UARTIMSC Register

Description

Interrupt Mask Set/Clear Register, UARTIMSC

Table 463. UARTIMSC Register

Bits	Name	Description	Type	Reset
31:11	Reserved.	-	-	-
10	OEIM	Overrun error interrupt mask. A read returns the current mask for the UARTOEINTR interrupt. On a write of 1, the mask of the UARTOEINTR interrupt is set. A write of 0 clears the mask.	RW	0x0
9	BEIM	Break error interrupt mask. A read returns the current mask for the UARTBEINTR interrupt. On a write of 1, the mask of the UARTBEINTR interrupt is set. A write of 0 clears the mask.	RW	0x0

Bits	Name	Description	Type	Reset
8	PEIM	Parity error interrupt mask. A read returns the current mask for the UARTPEINTR interrupt. On a write of 1, the mask of the UARTPEINTR interrupt is set. A write of 0 clears the mask.	RW	0x0
7	FEIM	Framing error interrupt mask. A read returns the current mask for the UARTFEINTR interrupt. On a write of 1, the mask of the UARTFEINTR interrupt is set. A write of 0 clears the mask.	RW	0x0
6	RTIM	Receive timeout interrupt mask. A read returns the current mask for the UARTRTINTR interrupt. On a write of 1, the mask of the UARTRTINTR interrupt is set. A write of 0 clears the mask.	RW	0x0
5	TXIM	Transmit interrupt mask. A read returns the current mask for the UARTRXINTR interrupt. On a write of 1, the mask of the UARTRXINTR interrupt is set. A write of 0 clears the mask.	RW	0x0
4	RXIM	Receive interrupt mask. A read returns the current mask for the UARTRXINTR interrupt. On a write of 1, the mask of the UARTRXINTR interrupt is set. A write of 0 clears the mask.	RW	0x0
3	DSRMIM	nUARTDSR modem interrupt mask. A read returns the current mask for the UARTDSRINTR interrupt. On a write of 1, the mask of the UARTDSRINTR interrupt is set. A write of 0 clears the mask.	RW	0x0
2	DCDMIM	nUARTDCD modem interrupt mask. A read returns the current mask for the UARTDCDINTR interrupt. On a write of 1, the mask of the UARTDCDINTR interrupt is set. A write of 0 clears the mask.	RW	0x0
1	CTSMIM	nUARTCTS modem interrupt mask. A read returns the current mask for the UARTCTSINTR interrupt. On a write of 1, the mask of the UARTCTSINTR interrupt is set. A write of 0 clears the mask.	RW	0x0
0	RIMIM	nUARTRI modem interrupt mask. A read returns the current mask for the UARTRIINTR interrupt. On a write of 1, the mask of the UARTRIINTR interrupt is set. A write of 0 clears the mask.	RW	0x0

UARTRIS Register

Description

Raw Interrupt Status Register, UARTRIS

Table 464. UARTRIS Register

Bits	Name	Description	Type	Reset
31:11	Reserved.	-	-	-
10	OERIS	Overrun error interrupt status. Returns the raw interrupt state of the UARTOEINTR interrupt.	RO	0x0
9	BERIS	Break error interrupt status. Returns the raw interrupt state of the UARTBEINTR interrupt.	RO	0x0

Bits	Name	Description	Type	Reset
8	PERIS	Parity error interrupt status. Returns the raw interrupt state of the UARTPEINTR interrupt.	RO	0x0
7	FERIS	Framing error interrupt status. Returns the raw interrupt state of the UARTFEINTR interrupt.	RO	0x0
6	RTRIS	Receive timeout interrupt status. Returns the raw interrupt state of the UARTRTINTR interrupt. a	RO	0x0
5	TXRIS	Transmit interrupt status. Returns the raw interrupt state of the UARTRXINTR interrupt.	RO	0x0
4	RXRIS	Receive interrupt status. Returns the raw interrupt state of the UARTRXINTR interrupt.	RO	0x0
3	DSRRMIS	nUARTDSR modem interrupt status. Returns the raw interrupt state of the UARTDSRINTR interrupt.	RO	-
2	DCDRMIS	nUARTDCD modem interrupt status. Returns the raw interrupt state of the UARTDCDINTR interrupt.	RO	-
1	CTSRMIS	nUARTCTS modem interrupt status. Returns the raw interrupt state of the UARTCTSINTR interrupt.	RO	-
0	RIRMIS	nUARTRI modem interrupt status. Returns the raw interrupt state of the UARTRIINTR interrupt.	RO	-

UARTMIS Register

Description

Masked Interrupt Status Register, UARTMIS

Table 465. UARTMIS Register

Bits	Name	Description	Type	Reset
31:11	Reserved.	-	-	-
10	OEMIS	Overrun error masked interrupt status. Returns the masked interrupt state of the UARTOEINTR interrupt.	RO	0x0
9	BEMIS	Break error masked interrupt status. Returns the masked interrupt state of the UARTBEINTR interrupt.	RO	0x0
8	PEMIS	Parity error masked interrupt status. Returns the masked interrupt state of the UARTPEINTR interrupt.	RO	0x0
7	FEMIS	Framing error masked interrupt status. Returns the masked interrupt state of the UARTFEINTR interrupt.	RO	0x0
6	RTMIS	Receive timeout masked interrupt status. Returns the masked interrupt state of the UARTRTINTR interrupt.	RO	0x0
5	TXMIS	Transmit masked interrupt status. Returns the masked interrupt state of the UARTRXINTR interrupt.	RO	0x0
4	RXMIS	Receive masked interrupt status. Returns the masked interrupt state of the UARTRXINTR interrupt.	RO	0x0
3	DSRMMIS	nUARTDSR modem masked interrupt status. Returns the masked interrupt state of the UARTDSRINTR interrupt.	RO	-
2	DCDMMIS	nUARTDCD modem masked interrupt status. Returns the masked interrupt state of the UARTDCDINTR interrupt.	RO	-

Bits	Name	Description	Type	Reset
1	CTSMMS	nUARTCTS modem masked interrupt status. Returns the masked interrupt state of the UARTCTSINTR interrupt.	RO	-
0	RIMMS	nUARTRI modem masked interrupt status. Returns the masked interrupt state of the UARTRIINTR interrupt.	RO	-

UARTICR Register

Description

Interrupt Clear Register, UARTICR

Table 466. UARTICR Register

Bits	Name	Description	Type	Reset
31:11	Reserved.	-	-	-
10	OEIC	Overrun error interrupt clear. Clears the UARTOEINTR interrupt.	WC	-
9	BEIC	Break error interrupt clear. Clears the UARTBEINTR interrupt.	WC	-
8	PEIC	Parity error interrupt clear. Clears the UARTPEINTR interrupt.	WC	-
7	FEIC	Framing error interrupt clear. Clears the UARTFEINTR interrupt.	WC	-
6	RTIC	Receive timeout interrupt clear. Clears the UARTRTINTR interrupt.	WC	-
5	TXIC	Transmit interrupt clear. Clears the UARCTXINTR interrupt.	WC	-
4	RXIC	Receive interrupt clear. Clears the UARTRXINTR interrupt.	WC	-
3	DSRMIC	nUARTDSR modem interrupt clear. Clears the UARTDSRINTR interrupt.	WC	-
2	DCDMIC	nUARTDCD modem interrupt clear. Clears the UARTDCDINTR interrupt.	WC	-
1	CTSMIC	nUARTCTS modem interrupt clear. Clears the UARTCTSINTR interrupt.	WC	-
0	RIMIC	nUARTRI modem interrupt clear. Clears the UARTRIINTR interrupt.	WC	-

UARTDMACR Register

Description

DMA Control Register, UARTDMACR

Table 467. UARTDMACR Register

Bits	Name	Description	Type	Reset
31:3	Reserved.	-	-	-
2	DMAONERR	DMA on error. If this bit is set to 1, the DMA receive request outputs, UARTRXDMSREQ or UARTRXDMABREQ, are disabled when the UART error interrupt is asserted.	RW	0x0
1	TXDMAE	Transmit DMA enable. If this bit is set to 1, DMA for the transmit FIFO is enabled.	RW	0x0

Bits	Name	Description	Type	Reset
0	RXDMAE	Receive DMA enable. If this bit is set to 1, DMA for the receive FIFO is enabled.	RW	0x0

4.4. I2C

Synopsys Documentation

Synopsys Proprietary. Used with permission.

I2C is a commonly used 2-wire interface that can be used to connect devices for low speed data transfer using clock **SCL** and data **SDA** wires.

RP2040 has two identical instances of an I2C controller. The external pins of each controller are connected to GPIO pins as defined in the GPIO muxing [table](#) in [Section 2.18.2](#). The muxing options give some IO flexibility.

4.4.1. Features

Each I2C controller is based on a configuration of the Synopsys DW_apb_i2c (v2.01) IP. The following features are supported:

- Master or Slave (Default to Master mode)
- Standard mode, Fast mode or Fast mode plus
- Default slave address 0x055
- Supports 10-bit addressing in Master mode
- 16-element transmit buffer
- 16-element receive buffer
- Can be driven from DMA
- Can generate interrupts

4.4.1.1. Standard

The I2C controller was designed for I2C Bus specification, version 6.0, dated April 2014.

4.4.1.2. Clocking

The I2C controller is connected to `clk_sys`. The I2C clock is generated by dividing down this clock, controlled by registers inside the block.

4.4.1.3. IOs

Each controller must connect its clock `SCL` and data `SDA` to one pair of GPIOs. The I2C standard requires that drivers drive a signal low, or when not driven the signal will be pulled high. This applies to SCL and SDA. The GPIO pads should be configured for:

- pull-up enabled
- slew rate limited
- schmitt trigger enabled

i NOTE

There should also be external pull-ups on the board as the internal pad pull-ups may not be strong enough to pull up external circuits.

4.4.2. IP Configuration

I2C configuration details (each instance is fully independent):

- 32-bit APB access
- Supports Standard mode, Fast mode or Fast mode plus (not High speed)
- Default slave address of 0x055
- Master or Slave mode
- Master by default (Slave mode disabled at reset)
- 10-bit addressing supported in master mode (7-bit by default)
- 16 entry transmit buffer
- 16 entry receive buffer

- Allows restart conditions when a master (can be disabled for legacy device support)
- Configurable timing to adjust TsuDAT/ThDAT
- General calls responded to on reset
- Interface to DMA
- Single interrupt output
- Configurable timing to adjust clock frequency
- Spike suppression (default 7 clk_sys cycles)
- Can NACK after data received by Slave
- Hold transfer when TX FIFO empty
- Hold bus until space available in RX FIFO
- Restart detect interrupt in Slave mode
- Optional blocking Master commands (not enabled by default)

4.4.3. I2C Overview

The I2C bus is a 2-wire serial interface, consisting of a serial data line **SDA** and a serial clock **SCL**. These wires carry information between the devices connected to the bus. Each device is recognized by a unique address and can operate as either a “transmitter” or “receiver”, depending on the function of the device. Devices can also be considered as masters or slaves when performing data transfers. A master is a device that initiates a data transfer on the bus and generates the clock signals to permit that transfer. At that time, any device addressed is considered a slave.

i NOTE

The I2C block must only be programmed to operate in either master OR slave mode only. Operating as a master and slave simultaneously is not supported.

The I2C block can operate in these modes:

- standard mode (with data rates from 0 to 100 Kb/s),
- fast mode (with data rates less than or equal to 400 Kb/s),
- fast mode plus (with data rates less than or equal to 1000 Kb/s).

These modes are not supported:

- High-speed mode (with data rates less than or equal to 3.4 Mb/s),
- Ultra-Fast Speed Mode (with data rates less than or equal to 5 Mb/s).

i NOTE

References to fast mode also apply to fast mode plus, unless specifically stated otherwise.

The I2C block can communicate with devices in one of these modes as long as they are attached to the bus. Additionally, fast mode devices are downward compatible. For instance, fast mode devices can communicate with standard mode devices in 0 to 100 Kb/s I2C bus system. However standard mode devices are not upward compatible and should not be incorporated in a fast-mode I2C bus system as they cannot follow the higher transfer rate and unpredictable states would occur.

An example of high-speed mode devices are LCD displays, high-bit count ADCs, and high capacity EEPROMs. These devices typically need to transfer large amounts of data. Most maintenance and control applications, the common use for the I2C bus, typically operate at 100 kHz (in standard and fast modes). Any DW_apb_i2c device can be attached to an I2C-

bus and every device can talk with any master, passing information back and forth. There needs to be at least one master (such as a microcontroller or DSP) on the bus but there can be multiple masters, which require them to arbitrate for ownership. Multiple masters and arbitration are explained later in this chapter. The I2C block does not support SMBus and PMBus protocols (for System Management and Power management).

The DW_apb_i2c is made up of an AMBA APB slave interface, an I2C interface, and FIFO logic to maintain coherency between the two interfaces. The blocks of the component are illustrated in [Figure 62](#).

Figure 62. I2C Block diagram

The following define the functions of the blocks in [Figure 62](#):

- **AMBA Bus Interface Unit** – Takes the APB interface signals and translates them into a common generic interface that allows the register file to be bus protocol-agnostic.
- **Register File** – Contains configuration registers and is the interface with software.
- **Slave State Machine** – Follows the protocol for a slave and monitors bus for address match.
- **Master State Machine** – Generates the I2C protocol for the master transfers.
- **Clock Generator** – Calculates the required timing to do the following:
 - Generate the **SCL** clock when configured as a master
 - Check for bus idle
 - Generate a START and a STOP
 - Setup the data and hold the data
- **Rx Shift** – Takes data into the design and extracts it in byte format.
- **Tx Shift** – Presents data supplied by CPU for transfer on the I2C bus.
- **Rx Filter** – Detects the events in the bus; for example, start, stop and arbitration lost.
- **Toggle** – Generates pulses on both sides and toggles to transfer signals across clock domains.
- **Synchronizer** – Transfers signals from one clock domain to another.
- **DMA Interface** – Generates the handshaking signals to the central DMA controller in order to automate the data transfer without CPU intervention.
- **Interrupt Controller** – Generates the raw interrupt and interrupt flags, allowing them to be set and cleared.
- **RX FIFO/TX FIFO** – Holds the RX FIFO and TX FIFO register banks and controllers, along with their status levels.

4.4.4. I2C Terminology

The following terms are used and are defined as follows:

4.4.4.1. I2C Bus Terms

The following terms relate to how the role of the I2C device and how it interacts with other I2C devices on the bus.

- **Transmitter** – the device that sends data to the bus. A transmitter can either be a device that initiates the data transmission to the bus (a master-transmitter) or responds to a request from the master to send data to the bus (a slave-transmitter).
- **Receiver** – the device that receives data from the bus. A receiver can either be a device that receives data on its own request (a master-receiver) or in response to a request from the master (a slave-receiver).
- **Master** – the component that initializes a transfer (START command), generates the clock **SCL** signal and terminates the transfer (STOP command). A master can be either a transmitter or a receiver.
- **Slave** – the device addressed by the master. A slave can be either receiver or transmitter.
- **Multi-master** – the ability for more than one master to co-exist on the bus at the same time without collision or data loss.
- **Arbitration** – the predefined procedure that authorizes only one master at a time to take control of the bus. For more information about this behaviour, refer to [Section 4.4.8](#).
- **Synchronization** – the predefined procedure that synchronizes the clock signals provided by two or more masters. For more information about this feature, refer to [Section 4.4.9](#).
- **SDA** – data signal line (Serial Data)
- **SCL** – clock signal line (Serial CLock)

4.4.4.2. Bus Transfer Terms

The following terms are specific to data transfers that occur to/from the I2C bus.

- **START (RESTART)** – data transfer begins with a START or RESTART condition. The level of the **SDA** data line changes from high to low, while the **SCL** clock line remains high. When this occurs, the bus becomes busy.

NOTE

START and RESTART conditions are functionally identical.

- **STOP** – data transfer is terminated by a STOP condition. This occurs when the level on the **SDA** data line passes from the low state to the high state, while the **SCL** clock line remains high. When the data transfer has been terminated, the bus is free or idle once again. The bus stays busy if a RESTART is generated instead of a STOP condition.

4.4.5. I2C Behaviour

The DW_apb_i2c can be controlled via software to be either:

- An I2C master only, communicating with other I2C slaves; OR
- An I2C slave only, communicating with one or more I2C masters.

The master is responsible for generating the clock and controlling the transfer of data. The slave is responsible for either transmitting or receiving data to/from the master. The acknowledgement of data is sent by the device that is receiving data, which can be either a master or a slave. As mentioned previously, the I2C protocol also allows multiple masters to reside on the I2C bus and uses an arbitration procedure to determine bus ownership.

Each slave has a unique address that is determined by the system designer. When a master wants to communicate with a slave, the master transmits a START/RESTART condition that is then followed by the slave's address and a control bit (R/W) to determine if the master wants to transmit data or receive data from the slave. The slave then sends an acknowledge (ACK) pulse after the address.

If the master (master-transmitter) is writing to the slave (slave-receiver), the receiver gets one byte of data. This transaction continues until the master terminates the transmission with a STOP condition. If the master is reading from a slave (master-receiver), the slave transmits (slave-transmitter) a byte of data to the master, and the master then acknowledges the transaction with the ACK pulse. This transaction continues until the master terminates the transmission by not acknowledging (NACK) the transaction after the last byte is received, and then the master issues a STOP condition or addresses another slave after issuing a RESTART condition. This behaviour is illustrated in Figure 63.

Figure 63. Data transfer on the I2C Bus

The DW_apb_i2c is a synchronous serial interface. The SDA line is a bidirectional signal and changes only while the SCL line is low, except for STOP, START, and RESTART conditions. The output drivers are open-drain or open-collector to perform wire-AND functions on the bus. The maximum number of devices on the bus is limited by only the maximum capacitance specification of 400 pF. Data is transmitted in byte packages.

The I2C protocols implemented in DW_apb_i2c are described in more details in Section 4.4.6 section.

4.4.5.1. START and STOP Generation

When operating as an I2C master, putting data into the transmit FIFO causes the DW_apb_i2c to generate a START condition on the I2C bus. Writing a 1 to IC_DATA_CMD.STOP causes the DW_apb_i2c to generate a STOP condition on the I2C bus; a STOP condition is not issued if this bit is not set, even if the transmit FIFO is empty.

When operating as a slave, the DW_apb_i2c does not generate START and STOP conditions, as per the protocol. However, if a read request is made to the DW_apb_i2c, it holds the SCL line low until read data has been supplied to it. This stalls the I2C bus until read data is provided to the slave DW_apb_i2c, or the DW_apb_i2c slave is disabled by writing a 0 to IC_ENABLE.ENABLE.

4.4.5.2. Combined Formats

The DW_apb_i2c supports mixed read and write combined format transactions in both 7-bit and 10-bit addressing modes. The DW_apb_i2c does not support mixed address and mixed address format—that is, a 7-bit address transaction followed by a 10-bit address transaction or vice versa—combined format transactions. To initiate combined format transfers, IC_CON.IC_RESTART_EN should be set to 1. With this value set and operating as a master, when the DW_apb_i2c completes an I2C transfer, it checks the transmit FIFO and executes the next transfer. If the direction of this transfer differs from the previous transfer, the combined format is used to issue the transfer. If the transmit FIFO is empty when the current I2C transfer completes:

- IC_DATA_CMD.STOP is checked and:
 - If set to 1, a STOP bit is issued.
 - If set to 0, the SCL is held low until the next command is written to the transmit FIFO.

For more details, refer to Section 4.4.7.

4.4.6. I2C Protocols

The DW_apb_i2c has the protocols discussed in this section.

4.4.6.1. START and STOP Conditions

When the bus is idle, both the **SCL** and **SDA** signals are pulled high through external pull-up resistors on the bus. When the master wants to start a transmission on the bus, the master issues a START condition. This is defined to be a high-to-low transition of the **SDA** signal while **SCL** is 1. When the master wants to terminate the transmission, the master issues a STOP condition. This is defined to be a low-to-high transition of the **SDA** line while **SCL** is 1. [Figure 64](#) shows the timing of the START and STOP conditions. When data is being transmitted on the bus, the **SDA** line must be stable when **SCL** is 1.

Figure 64. I2C START and STOP Condition

NOTE

The signal transitions for the START/STOP conditions, as depicted in [Figure 64](#), reflect those observed at the output signals of the Master driving the I2C bus. Care should be taken when observing the **SDA/SCL** signals at the input signals of the Slave(s), because unequal line delays may result in an incorrect **SDA/SCL** timing relationship.

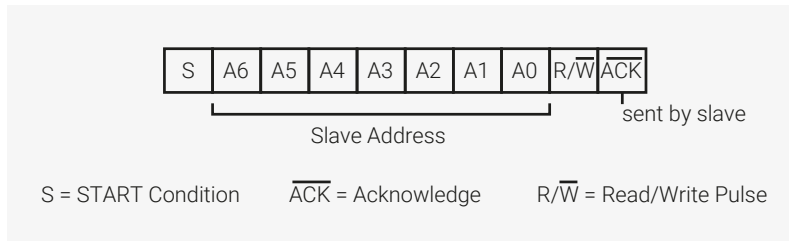

4.4.6.2. Addressing Slave Protocol

There are two address formats: the 7-bit address format and the 10-bit address format.

4.4.6.2.1. 7-bit Address Format

During the 7-bit address format, the first seven bits (bits 7:1) of the first byte set the slave address and the LSB bit (bit 0) is the R/W bit as shown in [Figure 65](#). When bit 0 (R/W) is set to 0, the master writes to the slave. When bit 0 (R/W) is set to 1, the master reads from the slave.

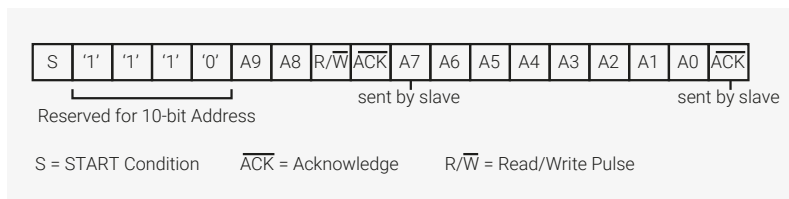

Figure 65. I2C 7-bit Address Format

4.4.6.2.2. 10-bit Address Format

During 10-bit addressing, two bytes are transferred to set the 10-bit address. The transfer of the first byte contains the following bit definition. The first five bits (bits 7:3) notify the slaves that this is a 10-bit transfer followed by the next two bits (bits 2:1), which set the slaves address bits 9:8, and the LSB bit (bit 0) is the R/W bit. The second byte transferred sets bits 7:0 of the slave address. [Figure 66](#) shows the 10-bit address format.

Figure 66. 10-bit Address Format

[This table](#) defines the special purpose and reserved first byte addresses.

Table 476. I2C/SMBus Definition of Bits in First Byte

Slave Address	R/W Bit	Description
0000 000	0	General Call Address. DW_apb_i2c places the data in the receive buffer and issues a General Call interrupt.
0000 000	1	START byte. For more details, refer to Section 4.4.6.4 .
0000 001	X	CBUS address. DW_apb_i2c ignores these accesses.
0000 010	X	Reserved.
0000 011	X	Reserved.
0000 1XX	X	High-speed master code (for more information, refer to Section 4.4.8).
1111 1XX	X	Reserved.
1111 0XX	X	10-bit slave addressing.
0001 000	X	SMBus Host (not supported)
0001 100	X	SMBus Alert Response Address (not supported)
1100 001	X	SMBus Device Default Address (not supported)

DW_apb_i2c does not restrict you from using these reserved addresses. However, if you use these reserved addresses, you may run into incompatibilities with other I2C components.

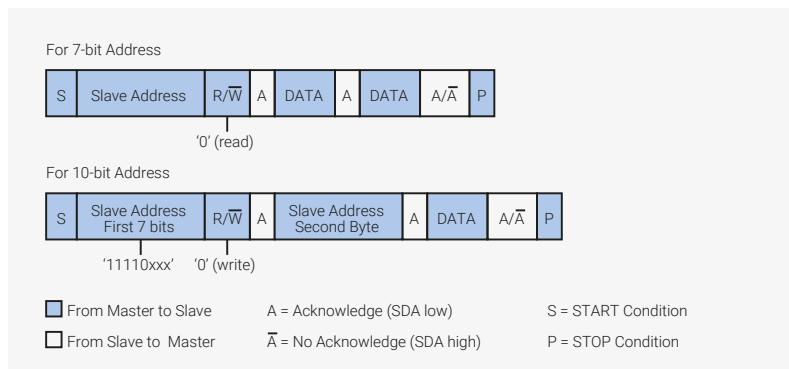

4.4.6.3. Transmitting and Receiving Protocol

The master can initiate data transmission and reception to/from the bus, acting as either a master-transmitter or master-receiver. A slave responds to requests from the master to either transmit data or receive data to/from the bus, acting as either a slave-transmitter or slave-receiver, respectively.

4.4.6.3.1. Master-Transmitter and Slave-Receiver

All data is transmitted in byte format, with no limit on the number of bytes transferred per data transfer. After the master sends the address and R/W bit or the master transmits a byte of data to the slave, the slave-receiver must respond with the acknowledge signal (ACK). When a slave-receiver does not respond with an ACK pulse, the master aborts the transfer by issuing a STOP condition. The slave must leave the SDA line high so that the master can abort the transfer. If the master-transmitter is transmitting data as shown in [Figure 67](#), then the slave-receiver responds to the master-transmitter with an acknowledge pulse after every byte of data is received.

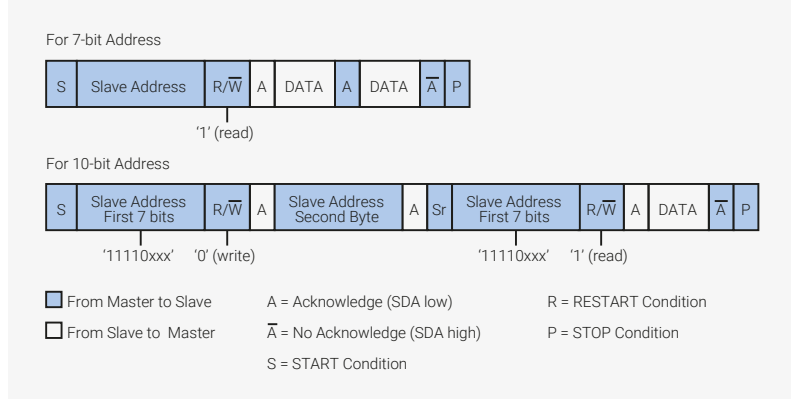

Figure 67. I2C Master-Transmitter Protocol

4.4.6.3.2. Master-Receiver and Slave-Transmitter

If the master is receiving data as shown in Figure 68, then the master responds to the slave-transmitter with an acknowledge pulse after a byte of data has been received, except for the last byte. This is the way the master-receiver notifies the slave-transmitter that this is the last byte. The slave-transmitter relinquishes the SDA line after detecting the No Acknowledge (NACK) so that the master can issue a STOP condition.

Figure 68. I2C Master-Receiver Protocol

When a master does not want to relinquish the bus with a STOP condition, the master can issue a RESTART condition. This is identical to a START condition except it occurs after the ACK pulse. Operating in master mode, the DW_apb_i2c can then communicate with the same slave using a transfer of a different direction. For a description of the combined format transactions that the DW_apb_i2c supports, refer to Section 4.4.5.2.

NOTE

The DW_apb_i2c must be completely disabled before the target slave address register (*IC_TAR*) can be reprogrammed.

4.4.6.4. START BYTE Transfer Protocol

The START BYTE transfer protocol is set up for systems that do not have an on-board dedicated I2C hardware module. When the DW_apb_i2c is addressed as a slave, it always samples the I2C bus at the highest speed supported so that it never requires a START BYTE transfer. However, when DW_apb_i2c is a master, it supports the generation of START BYTE transfers at the beginning of every transfer in case a slave device requires it.

This protocol consists of seven zeros being transmitted followed by a one, as illustrated in Figure 69. This allows the processor that is polling the bus to under-sample the address phase until zero is detected. Once the microcontroller detects a zero, it switches from the under sampling rate to the correct rate of the master.

Figure 69. I2C Start Byte Transfer

The START BYTE procedure is as follows:

1. Master generates a START condition.
2. Master transmits the START byte (0000 0001).
3. Master transmits the ACK clock pulse. (Present only to conform with the byte handling format used on the bus)
4. No slave sets the ACK signal to zero.

- 5. Master generates a RESTART (R) condition.

A hardware receiver does not respond to the START BYTE because it is a reserved address and resets after the RESTART condition is generated.

4.4.7. Tx FIFO Management and START, STOP and RESTART Generation

When operating as a master, the DW_apb_i2c component supports the mode of Tx FIFO management illustrated in Figure 70

4.4.7.1. Tx FIFO Management

The component does not generate a STOP if the Tx FIFO becomes empty; in this situation the component holds the SCL line low, stalling the bus until a new entry is available in the Tx FIFO. A STOP condition is generated only when the user specifically requests it by setting bit nine (Stop bit) of the command written to IC_DATA_CMD register. Figure 70 shows the bits in the IC_DATA_CMD register.

Figure 70. IC_DATA_CMD Register

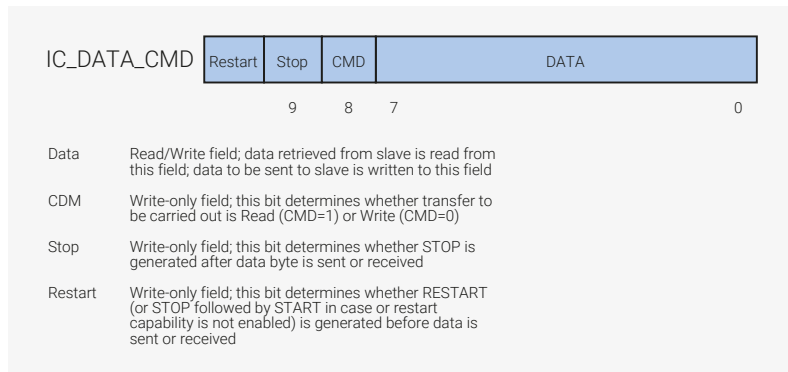

Figure 71 illustrates the behaviour of the DW_apb_i2c when the Tx FIFO becomes empty while operating as a master transmitter, as well as showing the generation of a STOP condition.

Figure 71. Master Transmitter - Tx FIFO Empties/STOP Generation

Figure 72 illustrates the behaviour of the DW_apb_i2c when the Tx FIFO becomes empty while operating as a master receiver, as well as showing the generation of a STOP condition.

Figure 72. Master Receiver - Tx FIFO Empties/STOP Generation

Figure 73 and Figure 74 illustrate configurations where the user can control the generation of RESTART conditions on the I2C bus. If bit 10 (Restart) of the IC_DATA_CMD register is set and the restart capability is enabled (IC_RESTART_EN=1), a RESTART is generated before the data byte is written to or read from the slave. If the restart capability is not enabled a STOP followed by a START is generated in place of the RESTART. Figure 73 illustrates this situation during operation as a master transmitter.

Figure 73. Master Transmitter – Restart Bit of IC_DATA_CMD Is Set

Figure 74 illustrates the same situation, but during operation as a master receiver.

Figure 74. Master Receiver – Restart Bit of IC_DATA_CMD Is Set

Figure 75 illustrates operation as a master transmitter where the Stop bit of the IC_DATA_CMD register is set and the Tx FIFO is not empty

Figure 75. Master Transmitter – Stop Bit of IC_DATA_CMD Set/Tx FIFO Not Empty

Figure 76 illustrates operation as a master transmitter where the first byte loaded into the Tx FIFO is allowed to go empty with the Restart bit set

Figure 76. Master Transmitter – First Byte Loaded Into Tx FIFO Allowed to Empty, Restart Bit Set

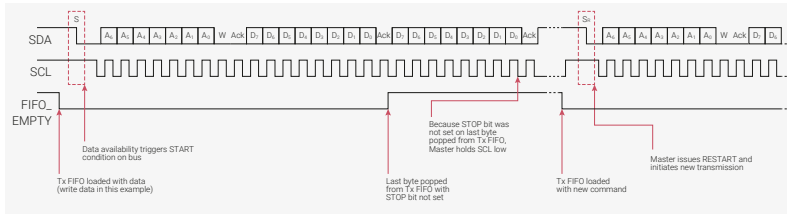

Figure 77 illustrates operation as a master receiver where the Stop bit of the IC_DATA_CMD register is set and the Tx FIFO is not empty

Figure 77. Master Receiver – Stop Bit of IC_DATA_CMD Set/Tx FIFO Not Empty

Figure 78 illustrates operation as a master receiver where the first command loaded after the Tx FIFO is allowed to empty and the Restart bit is set

Figure 78. Master Receiver – First Command Loaded After Tx FIFO Allowed to Empty/Restart Bit Set

4.4.8. Multiple Master Arbitration

The DW_apb_i2c bus protocol allows multiple masters to reside on the same bus. If there are two masters on the same I2C-bus, there is an arbitration procedure if both try to take control of the bus at the same time by generating a START condition at the same time. Once a master (for example, a microcontroller) has control of the bus, no other master can take control until the first master sends a STOP condition and places the bus in an idle state.

Arbitration takes place on the SDA line, while the SCL line is one. The master, which transmits a one while the other master transmits zero, loses arbitration and turns off its data output stage. The master that lost arbitration can continue to generate clocks until the end of the byte transfer. If both masters are addressing the same slave device, the arbitration could go into the data phase.

Upon detecting that it has lost arbitration to another master, the DW_apb_i2c will stop generating SCL (will disable the output driver). Figure 79 illustrates the timing of when two masters are arbitrating on the bus.

Figure 79. Multiple Master Arbitration

Control of the bus is determined by address or master code and data sent by competing masters, so there is no central master nor any order of priority on the bus.

Arbitration is not allowed between the following conditions:

- A RESTART condition and a data bit
- A STOP condition and a data bit
- A RESTART condition and a STOP condition

NOTE

Slaves are not involved in the arbitration process.

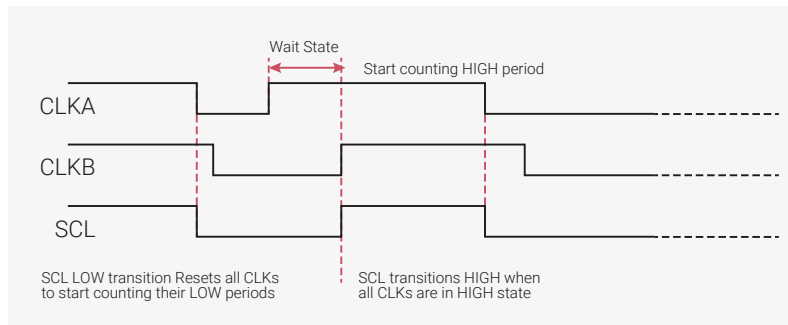

4.4.9. Clock Synchronization

When two or more masters try to transfer information on the bus at the same time, they must arbitrate and synchronize the SCL clock. All masters generate their own clock to transfer messages. Data is valid only during the high period of SCL

clock. Clock synchronization is performed using the wired-AND connection to the **SCL** signal. When the master transitions the **SCL** clock to zero, the master starts counting the low time of the **SCL** clock and transitions the **SCL** clock signal to one at the beginning of the next clock period. However, if another master is holding the **SCL** line to 0, then the master goes into a HIGH wait state until the **SCL** clock line transitions to one.

All masters then count off their high time, and the master with the shortest high time transitions the **SCL** line to zero. The masters then count out their low time and the one with the longest low time forces the other masters into a HIGH wait state. Therefore, a synchronized **SCL** clock is generated, which is illustrated in Figure 80. Optionally, slaves may hold the **SCL** line low to slow down the timing on the I2C bus.

Figure 80. Multi-Master Clock Synchronization

4.4.10. Operation Modes

This section provides information on operation modes.

i NOTE

It is important to note that the DW_apb_i2c should only be set to operate as an I2C Master, or I2C Slave, but not both simultaneously. This is achieved by ensuring that `IC_CON.IC_SLAVE_DISABLE` and `IC_CON.IC_MASTER_MODE` are never set to zero and one, respectively.

4.4.10.1. Slave Mode Operation

This section discusses slave mode procedures.

4.4.10.1.1. Initial Configuration

To use the DW_apb_i2c as a slave, perform the following steps:

1. Disable the DW_apb_i2c by writing a '0' to `IC_ENABLE.ENABLE`.
2. Write to the `IC_SAR` register (bits 9:0) to set the slave address. This is the address to which the DW_apb_i2c responds.
3. Write to the `IC_CON` register to specify which type of addressing is supported (7-bit or 10-bit by setting bit 3). Enable the DW_apb_i2c in slave-only mode by writing a '0' into bit six (`IC_SLAVE_DISABLE`) and a '0' to bit zero (`MASTER_MODE`).

i NOTE

Slaves and masters do not have to be programmed with the same type of addressing 7-bit or 10-bit address. For instance, a slave can be programmed with 7-bit addressing and a master with 10-bit addressing, and vice versa.

1. Enable the DW_apb_i2c by writing a '1' to [IC_ENABLE.ENABLE](#).

i NOTE

Depending on the reset values chosen, steps two and three may not be necessary because the reset values can be configured. For instance, if the device is only going to be a master, there would be no need to set the slave address because you can configure DW_apb_i2c to have the slave disabled after reset and to enable the master after reset. The values stored are static and do not need to be reprogrammed if the DW_apb_i2c is disabled.

⊖ WARNING

It is recommended that the DW_apb_i2c Slave be brought out of reset only when the I2C bus is IDLE. De-asserting the reset when a transfer is ongoing on the bus causes internal synchronization flip-flops used to synchronize **SDA** and **SCL** to toggle from a reset value of one to the actual value on the bus. This can result in **SDA** toggling from one to zero while **SCL** is one, thereby causing a false START condition to be detected by the DW_apb_i2c Slave. This scenario can also be avoided by configuring the DW_apb_i2c with `IC_SLAVE_DISABLE = 1` and `IC_MASTER_MODE = 1` so that the Slave interface is disabled after reset. It can then be enabled by programming `IC_CON[0] = 0` and `IC_CON[6] = 0` after the internal **SDA** and **SCL** have synchronized to the value on the bus; this takes approximately six `ic_clk` cycles after reset de-assertion.

4.4.10.1.2. Slave-Transmitter Operation for a Single Byte

When another I2C master device on the bus addresses the DW_apb_i2c and requests data, the DW_apb_i2c acts as a slave-transmitter and the following steps occur:

1. The other I2C master device initiates an I2C transfer with an address that matches the slave address in the [IC_SAR](#) register of the DW_apb_i2c.
2. The DW_apb_i2c acknowledges the sent address and recognizes the direction of the transfer to indicate that it is acting as a slave-transmitter.
3. The DW_apb_i2c asserts the RD_REQ interrupt (bit five of the [IC_RAW_INTR_STAT](#) register) and holds the **SCL** line low. It is in a wait state until software responds. If the RD_REQ interrupt has been masked, due to [IC_INTR_MASK.M_RD_REQ](#) being set to zero, then it is recommended that a hardware and/or software timing routine be used to instruct the CPU to perform periodic reads of the [IC_RAW_INTR_STAT](#) register.
 - a. Reads that indicate [IC_RAW_INTR_STAT.R_RD_REQ](#) being set to one must be treated as the equivalent of the RD_REQ interrupt being asserted.
 - b. Software must then act to satisfy the I2C transfer.
 - c. The timing interval used should be in the order of 10 times the fastest **SCL** clock period the DW_apb_i2c can handle. For example, for 400 kb/s, the timing interval is 25µs.

NOTE

The value of 10 is recommended here because this is approximately the amount of time required for a single byte of data transferred on the I2C bus.

1. If there is any data remaining in the Tx FIFO before receiving the read request, then the DW_apb_i2c asserts a TX_ABRT interrupt (bit six of the [IC_RAW_INTR_STAT](#) register) to flush the old data from the TX FIFO. If the TX_ABRT interrupt has been masked, due to [IC_INTR_MASK.M_TX_ABRT](#) being set to zero, then it is recommended that re-using the timing routine (described in the previous step), or a similar one, be used to read the [IC_RAW_INTR_STAT](#) register.

NOTE

Because the DW_apb_i2c's Tx FIFO is forced into a flushed/reset state whenever a TX_ABRT event occurs, it is necessary for software to release the DW_apb_i2c from this state by reading the [IC_CLR_TX_ABRT](#) register before attempting to write into the Tx FIFO. See register [IC_RAW_INTR_STAT](#) for more details.

- a. Reads that indicate bit six (R_TX_ABRT) being set to one must be treated as the equivalent of the TX_ABRT interrupt being asserted.
- b. There is no further action required from software.
- c. The timing interval used should be similar to that described in the previous step for the [IC_RAW_INTR_STAT](#)RD_REQ register.
 1. Software writes to the [IC_DATA_CMD](#) register with the data to be written (by writing a '0' in bit 8).
 2. Software must clear the RD_REQ and TX_ABRT interrupts (bits five and six, respectively) of the [IC_RAW_INTR_STAT](#) register before proceeding. If the RD_REQ and/or TX_ABRT interrupts have been masked, then clearing of the [IC_RAW_INTR_STAT](#) register will have already been performed when either the R_RD_REQ or R_TX_ABRT bit has been read as one.
 3. The DW_apb_i2c releases the SCL and transmits the byte.
 4. The master may hold the I2C bus by issuing a RESTART condition or release the bus by issuing a STOP condition.

NOTE

Slave-Transmitter Operation for a Single Byte is not applicable in Ultra-Fast Mode as Read transfers are not supported.

4.4.10.1.3. Slave-Receiver Operation for a Single Byte

When another I2C master device on the bus addresses the DW_apb_i2c and is sending data, the DW_apb_i2c acts as a slave-receiver and the following steps occur:

1. The other I2C master device initiates an I2C transfer with an address that matches the DW_apb_i2c's slave address in the [IC_SAR](#) register.
2. The DW_apb_i2c acknowledges the sent address and recognizes the direction of the transfer to indicate that the DW_apb_i2c is acting as a slave-receiver.
3. DW_apb_i2c receives the transmitted byte and places it in the receive buffer.

NOTE

If the Rx FIFO is completely filled with data when a byte is pushed, then the DW_apb_i2c slave holds the I2C **SCL** line low until the Rx FIFO has some space, and then continues with the next read request.

1. DW_apb_i2c asserts the RX_FULL interrupt `IC_RAW_INTR_STAT.RX_FULL`. If the RX_FULL interrupt has been masked, due to setting `IC_INTR_MASK.M_RX_FULL` register to zero or setting `IC_TX_TL` to a value larger than zero, then it is recommended that a timing routine (described in [Section 4.4.10.1.2](#)) be implemented for periodic reads of the `IC_STATUS` register. Reads of the `IC_STATUS` register, with bit 3 (RFNE) set at one, must then be treated by software as the equivalent of the RX_FULL interrupt being asserted.
2. Software may read the byte from the `IC_DATA_CMD` register (bits 7:0).
3. The other master device may hold the I2C bus by issuing a RESTART condition, or release the bus by issuing a STOP condition.

4.4.10.1.4. Slave-Transfer Operation For Bulk Transfers

In the standard I2C protocol, all transactions are single byte transactions and the programmer responds to a remote master read request by writing one byte into the slave's TX FIFO. When a slave (slave-transmitter) is issued with a read request (RD_REQ) from the remote master (master-receiver), at a minimum there should be at least one entry placed into the slave-transmitter's TX FIFO. DW_apb_i2c is designed to handle more data in the TX FIFO so that subsequent read requests can take that data without raising an interrupt to get more data. Ultimately, this eliminates the possibility of significant latencies being incurred between raising the interrupt for data each time had there been a restriction of having only one entry placed in the TX FIFO. This mode only occurs when DW_apb_i2c is acting as a slave-transmitter. If the remote master acknowledges the data sent by the slave-transmitter and there is no data in the slave's TX FIFO, the DW_apb_i2c holds the I2C **SCL** line low while it raises the read request interrupt (RD_REQ) and waits for data to be written into the TX FIFO before it can be sent to the remote master.

If the RD_REQ interrupt is masked, due to `IC_INTR_STAT.M_RD_REQ` set to zero, then it is recommended that a timing routine be used to activate periodic reads of the `IC_RAW_INTR_STAT` register. Reads of `IC_RAW_INTR_STAT` that return bit five (R_RD_REQ) set to one must be treated as the equivalent of the RD_REQ interrupt referred to in this section. This timing routine is similar to that described in [Section 4.4.10.1.2](#).

The RD_REQ interrupt is raised upon a read request, and like interrupts, must be cleared when exiting the interrupt service handling routine (ISR). The ISR allows you to either write one byte or more than one byte into the Tx FIFO. During the transmission of these bytes to the master, if the master acknowledges the last byte, then the slave must raise the RD_REQ again because the master is requesting for more data. If the programmer knows in advance that the remote master is requesting a packet of 'n' bytes, then when another master addresses DW_apb_i2c and requests data, the Tx FIFO could be written with 'n' bytes and the remote master receives it as a continuous stream of data. For example, the DW_apb_i2c slave continues to send data to the remote master as long as the remote master is acknowledging the data sent and there is data available in the Tx FIFO. There is no need to hold the **SCL** line low or to issue RD_REQ again.

If the remote master is to receive 'n' bytes from the DW_apb_i2c but the programmer wrote a number of bytes larger than 'n' to the Tx FIFO, then when the slave finishes sending the requested 'n' bytes, it clears the Tx FIFO and ignores any excess bytes.

The DW_apb_i2c generates a transmit abort (TX_ABRT) event to indicate the clearing of the Tx FIFO in this example. At the time an ACK/NACK is expected, if a NACK is received, then the remote master has all the data it wants. At this time, a flag is raised within the slave's state machine to clear the leftover data in the Tx FIFO. This flag is transferred to the processor bus clock domain where the FIFO exists and the contents of the Tx FIFO is cleared at that time.

4.4.10.2. Master Mode Operation

This section discusses master mode procedures.

4.4.10.2.1. Initial Configuration

To use the DW_apb_i2c as a master perform the following steps:

1. Disable the DW_apb_i2c by writing zero to [IC_ENABLE.ENABLE](#).
2. Write to the [IC_CON](#) register to set the maximum speed mode supported (bits 2:1) and the desired speed of the DW_apb_i2c master-initiated transfers, either 7-bit or 10-bit addressing (bit 4). Ensure that bit six ([IC_SLAVE_DISABLE](#)) is written with a '1' and bit zero ([MASTER_MODE](#)) is written with a '1'.

Note: Slaves and masters do not have to be programmed with the same type of 7-bit or 10-bit address. For instance, a slave can be programmed with 7-bit addressing and a master with 10-bit addressing, and vice versa.

1. Write to the [IC_TAR](#) register the address of the I2C device to be addressed (bits 9:0). This register also indicates whether a General Call or a START BYTE command is going to be performed by I2C.
2. Enable the DW_apb_i2c by writing a one to [IC_ENABLE.ENABLE](#).
3. Now write transfer direction and data to be sent to the [IC_DATA_CMD](#) register. If the [IC_DATA_CMD](#) register is written before the DW_apb_i2c is enabled, the data and commands are lost as the buffers are kept cleared when DW_apb_i2c is disabled. This step generates the START condition and the address byte on the DW_apb_i2c. Once DW_apb_i2c is enabled and there is data in the TX FIFO, DW_apb_i2c starts reading the data.

i NOTE

Depending on the reset values chosen, steps two, three, four, and five may not be necessary because the reset values can be configured. The values stored are static and do not need to be reprogrammed if the DW_apb_i2c is disabled, with the exception of the transfer direction and data.

4.4.10.2.2. Master Transmit and Master Receive

The DW_apb_i2c supports switching back and forth between reading and writing dynamically. To transmit data, write the data to be written to the lower byte of the I2C Rx/Tx Data Buffer and Command Register ([IC_DATA_CMD](#)). The CMD bit [8] should be written to zero for I2C write operations. Subsequently, a read command may be issued by writing "don't cares" to the lower byte of the [IC_DATA_CMD](#) register, and a one should be written to the CMD bit. The DW_apb_i2c master continues to initiate transfers as long as there are commands present in the transmit FIFO. If the transmit FIFO becomes empty the master either inserts a STOP condition after completing the current transfers.

- If set to one, it issues a STOP condition after completing the current transfer.
- If set to zero, it holds **SCL** low until next command is written to the transmit FIFO.

For more details, refer to [Section 4.4.7](#).

4.4.10.3. Disabling DW_apb_i2c

The register [IC_ENABLE_STATUS](#) is added to allow software to unambiguously determine when the hardware has completely shutdown in response to [IC_ENABLE.ENABLE](#) being set from one to zero.

Only one register is required to be monitored, as opposed to monitoring two registers ([IC_STATUS](#) and [IC_RAW_INTR_STAT](#)) which was a requirement for earlier versions of DW_apb_i2c.

NOTE

The DW_apb_i2c Master can be disabled only if the current command being processed—when the `ic_enable` de-assertion occurs—has the STOP bit set to one. When an attempt is made to disable the DW_apb_i2c Master while processing a command without the STOP bit set, the DW_apb_i2c Master continues to remain active, holding the SCL line low until a new command is received in the Tx FIFO. When the DW_apb_i2c Master is processing a command without the STOP bit set, you can issue the ABORT (`IC_ENABLE.ABORT`) to relinquish the I2C bus and then disable DW_apb_i2c.

4.4.10.3.1. Procedure

1. Define a timer interval (`t_i2c_poll`) equal to the 10 times the signaling period for the highest I2C transfer speed used in the system and supported by DW_apb_i2c. For example, if the highest I2C transfer mode is 400 kb/s, then this `t_i2c_poll` is 25µs.
2. Define a maximum time-out parameter, `MAX_T_POLL_COUNT`, such that if any repeated polling operation exceeds this maximum value, an error is reported.
3. Execute a blocking thread/process/function that prevents any further I2C master transactions to be started by software, but allows any pending transfers to be completed.

NOTE

This step can be ignored if DW_apb_i2c is programmed to operate as an I2C slave only.

1. The variable `POLL_COUNT` is initialized to zero.
2. Set bit zero of the `IC_ENABLE` register to zero.
3. Read the `IC_ENABLE_STATUS` register and test the `IC_EN` bit (bit 0). Increment `POLL_COUNT` by one. If `POLL_COUNT >= MAX_T_POLL_COUNT`, exit with the relevant error code.
4. If `IC_ENABLE_STATUS[0]` is one, then sleep for `t_i2c_poll` and proceed to the previous step. Otherwise, exit with a relevant success code.

4.4.10.4. Aborting I2C Transfers

The ABORT control bit of the `IC_ENABLE` register allows the software to relinquish the I2C bus before completing the issued transfer commands from the Tx FIFO. In response to an ABORT request, the controller issues the STOP condition over the I2C bus, followed by Tx FIFO flush. Aborting the transfer is allowed only in master mode of operation.

4.4.10.4.1. Procedure

1. Stop filling the Tx FIFO (`IC_DATA_CMD`) with new commands.
2. When operating in DMA mode, disable the transmit DMA by setting `TDMAE` to zero.
3. Set `IC_ENABLE.ABORT` to one.
4. Wait for the `M_TX_ABRT` interrupt.
5. Read the `IC_TX_ABRT_SOURCE` register to identify the source as `ABRT_USER_ABRT`.

4.4.11. Spike Suppression

The DW_apb_i2c contains programmable spike suppression logic that match requirements imposed by the I2C Bus Specification for SS/FS modes. This logic is based on counters that monitor the input signals (SCL and SDA), checking if

they remain stable for a predetermined amount of `ic_clk` cycles before they are sampled internally. There is one separate counter for each signal (`SCL` and `SDA`). The number of `ic_clk` cycles can be programmed by the user and should be calculated taking into account the frequency of `ic_clk` and the relevant spike length specification. Each counter is started whenever its input signal changes its value. Depending on the behaviour of the input signal, one of the following scenarios occurs:

- The input signal remains unchanged until the counter reaches its count limit value. When this happens, the internal version of the signal is updated with the input value, and the counter is reset and stopped. The counter is not restarted until a new change on the input signal is detected.
- The input signal changes again before the counter reaches its count limit value. When this happens, the counter is reset and stopped, but the internal version of the signal is not updated. The counter remains stopped until a new change on the input signal is detected.

The timing diagram in [Figure 81](#) illustrates the behaviour described above.

Figure 81. Spike Suppression Example

NOTE

There is a 2-stage synchronizer on the `SCL` input, but for the sake of simplicity this synchronization delay was not included in the timing diagram in [Figure 81](#).

The I2C Bus Specification calls for different maximum spike lengths according to the operating mode—50 ns for SS and FS, so this register is required to store the values needed:

- Register `IC_FS_SPKLEN` holds the maximum spike length for SS and FS modes

This register is 8 bits wide and accessible through the APB interface for read and write purposes; however, they can be written to only when the `DW_apb_i2c` is disabled. The minimum value that can be programmed into these registers is one; attempting to program a value smaller than one results in the value one being written.

The default value for these registers is based on the value of 100ns for `ic_clk` period, so does should be updated for the `clk_sys` period in use on RP2040.

NOTE

- Because the minimum value that can be programmed into the `IC_FS_SPKLEN` register is one, the spike length specification can be exceeded for low frequencies of `ic_clk`. Consider the simple example of a 10 MHz (100 ns period) `ic_clk`; in this case, the minimum spike length that can be programmed is 100 ns, which means that spikes up to this length are suppressed.
- Standard synchronization logic (two flip-flops in series) is implemented upstream of the spike suppression logic and is not affected in any way by the contents of the spike length registers or the operation of the spike suppression logic; the two operations (synchronization and spike suppression) are completely independent. Because the `SCL` and `SDA` inputs are asynchronous to `ic_clk`, there is one `ic_clk` cycle uncertainty in the sampling of these signals; that is, depending on when they occur relative to the rising edge of `ic_clk`, spikes of the same original length might show a difference of one `ic_clk` cycle after being sampled.
- Spike suppression is symmetrical; that is, the behaviour is exactly the same for transitions from zero to one and from one to zero.

4.4.12. Fast Mode Plus Operation

In fast mode plus, the `DW_apb_i2c` allows the fast mode operation to be extended to support speeds up to 1000 Kb/s. To enable the `DW_apb_i2c` for fast mode plus operation, perform the following steps before initiating any data transfer:

1. Set `ic_clk` frequency greater than or equal to 32 MHz (refer to [Section 4.4.14.2.1](#)).
2. Program the `IC_CON` register `[2:1] = 2'b10` for fast mode or fast mode plus.
3. Program `IC_FS_SCL_LCNT` and `IC_FS_SCL_HCNT` registers to meet the fast mode plus `SCL` (refer to [Section 4.4.14](#)).
4. Program the `IC_FS_SPKLEN` register to suppress the maximum spike of 50ns.
5. Program the `IC_SDA_SETUP` register to meet the minimum data setup time (tSU; DAT).

4.4.13. Bus Clear Feature

`DW_apb_i2c` supports the bus clear feature that provides graceful recovery of data `SDA` and clock `SCL` lines during unlikely events in which either the clock or data line is stuck at LOW.

4.4.13.1. `SDA` Line Stuck at LOW Recovery

In case of `SDA` line stuck at LOW, the master performs the following actions to recover as shown in [Figure 82](#) and [Figure 83](#):

1. Master sends a maximum of nine clock pulses to recover the bus LOW within those nine clocks.
 - The number of clock pulses will vary with the number of bits that remain to be sent by the slave. As the maximum number of bits is nine, master sends up to nine clock pulses and allows the slave to recover it.
 - The master attempts to assert a Logic 1 on the `SDA` line and check whether `SDA` is recovered. If the `SDA` is not recovered, it will continue to send a maximum of nine `SCL` clocks.
2. If `SDA` line is recovered within nine clock pulses then the master will send the STOP to release the bus.
3. If `SDA` line is not recovered even after the ninth clock pulse then system needs a hardware reset.

Figure 82. SDA Recovery with 9 SCL Clocks

Figure 83. SDA Recovery with 6 SCL Clocks

4.4.13.2. SCL Line is Stuck at LOW

In the unlikely event (due to an electric failure of a circuit) where the clock (SCL) is stuck to LOW, there is no effective method to overcome this problem but to reset the bus using the hardware reset signal.

4.4.14. IC_CLK Frequency Configuration

When the DW_apb_i2c is configured as a Standard (SS), Fast (FS)/Fast-Mode Plus (FM+), the *CNT registers must be set before any I2C bus transaction can take place in order to ensure proper I/O timing. The *CNT registers are:

- IC_SS_SCL_HCNT
- IC_SS_SCL_LCNT
- IC_FS_SCL_HCNT
- IC_FS_SCL_LCNT

NOTE

The tBUF timing and setup/hold time of START, STOP and RESTART registers uses *HCNT/*LCNT register settings for the corresponding speed mode.

NOTE

It is not necessary to program any of the *CNT registers if the DW_apb_i2c is enabled to operate only as an I2C slave, since these registers are used only to determine the SCL timing requirements for operation as an I2C master.

Table 477 lists the derivation of I2C timing parameters from the *CNT programming registers.

Table 477. Derivation of I2C Timing Parameters from *CNT Registers

Timing Parameter	Symbol	Standard Speed	Fast Speed / Fast Speed Plus
LOW period of the SCL clock	tLOW	IC_SS_SCL_LCNT	IC_FS_SCL_LCNT
HIGH period of the SCL clock	tHIGH	IC_SS_SCL_HCNT	IC_FS_SCL_HCNT
Setup time for a repeated START condition	tSU;STA	IC_SS_SCL_LCNT	IC_FS_SCL_HCNT
Hold time (repeated) START condition*	tHD;STA	IC_SS_SCL_HCNT	IC_FS_SCL_HCNT
Setup time for STOP condition	tSU;STO	IC_SS_SCL_HCNT	IC_FS_SCL_HCNT

Timing Parameter	Symbol	Standard Speed	Fast Speed / Fast Speed Plus
Bus free time between a STOP and a START condition	tBUF	IC_SS_SCL_LCNT	IC_FS_SCL_LCNT
Spike length	tSP	IC_FS_SPKLEN	IC_FS_SPKLEN
Data hold time	tHD;DAT	IC_SDA_HOLD	IC_SDA_HOLD
Data setup time	tSU;DAT	IC_SDA_SETUP	IC_SDA_SETUP

4.4.14.1. Minimum High and Low Counts in SS, FS, and FM+ Modes.

When the DW_apb_i2c operates as an I2C master, in both transmit and receive transfers:

- IC_SS_SCL_LCNT and IC_FS_SCL_LCNT register values must be larger than IC_FS_SPKLEN + 7.
- IC_SS_SCL_HCNT and IC_FS_SCL_HCNT register values must be larger than IC_FS_SPKLEN + 5.

Details regarding the DW_apb_i2c high and low counts are as follows:

- The minimum value of IC*_SPKLEN + 7 for the *_LCNT registers is due to the time required for the DW_apb_i2c to drive SDA after a negative edge of SCL.
- The minimum value of IC*_SPKLEN + 5 for the *_HCNT registers is due to the time required for the DW_apb_i2c to sample SDA during the high period of SCL.
- The DW_apb_i2c adds one cycle to the programmed *_LCNT value in order to generate the low period of the SCL clock; this is due to the counting logic for SCL low counting to (*_LCNT + 1).
- The DW_apb_i2c adds IC*_SPKLEN + 7 cycles to the programmed *_HCNT value in order to generate the high period of the SCL clock; this is due to the following factors:
 - The counting logic for SCL high counts to (*_HCNT+1).
 - The digital filtering applied to the SCL line incurs a delay of SPKLEN + 2 ic_clk cycles, where SPKLEN is:
 - IC_FS_SPKLEN if the component is operating in SS or FS
 - Whenever SCL is driven one to zero by the DW_apb_i2c—that is, completing the SCL high time—an internal logic latency of three ic_clk cycles is incurred. Consequently, the minimum SCL low time of which the DW_apb_i2c is capable is nine ic_clk periods (7 + 1 + 1), while the minimum SCL high time is thirteen ic_clk periods (6 + 1 + 3 + 3).

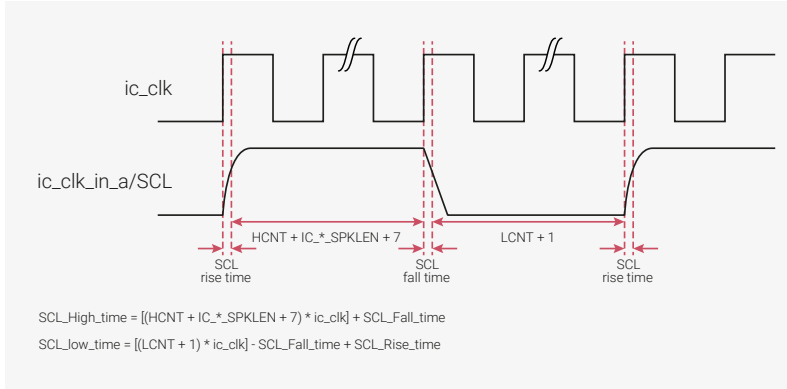

NOTE

The total high time and low time of SCL generated by the DW_apb_i2c master is also influenced by the rise time and fall time of the SCL line, as shown in the illustration and equations in Figure 84. It should be noted that the SCL rise and fall time parameters vary, depending on external factors such as:

- Characteristics of IO driver
- Pull-up resistor value
- Total capacitance on SCL line, and so on

These characteristics are beyond the control of the DW_apb_i2c.

Figure 84. Impact of SCL Rise Time and Fall Time on Generated SCL

4.4.14.2. Minimum IC_CLK Frequency

This section describes the minimum *ic_clk* frequencies that the DW_apb_i2c supports for each speed mode, and the associated high and low count values. In Slave mode, *IC_SDA_HOLD* (Thd;dat) and *IC_SDA_SETUP* (Tsu;dat) need to be programmed to satisfy the I2C protocol timing requirements. The following examples are for the case where *IC_FS_SPKLEN* is programmed to two.

4.4.14.2.1. Standard Mode (SM), Fast Mode (FM), and Fast Mode Plus (FM+)

This section details how to derive a minimum *ic_clk* value for standard and fast modes of the DW_apb_i2c. Although the following method shows how to do fast mode calculations, you can also use the same method in order to do calculations for standard mode and fast mode plus.

NOTE

The following computations do not consider the *SCL_Rise_time* and *SCL_Fall_time*.

Given conditions and calculations for the minimum DW_apb_i2c *ic_clk* value in fast mode:

- Fast mode has data rate of 400kb/s; implies *SCL* period of 1/400khz = 2.5µs
- Minimum *hcnt* value of 14 as a seed value; *IC_HCNT_FS* = 14
- Protocol minimum *SCL* high and low times:
 - *MIN_SCL_LOWtime_FS* = 1300ns
 - *MIN_SCL_HIGHTime_FS* = 600ns

Derived equations:

$$SCL_PERIOD_FS / (IC_HCNT_FS + IC_LCNT_FS) = IC_CLK_PERIOD$$

$$IC_LCNT_FS \times IC_CLK_PERIOD = MIN_SCL_LOWtime_FS$$

Combined, the previous equations produce the following:

$$IC_LCNT_FS \times (SCL_PERIOD_FS / (IC_LCNT_FS + IC_HCNT_FS)) = MIN_SCL_LOWtime_FS$$

Solving for *IC_LCNT_FS*:

$$IC_LCNT_FS \times (2.5\mu s / (IC_LCNT_FS + 14)) = 1.3\mu s$$

The previous equation gives:

$$IC_LCNT_FS = \text{roundup}(15.166) = 16$$

These calculations produce IC_LCNT_FS = 16 and IC_HCNT_FS = 14, giving an **ic_clk** value of:

$$2.5 \mu s / (16 + 14) = 83.3ns = 12MHz$$

Testing these results shows that protocol requirements are satisfied.

Table 478 lists the minimum **ic_clk** values for all modes with high and low count values.

Table 478. **ic_clk** in Relation to High and Low Counts

Speed Mode	ic_clkfreq (MHz)	Minimum Value of IC*_SPKLEN	SCL Low Time in `ic_clk`s	SCL Low Program Value	SCL Low Time	SCL High Time in `ic_clk`s	SCL High Program Value	SCL High Time
SS	2.7	1	13	12	4.7 μs	14	6	5.2 μs
FS	12.0	1	16	15	1.33 μs	14	6	1.16 μs
FM+	32	2	16	15	500 ns	16	7	500 ns

- The IC*_SCL_LCNT and IC*_SCL_HCNT registers are programmed using the **SCL** low and high program values in Table 3-5, which are calculated using **SCL** low count minus one, and **SCL** high counts minus eight, respectively. The values in Table 3-5 are based on IC_SDA_RX_HOLD = 0. The maximum IC_SDA_RX_HOLD value depends on the **IC*_CNT** registers in Master mode.
- In order to compute the HCNT and LCNT considering RC timings, use the following equations:
 - $IC_HCNT_* = [(HCNT + IC_*_SPKLEN + 7) * ic_clk] + SCL_Fall_time$
 - $IC_LCNT_* = [(LCNT + 1) * ic_clk] - SCL_Fall_time + SCL_Rise_time$

4.4.14.3. Calculating High and Low Counts

The calculations below show how to calculate **SCL** high and low counts for each speed mode in the DW_apb_i2c. For the calculations to work, the **ic_clk** frequencies used must not be less than the minimum **ic_clk** frequencies specified in Table XXXX.

The default **ic_clk** period value is set to 100ns, so default **SCL** high and low count values are calculated for each speed mode based on this clock. These values need updating according to the guidelines below.

The equation to calculate the proper number of **ic_clk** signals required for setting the proper **SCL** clocks high and low times is as follows:

$$IC_xCNT = (\text{ROUNDUP}(\text{MIN_SCL_xxxtime} * \text{OSCFREQ}, 0))$$

MIN_SCL_HIGHTime = Minimum High Period

MIN_SCL_HIGHTime = 4000 ns for 100 kbps,
 600 ns for 400 kbps,
 260 ns for 1000 kbps,
 60 ns for 3.4 Mbs, bus loading = 100pF
 120 ns for 3.4 Mbs, bus loading = 400pF

```

MIN_SCL_LOWtime = Minimum Low Period
MIN_SCL_LOWtime = 4700 ns for 100 kbps,
                  1300 ns for 400 kbps,
                  500 ns for 1000 kbps,
                  160 ns for 3.4Mbs, bus loading = 100pF
                  320 ns for 3.4Mbs, bus loading = 400pF

```

```

OSCFREQ = ic_clk Clock Frequency (Hz).

```

For example:

```

OSCFREQ = 100 MHz
I2Cmode = fast, 400 kbit/s
MIN_SCL_HIGHTime = 600 ns.
MIN_SCL_LOWtime = 1300 ns.

IC_xCNT = (ROUNDUP(MIN_SCL_HIGH_LOWtime*OSCFREQ, 0))

IC_HCNT = (ROUNDUP(600 ns * 100 MHz, 0))
IC_HCNTSCL PERIOD = 60
IC_LCNT = (ROUNDUP(1300 ns * 100 MHz, 0))
IC_LCNTSCL PERIOD = 130
Actual MIN_SCL_HIGHTime = 60*(1/100 MHz) = 600 ns
Actual MIN_SCL_LOWtime = 130*(1/100 MHz) = 1300 ns

```

4.4.15. DMA Controller Interface

The DW_apb_i2c has built-in DMA capability; it has a handshaking interface to the DMA Controller to request and control transfers. The APB bus is used to perform the data transfer to or from the DMA. DMA transfers are transferred as single accesses as data rate is relatively low.

4.4.15.1. Enabling the DMA Controller Interface

To enable the DMA Controller interface on the DW_apb_i2c, you must write the DMA Control Register ([IC_DMA_CR](#)). Writing a one into the TDMAE bit field of [IC_DMA_CR](#) register enables the DW_apb_i2c transmit handshaking interface. Writing a one into the RDMAE bit field of the [IC_DMA_CR](#) register enables the DW_apb_i2c receive handshaking interface.

4.4.15.2. Overview of Operation

TO DO: GRAHAM/LIAM: Review this section

The DMA Controller is programmed with the number of data items (block size) that are to be transmitted or received by DW_apb_i2c.

The block is broken into a number of transactions, each initiated by a request from the DW_apb_i2c. Each transfer is one item on the bus.

For example, where the block size programmed into the DMA Controller is four. The DMA block transfer consists of a series of four single transactions. If the DW_apb_i2c makes a transmit request to this channel, a single data item is written to the DW_apb_i2c TX FIFO. Similarly, if the DW_apb_i2c makes a receive request to this channel, a single data item is read from the DW_apb_i2c RX FIFO. Four separate requests must be made to this DMA channel before all four data items are written or read.

4.4.15.3. Watermark Levels

In DW_apb_i2c the registers for setting watermarks to allow DMA bursts do not need be set to anything other than their reset value. Specifically [IC_DMA_TDLR](#) and [IC_DMA_RDLR](#) can be left at reset values of zero. This is because only single transfers are needed due to the low bandwidth of I2C relative to system bandwidth, and also the DMA controller normally has highest priority on the system bus so will generally complete very quickly.

4.4.15.4. Operation of Interrupt Registers

Table 3-10 lists the operation of the DW_apb_i2c interrupt registers and how they are set and cleared. Some bits are set by hardware and cleared by software, whereas other bits are set and cleared by hardware.

Table 479. Clearing and Setting of Interrupt Registers

Interrupt Bit Fields	Set by Hardware/Cleared by Software	Set and Cleared by Hardware
MST_ON_HOLD	N	Y
RESTART_DET	Y	N
GEN_CALL	Y	N
START_DET	Y	N
STOP_DET	Y	N
ACTIVITY	Y	N
RX_DONE	Y	N
TX_ABRT	Y	N
RD_REQ	Y	N
TX_EMPTY	N	Y
TX_OVER	Y	N
RX_FULL	N	Y
RX_OVER	Y	N
RX_UNDER	Y	N

4.4.16. List of Registers

Table 480. List of I2C registers

Offset	Name	Info
0x00	IC_CON	I2C Control Register
0x04	IC_TAR	I2C Target Address Register
0x08	IC_SAR	I2C Slave Address Register
0x10	IC_DATA_CMD	I2C Rx/Tx Data Buffer and Command Register
0x14	IC_SS_SCL_HCNT	Standard Speed I2C Clock SCL High Count Register
0x18	IC_SS_SCL_LCNT	Standard Speed I2C Clock SCL Low Count Register
0x1c	IC_FS_SCL_HCNT	Fast Mode or Fast Mode Plus I2C Clock SCL High Count Register
0x20	IC_FS_SCL_LCNT	Fast Mode or Fast Mode Plus I2C Clock SCL Low Count Register
0x2c	IC_INTR_STAT	I2C Interrupt Status Register
0x30	IC_INTR_MASK	I2C Interrupt Mask Register

Offset	Name	Info
0x34	IC_RAW_INTR_STAT	I2C Raw Interrupt Status Register

0x6c	IC_ENABLE	I2C ENABLE Register
0x70	IC_STATUS	I2C STATUS Register
0x74	IC_TXFLR	I2C Transmit FIFO Level Register
0x78	IC_RXFLR	I2C Receive FIFO Level Register
0x7c	IC_SDA_HOLD	I2C SDA Hold Time Length Register
0x80	IC_TX_ABRT_SOURCE	I2C Transmit Abort Source Register
0x84	IC_SLV_DATA_NACK_ONLY	Generate Slave Data NACK Register
0x88	IC_DMA_CR	DMA Control Register
0x8c	IC_DMA_TDLR	DMA Transmit Data Level Register
0x90	IC_DMA_RDLR	DMA Transmit Data Level Register
0x94	IC_SDA_SETUP	I2C SDA Setup Register
0x98	IC_ACK_GENERAL_CALL	I2C ACK General Call Register
0x9c	IC_ENABLE_STATUS	I2C Enable Status Register
0xa0	IC_FS_SPKLEN	I2C SS, FS or FM+ spike suppression limit
0xa8	IC_CLR_RESTART_DET	Clear RESTART_DET Interrupt Register
0xf4	IC_COMP_PARAM_1	Component Parameter Register 1
0xf8	IC_COMP_VERSION	I2C Component Version Register
0xfc	IC_COMP_TYPE	I2C Component Type Register

IC_CON Register

Description

I2C Control Register. This register can be written only when the DW_apb_i2c is disabled, which corresponds to the IC_ENABLE[0] register being set to 0. Writes at other times have no effect.

Read/Write Access: - bit 10 is read only. - bit 11 is read only - bit 16 is read only - bit 17 is read only - bits 18 and 19 are read only.

Table 481. IC_CON Register

Bits	Name	Description	Type	Reset
31:11	Reserved.	-	-	-
10	STOP_DET_IF_MASTER_ACTIVE	Master issues the STOP_DET interrupt irrespective of whether master is active or not	RO	0x0
9	RX_FIFO_FULL_HOLD_CTRL	This bit controls whether DW_apb_i2c should hold the bus when the Rx FIFO is physically full to its RX_BUFFER_DEPTH, as described in the IC_RX_FULL_HOLD_BUS_EN parameter. Reset value: 0x0. 0x0 -> Overflow when RX_FIFO is full 0x1 -> Hold bus when RX_FIFO is full	RW	0x0
8	TX_EMPTY_CTRL	This bit controls the generation of the TX_EMPTY interrupt, as described in the IC_RAW_INTR_STAT register. Reset value: 0x0. 0x0 -> Default behaviour of TX_EMPTY interrupt 0x1 -> Controlled generation of TX_EMPTY interrupt	RW	0x0
7	STOP_DET_IF_ADDRESSSED	In slave mode: - 1'b1: issues the STOP_DET interrupt only when it is addressed. - 0'b0: issues the STOP_DET interrupt irrespective of whether it's addressed or not. Reset value: 0x0 NOTE: During a general call address, this slave does not issue the STOP_DET interrupt if STOP_DET_IF_ADDRESSSED = 1'b1, even if the slave responds to the general call address by generating ACK. The STOP_DET interrupt is generated only when the transmitted address matches the slave address (SAR). 0x0 -> slave issues STOP_DET intr always 0x1 -> slave issues STOP_DET intr only if addressed	RW	0x0
6	IC_SLAVE_DISABLE	This bit controls whether I2C has its slave disabled, which means once the preseln signal is applied, then this bit is set and the slave is disabled. If this bit is set (slave is disabled), DW_apb_i2c functions only as a master and does not perform any action that requires a slave. NOTE: Software should ensure that if this bit is written with 0, then bit 0 should also be written with a 0. 0x0 -> Slave mode is enabled 0x1 -> Slave mode is disabled	RW	0x1

Bits	Name	Description	Type	Reset
5	IC_RESTART_EN	<p>Determines whether RESTART conditions may be sent when acting as a master. Some older slaves do not support handling RESTART conditions; however, RESTART conditions are used in several DW_apb_i2c operations. When RESTART is disabled, the master is prohibited from performing the following functions: - Sending a START BYTE - Performing any high-speed mode operation - High-speed mode operation - Performing direction changes in combined format mode - Performing a read operation with a 10-bit address By replacing RESTART condition followed by a STOP and a subsequent START condition, split operations are broken down into multiple DW_apb_i2c transfers. If the above operations are performed, it will result in setting bit 6 (TX_ABRT) of the IC_RAW_INTR_STAT register.</p> <p>Reset value: ENABLED 0x0 -> Master restart disabled 0x1 -> Master restart enabled</p>	RW	0x1
4	IC_10BITADDR_MASTER	<p>Controls whether the DW_apb_i2c starts its transfers in 7- or 10-bit addressing mode when acting as a master. - 0: 7-bit addressing - 1: 10-bit addressing 0x0 -> Master 7Bit addressing mode 0x1 -> Master 10Bit addressing mode</p>	RW	0x0
3	IC_10BITADDR_SLAVE	<p>When acting as a slave, this bit controls whether the DW_apb_i2c responds to 7- or 10-bit addresses. - 0: 7-bit addressing. The DW_apb_i2c ignores transactions that involve 10-bit addressing; for 7-bit addressing, only the lower 7 bits of the IC_SAR register are compared. - 1: 10-bit addressing. The DW_apb_i2c responds to only 10-bit addressing transfers that match the full 10 bits of the IC_SAR register. 0x0 -> Slave 7Bit addressing 0x1 -> Slave 10Bit addressing</p>	RW	0x0

Bits	Name	Description	Type	Reset
2:1	SPEED	<p>These bits control at which speed the DW_apb_i2c operates; its setting is relevant only if one is operating the DW_apb_i2c in master mode. Hardware protects against illegal values being programmed by software. These bits must be programmed appropriately for slave mode also, as it is used to capture correct value of spike filter as per the speed mode.</p> <p>This register should be programmed only with a value in the range of 1 to IC_MAX_SPEED_MODE; otherwise, hardware updates this register with the value of IC_MAX_SPEED_MODE.</p> <p>1: standard mode (100 kbit/s)</p> <p>2: fast mode (<=400 kbit/s) or fast mode plus (<=1000Kbit/s)</p> <p>3: high speed mode (3.4 Mbit/s)</p> <p>Note: This field is not applicable when IC_ULTRA_FAST_MODE=1 0x1 -> Standard Speed mode of operation 0x2 -> Fast or Fast Plus mode of operation 0x3 -> High Speed mode of operation</p>	RW	0x2
0	MASTER_MODE	<p>This bit controls whether the DW_apb_i2c master is enabled.</p> <p>NOTE: Software should ensure that if this bit is written with '1' then bit 6 should also be written with a '1'.</p> <p>0x0 -> Master mode is disabled 0x1 -> Master mode is enabled</p>	RW	0x1

IC_TAR Register

Description

I2C Target Address Register

This register is 12 bits wide, and bits 31:12 are reserved. This register can be written to only when IC_ENABLE[0] is set to 0.

Note: If the software or application is aware that the DW_apb_i2c is not using the TAR address for the pending commands in the Tx FIFO, then it is possible to update the TAR address even while the Tx FIFO has entries (IC_STATUS[2]= 0). - It is not necessary to perform any write to this register if DW_apb_i2c is enabled as an I2C slave only.

Table 482. IC_TAR Register

Bits	Name	Description	Type	Reset
31:12	Reserved.	-	-	-

Bits	Name	Description	Type	Reset
11	SPECIAL	This bit indicates whether software performs a Device-ID or General Call or START BYTE command. - 0: ignore bit 10 GC_OR_START and use IC_TAR normally - 1: perform special I2C command as specified in Device_ID or GC_OR_START bit Reset value: 0x0 0x0 -> Disables programming of GENERAL_CALL or START_BYTE transmission 0x1 -> Enables programming of GENERAL_CALL or START_BYTE transmission	RW	0x0
10	GC_OR_START	If bit 11 (SPECIAL) is set to 1 and bit 13(Device-ID) is set to 0, then this bit indicates whether a General Call or START byte command is to be performed by the DW_apb_i2c. - 0: General Call Address - after issuing a General Call, only writes may be performed. Attempting to issue a read command results in setting bit 6 (TX_ABRT) of the IC_RAW_INTR_STAT register. The DW_apb_i2c remains in General Call mode until the SPECIAL bit value (bit 11) is cleared. - 1: START BYTE Reset value: 0x0 0x0 -> GENERAL_CALL byte transmission 0x1 -> START byte transmission	RW	0x0
9:0	IC_TAR	This is the target address for any master transaction. When transmitting a General Call, these bits are ignored. To generate a START BYTE, the CPU needs to write only once into these bits. If the IC_TAR and IC_SAR are the same, loopback exists but the FIFOs are shared between master and slave, so full loopback is not feasible. Only one direction loopback mode is supported (simplex), not duplex. A master cannot transmit to itself; it can transmit to only a slave.	RW	0x055

IC_SAR Register

Description

I2C Slave Address Register

Table 483. IC_SAR Register

Bits	Name	Description	Type	Reset
31:10	Reserved.	-	-	-
9:0	IC_SAR	<p>The IC_SAR holds the slave address when the I2C is operating as a slave. For 7-bit addressing, only IC_SAR[6:0] is used.</p> <p>This register can be written only when the I2C interface is disabled, which corresponds to the IC_ENABLE[0] register being set to 0. Writes at other times have no effect.</p> <p>Note: The default values cannot be any of the reserved address locations: that is, 0x00 to 0x07, or 0x78 to 0x7f. The correct operation of the device is not guaranteed if you program the IC_SAR or IC_TAR to a reserved value. Refer to Table 'I2C/SMBus Definition of Bits in First Byte' for a complete list of these reserved values.</p>	RW	0x055

IC_DATA_CMD Register

Description

I2C Rx/Tx Data Buffer and Command Register; this is the register the CPU writes to when filling the TX FIFO and the CPU reads from when retrieving bytes from RX FIFO.

The size of the register changes as follows:

Write: - 11 bits when IC_EMPTYFIFO_HOLD_MASTER_EN=1 - 9 bits when IC_EMPTYFIFO_HOLD_MASTER_EN=0 Read: - 12 bits when IC_FIRST_DATA_BYTE_STATUS = 1 - 8 bits when IC_FIRST_DATA_BYTE_STATUS = 0 Note: In order for the DW_apb_i2c to continue acknowledging reads, a read command should be written for every byte that is to be received; otherwise the DW_apb_i2c will stop acknowledging.

Table 484. IC_DATA_CMD Register

Bits	Name	Description	Type	Reset
31:12	Reserved.	-	-	-
11	FIRST_DATA_BYTE	<p>Indicates the first data byte received after the address phase for receive transfer in Master receiver or Slave receiver mode.</p> <p>Reset value : 0x0</p> <p>NOTE: In case of APB_DATA_WIDTH=8,</p> <ol style="list-style-type: none"> The user has to perform two APB Reads to IC_DATA_CMD in order to get status on 11 bit. In order to read the 11 bit, the user has to perform the first data byte read [7:0] (offset 0x10) and then perform the second read [15:8] (offset 0x11) in order to know the status of 11 bit (whether the data received in previous read is a first data byte or not). The 11th bit is an optional read field, user can ignore 2nd byte read [15:8] (offset 0x11) if not interested in FIRST_DATA_BYTE status. <p>0x0 -> Sequential data byte received 0x1 -> Non sequential data byte received</p>	RO	0x0

Bits	Name	Description	Type	Reset
10	RESTART	<p>This bit controls whether a RESTART is issued before the byte is sent or received.</p> <p>1 - If IC_RESTART_EN is 1, a RESTART is issued before the data is sent/received (according to the value of CMD), regardless of whether or not the transfer direction is changing from the previous command; if IC_RESTART_EN is 0, a STOP followed by a START is issued instead.</p> <p>0 - If IC_RESTART_EN is 1, a RESTART is issued only if the transfer direction is changing from the previous command; if IC_RESTART_EN is 0, a STOP followed by a START is issued instead.</p> <p>Reset value: 0x0 0x0 -> Donot Issue RESTART before this command 0x1 -> Issue RESTART before this command</p>	SC	0x0
9	STOP	<p>This bit controls whether a STOP is issued after the byte is sent or received.</p> <p>- 1 - STOP is issued after this byte, regardless of whether or not the Tx FIFO is empty. If the Tx FIFO is not empty, the master immediately tries to start a new transfer by issuing a START and arbitrating for the bus. - 0 - STOP is not issued after this byte, regardless of whether or not the Tx FIFO is empty. If the Tx FIFO is not empty, the master continues the current transfer by sending/receiving data bytes according to the value of the CMD bit. If the Tx FIFO is empty, the master holds the SCL line low and stalls the bus until a new command is available in the Tx FIFO. Reset value: 0x0 0x0 -> Donot Issue STOP after this command 0x1 -> Issue STOP after this command</p>	SC	0x0

Bits	Name	Description	Type	Reset
8	CMD	<p>This bit controls whether a read or a write is performed. This bit does not control the direction when the DW_apb_i2con acts as a slave. It controls only the direction when it acts as a master.</p> <p>When a command is entered in the TX FIFO, this bit distinguishes the write and read commands. In slave-receiver mode, this bit is a 'don't care' because writes to this register are not required. In slave-transmitter mode, a '0' indicates that the data in IC_DATA_CMD is to be transmitted.</p> <p>When programming this bit, you should remember the following: attempting to perform a read operation after a General Call command has been sent results in a TX_ABRT interrupt (bit 6 of the IC_RAW_INTR_STAT register), unless bit 11 (SPECIAL) in the IC_TAR register has been cleared. If a '1' is written to this bit after receiving a RD_REQ interrupt, then a TX_ABRT interrupt occurs.</p> <p>Reset value: 0x0 0x0 -> Master Write Command 0x1 -> Master Read Command</p>	SC	0x0
7:0	DAT	<p>This register contains the data to be transmitted or received on the I2C bus. If you are writing to this register and want to perform a read, bits 7:0 (DAT) are ignored by the DW_apb_i2c. However, when you read this register, these bits return the value of data received on the DW_apb_i2c interface.</p> <p>Reset value: 0x0</p>	RW	0x00

IC_SS_SCL_HCNT Register

Description

Standard Speed I2C Clock SCL High Count Register

Table 485.
IC_SS_SCL_HCNT
Register

Bits	Name	Description	Type	Reset
31:16	Reserved.	-	-	-
15:0	IC_SS_SCL_HCNT	<p>This register must be set before any I2C bus transaction can take place to ensure proper I/O timing. This register sets the SCL clock high-period count for standard speed. For more information, refer to 'IC_CLK Frequency Configuration'.</p> <p>This register can be written only when the I2C interface is disabled which corresponds to the IC_ENABLE[0] register being set to 0. Writes at other times have no effect.</p> <p>The minimum valid value is 6; hardware prevents values less than this being written, and if attempted results in 6 being set. For designs with APB_DATA_WIDTH = 8, the order of programming is important to ensure the correct operation of the DW_apb_i2c. The lower byte must be programmed first. Then the upper byte is programmed.</p> <p>NOTE: This register must not be programmed to a value higher than 65525, because DW_apb_i2c uses a 16-bit counter to flag an I2C bus idle condition when this counter reaches a value of IC_SS_SCL_HCNT + 10.</p>	RW	0x0028

IC_SS_SCL_LCNT Register

Description

Standard Speed I2C Clock SCL Low Count Register

Table 486.
IC_SS_SCL_LCNT
Register

Bits	Name	Description	Type	Reset
31:16	Reserved.	-	-	-
15:0	IC_SS_SCL_LCNT	<p>This register must be set before any I2C bus transaction can take place to ensure proper I/O timing. This register sets the SCL clock low period count for standard speed. For more information, refer to 'IC_CLK Frequency Configuration'.</p> <p>This register can be written only when the I2C interface is disabled which corresponds to the IC_ENABLE[0] register being set to 0. Writes at other times have no effect.</p> <p>The minimum valid value is 8; hardware prevents values less than this being written, and if attempted, results in 8 being set. For designs with APB_DATA_WIDTH = 8, the order of programming is important to ensure the correct operation of DW_apb_i2c. The lower byte must be programmed first, and then the upper byte is programmed.</p>	RW	0x002f

IC_FS_SCL_HCNT Register

Description

Fast Mode or Fast Mode Plus I2C Clock SCL High Count Register

Table 487.
IC_FS_SCL_HCNT
Register

Bits	Name	Description	Type	Reset
31:16	Reserved.	-	-	-
15:0	IC_FS_SCL_HCNT	<p>This register must be set before any I2C bus transaction can take place to ensure proper I/O timing. This register sets the SCL clock high-period count for fast mode or fast mode plus. It is used in high-speed mode to send the Master Code and START BYTE or General CALL. For more information, refer to 'IC_CLK Frequency Configuration'.</p> <p>This register goes away and becomes read-only returning 0s if IC_MAX_SPEED_MODE = standard. This register can be written only when the I2C interface is disabled, which corresponds to the IC_ENABLE[0] register being set to 0. Writes at other times have no effect.</p> <p>The minimum valid value is 6; hardware prevents values less than this being written, and if attempted results in 6 being set. For designs with APB_DATA_WIDTH == 8 the order of programming is important to ensure the correct operation of the DW_apb_i2c. The lower byte must be programmed first. Then the upper byte is programmed.</p>	RW	0x0006

Bits	Name	Description	Type	Reset
31:16	Reserved.	-	-	-
15:0	IC_FS_SCL_LCNT	<p>This register must be set before any I2C bus transaction can take place to ensure proper I/O timing. This register sets the SCL clock low period count for fast speed. It is used in high-speed mode to send the Master Code and START BYTE or General CALL. For more information, refer to 'IC_CLK Frequency Configuration'.</p> <p>This register goes away and becomes read-only returning 0s if IC_MAX_SPEED_MODE = standard.</p> <p>This register can be written only when the I2C interface is disabled, which corresponds to the IC_ENABLE[0] register being set to 0. Writes at other times have no effect.</p> <p>The minimum valid value is 8; hardware prevents values less than this being written, and if attempted results in 8 being set. For designs with APB_DATA_WIDTH = 8 the order of programming is important to ensure the correct operation of the DW_apb_i2c. The lower byte must be programmed first. Then the upper byte is programmed. If the value is less than 8 then the count value gets changed to 8.</p>	RW	0x000d

IC_INTR_STAT Register

Description

I2C Interrupt Status Register

Each bit in this register has a corresponding mask bit in the IC_INTR_MASK register. These bits are cleared by reading the matching interrupt clear register. The unmasked raw versions of these bits are available in the IC_RAW_INTR_STAT register.

Table 489.
IC_INTR_STAT
Register

Bits	Name	Description	Type	Reset
31:14	Reserved.	-	-	-
13	R_MASTER_ON_HOLD	<p>See IC_RAW_INTR_STAT for a detailed description of R_MASTER_ON_HOLD bit.</p> <p>Reset value: 0x0 0x0 -> R_MASTER_ON_HOLD interrupt is inactive 0x1 -> R_MASTER_ON_HOLD interrupt is active</p>	RO	0x0
12	R_RESTART_DET	<p>See IC_RAW_INTR_STAT for a detailed description of R_RESTART_DET bit.</p> <p>Reset value: 0x0 0x0 -> R_RESTART_DET interrupt is inactive 0x1 -> R_RESTART_DET interrupt is active</p>	RO	0x0

Bits	Name	Description	Type	Reset
11	R_GEN_CALL	See IC_RAW_INTR_STAT for a detailed description of R_GEN_CALL bit. Reset value: 0x0 0x0 -> R_GEN_CALL interrupt is inactive 0x1 -> R_GEN_CALL interrupt is active	RO	0x0
10	R_START_DET	See IC_RAW_INTR_STAT for a detailed description of R_START_DET bit. Reset value: 0x0 0x0 -> R_START_DET interrupt is inactive 0x1 -> R_START_DET interrupt is active	RO	0x0
9	R_STOP_DET	See IC_RAW_INTR_STAT for a detailed description of R_STOP_DET bit. Reset value: 0x0 0x0 -> R_STOP_DET interrupt is inactive 0x1 -> R_STOP_DET interrupt is active	RO	0x0
8	R_ACTIVITY	See IC_RAW_INTR_STAT for a detailed description of R_ACTIVITY bit. Reset value: 0x0 0x0 -> R_ACTIVITY interrupt is inactive 0x1 -> R_ACTIVITY interrupt is active	RO	0x0
7	R_RX_DONE	See IC_RAW_INTR_STAT for a detailed description of R_RX_DONE bit. Reset value: 0x0 0x0 -> R_RX_DONE interrupt is inactive 0x1 -> R_RX_DONE interrupt is active	RO	0x0
6	R_TX_ABRT	See IC_RAW_INTR_STAT for a detailed description of R_TX_ABRT bit. Reset value: 0x0 0x0 -> R_TX_ABRT interrupt is inactive 0x1 -> R_TX_ABRT interrupt is active	RO	0x0
5	R_RD_REQ	See IC_RAW_INTR_STAT for a detailed description of R_RD_REQ bit. Reset value: 0x0 0x0 -> R_RD_REQ interrupt is inactive 0x1 -> R_RD_REQ interrupt is active	RO	0x0
4	R_TX_EMPTY	See IC_RAW_INTR_STAT for a detailed description of R_TX_EMPTY bit. Reset value: 0x0 0x0 -> R_TX_EMPTY interrupt is inactive 0x1 -> R_TX_EMPTY interrupt is active	RO	0x0

Bits	Name	Description	Type	Reset
3	R_TX_OVER	See IC_RAW_INTR_STAT for a detailed description of R_TX_OVER bit. Reset value: 0x0 0x0 -> R_TX_OVER interrupt is inactive 0x1 -> R_TX_OVER interrupt is active	RO	0x0
2	R_RX_FULL	See IC_RAW_INTR_STAT for a detailed description of R_RX_FULL bit. Reset value: 0x0 0x0 -> R_RX_FULL interrupt is inactive 0x1 -> R_RX_FULL interrupt is active	RO	0x0
1	R_RX_OVER	See IC_RAW_INTR_STAT for a detailed description of R_RX_OVER bit. Reset value: 0x0 0x0 -> R_RX_OVER interrupt is inactive 0x1 -> R_RX_OVER interrupt is active	RO	0x0
0	R_RX_UNDER	See IC_RAW_INTR_STAT for a detailed description of R_RX_UNDER bit. Reset value: 0x0 0x0 -> RX_UNDER interrupt is inactive 0x1 -> RX_UNDER interrupt is active	RO	0x0

IC_INTR_MASK Register

Description

I2C Interrupt Mask Register.

These bits mask their corresponding interrupt status bits. This register is active low; a value of 0 masks the interrupt, whereas a value of 1 unmask the interrupt.

Table 490.
IC_INTR_MASK
Register

Bits	Name	Description	Type	Reset
31:14	Reserved.	-	-	-
13	M_MASTER_ON_HOLD_READ_ONLY	This M_MASTER_ON_HOLD_read_only bit masks the R_MASTER_ON_HOLD interrupt in IC_INTR_STAT register. Reset value: 0x0 0x0 -> MASTER_ON_HOLD interrupt is masked 0x1 -> MASTER_ON_HOLD interrupt is unmasked	RO	0x0
12	M_RESTART_DET	This bit masks the R_RESTART_DET interrupt in IC_INTR_STAT register. Reset value: 0x0 0x0 -> RESTART_DET interrupt is masked 0x1 -> RESTART_DET interrupt is unmasked	RW	0x0

Bits	Name	Description	Type	Reset
11	M_GEN_CALL	This bit masks the R_GEN_CALL interrupt in IC_INTR_STAT register. Reset value: 0x1 0x0 -> GEN_CALL interrupt is masked 0x1 -> GEN_CALL interrupt is unmasked	RW	0x1
10	M_START_DET	This bit masks the R_START_DET interrupt in IC_INTR_STAT register. Reset value: 0x0 0x0 -> START_DET interrupt is masked 0x1 -> START_DET interrupt is unmasked	RW	0x0
9	M_STOP_DET	This bit masks the R_STOP_DET interrupt in IC_INTR_STAT register. Reset value: 0x0 0x0 -> STOP_DET interrupt is masked 0x1 -> STOP_DET interrupt is unmasked	RW	0x0
8	M_ACTIVITY	This bit masks the R_ACTIVITY interrupt in IC_INTR_STAT register. Reset value: 0x0 0x0 -> ACTIVITY interrupt is masked 0x1 -> ACTIVITY interrupt is unmasked	RW	0x0
7	M_RX_DONE	This bit masks the R_RX_DONE interrupt in IC_INTR_STAT register. Reset value: 0x1 0x0 -> RX_DONE interrupt is masked 0x1 -> RX_DONE interrupt is unmasked	RW	0x1
6	M_TX_ABRT	This bit masks the R_TX_ABRT interrupt in IC_INTR_STAT register. Reset value: 0x1 0x0 -> TX_ABORT interrupt is masked 0x1 -> TX_ABORT interrupt is unmasked	RW	0x1
5	M_RD_REQ	This bit masks the R_RD_REQ interrupt in IC_INTR_STAT register. Reset value: 0x1 0x0 -> RD_REQ interrupt is masked 0x1 -> RD_REQ interrupt is unmasked	RW	0x1
4	M_TX_EMPTY	This bit masks the R_TX_EMPTY interrupt in IC_INTR_STAT register. Reset value: 0x1 0x0 -> TX_EMPTY interrupt is masked 0x1 -> TX_EMPTY interrupt is unmasked	RW	0x1

Bits	Name	Description	Type	Reset
3	M_TX_OVER	This bit masks the R_TX_OVER interrupt in IC_INTR_STAT register. Reset value: 0x1 0x0 -> TX_OVER interrupt is masked 0x1 -> TX_OVER interrupt is unmasked	RW	0x1
2	M_RX_FULL	This bit masks the R_RX_FULL interrupt in IC_INTR_STAT register. Reset value: 0x1 0x0 -> RX_FULL interrupt is masked 0x1 -> RX_FULL interrupt is unmasked	RW	0x1
1	M_RX_OVER	This bit masks the R_RX_OVER interrupt in IC_INTR_STAT register. Reset value: 0x1 0x0 -> RX_OVER interrupt is masked 0x1 -> RX_OVER interrupt is unmasked	RW	0x1
0	M_RX_UNDER	This bit masks the R_RX_UNDER interrupt in IC_INTR_STAT register. Reset value: 0x1 0x0 -> RX_UNDER interrupt is masked 0x1 -> RX_UNDER interrupt is unmasked	RW	0x1

IC_RAW_INTR_STAT Register

Description

I2C Raw Interrupt Status Register

Unlike the IC_INTR_STAT register, these bits are not masked so they always show the true status of the DW_apb_i2c.

Table 491.
IC_RAW_INTR_STAT
Register

Bits	Name	Description	Type	Reset
31:14	Reserved.	-	-	-
13	MASTER_ON_HOLD	Indicates whether master is holding the bus and TX FIFO is empty. Enabled only when I2C_DYNAMIC_TAR_UPDATE=1 and IC_EMPTYFIFO_HOLD_MASTER_EN=1. Reset value: 0x0 0x0 -> MASTER_ON_HOLD interrupt is inactive 0x1 -> MASTER_ON_HOLD interrupt is active	RO	0x0

Bits	Name	Description	Type	Reset
12	RESTART_DET	<p>Indicates whether a RESTART condition has occurred on the I2C interface when DW_apb_i2c is operating in Slave mode and the slave is being addressed. Enabled only when IC_SLV_RESTART_DET_EN=1.</p> <p>Note: However, in high-speed mode or during a START BYTE transfer, the RESTART comes before the address field as per the I2C protocol. In this case, the slave is not the addressed slave when the RESTART is issued, therefore DW_apb_i2c does not generate the RESTART_DET interrupt.</p> <p>Reset value: 0x0 0x0 -> RESTART_DET interrupt is inactive 0x1 -> RESTART_DET interrupt is active</p>	RO	0x0
11	GEN_CALL	<p>Set only when a General Call address is received and it is acknowledged. It stays set until it is cleared either by disabling DW_apb_i2c or when the CPU reads bit 0 of the IC_CLR_GEN_CALL register. DW_apb_i2c stores the received data in the Rx buffer.</p> <p>Reset value: 0x0 0x0 -> GEN_CALL interrupt is inactive 0x1 -> GEN_CALL interrupt is active</p>	RO	0x0
10	START_DET	<p>Indicates whether a START or RESTART condition has occurred on the I2C interface regardless of whether DW_apb_i2c is operating in slave or master mode.</p> <p>Reset value: 0x0 0x0 -> START_DET interrupt is inactive 0x1 -> START_DET interrupt is active</p>	RO	0x0

Bits	Name	Description	Type	Reset
9	STOP_DET	<p>Indicates whether a STOP condition has occurred on the I2C interface regardless of whether DW_apb_i2c is operating in slave or master mode.</p> <p>In Slave Mode: - If IC_CON[7]=1'b1 (STOP_DET_IFADDRESSED), the STOP_DET interrupt will be issued only if slave is addressed. Note: During a general call address, this slave does not issue a STOP_DET interrupt if STOP_DET_IF_ADDRESSED=1'b1, even if the slave responds to the general call address by generating ACK. The STOP_DET interrupt is generated only when the transmitted address matches the slave address (SAR). - If IC_CON[7]=1'b0 (STOP_DET_IFADDRESSED), the STOP_DET interrupt is issued irrespective of whether it is being addressed. In Master Mode: - If IC_CON[10]=1'b1 (STOP_DET_IF_MASTER_ACTIVE), the STOP_DET interrupt will be issued only if Master is active. - If IC_CON[10]=1'b0 (STOP_DET_IFADDRESSED), the STOP_DET interrupt will be issued irrespective of whether master is active or not.</p> <p>Reset value: 0x0 0x0 -> STOP_DET interrupt is inactive 0x1 -> STOP_DET interrupt is active</p>	RO	0x0
8	ACTIVITY	<p>This bit captures DW_apb_i2c activity and stays set until it is cleared. There are four ways to clear it: - Disabling the DW_apb_i2c - Reading the IC_CLR_ACTIVITY register - Reading the IC_CLR_INTR register - System reset Once this bit is set, it stays set unless one of the four methods is used to clear it. Even if the DW_apb_i2c module is idle, this bit remains set until cleared, indicating that there was activity on the bus.</p> <p>Reset value: 0x0 0x0 -> RAW_INTR_ACTIVITY interrupt is inactive 0x1 -> RAW_INTR_ACTIVITY interrupt is active</p>	RO	0x0
7	RX_DONE	<p>When the DW_apb_i2c is acting as a slave-transmitter, this bit is set to 1 if the master does not acknowledge a transmitted byte. This occurs on the last byte of the transmission, indicating that the transmission is done.</p> <p>Reset value: 0x0 0x0 -> RX_DONE interrupt is inactive 0x1 -> RX_DONE interrupt is active</p>	RO	0x0

Bits	Name	Description	Type	Reset
6	TX_ABRT	<p>This bit indicates if DW_apb_i2c, as an I2C transmitter, is unable to complete the intended actions on the contents of the transmit FIFO. This situation can occur both as an I2C master or an I2C slave, and is referred to as a 'transmit abort'. When this bit is set to 1, the IC_TX_ABRT_SOURCE register indicates the reason why the transmit abort takes places.</p> <p>Note: The DW_apb_i2c flushes/resets/empties the TX_FIFO and RX_FIFO whenever there is a transmit abort caused by any of the events tracked by the IC_TX_ABRT_SOURCE register. The FIFOs remains in this flushed state until the register IC_CLR_TX_ABRT is read. Once this read is performed, the Tx FIFO is then ready to accept more data bytes from the APB interface.</p> <p>Reset value: 0x0 0x0 -> TX_ABRT interrupt is inactive 0x1 -> TX_ABRT interrupt is active</p>	RO	0x0
5	RD_REQ	<p>This bit is set to 1 when DW_apb_i2c is acting as a slave and another I2C master is attempting to read data from DW_apb_i2c. The DW_apb_i2c holds the I2C bus in a wait state (SCL=0) until this interrupt is serviced, which means that the slave has been addressed by a remote master that is asking for data to be transferred. The processor must respond to this interrupt and then write the requested data to the IC_DATA_CMD register. This bit is set to 0 just after the processor reads the IC_CLR_RD_REQ register.</p> <p>Reset value: 0x0 0x0 -> RD_REQ interrupt is inactive 0x1 -> RD_REQ interrupt is active</p>	RO	0x0
4	TX_EMPTY	<p>The behavior of the TX_EMPTY interrupt status differs based on the TX_EMPTY_CTRL selection in the IC_CON register. - When TX_EMPTY_CTRL = 0: This bit is set to 1 when the transmit buffer is at or below the threshold value set in the IC_TX_TL register. - When TX_EMPTY_CTRL = 1: This bit is set to 1 when the transmit buffer is at or below the threshold value set in the IC_TX_TL register and the transmission of the address/data from the internal shift register for the most recently popped command is completed. It is automatically cleared by hardware when the buffer level goes above the threshold. When IC_ENABLE[0] is set to 0, the TX FIFO is flushed and held in reset. There the TX FIFO looks like it has no data within it, so this bit is set to 1, provided there is activity in the master or slave state machines. When there is no longer any activity, then with ic_en=0, this bit is set to 0.</p> <p>Reset value: 0x0. 0x0 -> TX_EMPTY interrupt is inactive 0x1 -> TX_EMPTY interrupt is active</p>	RO	0x0

Bits	Name	Description	Type	Reset
3	TX_OVER	<p>Set during transmit if the transmit buffer is filled to IC_TX_BUFFER_DEPTH and the processor attempts to issue another I2C command by writing to the IC_DATA_CMD register. When the module is disabled, this bit keeps its level until the master or slave state machines go into idle, and when ic_en goes to 0, this interrupt is cleared.</p> <p>Reset value: 0x0 0x0 -> TX_OVER interrupt is inactive 0x1 -> TX_OVER interrupt is active</p>	RO	0x0
2	RX_FULL	<p>Set when the receive buffer reaches or goes above the RX_TL threshold in the IC_RX_TL register. It is automatically cleared by hardware when buffer level goes below the threshold. If the module is disabled (IC_ENABLE[0]=0), the RX FIFO is flushed and held in reset; therefore the RX FIFO is not full. So this bit is cleared once the IC_ENABLE bit 0 is programmed with a 0, regardless of the activity that continues.</p> <p>Reset value: 0x0 0x0 -> RX_FULL interrupt is inactive 0x1 -> RX_FULL interrupt is active</p>	RO	0x0
1	RX_OVER	<p>Set if the receive buffer is completely filled to IC_RX_BUFFER_DEPTH and an additional byte is received from an external I2C device. The DW_apb_i2c acknowledges this, but any data bytes received after the FIFO is full are lost. If the module is disabled (IC_ENABLE[0]=0), this bit keeps its level until the master or slave state machines go into idle, and when ic_en goes to 0, this interrupt is cleared.</p> <p>Note: If bit 9 of the IC_CON register (RX_FIFO_FULL_HLD_CTRL) is programmed to HIGH, then the RX_OVER interrupt never occurs, because the Rx FIFO never overflows.</p> <p>Reset value: 0x0 0x0 -> RX_OVER interrupt is inactive 0x1 -> RX_OVER interrupt is active</p>	RO	0x0
0	RX_UNDER	<p>Set if the processor attempts to read the receive buffer when it is empty by reading from the IC_DATA_CMD register. If the module is disabled (IC_ENABLE[0]=0), this bit keeps its level until the master or slave state machines go into idle, and when ic_en goes to 0, this interrupt is cleared.</p> <p>Reset value: 0x0 0x0 -> RX_UNDER interrupt is inactive 0x1 -> RX_UNDER interrupt is active</p>	RO	0x0

IC_RX_TL Register

Description

I2C Receive FIFO Threshold Register

Table 492. IC_RX_TL Register

Bits	Name	Description	Type	Reset
31:8	Reserved.	-	-	-
7:0	RX_TL	Receive FIFO Threshold Level. Controls the level of entries (or above) that triggers the RX_FULL interrupt (bit 2 in IC_RAW_INTR_STAT register). The valid range is 0-255, with the additional restriction that hardware does not allow this value to be set to a value larger than the depth of the buffer. If an attempt is made to do that, the actual value set will be the maximum depth of the buffer. A value of 0 sets the threshold for 1 entry, and a value of 255 sets the threshold for 256 entries.	RW	0x00

IC_TX_TL Register

Description

I2C Transmit FIFO Threshold Register

Table 493. IC_TX_TL Register

Bits	Name	Description	Type	Reset
31:8	Reserved.	-	-	-
7:0	TX_TL	Transmit FIFO Threshold Level. Controls the level of entries (or below) that trigger the TX_EMPTY interrupt (bit 4 in IC_RAW_INTR_STAT register). The valid range is 0-255, with the additional restriction that it may not be set to value larger than the depth of the buffer. If an attempt is made to do that, the actual value set will be the maximum depth of the buffer. A value of 0 sets the threshold for 0 entries, and a value of 255 sets the threshold for 255 entries.	RW	0x00

IC_CLR_INTR Register

Description

Clear Combined and Individual Interrupt Register

Table 494.
IC_CLR_INTR Register

Bits	Name	Description	Type	Reset
31:1	Reserved.	-	-	-
0	CLR_INTR	Read this register to clear the combined interrupt, all individual interrupts, and the IC_TX_ABRT_SOURCE register. This bit does not clear hardware clearable interrupts but software clearable interrupts. Refer to Bit 9 of the IC_TX_ABRT_SOURCE register for an exception to clearing IC_TX_ABRT_SOURCE. Reset value: 0x0	RO	0x0

IC_CLR_RX_UNDER Register

Description

Clear RX_UNDER Interrupt Register

Table 495.
IC_CLR_RX_UNDER Register

Bits	Name	Description	Type	Reset
31:1	Reserved.	-	-	-
0	CLR_RX_UNDER	Read this register to clear the RX_UNDER interrupt (bit 0) of the IC_RAW_INTR_STAT register. Reset value: 0x0	RO	0x0

IC_CLR_RX_OVER Register

Description

Clear RX_OVER Interrupt Register

Table 496.
IC_CLR_RX_OVER Register

Bits	Name	Description	Type	Reset
31:1	Reserved.	-	-	-
0	CLR_RX_OVER	Read this register to clear the RX_OVER interrupt (bit 1) of the IC_RAW_INTR_STAT register. Reset value: 0x0	RO	0x0

IC_CLR_TX_OVER Register

Description

Clear TX_OVER Interrupt Register

Table 497.
IC_CLR_TX_OVER Register

Bits	Name	Description	Type	Reset
31:1	Reserved.	-	-	-
0	CLR_TX_OVER	Read this register to clear the TX_OVER interrupt (bit 3) of the IC_RAW_INTR_STAT register. Reset value: 0x0	RO	0x0

IC_CLR_RD_REQ Register

Description

Clear RD_REQ Interrupt Register

Table 498.
IC_CLR_RD_REQ
Register

Bits	Name	Description	Type	Reset
31:1	Reserved.	-	-	-
0	CLR_RD_REQ	Read this register to clear the RD_REQ interrupt (bit 5) of the IC_RAW_INTR_STAT register. Reset value: 0x0	RO	0x0

IC_CLR_TX_ABRT Register

Description

Clear TX_ABRT Interrupt Register

Table 499.
IC_CLR_TX_ABRT
Register

Bits	Name	Description	Type	Reset
31:1	Reserved.	-	-	-
0	CLR_TX_ABRT	Read this register to clear the TX_ABRT interrupt (bit 6) of the IC_RAW_INTR_STAT register, and the IC_TX_ABRT_SOURCE register. This also releases the TX FIFO from the flushed/reset state, allowing more writes to the TX FIFO. Refer to Bit 9 of the IC_TX_ABRT_SOURCE register for an exception to clearing IC_TX_ABRT_SOURCE. Reset value: 0x0	RO	0x0

IC_CLR_RX_DONE Register

Description

Clear RX_DONE Interrupt Register

Table 500.
IC_CLR_RX_DONE
Register

Bits	Name	Description	Type	Reset
31:1	Reserved.	-	-	-
0	CLR_RX_DONE	Read this register to clear the RX_DONE interrupt (bit 7) of the IC_RAW_INTR_STAT register. Reset value: 0x0	RO	0x0

IC_CLR_ACTIVITY Register

Description

Clear ACTIVITY Interrupt Register

Table 501.
IC_CLR_ACTIVITY
Register

Bits	Name	Description	Type	Reset
31:1	Reserved.	-	-	-
0	CLR_ACTIVITY	Reading this register clears the ACTIVITY interrupt if the I2C is not active anymore. If the I2C module is still active on the bus, the ACTIVITY interrupt bit continues to be set. It is automatically cleared by hardware if the module is disabled and if there is no further activity on the bus. The value read from this register to get status of the ACTIVITY interrupt (bit 8) of the IC_RAW_INTR_STAT register. Reset value: 0x0	RO	0x0

IC_CLR_STOP_DET Register

Description

Clear STOP_DET Interrupt Register

Table 502.
IC_CLR_STOP_DET
Register

Bits	Name	Description	Type	Reset
31:1	Reserved.	-	-	-
0	CLR_STOP_DET	Read this register to clear the STOP_DET interrupt (bit 9) of the IC_RAW_INTR_STAT register. Reset value: 0x0	RO	0x0

IC_CLR_START_DET Register

Description

Clear START_DET Interrupt Register

Table 503.
IC_CLR_START_DET
Register

Bits	Name	Description	Type	Reset
31:1	Reserved.	-	-	-
0	CLR_START_DET	Read this register to clear the START_DET interrupt (bit 10) of the IC_RAW_INTR_STAT register. Reset value: 0x0	RO	0x0

IC_CLR_GEN_CALL Register

Description

Clear GEN_CALL Interrupt Register

Table 504.
IC_CLR_GEN_CALL
Register

Bits	Name	Description	Type	Reset
31:1	Reserved.	-	-	-
0	CLR_GEN_CALL	Read this register to clear the GEN_CALL interrupt (bit 11) of IC_RAW_INTR_STAT register. Reset value: 0x0	RO	0x0

IC_ENABLE Register

Description

I2C Enable Register

Table 505. IC_ENABLE Register

Bits	Name	Description	Type	Reset
31:3	Reserved.	-	-	-
2	TX_CMD_BLOCK	In Master mode: - 1'b1: Blocks the transmission of data on I2C bus even if Tx FIFO has data to transmit. - 1'b0: The transmission of data starts on I2C bus automatically, as soon as the first data is available in the Tx FIFO. Note: To block the execution of Master commands, set the TX_CMD_BLOCK bit only when Tx FIFO is empty (IC_STATUS[2]==1) and Master is in Idle state (IC_STATUS[5] == 0). Any further commands put in the Tx FIFO are not executed until TX_CMD_BLOCK bit is unset. Reset value: IC_TX_CMD_BLOCK_DEFAULT 0x0 -> Tx Command execution not blocked 0x1 -> Tx Command execution blocked	RW	0x0
1	ABORT	When set, the controller initiates the transfer abort. - 0: ABORT not initiated or ABORT done - 1: ABORT operation in progress The software can abort the I2C transfer in master mode by setting this bit. The software can set this bit only when ENABLE is already set; otherwise, the controller ignores any write to ABORT bit. The software cannot clear the ABORT bit once set. In response to an ABORT, the controller issues a STOP and flushes the Tx FIFO after completing the current transfer, then sets the TX_ABORT interrupt after the abort operation. The ABORT bit is cleared automatically after the abort operation. For a detailed description on how to abort I2C transfers, refer to 'Aborting I2C Transfers'. Reset value: 0x0 0x0 -> ABORT operation not in progress 0x1 -> ABORT operation in progress	RW	0x0

Bits	Name	Description	Type	Reset
0	ENABLE	<p>Controls whether the DW_apb_i2c is enabled. - 0: Disables DW_apb_i2c (TX and RX FIFOs are held in an erased state) - 1: Enables DW_apb_i2c Software can disable DW_apb_i2c while it is active. However, it is important that care be taken to ensure that DW_apb_i2c is disabled properly. A recommended procedure is described in 'Disabling DW_apb_i2c'.</p> <p>When DW_apb_i2c is disabled, the following occurs: - The TX FIFO and RX FIFO get flushed. - Status bits in the IC_INTR_STAT register are still active until DW_apb_i2c goes into IDLE state. If the module is transmitting, it stops as well as deletes the contents of the transmit buffer after the current transfer is complete. If the module is receiving, the DW_apb_i2c stops the current transfer at the end of the current byte and does not acknowledge the transfer.</p> <p>In systems with asynchronous pclk and ic_clk when IC_CLK_TYPE parameter set to asynchronous (1), there is a two ic_clk delay when enabling or disabling the DW_apb_i2c. For a detailed description on how to disable DW_apb_i2c, refer to 'Disabling DW_apb_i2c'</p> <p>Reset value: 0x0 0x0 -> I2C is disabled 0x1 -> I2C is enabled</p>	RW	0x0

IC_STATUS Register

Description

I2C Status Register

This is a read-only register used to indicate the current transfer status and FIFO status. The status register may be read at any time. None of the bits in this register request an interrupt.

When the I2C is disabled by writing 0 in bit 0 of the IC_ENABLE register: - Bits 1 and 2 are set to 1 - Bits 3 and 10 are set to 0
When the master or slave state machines goes to idle and ic_en=0: - Bits 5 and 6 are set to 0

Table 506. IC_STATUS Register

Bits	Name	Description	Type	Reset
31:7	Reserved.	-	-	-
6	SLV_ACTIVITY	<p>Slave FSM Activity Status. When the Slave Finite State Machine (FSM) is not in the IDLE state, this bit is set. - 0: Slave FSM is in IDLE state so the Slave part of DW_apb_i2c is not Active - 1: Slave FSM is not in IDLE state so the Slave part of DW_apb_i2c is Active Reset value: 0x0 0x0 -> Slave is idle 0x1 -> Slave not idle</p>	RO	0x0

Bits	Name	Description	Type	Reset
5	MST_ACTIVITY	Master FSM Activity Status. When the Master Finite State Machine (FSM) is not in the IDLE state, this bit is set. - 0: Master FSM is in IDLE state so the Master part of DW_apb_i2c is not Active - 1: Master FSM is not in IDLE state so the Master part of DW_apb_i2c is Active Note: IC_STATUS[0]-that is, ACTIVITY bit-is the OR of SLV_ACTIVITY and MST_ACTIVITY bits. Reset value: 0x0 0x0 -> Master is idle 0x1 -> Master not idle	RO	0x0
4	RFF	Receive FIFO Completely Full. When the receive FIFO is completely full, this bit is set. When the receive FIFO contains one or more empty location, this bit is cleared. - 0: Receive FIFO is not full - 1: Receive FIFO is full Reset value: 0x0 0x0 -> Rx FIFO not full 0x1 -> Rx FIFO is full	RO	0x0
3	RFNE	Receive FIFO Not Empty. This bit is set when the receive FIFO contains one or more entries; it is cleared when the receive FIFO is empty. - 0: Receive FIFO is empty - 1: Receive FIFO is not empty Reset value: 0x0 0x0 -> Rx FIFO is empty 0x1 -> Rx FIFO not empty	RO	0x0
2	TFE	Transmit FIFO Completely Empty. When the transmit FIFO is completely empty, this bit is set. When it contains one or more valid entries, this bit is cleared. This bit field does not request an interrupt. - 0: Transmit FIFO is not empty - 1: Transmit FIFO is empty Reset value: 0x1 0x0 -> Tx FIFO not empty 0x1 -> Tx FIFO is empty	RO	0x1
1	TFNF	Transmit FIFO Not Full. Set when the transmit FIFO contains one or more empty locations, and is cleared when the FIFO is full. - 0: Transmit FIFO is full - 1: Transmit FIFO is not full Reset value: 0x1 0x0 -> Tx FIFO is full 0x1 -> Tx FIFO not full	RO	0x1
0	ACTIVITY	I2C Activity Status. Reset value: 0x0 0x0 -> I2C is idle 0x1 -> I2C is active	RO	0x0

IC_TXFLR Register

Description

I2C Transmit FIFO Level Register This register contains the number of valid data entries in the transmit FIFO buffer. It is cleared whenever: - The I2C is disabled - There is a transmit abort - that is, TX_ABRT bit is set in the IC_RAW_INTR_STAT register - The slave bulk transmit mode is aborted The register increments whenever data is placed into the transmit FIFO and decrements when data is taken from the transmit FIFO.

Table 507. IC_TXFLR Register

Bits	Name	Description	Type	Reset
31:5	Reserved.	-	-	-
4:0	TXFLR	Transmit FIFO Level. Contains the number of valid data entries in the transmit FIFO. Reset value: 0x0	RO	0x00

IC_RXFLR Register

Description

I2C Receive FIFO Level Register This register contains the number of valid data entries in the receive FIFO buffer. It is cleared whenever: - The I2C is disabled - Whenever there is a transmit abort caused by any of the events tracked in IC_TX_ABRT_SOURCE The register increments whenever data is placed into the receive FIFO and decrements when data is taken from the receive FIFO.

Table 508. IC_RXFLR Register

Bits	Name	Description	Type	Reset
31:5	Reserved.	-	-	-
4:0	RXFLR	Receive FIFO Level. Contains the number of valid data entries in the receive FIFO. Reset value: 0x0	RO	0x00

IC_SDA_HOLD Register

Description

I2C SDA Hold Time Length Register

The bits [15:0] of this register are used to control the hold time of SDA during transmit in both slave and master mode (after SCL goes from HIGH to LOW).

The bits [23:16] of this register are used to extend the SDA transition (if any) whenever SCL is HIGH in the receiver in either master or slave mode.

Writes to this register succeed only when IC_ENABLE[0]=0.

The values in this register are in units of ic_clk period. The value programmed in IC_SDA_TX_HOLD must be greater than the minimum hold time in each mode one cycle in master mode, seven cycles in slave mode for the value to be implemented.

The programmed SDA hold time during transmit (IC_SDA_TX_HOLD) cannot exceed at any time the duration of the low part of scl. Therefore the programmed value cannot be larger than N_SCL_LOW-2, where N_SCL_LOW is the duration of the low part of the scl period measured in ic_clk cycles.

Table 509. IC_SDA_HOLD Register

Bits	Name	Description	Type	Reset
31:24	Reserved.	-	-	-
23:16	IC_SDA_RX_HOLD	Sets the required SDA hold time in units of ic_clk period, when DW_apb_i2c acts as a receiver. Reset value: IC_DEFAULT_SDA_HOLD[23:16].	RW	0x00
15:0	IC_SDA_TX_HOLD	Sets the required SDA hold time in units of ic_clk period, when DW_apb_i2c acts as a transmitter. Reset value: IC_DEFAULT_SDA_HOLD[15:0].	RW	0x0001

IC_TX_ABRT_SOURCE Register

Description

I2C Transmit Abort Source Register

This register has 32 bits that indicate the source of the TX_ABRT bit. Except for Bit 9, this register is cleared whenever the IC_CLR_TX_ABRT register or the IC_CLR_INTR register is read. To clear Bit 9, the source of the ABRT_SBYTE_NORSTRT must be fixed first; RESTART must be enabled (IC_CON[5]=1), the SPECIAL bit must be cleared (IC_TAR[11]), or the GC_OR_START bit must be cleared (IC_TAR[10]).

Once the source of the ABRT_SBYTE_NORSTRT is fixed, then this bit can be cleared in the same manner as other bits in this register. If the source of the ABRT_SBYTE_NORSTRT is not fixed before attempting to clear this bit, Bit 9 clears for one cycle and is then re-asserted.

Table 510.
IC_TX_ABRT_SOURCE
Register

Bits	Name	Description	Type	Reset
31:23	TX_FLUSH_CNT	This field indicates the number of Tx FIFO Data Commands which are flushed due to TX_ABRT interrupt. It is cleared whenever I2C is disabled. Reset value: 0x0 Role of DW_apb_i2c: Master-Transmitter or Slave-Transmitter	RO	0x000
22:17	Reserved.	-	-	-
16	ABRT_USER_ABR T	This is a master-mode-only bit. Master has detected the transfer abort (IC_ENABLE[1]) Reset value: 0x0 Role of DW_apb_i2c: Master-Transmitter 0x0 -> Transfer abort detected by master- scenario not present 0x1 -> Transfer abort detected by master	RO	0x0
15	ABRT_SLVRD_INT X	1: When the processor side responds to a slave mode request for data to be transmitted to a remote master and user writes a 1 in CMD (bit 8) of IC_DATA_CMD register. Reset value: 0x0 Role of DW_apb_i2c: Slave-Transmitter 0x0 -> Slave trying to transmit to remote master in read mode- scenario not present 0x1 -> Slave trying to transmit to remote master in read mode	RO	0x0

Bits	Name	Description	Type	Reset
14	ABRT_SLV_ARBLO ST	<p>This field indicates that a Slave has lost the bus while transmitting data to a remote master.</p> <p>IC_TX_ABRT_SOURCE[12] is set at the same time. Note: Even though the slave never 'owns' the bus, something could go wrong on the bus. This is a fail safe check. For instance, during a data transmission at the low-to-high transition of SCL, if what is on the data bus is not what is supposed to be transmitted, then DW_apb_i2c no longer own the bus.</p> <p>Reset value: 0x0</p> <p>Role of DW_apb_i2c: Slave-Transmitter 0x0 -> Slave lost arbitration to remote master- scenario not present 0x1 -> Slave lost arbitration to remote master</p>	RO	0x0
13	ABRT_SLVFLUSH_ TXFIFO	<p>This field specifies that the Slave has received a read command and some data exists in the TX FIFO, so the slave issues a TX_ABRT interrupt to flush old data in TX FIFO.</p> <p>Reset value: 0x0</p> <p>Role of DW_apb_i2c: Slave-Transmitter 0x0 -> Slave flushes existing data in TX-FIFO upon getting read command- scenario not present 0x1 -> Slave flushes existing data in TX-FIFO upon getting read command</p>	RO	0x0
12	ARB_LOST	<p>This field specifies that the Master has lost arbitration, or if IC_TX_ABRT_SOURCE[14] is also set, then the slave transmitter has lost arbitration.</p> <p>Reset value: 0x0</p> <p>Role of DW_apb_i2c: Master-Transmitter or Slave-Transmitter 0x0 -> Master or Slave-Transmitter lost arbitration- scenario not present 0x1 -> Master or Slave-Transmitter lost arbitration</p>	RO	0x0
11	ABRT_MASTER_DI S	<p>This field indicates that the User tries to initiate a Master operation with the Master mode disabled.</p> <p>Reset value: 0x0</p> <p>Role of DW_apb_i2c: Master-Transmitter or Master-Receiver 0x0 -> User initiating master operation when MASTER disabled- scenario not present 0x1 -> User initiating master operation when MASTER disabled</p>	RO	0x0

Bits	Name	Description	Type	Reset
10	ABRT_10B_RD_NO RSTRT	<p>This field indicates that the restart is disabled (IC_RESTART_EN bit (IC_CON[5]) =0) and the master sends a read command in 10-bit addressing mode.</p> <p>Reset value: 0x0</p> <p>Role of DW_apb_i2c: Master-Receiver 0x0 -> Master not trying to read in 10Bit addressing mode when RESTART disabled 0x1 -> Master trying to read in 10Bit addressing mode when RESTART disabled</p>	RO	0x0
9	ABRT_SBYTE_NO RSTRT	<p>To clear Bit 9, the source of the ABRT_SBYTE_NORSTRT must be fixed first; restart must be enabled (IC_CON[5]=1), the SPECIAL bit must be cleared (IC_TAR[11]), or the GC_OR_START bit must be cleared (IC_TAR[10]). Once the source of the ABRT_SBYTE_NORSTRT is fixed, then this bit can be cleared in the same manner as other bits in this register. If the source of the ABRT_SBYTE_NORSTRT is not fixed before attempting to clear this bit, bit 9 clears for one cycle and then gets reasserted. When this field is set to 1, the restart is disabled (IC_RESTART_EN bit (IC_CON[5]) =0) and the user is trying to send a START Byte.</p> <p>Reset value: 0x0</p> <p>Role of DW_apb_i2c: Master 0x0 -> User trying to send START byte when RESTART disabled- scenario not present 0x1 -> User trying to send START byte when RESTART disabled</p>	RO	0x0
8	ABRT_HS_NORST RT	<p>This field indicates that the restart is disabled (IC_RESTART_EN bit (IC_CON[5]) =0) and the user is trying to use the master to transfer data in High Speed mode.</p> <p>Reset value: 0x0</p> <p>Role of DW_apb_i2c: Master-Transmitter or Master-Receiver 0x0 -> User trying to switch Master to HS mode when RESTART disabled- scenario not present 0x1 -> User trying to switch Master to HS mode when RESTART disabled</p>	RO	0x0
7	ABRT_SBYTE_ACK DET	<p>This field indicates that the Master has sent a START Byte and the START Byte was acknowledged (wrong behavior).</p> <p>Reset value: 0x0</p> <p>Role of DW_apb_i2c: Master 0x0 -> ACK detected for START byte- scenario not present 0x1 -> ACK detected for START byte</p>	RO	0x0

Bits	Name	Description	Type	Reset
6	ABRT_HS_ACKDE T	This field indicates that the Master is in High Speed mode and the High Speed Master code was acknowledged (wrong behavior). Reset value: 0x0 Role of DW_apb_i2c: Master 0x0 -> HS Master code ACKed in HS Mode- scenario not present 0x1 -> HS Master code ACKed in HS Mode	RO	0x0
5	ABRT_GCALL_REA D	This field indicates that DW_apb_i2c in the master mode has sent a General Call but the user programmed the byte following the General Call to be a read from the bus (IC_DATA_CMD[9] is set to 1). Reset value: 0x0 Role of DW_apb_i2c: Master-Transmitter 0x0 -> GCALL is followed by read from bus-scenario not present 0x1 -> GCALL is followed by read from bus	RO	0x0
4	ABRT_GCALL_NO ACK	This field indicates that DW_apb_i2c in master mode has sent a General Call and no slave on the bus acknowledged the General Call. Reset value: 0x0 Role of DW_apb_i2c: Master-Transmitter 0x0 -> GCALL not ACKed by any slave-scenario not present 0x1 -> GCALL not ACKed by any slave	RO	0x0
3	ABRT_TXDATA_N OACK	This field indicates the master-mode only bit. When the master receives an acknowledgement for the address, but when it sends data byte(s) following the address, it did not receive an acknowledge from the remote slave(s). Reset value: 0x0 Role of DW_apb_i2c: Master-Transmitter 0x0 -> Transmitted data non-ACKed by addressed slave-scenario not present 0x1 -> Transmitted data not ACKed by addressed slave	RO	0x0
2	ABRT_10ADDR2_ NOACK	This field indicates that the Master is in 10-bit address mode and that the second address byte of the 10-bit address was not acknowledged by any slave. Reset value: 0x0 Role of DW_apb_i2c: Master-Transmitter or Master-Receiver 0x0 -> This abort is not generated 0x1 -> Byte 2 of 10Bit Address not ACKed by any slave	RO	0x0

Bits	Name	Description	Type	Reset
1	ABRT_10ADDR1_NOACK	<p>This field indicates that the Master is in 10-bit address mode and the first 10-bit address byte was not acknowledged by any slave.</p> <p>Reset value: 0x0</p> <p>Role of DW_apb_i2c: Master-Transmitter or Master-Receiver 0x0 -> This abort is not generated 0x1 -> Byte 1 of 10Bit Address not ACKed by any slave</p>	RO	0x0
0	ABRT_7B_ADDR_NOACK	<p>This field indicates that the Master is in 7-bit addressing mode and the address sent was not acknowledged by any slave.</p> <p>Reset value: 0x0</p> <p>Role of DW_apb_i2c: Master-Transmitter or Master-Receiver 0x0 -> This abort is not generated 0x1 -> This abort is generated because of NOACK for 7-bit address</p>	RO	0x0

IC_SLV_DATA_NACK_ONLY Register

Description

Generate Slave Data NACK Register

The register is used to generate a NACK for the data part of a transfer when DW_apb_i2c is acting as a slave-receiver. This register only exists when the IC_SLV_DATA_NACK_ONLY parameter is set to 1. When this parameter disabled, this register does not exist and writing to the register's address has no effect.

A write can occur on this register if both of the following conditions are met: - DW_apb_i2c is disabled (IC_ENABLE[0] = 0) - Slave part is inactive (IC_STATUS[6] = 0) Note: The IC_STATUS[6] is a register read-back location for the internal slv_activity signal; the user should poll this before writing the ic_slv_data_nack_only bit.

Table 511.
IC_SLV_DATA_NACK_ONLY Register

Bits	Name	Description	Type	Reset
31:1	Reserved.	-	-	-
0	NACK	<p>Generate NACK. This NACK generation only occurs when DW_apb_i2c is a slave-receiver. If this register is set to a value of 1, it can only generate a NACK after a data byte is received; hence, the data transfer is aborted and the data received is not pushed to the receive buffer.</p> <p>When the register is set to a value of 0, it generates NACK/ACK, depending on normal criteria. - 1: generate NACK after data byte received - 0: generate NACK/ACK normally Reset value: 0x0 0x0 -> Slave receiver generates NACK normally 0x1 -> Slave receiver generates NACK upon data reception only</p>	RW	0x0

IC_DMA_CR Register

Description

DMA Control Register

The register is used to enable the DMA Controller interface operation. There is a separate bit for transmit and receive. This can be programmed regardless of the state of IC_ENABLE.

Table 512.
IC_DMA_CR Register

Bits	Name	Description	Type	Reset
31:2	Reserved.	-	-	-
1	TDMAE	<p>Transmit DMA Enable. This bit enables/disables the transmit FIFO DMA channel. Reset value: 0x0 0x0 -> transmit FIFO DMA channel disabled 0x1 -> Transmit FIFO DMA channel enabled</p>	RW	0x0
0	RDMAE	<p>Receive DMA Enable. This bit enables/disables the receive FIFO DMA channel. Reset value: 0x0 0x0 -> Receive FIFO DMA channel disabled 0x1 -> Receive FIFO DMA channel enabled</p>	RW	0x0

IC_DMA_TDLR Register

Description

DMA Transmit Data Level Register

Table 513.
IC_DMA_TDLR
Register

Bits	Name	Description	Type	Reset
31:4	Reserved.	-	-	-
3:0	DMATDL	Transmit Data Level. This bit field controls the level at which a DMA request is made by the transmit logic. It is equal to the watermark level; that is, the dma_tx_req signal is generated when the number of valid data entries in the transmit FIFO is equal to or below this field value, and TDMAE = 1. Reset value: 0x0	RW	0x0

IC_DMA_RDLR Register

Description

I2C Receive Data Level Register

Table 514.
IC_DMA_RDLR
Register

Bits	Name	Description	Type	Reset
31:4	Reserved.	-	-	-
3:0	DMARDL	Receive Data Level. This bit field controls the level at which a DMA request is made by the receive logic. The watermark level = DMARDL+1; that is, dma_rx_req is generated when the number of valid data entries in the receive FIFO is equal to or more than this field value + 1, and RDMAE = 1. For instance, when DMARDL is 0, then dma_rx_req is asserted when 1 or more data entries are present in the receive FIFO. Reset value: 0x0	RW	0x0

IC_SDA_SETUP Register

Description

I2C SDA Setup Register

This register controls the amount of time delay (in terms of number of ic_clk clock periods) introduced in the rising edge of SCL - relative to SDA changing - when DW_apb_i2c services a read request in a slave-transmitter operation. The relevant I2C requirement is tSU:DAT (note 4) as detailed in the I2C Bus Specification. This register must be programmed with a value equal to or greater than 2.

Writes to this register succeed only when IC_ENABLE[0] = 0.

Note: The length of setup time is calculated using $[(IC_SDA_SETUP - 1) * (ic_clk_period)]$, so if the user requires 10 ic_clk periods of setup time, they should program a value of 11. The IC_SDA_SETUP register is only used by the DW_apb_i2c when operating as a slave transmitter.

Table 515.
IC_SDA_SETUP
Register

Bits	Name	Description	Type	Reset
31:8	Reserved.	-	-	-
7:0	SDA_SETUP	SDA Setup. It is recommended that if the required delay is 1000ns, then for an ic_clk frequency of 10 MHz, IC_SDA_SETUP should be programmed to a value of 11. IC_SDA_SETUP must be programmed with a minimum value of 2.	RW	0x64

IC_ACK_GENERAL_CALL Register

Description

I2C ACK General Call Register

The register controls whether DW_apb_i2c responds with a ACK or NACK when it receives an I2C General Call address.

This register is applicable only when the DW_apb_i2c is in slave mode.

Table 516.
IC_ACK_GENERAL_CALL
Register

Bits	Name	Description	Type	Reset
31:1	Reserved.	-	-	-
0	ACK_GEN_CALL	ACK General Call. When set to 1, DW_apb_i2c responds with a ACK (by asserting ic_data_oe) when it receives a General Call. Otherwise, DW_apb_i2c responds with a NACK (by negating ic_data_oe). 0x0 -> Generate NACK for a General Call 0x1 -> Generate ACK for a General Call	RW	0x1

IC_ENABLE_STATUS Register

Description

I2C Enable Status Register

The register is used to report the DW_apb_i2c hardware status when the IC_ENABLE[0] register is set from 1 to 0; that is, when DW_apb_i2c is disabled.

If IC_ENABLE[0] has been set to 1, bits 2:1 are forced to 0, and bit 0 is forced to 1.

If IC_ENABLE[0] has been set to 0, bits 2:1 is only be valid as soon as bit 0 is read as '0'.

Note: When IC_ENABLE[0] has been set to 0, a delay occurs for bit 0 to be read as 0 because disabling the DW_apb_i2c depends on I2C bus activities.

Table 517.
IC_ENABLE_STATUS
Register

Bits	Name	Description	Type	Reset
31:3	Reserved.	-	-	-

Bits	Name	Description	Type	Reset
2	SLV_RX_DATA_LOST	<p>Slave Received Data Lost. This bit indicates if a Slave-Receiver operation has been aborted with at least one data byte received from an I2C transfer due to the setting bit 0 of IC_ENABLE from 1 to 0. When read as 1, DW_apb_i2c is deemed to have been actively engaged in an aborted I2C transfer (with matching address) and the data phase of the I2C transfer has been entered, even though a data byte has been responded with a NACK.</p> <p>Note: If the remote I2C master terminates the transfer with a STOP condition before the DW_apb_i2c has a chance to NACK a transfer, and IC_ENABLE[0] has been set to 0, then this bit is also set to 1.</p> <p>When read as 0, DW_apb_i2c is deemed to have been disabled without being actively involved in the data phase of a Slave-Receiver transfer.</p> <p>Note: The CPU can safely read this bit when IC_EN (bit 0) is read as 0.</p> <p>Reset value: 0x0 0x0 -> Slave RX Data is not lost 0x1 -> Slave RX Data is lost</p>	RO	0x0

Bits	Name	Description	Type	Reset
1	SLV_DISABLED_WHILE_BUSY	<p>Slave Disabled While Busy (Transmit, Receive). This bit indicates if a potential or active Slave operation has been aborted due to the setting bit 0 of the IC_ENABLE register from 1 to 0. This bit is set when the CPU writes a 0 to the IC_ENABLE register while:</p> <p>(a) DW_apb_i2c is receiving the address byte of the Slave-Transmitter operation from a remote master;</p> <p>OR,</p> <p>(b) address and data bytes of the Slave-Receiver operation from a remote master.</p> <p>When read as 1, DW_apb_i2c is deemed to have forced a NACK during any part of an I2C transfer, irrespective of whether the I2C address matches the slave address set in DW_apb_i2c (IC_SAR register) OR if the transfer is completed before IC_ENABLE is set to 0 but has not taken effect.</p> <p>Note: If the remote I2C master terminates the transfer with a STOP condition before the DW_apb_i2c has a chance to NACK a transfer, and IC_ENABLE[0] has been set to 0, then this bit will also be set to 1.</p> <p>When read as 0, DW_apb_i2c is deemed to have been disabled when there is master activity, or when the I2C bus is idle.</p> <p>Note: The CPU can safely read this bit when IC_EN (bit 0) is read as 0.</p> <p>Reset value: 0x0 0x0 -> Slave is disabled when it is idle 0x1 -> Slave is disabled when it is active</p>	RO	0x0
0	IC_EN	<p>ic_en Status. This bit always reflects the value driven on the output port ic_en. - When read as 1, DW_apb_i2c is deemed to be in an enabled state. - When read as 0, DW_apb_i2c is deemed completely inactive. Note: The CPU can safely read this bit anytime. When this bit is read as 0, the CPU can safely read SLV_RX_DATA_LOST (bit 2) and SLV_DISABLED_WHILE_BUSY (bit 1).</p> <p>Reset value: 0x0 0x0 -> I2C disabled 0x1 -> I2C enabled</p>	RO	0x0

IC_FS_SPKLEN Register

Description

I2C SS, FS or FM+ spike suppression limit

This register is used to store the duration, measured in ic_clk cycles, of the longest spike that is filtered out by the spike

suppression logic when the component is operating in SS, FS or FM+ modes. The relevant I2C requirement is tSP (table 4) as detailed in the I2C Bus Specification. This register must be programmed with a minimum value of 1.

Table 518.
IC_FS_SPKLEN
Register

Bits	Name	Description	Type	Reset
31:8	Reserved.	-	-	-
7:0	IC_FS_SPKLEN	This register must be set before any I2C bus transaction can take place to ensure stable operation. This register sets the duration, measured in ic_clk cycles, of the longest spike in the SCL or SDA lines that will be filtered out by the spike suppression logic. This register can be written only when the I2C interface is disabled which corresponds to the IC_ENABLE[0] register being set to 0. Writes at other times have no effect. The minimum valid value is 1; hardware prevents values less than this being written, and if attempted results in 1 being set. or more information, refer to 'Spike Suppression'.	RW	0x07

IC_CLR_RESTART_DET Register

Description

Clear RESTART_DET Interrupt Register

Table 519.
IC_CLR_RESTART_DET

4.5. SPI

ARM Documentation

Excerpted from the [ARM PrimeCell Synchronous Serial Port \(PL022\) Technical Reference Manual](#). Used with permission.

RP2040 has two identical SPI controllers, both based on an ARM Primecell Synchronous Serial Port (SSP) (PL022) (Revision r1p4). Note this is NOT the same as the QSPI interface covered in section [SSI](#).

Each controller supports the following features:

- Master or Slave modes
 - Motorola SPI-compatible interface
 - Texas Instruments synchronous serial interface
 - National Semiconductor Microwire interface
- 8 deep Tx and Rx FIFOs
- Interrupt generation to service FIFOs or indicate error conditions
- Can be driven from DMA
- Programmable clock rate
- Programmable data size 4-16 bits

Each controller can be connected to a number of GPIO pins as defined in the GPIO muxing [Table 274](#) in [Section 2.18.2](#). Connections to the GPIO muxing are prefixed with the SPI instance name `spi0_` or `spi1_`, and include the following:

- clock `sclk` (referred to as SSPCLKOUT in the following sections)
- active low chip select or frame sync `ss_n` (referred to as SSPFSSOUT in the following sections)
- transmit data `tx` (referred to as SSPTXD in the following sections)
- receive data `rd` (referred to as SSPRXD in the following sections)

The SPI uses `clk_peri` as its reference clock for SPI timing, and is referred to as SSPCLK in the following sections. `clk_sys` is used as the bus clock, and is referred to as PCLK in the following sections (also see [Figure 26](#)).

4.5.1. Overview

The PrimeCell SSP is a master or slave interface for synchronous serial communication with peripheral devices that have Motorola SPI, National Semiconductor Microwire, or Texas Instruments synchronous serial interfaces.

The PrimeCell SSP performs serial-to-parallel conversion on data received from a peripheral device. The CPU accesses data, control, and status information through the AMBA APB interface. The transmit and receive paths are buffered with internal FIFO memories enabling up to eight 16-bit values to be stored independently in both transmit and receive modes. Serial data is transmitted on SSPTXD and received on SSPRXD.

The PrimeCell SSP includes a programmable bit rate clock divider and prescaler to generate the serial output clock, SSPCLKOUT, from the input clock, SSPCLK. Bit rates are supported to 2MHz and higher, subject to choice of frequency for SSPCLK, and the maximum bit rate is determined by peripheral devices.

You can use the control registers SSPCR0 and SSPCR1 to program the PrimeCell SSP operating mode, frame format, and size.

The following individually maskable interrupts are generated:

- SSPTXINTR requests servicing of the transmit buffer
- SSPRXINTR requests servicing of the receive buffer
- SSPRORINTR indicates an overrun condition in the receive FIFO
- SSPRTINTR indicates that a timeout period expired while data was present in the receive FIFO.

A single combined interrupt is asserted if any of the individual interrupts are asserted and unmasked. This interrupt is connected to the processor interrupt controllers in RP2040.

In addition to the above interrupts, a set of DMA signals are provided for interfacing with a DMA controller.

Depending on the operating mode selected, the SSPFSSOUT output operates as:

- an active-HIGH frame synchronization output for Texas Instruments synchronous serial frame format
- an active-LOW slave select for SPI and Microwire.

4.5.2. Functional Description

Figure 85. PrimeCell SSP block diagram. For clarity, does not show the test logic.

4.5.2.1. AMBA APB interface

The AMBA APB interface generates read and write decodes for accesses to status and control registers, and transmit and receive FIFO memories.

4.5.2.2. Register block

The register block stores data written, or to be read, across the AMBA APB interface.

4.5.2.3. Clock prescaler

When configured as a master, an internal prescaler, comprising two free-running reloadable serially linked counters, provides the serial output clock SSPCLKOUT.

You can program the clock prescaler, using the SSPCSR register, to divide SSPCLK by a factor of 2-254 in steps of two. By not utilizing the least significant bit of the SSPCSR register, division by an odd number is not possible which ensures that a symmetrical, equal mark space ratio, clock is generated. See [SSPCPSR](#).

The output of the prescaler is divided again by a factor of 1-256, by programming the SSPCR0 control register, to give the final master output clock SSPCLKOUT.

4.5.2.4. Transmit FIFO

The common transmit FIFO is a 16-bit wide, 8-locations deep memory buffer. CPU data written across the AMBA APB interface are stored in the buffer until read out by the transmit logic.

When configured as a master or a slave, parallel data is written into the transmit FIFO prior to serial conversion, and transmission to the attached slave or master respectively, through the SSPTXD pin.

4.5.2.5. Receive FIFO

The common receive FIFO is a 16-bit wide, 8-locations deep memory buffer. Received data from the serial interface are stored in the buffer until read out by the CPU across the AMBA APB interface.

When configured as a master or slave, serial data received through the SSPRXD pin is registered prior to parallel loading into the attached slave or master receive FIFO respectively.

4.5.2.6. Transmit and receive logic

When configured as a master, the clock to the attached slaves is derived from a divided-down version of SSPCLK through the previously described prescaler operations. The master transmit logic successively reads a value from its transmit FIFO and performs parallel to serial conversion on it. Then, the serial data stream and frame control signal, synchronized to SSPCLKOUT, are output through the SSPTXD pin to the attached slaves. The master receive logic performs serial to parallel conversion on the incoming synchronous SSPRXD data stream, extracting and storing values into its receive FIFO, for subsequent reading through the APB interface.

When configured as a slave, the SSPCLKIN clock is provided by an attached master and used to time its transmission and reception sequences. The slave transmit logic, under control of the master clock, successively reads a value from its transmit FIFO, performs parallel to serial conversion, then outputs the serial data stream and frame control signal through the slave SSPTXD pin. The slave receive logic performs serial to parallel conversion on the incoming SSPRXD data stream, extracting and storing values into its receive FIFO, for subsequent reading through the APB interface.

4.5.2.7. Interrupt generation logic

The PrimeCell SSP generates four individual maskable, active-HIGH interrupts. A combined interrupt output is generated as an OR function of the individual interrupt requests.

The transmit and receive dynamic data-flow interrupts, SSPTXINTR and SSPRXINTR, are separated from the status interrupts so that data can be read or written in response to the FIFO trigger levels.

4.5.2.8. DMA interface

The PrimeCell SSP provides an interface to connect to a DMA controller, see [Section 4.5.3.16](#).

4.5.2.9. Synchronizing registers and logic

The PrimeCell SSP supports both asynchronous and synchronous operation of the clocks, PCLK and SSPCLK. Synchronization registers and handshaking logic have been implemented, and are active at all times. Synchronization of control signals is performed on both directions of data flow, that is:

- from the PCLK to the SSPCLK domain
- from the SSPCLK to the PCLK domain.

4.5.3. Operation

4.5.3.1. Interface reset

The PrimeCell SSP is reset by the global reset signal, PRESETn, and a block-specific reset signal, nSSPRST. The device reset controller asserts nSSPRST asynchronously and negates it synchronously to SSPCLK.

4.5.3.2. Configuring the SSP

Following reset, the PrimeCell SSP logic is disabled and must be configured when in this state. It is necessary to program control registers SSPCR0 and SSPCR1 to configure the peripheral as a master or slave operating under one of the following protocols:

- Motorola SPI
- Texas Instruments SSI
- National Semiconductor.

The bit rate, derived from the external SSPCLK, requires the programming of the clock prescale register SSPCPSR.

4.5.3.3. Enable PrimeCell SSP operation

You can either prime the transmit FIFO, by writing up to eight 16-bit values when the PrimeCell SSP is disabled, or permit the transmit FIFO service request to interrupt the CPU. Once enabled, transmission or reception of data begins on the transmit, SSPTXD, and receive, SSPRXD, pins.

4.5.3.4. Clock ratios

There is a constraint on the ratio of the frequencies of PCLK to SSPCLK. The frequency of SSPCLK must be less than or equal to that of PCLK. This ensures that control signals from the SSPCLK domain to the PCLK domain are guaranteed to get synchronized before one frame duration:

$$F_{SSPCLK} \leq F_{PCLK}$$

In the slave mode of operation, the SSPCLKIN signal from the external master is double-synchronized and then delayed to detect an edge. It takes three SSPCLKs to detect an edge on SSPCLKIN. SSPTXD has less setup time to the falling edge of SSPCLKIN on which the master is sampling the line.

The setup and hold times on SSPRXD, with reference to SSPCLKIN, must be more conservative to ensure that it is at the right value when the actual sampling occurs within the SSPMS. To ensure correct device operation, SSPCLK must be at least 12 times faster than the maximum expected frequency of SSPCLKIN.

The frequency selected for SSPCLK must accommodate the desired range of bit clock rates. The ratio of minimum SSPCLK frequency to SSPCLKOUT maximum frequency in the case of the slave mode is 12, and for the master mode, it is two.

To generate a maximum bit rate of 1.8432Mbps in the master mode, the frequency of SSPCLK must be at least 3.6864MHz. With an SSPCLK frequency of 3.6864MHz, the SSPCPSR register must be programmed with a value of 2, and the SCR[7:0] field in the SSPCR0 register must be programmed with a value of 0.

To work with a maximum bit rate of 1.8432Mbps in the slave mode, the frequency of SSPCLK must be at least 22.12MHz. With an SSPCLK frequency of 22.12MHz, the SSPCPSR register can be programmed with a value of 12, and the SCR[7:0] field in the SSPCR0 register can be programmed with a value of 0. Similarly, the ratio of SSPCLK maximum frequency to SSPCLKOUT minimum frequency is 254 x 256.

The minimum frequency of SSPCLK is governed by the following equations, both of which must be satisfied:

$$F_{SSPCLK}(min) = >2 \times F_{SSPCLKOUT}(max), \text{ for master mode}$$

$$F_{SSPCLK}(min) = >12 \times F_{SSPCLKIN}(max), \text{ for slave mode.}$$

The maximum frequency of SSPCLK is governed by the following equations, both of which must be satisfied:

$$F_{SSPCLK}(max) \leq 254 \times 256 \times F_{SSPCLKOUT}(min), \text{ for master mode}$$

$$F_{SSPCLK}(max) \leq 254 \times 256 \times F_{SSPCLKIN}(min), \text{ for slave mode.}$$

4.5.3.5. Programming the SSPCR0 Control Register

The SSPCR0 register is used to:

- program the serial clock rate
- select one of the three protocols

- select the data word size, where applicable.

The Serial Clock Rate (SCR) value, in conjunction with the SSPCPSR clock prescale divisor value, CPSDVSR, is used to derive the PrimeCell SSP transmit and receive bit rate from the external SSPCLK.

The frame format is programmed through the FRF bits, and the data word size through the DSS bits.

Bit phase and polarity, applicable to Motorola SPI format only, are programmed through the SPH and SPO bits.

4.5.3.6. Programming the SSPCR1 Control Register

The SSPCR1 register is used to:

- select master or slave mode
- enable a loop back test feature
- enable the PrimeCell SSP peripheral.

To configure the PrimeCell SSP as a master, clear the SSPCR1 register master or slave selection bit, MS, to 0. This is the default value on reset.

Setting the SSPCR1 register MS bit to 1 configures the PrimeCell SSP as a slave. When configured as a slave, enabling or disabling of the PrimeCell SSP SSPTXD signal is provided through the SSPCR1 slave mode SSPTXD output disable bit, SOD. You can use this in some multi-slave environments where masters might parallel broadcast.

To enable the operation of the PrimeCell SSP, set the Synchronous Serial Port Enable (SSE) bit to 1.

4.5.3.6.1. Bit rate generation

The serial bit rate is derived by dividing down the input clock, SSPCLK. The clock is first divided by an even prescale value CPSDVSR in the range 2-254, and is programmed in SSPCPSR. The clock is divided again by a value in the range 1-256, that is 1 + SCR, where SCR is the value programmed in SSPCR0.

The following equation defines the frequency of the output signal bit clock, SSPCLKOUT:

$$F_{SSPCLKOUT} = \frac{F_{SSPCLK}}{CPSDVSR \times (1 + SCR)}$$

For example, if SSPCLK is 3.6864MHz, and CPSDVSR = 2, then SSPCLKOUT has a frequency range from 7.2kHz-1.8432MHz.

4.5.3.7. Frame format

Each data frame is between 4-16 bits long, depending on the size of data programmed, and is transmitted starting with the MSB. You can select the following basic frame types:

- Texas Instruments synchronous serial
- Motorola SPI
- National Semiconductor Microwire.

For all formats, the serial clock, SSPCLKOUT, is held inactive while the PrimeCell SSP is idle, and transitions at the programmed frequency only during active transmission or reception of data. The idle state of SSPCLKOUT is utilized to provide a receive timeout indication that occurs when the receive FIFO still contains data after a timeout period.

For Motorola SPI and National Semiconductor Microwire frame formats, the serial frame, SSPFSSOUT, pin is active-LOW, and is asserted, pulled-down, during the entire transmission of the frame.

For Texas Instruments synchronous serial frame format, the SSPFSSOUT pin is pulsed for one serial clock period, starting at its rising edge, prior to the transmission of each frame. For this frame format, both the PrimeCell SSP and the off-chip slave device drive their output data on the rising edge of SSPCLKOUT, and latch data from the other device on the falling edge.

Unlike the full-duplex transmission of the other two frame formats, the National Semiconductor Microwire format uses a special master-slave messaging technique that operates at half-duplex. In this mode, when a frame begins, an 8-bit control message is transmitted to the off-chip slave. During this transmit, the SSS receives no incoming data. After the message has been sent, the off-chip slave decodes it and, after waiting one serial clock after the last bit of the 8-bit control message has been sent, responds with the requested data. The returned data can be 4-16 bits in length, making the total frame length in the range 13-25 bits.

4.5.3.8. Texas Instruments synchronous serial frame format

Figure 86 shows the Texas Instruments synchronous serial frame format for a single transmitted frame.

Figure 86. Texas Instruments synchronous serial frame format, single transfer

In this mode, SSPCLKOUT and SSPFSSOUT are forced LOW, and the transmit data line, SSPTXD is tristated whenever the PrimeCell SSP is idle. When the bottom entry of the transmit FIFO contains data, SSPFSSOUT is pulsed HIGH for one SSPCLKOUT period. The value to be transmitted is also transferred from the transmit FIFO to the serial shift register of the transmit logic. On the next rising edge of SSPCLKOUT, the MSB of the 4-bit to 16-bit data frame is shifted out on the SSPTXD pin. In a similar way, the MSB of the received data is shifted onto the SSPRXD pin by the off-chip serial slave device.

Both the PrimeCell SSP and the off-chip serial slave device then clock each data bit into their serial shifter on the falling edge of each SSPCLKOUT. The received data is transferred from the serial shifter to the receive FIFO on the first rising edge of PCLK after the LSB has been latched.

Figure 87 shows the Texas Instruments synchronous serial frame format when back-to-back frames are transmitted.

Figure 87. Texas Instruments synchronous serial frame format, continuous transfer

4.5.3.9. Motorola SPI frame format

The Motorola SPI interface is a four-wire interface where the SSPFSSOUT signal behaves as a slave select. The main feature of the Motorola SPI format is that you can program the inactive state and phase of the SSPCLKOUT signal using the SPO and SPH bits of the SSPSCR0 control register.

4.5.3.9.1. SPO, clock polarity

When the SPO clock polarity control bit is LOW, it produces a steady state LOW value on the SSPCLKOUT pin. If the SPO clock polarity control bit is HIGH, a steady state HIGH value is placed on the SSPCLKOUT pin when data is not being transferred.

4.5.3.9.2. SPH, clock phase

The SPH control bit selects the clock edge that captures data and enables it to change state. It has the most impact on the first bit transmitted by either permitting or not permitting a clock transition before the first data capture edge.

When the SPH phase control bit is LOW, data is captured on the first clock edge transition.

When the SPH clock phase control bit is HIGH, data is captured on the second clock edge transition.

4.5.3.10. Motorola SPI Format with SPO=0, SPH=0

Figure 88 and Figure 89 shows a continuous transmission signal sequence for Motorola SPI frame format with SPO=0, SPH=0. Figure 88 shows a single transmission signal sequence for Motorola SPI frame format with SPO=0, SPH=0.

Figure 88. Motorola SPI frame format, single transfer, with SPO=0 and SPH=0

Figure 89 shows a continuous transmission signal sequence for Motorola SPI frame format with SPO=0, SPH=0.

Figure 89. Motorola SPI frame format, single transfer, with SPO=0 and SPH=0

In this configuration, during idle periods:

- the SSPCLKOUT signal is forced LOW
- the SSPFSSOUT signal is forced HIGH
- the transmit data line SSPTXD is arbitrarily forced LOW
- the nSSPOE pad enable signal is forced HIGH, making the transmit pad high impedance
- when the PrimeCell SSP is configured as a master, the nSSPCTLOE line is driven LOW, enabling the SSPCLKOUT pad, active-LOW enable
- when the PrimeCell SSP is configured as a slave, the nSSPCTLOE line is driven HIGH, disabling the SSPCLKOUT pad, active-LOW enable.

If the PrimeCell SSP is enable, and there is valid data within the transmit FIFO, the start of transmission is signified by the SSPFSSOUT master signal being driven LOW. This causes slave data to be enabled onto the SSPTXD input line of the master. The nSSPOE line is driven LOW, enabling the master SSPTXD output pad.

One-half SSPCLKOUT period later, valid master data is transferred to the SSPTXD pin. Now that both the master and slave data have been set, the SSPCLKOUT master clock pin goes HIGH after one additional half SSPCLKOUT period.

The data is now captured on the rising and propagated on the falling edges of the SSPCLKOUT signal.

In the case of a single word transmission, after all bits of the data word have been transferred, the SSPFSSOUT line is returned to its idle HIGH state one SSPCLKOUT period after the last bit has been captured.

However, in the case of continuous back-to-back transmissions, the SSPFSSOUT signal must be pulsed HIGH between each data word transfer. This is because the slave select pin freezes the data in its serial peripheral register and does not permit it to be altered if the SPH bit is logic zero. Therefore, the master device must raise the SSPFSSIN pin of the slave device between each data transfer to enable the serial peripheral data write. On completion of the continuous transfer, the

SSPFSSOUT pin is returned to its idle state one SSPCLKOUT period after the last bit has been captured.

4.5.3.11. Motorola SPI Format with SPO=0, SPH=1

Figure 90 shows the transfer signal sequence for Motorola SPI format with SPO=0, SPH=1, and it covers both single and continuous transfers.

Figure 90. Motorola SPI frame format with SPO=0 and SPH=1, single and continuous transfers

In this configuration, during idle periods:

- the SSPCLKOUT signal is forced LOW
- The SSPFSSOUT signal is forced HIGH
- the transmit data line SSPTXD is arbitrarily forced LOW
- the nSSPOE pad enable signal is forced HIGH, making the transmit pad high impedance
- when the PrimeCell SSP is configured as a master, the nSSPCTLOE line is driven LOW, enabling the SSPCLKOUT pad, active-LOW enable
- when the PrimeCell SSP is configured as a slave, the nSSPCTLOE line is driven HIGH, disabling the SSPCLKOUT pad, active-LOW enable.

If the PrimeCell SSP is enabled, and there is valid data within the transmit FIFO, the start of transmission is signified by the SSPFSSOUT master signal being driven LOW. The nSSPOE line is driven LOW, enabling the master SSPTXD output pad. After an additional one half SSPCLKOUT period, both master and slave valid data is enabled onto their respective transmission lines. At the same time, the SSPCLKOUT is enabled with a rising edge transition.

Data is then captured on the falling edges and propagated on the rising edges of the SSPCLKOUT signal.

In the case of a single word transfer, after all bits have been transferred, the SSPFSSOUT line is returned to its idle HIGH state one SSPCLKOUT period after the last bit has been captured. For continuous back-to-back transfers, the SSPFSSOUT pin is held LOW between successive data words and termination is the same as that of the single word transfer.

4.5.3.12. Motorola SPI Format with SPO=1, SPH=0

Figure 91 and Figure 92 show single and continuous transmission signal sequences for Motorola SPI format with SPO=1, SPH=0.

Figure 91 shows a single transmission signal sequence for Motorola SPI format with SPO=1, SPH=0.

Figure 91. Motorola SPI frame format, single transfer, with SPO=1 and SPH=0

Figure 92 shows a continuous transmission signal sequence for Motorola SPI format with SPO=1, SPH=0.

NOTE

In Figure 91, Q is an undefined signal.

Figure 92. Motorola SPI frame format, continuous transfer, with SPO=1 and SPH=0

In this configuration, during idle periods:

- the SSPCLKOUT signal is forced HIGH
- the SSPFSSOUT signal is forced HIGH
- the transmit data line SSPTXD is arbitrarily forced LOW
- the nSSPOE pad enable signal is forced HIGH, making the transmit pad high impedance
- when the PrimeCell SSP is configured as a master, the nSSPCTL0E line is driven LOW, enabling the SSPCLKOUT pad, active-LOW enable
- when the PrimeCell SSP is configured as a slave, the nSSPCTL0E line is driven HIGH, disabling the SSPCLKOUT pad, active-LOW enable.

If the PrimeCell SSP is enabled, and there is valid data within the transmit FIFO, the start of transmission is signified by the SSPFSSOUT master signal being driven LOW, and this causes slave data to be immediately transferred onto the SSPRXD line of the master. The nSSPOE line is driven LOW, enabling the master SSPTXD output pad.

One half period later, valid master data is transferred to the SSPTXD line. Now that both the master and slave data have been set, the SSPCLKOUT master clock pin becomes LOW after one additional half SSPCLKOUT period. This means that data is captured on the falling edges and be propagated on the rising edges of the SSPCLKOUT signal.

In the case of a single word transmission, after all bits of the data word are transferred, the SSPFSSOUT line is returned to its idle HIGH state one SSPCLKOUT period after the last bit has been captured.

However, in the case of continuous back-to-back transmissions, the SSPFSSOUT signal must be pulsed HIGH between each data word transfer. This is because the slave select pin freezes the data in its serial peripheral register and does not permit it to be altered if the SPH bit is logic zero. Therefore, the master device must raise the SSPFSSIN pin of the slave device between each data transfer to enable the serial peripheral data write. On completion of the continuous transfer, the SSPFSSOUT pin is returned to its idle state one SSPCLKOUT period after the last bit has been captured.

4.5.3.13. Motorola SPI Format with SPO=1, SPH=1

Figure 93 shows the transfer signal sequence for Motorola SPI format with SPO=1, SPH=1, and it covers both single and continuous transfers.

Figure 93. Motorola SPI frame format with SPO=1 and SPH=1, single and continuous transfers

NOTE

In Figure 93, Q is an undefined signal.

In this configuration, during idle periods:

- the SSPCLKOUT signal is forced HIGH
- the SSPFSSOUT signal is forced HIGH
- the transmit data line SSPTXD is arbitrarily forced LOW
- the nSSPOE pad enable signal is forced HIGH, making the transmit pad high impedance
- when the PrimeCell SSP is configured as a master, the nSSPCTLOE line is driven LOW, enabling the SSPCLKOUT pad, active-LOW enable
- when the PrimeCell SSP is configured as a slave, the nSSPCTLOE line is driven HIGH, disabling the SSPCLKOUT pad, active-LOW enable.

If the PrimeCell SSP is enabled, and there is valid data within the transmit FIFO, the start of transmission is signified by the SSPFSSOUT master signal being driven LOW. The nSSPOE line is driven LOW, enabling the master SSPTXD output pad. After an additional one half SSPCLKOUT period, both master and slave data are enabled onto their respective transmission lines. At the same time, the SSPCLKOUT is enabled with a falling edge transition. Data is then captured on the rising edges and propagated on the falling edges of the SSPCLKOUT signal.

After all bits have been transferred, in the case of a single word transmission, the SSPFSSOUT line is returned to its idle HIGH state one SSPCLKOUT period after the last bit has been captured.

For continuous back-to-back transmissions, the SSPFSSOUT pin remains in its active-LOW state, until the final bit of the last word has been captured, and then returns to its idle state as the previous section describes.

For continuous back-to-back transfers, the SSPFSSOUT pin is held LOW between successive data words and termination is the same as that of the single word transfer.

4.5.3.14. National Semiconductor Microwire frame format

Figure 94 shows the National Semiconductor Microwire frame format for a single frame. Figure 95 shows the same format when back to back frames are transmitted.

Figure 94. Microwire frame format, single transfer

Microwire format is very similar to SPI format, except that transmission is half-duplex instead of full-duplex, using a master-slave message passing technique. Each serial transmission begins with an 8-bit control word that is transmitted from the PrimeCell SSP to the off-chip slave device. During this transmission, the PrimeCell SSP receives no incoming data. After the message has been sent, the off-chip slave decodes it and, after waiting one serial clock after the last bit of the 8-bit control message has been sent, responds with the required data. The returned data is 4 to 16 bits in length, making the total frame length in the range 13-25 bits.

In this configuration, during idle periods:

- SSPCLKOUT is forced LOW
- SSPFSSOUT is forced HIGH
- the transmit data line, SSPTXD, is arbitrarily forced LOW

- the nSSPOE pad enable signal is forced HIGH, making the transmit pad high impedance.

A transmission is triggered by writing a control byte to the transmit FIFO. The falling edge of SSPFSSOUT causes the value contained in the bottom entry of the transmit FIFO to be transferred to the serial shift register of the transmit logic, and the MSB of the 8-bit control frame to be shifted out onto the SSPTXD pin. SSPFSSOUT remains LOW for the duration of the frame transmission. The SSPRXD pin remains tristated during this transmission.

The off-chip serial slave device latches each control bit into its serial shifter on the rising edge of each SSPCLKOUT. After the last bit is latched by the slave device, the control byte is decoded during a one clock wait-state, and the slave responds by transmitting data back to the PrimeCell SSP. Each bit is driven onto SSPRXD line on the falling edge of SSPCLKOUT. The PrimeCell SSP in turn latches each bit on the rising edge of SSPCLKOUT. At the end of the frame, for single transfers, the SSPFSSOUT signal is pulled HIGH one clock period after the last bit has been latched in the receive serial shifter, that causes the data to be transferred to the receive FIFO.

NOTE

The off-chip slave device can tristate the receive line either on the falling edge of SSPCLKOUT after the LSB has been latched by the receive shifter, or when the SSPFSSOUT pin goes HIGH.

For continuous transfers, data transmission begins and ends in the same manner as a single transfer. However, the SSPFSSOUT line is continuously asserted, held LOW, and transmission of data occurs back-to-back. The control byte of the next frame follows directly after the LSB of the received data from the current frame. Each of the received values is transferred from the receive shifter on the falling edge SSPCLKOUT, after the LSB of the frame has been latched into the PrimeCell SSP.

Figure 95 shows the National Semiconductor Microwire frame format when back-to-back frames are transmitted.

Figure 95. Microwire frame format, continuous transfers

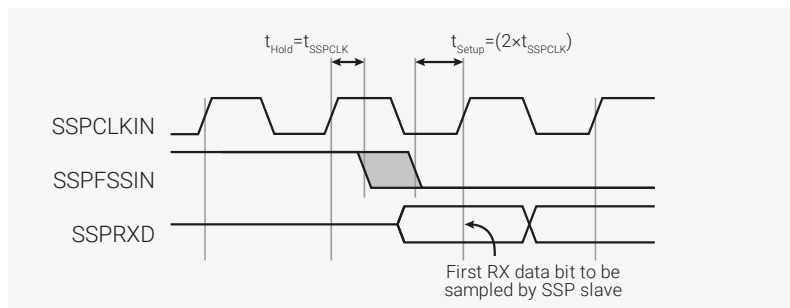

In Microwire mode, the PrimeCell SSP slave samples the first bit of receive data on the rising edge of SSPCLKIN after SSPFSSIN has gone LOW. Masters that drive a free-running SSPCLKIN must ensure that the SSPFSSIN signal has sufficient setup and hold margins with respect to the rising edge of SSPCLKIN.

Figure 96 shows these setup and hold time requirements.

With respect to the SSPCLKIN rising edge on which the first bit of receive data is to be sampled by the PrimeCell SSP slave, SSPFSSIN must have a setup of at least two times the period of SSPCLK on which the PrimeCell SSP operates.

With respect to the SSPCLKIN rising edge previous to this edge, SSPFSSIN must have a hold of at least one SSPCLK period.

Figure 96. Microwire frame format, SSPFSSIN input setup and hold requirements

4.5.3.15. Examples of master and slave configurations

Figure 97, Figure 98, and Figure 99 shows how you can connect the PrimeCell SSP (PL022) peripheral to other synchronous serial peripherals, when it is configured as a master or a slave.

NOTE

The SSP (PL022) does not support dynamic switching between master and slave in a system. Each instance is configured and connected either as a master or slave.

Figure 97 shows the PrimeCell SSP (PL022) instanced twice, as a single master and one slave. The master can broadcast to the slave through the master SSPTXD line. In response, the slave drives its nSSPOE signal HIGH, enabling its SSPTXD data onto the SSPRXD line of the master.

Figure 97. PrimeCell SSP master coupled to a PL022 slave

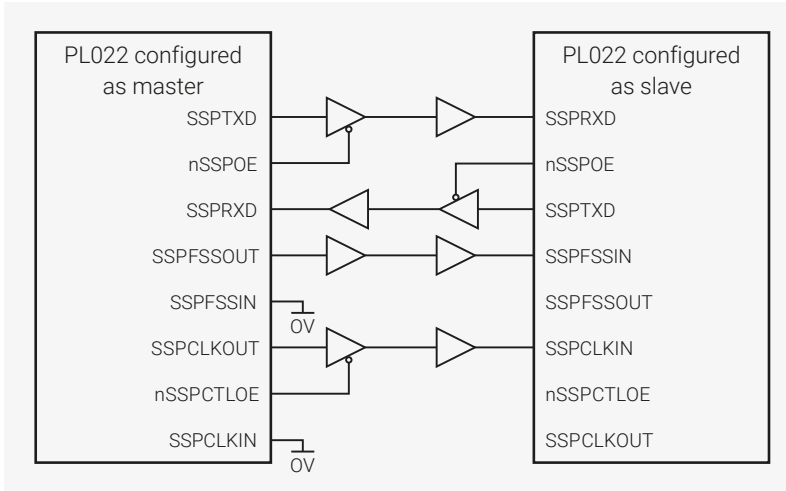

Figure 98 shows how an PrimeCell SSP (PL022), configured as master, interfaces to a Motorola SPI slave. The SPI Slave Select (SS) signal is permanently tied LOW and configures it as a slave. Similar to the above operation, the master can broadcast to the slave through the master PrimeCell SSP SSPTXD line. In response, the slave drives its SPI MISO port onto the SSPRXD line of the master.

Figure 98. PrimeCell SSP master coupled to an SPI slave

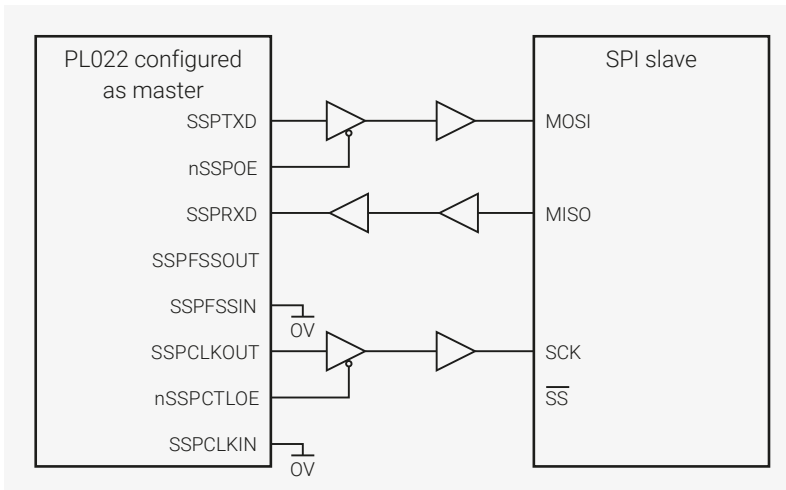

Figure 99 shows a Motorola SPI configured as a master and interfaced to an instance of a PrimeCell SSP (PL022) configured as a slave. In this case, the slave Select Signal (SS) is permanently tied HIGH to configure it as a master. The master can broadcast to the slave through the master SPI MOSI line and in response, the slave drives its nSSPOE signal LOW. This enables its SSPTXD data onto the MISO line of the master.

Figure 99. SPI master coupled to a PrimeCell SSP slave

4.5.3.16. PrimeCell DMA interface

The PrimeCell SSP provides an interface to connect to the DMA controller. The PrimeCell SSP DMA control register, SSPDMACR controls the DMA operation of the PrimeCell SSP.

The DMA interface includes the following signals, for receive:

SSPRXDMASREQ

Single-character DMA transfer request, asserted by the SSP. This signal is asserted when the receive FIFO contains at least one character.

SSPRXDMABREQ

Burst DMA transfer request, asserted by the SSP. This signal is asserted when the receive FIFO contains four or more characters.

SSPRXDMACLR

DMA request clear, asserted by the DMA controller to clear the receive request signals. If DMA burst transfer is requested, the clear signal is asserted during the transfer of the last data in the burst.

The DMA interface includes the following signals, for transmit:

SSPTXDMASREQ

Single-character DMA transfer request, asserted by the SSP. This signal is asserted when there is at least one empty location in the transmit FIFO.

SSPTXDMABREQ

Burst DMA transfer request, asserted by the SSP. This signal is asserted when the transmit FIFO contains four characters or fewer.

SSPTXDMACLR

DMA request clear, asserted by the DMA controller, to clear the transmit request signals. If a DMA burst transfer is requested, the clear signal is asserted during the transfer of the last data in the burst.

The burst transfer and single transfer request signals are not mutually exclusive. They can both be asserted at the same time. For example, when there is more data than the watermark level of four in the receive FIFO, the burst transfer request, and the single transfer request, are asserted. When the amount of data left in the receive FIFO is less than the watermark level, the single request only is asserted. This is useful for situations where the number of characters left to be received in the stream is less than a burst.

For example, if 19 characters must be received, the DMA controller then transfers four bursts of four characters, and three single transfers to complete the stream.

NOTE

For the remaining three characters, the PrimeCell SSP does not assert the burst request.

Each request signal remains asserted until the relevant DMA clear signal is asserted. After the request clear signal is deasserted, a request signal can become active again, depending on the conditions that previous sections describe. All request signals are deasserted if the PrimeCell SSP is disabled, or the DMA enable signal is cleared.

Table 523 shows the trigger points for DMABREQ, for both the transmit and receive FIFOs.

Table 523. DMA trigger points for the transmit and receive FIFOs

Burst length		
Watermark level	Transmit, number of empty locations	Receive, number of filled locations
1/2	4	4

Figure 100 shows the timing diagram for both a single transfer request, and a burst transfer request, with the appropriate DMA clear signal. The signals are all synchronous to PCLK.

Figure 100. DMA transfer waveforms

4.5.4. List of Registers

SSPCR1 Register**Description**

Control register 1, SSPCR1 on page 3-5

Table 526. SSPCR1 Register

Bits	Name	Description	Type	Reset
31:4	Reserved.	-	-	-
3	SOD	Slave-mode output disable. This bit is relevant only in the slave mode, MS=1. In multiple-slave systems, it is possible for an PrimeCell SSP master to broadcast a message to all slaves in the system while ensuring that only one slave drives data onto its serial output line. In such systems the RXD lines from multiple slaves could be tied together. To operate in such systems, the SOD bit can be set if the PrimeCell SSP slave is not supposed to drive the SSPTXD line: 0 SSP can drive the SSPTXD output in slave mode. 1 SSP must not drive the SSPTXD output in slave mode.	RW	0x0
2	MS	Master or slave mode select. This bit can be modified only when the PrimeCell SSP is disabled, SSE=0: 0 Device configured as master, default. 1 Device configured as slave.	RW	0x0
1	SSE	Synchronous serial port enable: 0 SSP operation disabled. 1 SSP operation enabled.	RW	0x0
0	LBM	Loop back mode: 0 Normal serial port operation enabled. 1 Output of transmit serial shifter is connected to input of receive serial shifter internally.	RW	0x0

SSPDR Register

Description

Data register, SSPDR on page 3-6

Table 527. SSPDR Register

Bits	Name	Description	Type	Reset
31:16	Reserved.	-	-	-
15:0	DATA	Transmit/Receive FIFO: Read Receive FIFO. Write Transmit FIFO. You must right-justify data when the PrimeCell SSP is programmed for a data size that is less than 16 bits. Unused bits at the top are ignored by transmit logic. The receive logic automatically right-justifies.	RWF	-

SSPSR Register

Description

Status register, SSPSR on page 3-7

Table 528. SSPSR Register

Bits	Name	Description	Type	Reset
31:5	Reserved.	-	-	-
4	BSY	PrimeCell SSP busy flag, RO: 0 SSP is idle. 1 SSP is currently transmitting and/or receiving a frame or the transmit FIFO is not empty.	RO	0x0
3	RFF	Receive FIFO full, RO: 0 Receive FIFO is not full. 1 Receive FIFO is full.	RO	0x0
2	RNE	Receive FIFO not empty, RO: 0 Receive FIFO is empty. 1 Receive FIFO is not empty.	RO	0x0
1	TNF	Transmit FIFO not full, RO: 0 Transmit FIFO is full. 1 Transmit FIFO is not full.	RO	0x1
0	TFE	Transmit FIFO empty, RO: 0 Transmit FIFO is not empty. 1 Transmit FIFO is empty.	RO	0x1

SSPCPSR Register

Description

Clock prescale register, SSPCPSR on page 3-8

Table 529. SSPCPSR Register

Bits	Name	Description	Type	Reset
31:8	Reserved.	-	-	-
7:0	CPSDVSR	Clock prescale divisor. Must be an even number from 2-254, depending on the frequency of SSPCLK. The least significant bit always returns zero on reads.	RW	0x00

SSPIMSC Register

Description

Interrupt mask set or clear register, SSPIMSC on page 3-9

Table 530. SSPIMSC Register

Bits	Name	Description	Type	Reset
31:4	Reserved.	-	-	-

Bits	Name	Description	Type	Reset
3	TXIM	Transmit FIFO interrupt mask: 0 Transmit FIFO half empty or less condition interrupt is masked. 1 Transmit FIFO half empty or less condition interrupt is not masked.	RW	0x0
2	RXIM	Receive FIFO interrupt mask: 0 Receive FIFO half full or less condition interrupt is masked. 1 Receive FIFO half full or less condition interrupt is not masked.	RW	0x0
1	RTIM	Receive timeout interrupt mask: 0 Receive FIFO not empty and no read prior to timeout period interrupt is masked. 1 Receive FIFO not empty and no read prior to timeout period interrupt is not masked.	RW	0x0
0	RORIM	Receive overrun interrupt mask: 0 Receive FIFO written to while full condition interrupt is masked. 1 Receive FIFO written to while full condition interrupt is not masked.	RW	0x0

SSPRIS Register

Description

Raw interrupt status register, SSPRIS on page 3-10

Table 531. SSPRIS Register

Bits	Name	Description	Type	Reset
31:4	Reserved.	-	-	-
3	TXRIS	Gives the raw interrupt state, prior to masking, of the SSPTXINTR interrupt	RO	0x1
2	RXRIS	Gives the raw interrupt state, prior to masking, of the SSPRXINTR interrupt	RO	0x0
1	RTRIS	Gives the raw interrupt state, prior to masking, of the SSPRTINTR interrupt	RO	0x0
0	RORRIS	Gives the raw interrupt state, prior to masking, of the SSPRORINTR interrupt	RO	0x0

SSPMIS Register

Description

Masked interrupt status register, SSPMIS on page 3-11

Table 532. SSPMIS Register

Bits	Name	Description	Type	Reset
31:4	Reserved.	-	-	-
3	TXMIS	Gives the transmit FIFO masked interrupt state, after masking, of the SSPTXINTR interrupt	RO	0x0
2	RXMIS	Gives the receive FIFO masked interrupt state, after masking, of the SSPRXINTR interrupt	RO	0x0
1	RTMIS	Gives the receive timeout masked interrupt state, after masking, of the SSPRTINTR interrupt	RO	0x0
0	RORMIS	Gives the receive over run masked interrupt status, after masking, of the SSPRORINTR interrupt	RO	0x0

SSPICR Register

Description

Interrupt clear register, SSPICR on page 3-11

4.6. PWM

4.6.1. Overview

Pulse width modulation (PWM) is a scheme where a digital signal provides a smoothly varying average voltage. This is achieved with positive pulses of some controlled width, at regular intervals. The fraction of time spent high is known as the duty cycle. This may be used to approximate an analog output, or control switchmode power electronics.

The RP2040 PWM block has 8 identical slices. Each slice can drive two PWM output signals, or measure the frequency or duty cycle of an input signal. This gives a total of up to 16 controllable PWM outputs. All 30 GPIO pins can be driven by the PWM block.

Figure 101. A single PWM slice. A 16-bit counter counts from 0 up to some programmed value, and then wraps to zero, or counts back down again, depending on PWM mode. The A and B outputs transition high and low based on the current count value and the preprogrammed A and B thresholds. The counter advances based on a number of events: it may be free-running, or gated by level or edge of an input signal on the B pin. A fractional divider slows the overall count rate for finer control of output frequency.

Each PWM slice is equipped with the following:

- 16-bit counter
- 8.4 fractional clock divider
- Two independent output channels, duty cycle from 0% to 100% **inclusive**
- Dual slope and trailing edge modulation
- Edge-sensitive input mode for frequency measurement
- Level-sensitive input mode for duty cycle measurement
- Configurable counter wrap value
 - Wrap and level registers are double buffered and can be changed race-free while PWM is running
- Interrupt request and DMA request on counter wrap
- Phase can be precisely advanced or retarded while running (increments of one count)

Slices can be enabled or disabled simultaneously via a single, global control register. The slices then run in perfect lockstep, so that more complex power circuitry can be switched by the outputs of multiple slices.

4.6.2. Programmer’s Model

All 30 GPIO pins on RP2040 can be used for PWM:

Table 543. Mapping of PWM channels to GPIO pins on RP2040. This is also shown in the main GPIO function table, Table 274

GPIO	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
PWM Channel	0A	0B	1A	1B	2A	2B	3A	3B	4A	4B	5A	5B	6A	6B	7A	7B
GPIO	16	17	18	19	20	21	22	23	24	25	26	27	28	29		
PWM Channel	0A	0B	1A	1B	2A	2B	3A	3B	4A	4B	5A	5B	6A	6B		

- The 16 PWM channels (8 2-channel slices) appear on GPIO0 to GPIO15, in the order PWM0 A, PWM0 B, PWM1 A...
- This repeats for GPIO16 to GPIO29. GPIO16 is PWM0 A, GPIO17 is PWM0 B, so on up to PWM6 B on GPIO29
- The same PWM output can be selected on two GPIO pins; the same signal will appear on each GPIO.

- If a PWM B pin is used as an input, and is selected on multiple GPIO pins, then the PWM slice will see the logical OR of those two GPIO inputs

4.6.2.1. Pulse Width Modulation

The PWM hardware functions by continuously comparing the input value to a free-running counter. This produces a toggling output where the amount of time spent at the high output level is proportional to the input value. The fraction of time spent at the high signal level is known as the duty cycle of the signal.

The counting period is controlled by the **TOP** register, with a maximum possible period of 65536 cycles, as the counter and **TOP** are 16 bits in size. The input values are configured via the **CC** register.

Figure 102. The counter repeatedly counts from 0 to TOP, forming a sawtooth shape. The counter is continuously compared with some input value. When the input value is higher than the counter, the output is driven high. Otherwise, the output is low. The output period T is defined by the TOP value of the counter, and how fast the counter is configured to count. The average output voltage, as a fraction of the IO power supply, is the input value divided by the counter period ($TOP + 1$)

This example shows the counting period and the A and B counter compare levels being configured on one of RP2040's PWM slices.

Pico Examples: https://github.com/raspberrypi/pico-examples/tree/pre_release/pwm/hello_pwm/hello_pwm.c Lines 18 - 33

```

18 // Tell GPIO 0 and 1 they are allocated to the PWM
19 gpio_set_function(0, GPIO_FUNC_PWM);
20 gpio_set_function(1, GPIO_FUNC_PWM);
21
22 // Find out which PWM slice is connected to GPIO 0 (it's slice 0)
23 pwm_inst_t slice = pwm_gpio_to_slice(0);
24
25 // Set period of 4 cycles (0 to 3 inclusive)
26 pwm_set_wrap(slice, 3);
27 // Set channel A output high for one cycle before dropping
28 pwm_set_chan_level(slice, PWM_CHAN_A, 1);
29 // Set initial B output high for three cycles before dropping
30 pwm_set_chan_level(slice, PWM_CHAN_B, 3);
31 // Set the PWM running
32 pwm_enable(slice, true);

```

Figure 103 shows how the PWM hardware operates once it has been configured in this way.

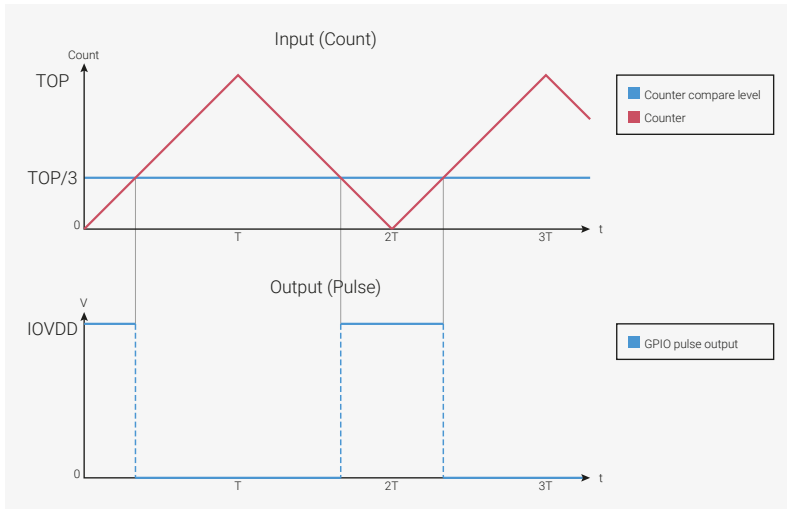

Figure 103. The slice counts repeatedly from 0 to 3, which is configured as the TOP value. The output waves therefore have a period of 4. Output A is high for 1 cycle in 4, so the average output voltage is 1/4 of the IO supply voltage. Output B is high for 3 cycles in every 4. Note the rising edges of A and B are always aligned.

The default behaviour of a PWM slice is to count upward until the value of the TOP register is reached, and then immediately wrap to 0. PWM slices also offer a phase-correct mode, enabled by setting CSR_PH_CORRECT to 1, where the counter starts to count downward after reaching TOP, until it reaches 0 again.

It is called phase-correct mode because the pulse is always centered on the same point, no matter the duty cycle. In other words, its phase is not a function of duty cycle. The output frequency is halved when phase-correct mode is enabled.

Figure 104. In phase-correct mode, the counter counts back down from TOP to 0 once it reaches TOP.

4.6.2.2. 0% and 100% Duty Cycle

The RP2040 PWM can produce toggle-free 0% and 100% duty cycle output.

Figure 105. Glitch-free 0% duty cycle output for $CC = 0$, and glitch-free 100% duty cycle output for $CC = TOP + 1$

A CC value of 0 will produce a 0% output, i.e. the output signal is always low. A CC value of $TOP + 1$ (i.e. equal to the period, in non-phase-correct mode) will produce a 100% output. For example, if TOP is programmed to 254, the counter will have a period of 255 cycles, and CC values in the range of 0 to 255 inclusive will produce duty cycles in the range 0% to 100% inclusive.

Glitch-free output at 0% and 100% is important e.g. to avoid switching losses when a MOSFET is controlled at its minimum and maximum current levels.

4.6.2.3. Double Buffering

Figure 106 shows how a change in input value will produce a change in output duty cycle. This can be used to approximate some analog waveform such as a sine wave.

Figure 106. The input value varies with each counter period: first $TOP / 3$, then $2 \times TOP / 3$, and finally $TOP + 1$ for 100% duty cycle. Each increase in the input value causes a corresponding increase in the output duty cycle.

In Figure 106, the input value only changes at the instant where the counter wraps through 0. Figure 107 shows what happens if the input value is allowed to change at any other time: an unwanted glitch is produced at the output.

Figure 107. The input value changes whilst the counter is mid-ramp. This produces additional toggling at the output.

The behaviour becomes even more perplexing if the **TOP** register is also modified. It would be difficult for software to write to **CC** or **TOP** with the correct timing. To solve this, each slice has two copies of the **CC** and **TOP** registers: one copy which software can modify, and another, internal copy which is updated from the first register at the instant the counter wraps. Software can modify its copy of the register at will, but the changes are not captured by the PWM output until the next wrap.

Figure 108 shows the sequence of events where a software interrupt handler changes the value of **CC_A** each time the counter wraps.

Figure 108. Each counter wrap causes the interrupt request signal to assert. The processor enters its interrupt handler, writes to its copy of the CC register, and clears the interrupt. When the counter wraps again, the latched version of the CC register is instantaneously updated with the most recent value written by software, and this value controls the duty cycle for the next period. The IRQ is reasserted so that software can write another fresh value to its copy of the CC register.

There is no limitation on what values can be written to **CC** or **TOP**, or when they are written. In normal PWM mode (**CSR_PH_CORRECT** is 0) the latched copies are updated when the counter wraps to 0, which occurs once every **TOP** + 1 cycles. In phase-correct mode (**CSR_PH_CORRECT** is 1), the latched copies are updated on the 0 to 0 count transition, i.e. the point where the counter stops counting downward and begins to count upward again.

4.6.2.4. Clock Divider

Each slice has a fractional clock divider, configured by the **DIV** register. This is an 8 integer bit, 4 fractional bit clock divider, which allows the count rate to be slowed by up to a factor of 256. The clock divider allows much lower output frequencies to be achieved – approximately 7.5 Hz from a 125 MHz system clock. Lower frequencies than this will require a system timer interrupt (Section 4.7)

It does this by generating an enable signal which gates the operation of the counter.

Figure 109. The clock divider generates an enable signal. The counter only counts on cycles where this signal is high. A clock divisor of 1 causes the enable to be asserted on every cycle, so the counter counts by one on every system clock cycle. Higher divisors cause the count enable to be asserted less frequently. Fractional division achieves an average fractional counting rate by spacing some enable pulses further apart than others.

The fractional divider is a first-order delta-sigma type.

The clock divider also allows the effective count range to be extended, when using level-sensitive or edge-sensitive modes to take duty cycle or frequency measurements.

4.6.2.5. Level-sensitive and Edge-sensitive Triggering

Figure 110. PWM slice event selection. The counter advances when its enable input is high, and this enable is generated in two sequential stages. First, any one of four event types (always on, pin B high, pin B rise, pin B fall) can generate enable pulses for the fractional clock divider. The divider can reduce the rate of the enable pulses, before passing them on to the counter.

By default, each slice's counter is free-running, and will count continuously whenever the slice is enabled. There are three other options available:

- Count continuously when a high level is detected on the B pin
- Count once with each rising edge detected on the B pin
- Count once with each falling edge detected on the B pin

These modes are selected by the `DIVMODE` field in each slice's `CSR`. In free-running mode, the A and B pins are both outputs. In any other mode, the B pin becomes an input, and controls the operation of the counter. `CC_B` is ignored when not in free-running mode.

By allowing the slice to run for a fixed amount of time in level-sensitive or edge-sensitive mode, it's possible to measure the duty cycle or frequency of an input signal. Due to the type of edge-detect circuit used, the low period and high period of the measured signal must both be strictly greater than the system clock period when taking frequency measurements.

The clock divider is still operational in level-sensitive and edge-sensitive mode. At maximum division (writing 0 to `DIV_INT`), the counter will only advance once per 256 high input cycles in level-sensitive modes, or once per 256 edges in edge-sensitive mode. This allows longer-running measurements to be taken, although the resolution is still just 16 bits.

Pico Examples: https://github.com/raspberrypi/pico-examples/tree/pre_release/pwm/measure_duty_cycle/measure_duty_cycle.c Lines 19 - 37

```

19 float measure_duty_cycle(uint gpio) {
20     // Only the PWM B pins can be used as inputs.
21     assert(pwm_gpio_to_channel(gpio) == PWM_CHAN_B);
22     pwm_inst_t slice = pwm_gpio_to_slice(gpio);
23
24     // Count once for every 100 cycles the PWM B input is high
25     pwm_config cfg = pwm_get_default_config();
26     pwm_config_divider_mode(&cfg, PWM_DIV_B_HIGH);
27     pwm_config_divider(&cfg, 100);
28     pwm_init(slice, &cfg, false);
29     gpio_set_function(gpio, GPIO_FUNC_PWM);
30
31     pwm_enable(slice, true);
32     sleep_ms(10);
33     pwm_enable(slice, false);
34     float counting_rate = clock_get_hz(clk_sys) / 100;
35     float max_possible_count = counting_rate * 0.01;
36     return pwm_get_counter(slice) / max_possible_count;
37 }

```

4.6.2.6. Configuring PWM Period

When free-running, the period of a PWM slice's output (measured in system clock cycles) is controlled by three parameters:

- The `TOP` register
- Whether phase-correct mode is enabled (`CSR_PH_CORRECT`)
- The `DIV` register

The slice counts from 0 to `TOP`, and then either wraps, or begins counting backward, depending on the setting of `CSR_PH_CORRECT`. The rate of counting is slowed by the clock divider, with a maximum speed of one count per cycle, and a

minimum speed of one count per $255\frac{15}{16}$ cycles. The period in clock cycles can be calculated as:

$$\text{period} = (\text{TOP} + 1) \times (\text{CSR_PH_CORRECT} + 1) \times \left(\text{DIV_INT} + \frac{\text{DIV_FRAC}}{16} \right)$$

The output frequency can then be determined based on the system clock frequency:

$$f_{PWM} = \frac{f_{sys}}{\text{period}} = \frac{f_{sys}}{(\text{TOP} + 1) \times (\text{CSR_PH_CORRECT} + 1) \times \left(\text{DIV_INT} + \frac{\text{DIV_FRAC}}{16} \right)}$$

4.6.2.7. Interrupt Request (IRQ) and DMA Data Request (DREQ)

The PWM block has a single IRQ output. The interrupt status registers `INTR`, `INTS` and `INTE` allow software to control which slices will assert this IRQ output, to check which slices are the cause of the IRQ's assertion, and to clear and acknowledge the interrupt.

A slice generates an interrupt request each time its counter wraps (or, if `CSR_PH_CORRECT` is enabled, each time the counter returns to 0). This sets the flag corresponding to this slice in the raw interrupt status register, `INTR`. If this slice's interrupt is enabled in `INTE`, then this flag will cause the PWM block's IRQ to be asserted, and the flag will also appear in the masked interrupt status register `INTS`.

Flags are cleared by writing a mask back to `INTR`. This is demonstrated in the "LED fade" Pico SDK example.

This scheme allows multiple slices to generate interrupts concurrently, and a system interrupt handler to determine which slices caused the most recent interruption, and handle appropriately. Normally this would mean reloading those slices' `TOP` or `CC` registers, but the PWM block can also be used as a source of regular interrupt requests for non-PWM-related purposes.

The same pulse which sets the interrupt flag in `INTR` is also available as a one-cycle data request to the RP2040 system DMA. For each cycle the DMA sees a DREQ asserted, it will make one data transfer to its programmed location, in as timely a manner as possible. In combination with the double-buffered behaviour of `CC` and `TOP`, this allows the DMA to efficiently stream data to a PWM slice at a rate of one transfer per counter period. Alternatively, a PWM slice could serve as a pacing timer for DMA transfers to some other memory-mapped hardware.

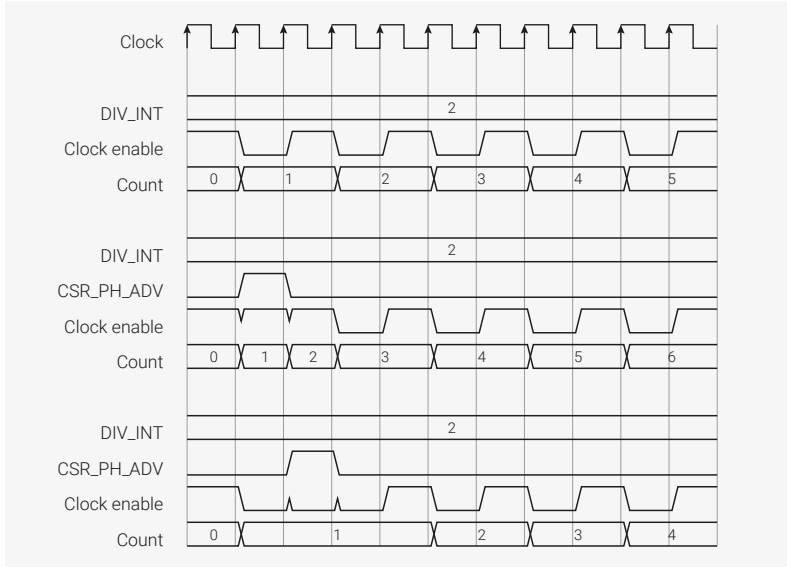

4.6.2.8. On-the-fly Phase Adjustment

For some applications it is necessary to control the phase relationship between two PWM outputs on different slices.

The global enable register `EN` contains an alias of the `CSR_EN` flag for each slice, and allows multiple slices to be started and stopped simultaneously. If two slices with the same output frequency are started at the same time, they will run in perfect lockstep, and have a fixed phase relationship, determined by the initial counter values.

The `CSR_PH_ADV` and `CSR_PH_RET` fields will advance or retard a slice's output phase by one count, whilst it is running. They do so by inserting or deleting pulses from the clock enable (the output of the clock divider), as shown in [Figure 111](#).

Figure 111. The clock enable signal, output by the clock divider, controls the rate of counting. Phase advance forces the clock enable high on cycles where it is low, causing the counter to jump forward by one count. Phase retard forces the clock enable low when it would be high, holding the counter back by one count.

The counter can not count faster than once per cycle, so PH_ADV requires DIV_INT > 1 or DIV_FRAC > 0. Likewise, the counter will not start to count backward if PH_RET is asserted when the clock enable is permanently low.

To advance or retard the phase by one count, software writes 1 to PH_ADV or PH_RET. Once an enable pulse has been inserted or deleted, the PH_ADV or PH_RET register bit will return to 0, and software can poll the CSR until this happens. PH_ADV will always insert a pulse into the next available gap, and PH_RET will always delete the next available pulse.

4.6.3. List Of Registers

Table 544. List of PWM registers

Offset	Name	Info
0x00	CH0_CSR	Control and status register
0x04	CH0_DIV	INT and FRAC form a fixed-point fractional number. Counting rate is system clock frequency divided by this number. Fractional division uses simple 1st-order sigma-delta.
0x08	CH0_CTR	Direct access to the PWM counter
0x0c	CH0_CC	Counter compare values
0x10	CH0_TOP	Counter wrap value
0x14	CH1_CSR	Control and status register

4.7. Timer

4.7.1. Overview

The timer peripheral on RP2040 supports the following features:

- A single 64-bit counter, incrementing once per microsecond with the reference generated in the Watchdog (see [Section 4.8.2](#)).
- This counter can be read from a pair of latching registers, for race-free reads over a 32-bit bus.
- Four alarms: match on the lower 32 bits of counter, IRQ on match.

Also note that each Cortex M0+ (see [Cortex-M0+](#)) is equipped with a 24-bit SysTick timer. This can be used to interrupt itself.

The timer uses a one microsecond reference that is generated in the Watchdog (see [Section 4.8.2](#)) which comes from `clk_ref`.

4.7.2. Counter

The timer has a 64-bit counter, but RP2040 only has a 32-bit data bus. This means that the `TIME` value is accessed through a pair of registers. These are:

- `TIMEHW` and `TIMELW` to write the time
- `TIMEHR` and `TIMELR` to read the time

These pairs are used by accessing the lower register, `L`, followed by the higher register, `H`. In the read case, reading the `L` register latches the value in the `H` register so that an accurate time can be read. Alternatively, `TIMERAWH` and `TIMERAWL`

can be used to read the raw time without any latching.

⚠ WARNING

While it is technically possible to set the time by writing to the `TIMEHW` and `TIMELW` registers, programmers are discouraged from doing this. This is because the timer value is expected to be monotonically increasing (with a 64-bit wrap) by the Pico SDK which uses it for timeouts, elapsed time etc.

4.7.3. Alarms

The timer has 4 alarms, and outputs a separate interrupt for each alarm. The alarms match on the lower 32 bits of the 64-bit counter which means they can be fired at a maximum of 2^{32} microseconds into the future. This is equivalent to:

- $2^{32} \div 10^6$: ~4295 seconds
- $4295 \div 60$: ~72 minutes

ℹ NOTE

This timer is expected to be used for short sleeps. If you want a longer alarm see [Section 4.9](#).

To enable an alarm:

- Enable the interrupt at the timer with a write to the appropriate alarm bit in `INTE`: i.e. `(1 << 0)` for `ALARM0`
- Enable the appropriate timer interrupt at the processor (see [Section 2.3.2](#))
- Write the time you would like the interrupt to fire to `ALARM0` (i.e. the current value in `TIMERAWL` plus your desired alarm time in microseconds). Writing the time to the `ALARM` register sets the `ARMED` bit as a side effect.

Once the alarm has fired, the `ARMED` bit will be set to `0`. To clear the latched interrupt, write a `1` to the appropriate bit in `INTR`.

4.7.4. Programmer's Model

ℹ NOTE

The Watchdog tick (see [Section 4.8.2](#)) must be running for the timer to start counting. The Pico SDK starts this tick at the start of day.

4.7.4.1. Reading the time

ℹ NOTE

Time here refers to the number of microseconds since the timer was started, it is not a clock. For that - see [Section 4.9](#).

The simplest form of reading the 64-bit time is to read `TIMELR` followed by `TIMEHR`. However, because RP2040 has 2 cores, it is unsafe to do this if the second core is executing code that can also access the timer. This is because reading `TIMELR` latches the value in `TIMEHR` (i.e. stops it updating) until `TIMEHR` is read. If one core reads `TIMELR` followed by another core reading `TIMELR`, the value in `TIMEHR` isn't necessarily accurate. The example below shows the simplest form of getting the 64-bit time.

Pico Examples: https://github.com/raspberrypi/pico-examples/tree/pre_release/timer/timer_lowlevel/timer_lowlevel.c Lines 13 - 21

```

13 // Simplest form of getting 64 bit time from the timer.
14 // It isn't safe when called from 2 cores because of the latching
15 // so isn't implemented this way in the sdk
16 static uint64_t get_time(void) {
17     // Reading low latches the high value
18     uint32_t lo = timer_hw->timelr;
19     uint32_t hi = timer_hw->timehr;
20     return ((uint64_t) hi << 32u) | lo;
21 }

```

The Pico SDK provides a `time_us_64` function that uses a more thorough method to get the 64-bit time, which makes use of the `TIMERAWH` and `TIMERAWL` registers. The `RAW` registers don't latch, and therefore make `time_us_64` safe to call from multiple cores at once.

Pico SDK: https://github.com/raspberrypi/pico-sdk/tree/pre_release/src/rp2_common/hardware_timer/timer.c Lines 33 - 49

```

33 uint64_t time_us_64() {
34     // Need to make sure that the upper 32 bits of the timer
35     // don't change, so read that first
36     uint32_t hi = timer_hw->t看merawh;
37     uint32_t lo;
38     do {
39         // Read the lower 32 bits
40         lo = timer_hw->timerawl;
41         // Now read the upper 32 bits again and
42         // check that it hasn't incremented. If it has loop around
43         // and read the lower 32 bits again to get an accurate value
44         uint32_t next_hi = timer_hw->timerawh;
45         if (hi == next_hi) break;
46         hi = next_hi;
47     } while (true);
48     return ((uint64_t) hi << 32u) | lo;
49 }

```

4.7.4.2. Set an alarm

The standalone timer example, `timer_lowlevel`, demonstrates how to set an alarm at a hardware level, without the additional abstraction over the timer that the Pico SDK provides. To use these abstractions see [Section 4.7.4.4](#).

Pico Examples: https://github.com/raspberrypi/pico-examples/tree/pre_release/timer/timer_lowlevel/timer_lowlevel.c Lines 25 - 72

```

25 // Use alarm 0
26 #define ALARM_NUM 0
27 #define ALARM_IRQ TIMER_IRQ_0
28
29 // Alarm interrupt handler
30 static volatile bool alarm_fired;
31
32 static void alarm_irq(void) {
33     // Clear the alarm irq
34     hw_clear_bits(&timer_hw->intr, 1u << ALARM_NUM);
35
36     // Assume alarm 0 has fired
37     printf("Alarm IRQ fired\n");
38     alarm_fired = true;
39 }

```

```

40
41 static void alarm_in_us(uint32_t delay_us) {
42     // Enable the interrupt for our alarm (the timer outputs 4 alarm irqs)
43     hw_set_bits(&timer_hw->inte, 1u << ALARM_NUM);
44     // Set irq handler for alarm irq
45     irq_set_exclusive_handler(ALARM_IRQ, alarm_irq);
46     // Enable the alarm irq
47     irq_enable(ALARM_IRQ, true);
48     // Enable interrupt in block and at processor
49
50     // Alarm is only 32 bits so if trying to delay more
51     // than that need to be careful and keep track of the upper
52     // bits
53     uint64_t target = timer_hw->timerawl + delay_us;
54
55     // Write the lower 32 bits of the target time to the alarm which
56     // will arm it
57     timer_hw->alarm[ALARM_NUM] = (uint32_t) target;
58 }
59
60 int main() {
61     setup_default_uart();
62     printf("Timer lowlevel!\n");
63
64     // Set alarm every 2 seconds
65     while (1) {
66         alarm_fired = false;
67         alarm_in_us(1000000 * 2);
68         // Wait for alarm to fire
69         while (!alarm_fired);
70     }
71 }

```

4.7.4.3. Busy wait

If you don't want to use an alarm to wait for a period of time, instead use a while loop. The Pico SDK provides various `busy_wait_` functions to do this:

Pico SDK: https://github.com/raspberrypi/pico-sdk/tree/pre_release/src/rp2_common/hardware_timer/timer.c Lines 53 - 81

```

53 void busy_wait_us_31(uint32_t delay_us) {
54     // we only allow 31 bits, otherwise we could have a race in the loop below with
55     // values very close to 2^32
56     assert(0 <= (int32_t)delay_us);
57     uint32_t start = timer_hw->timerawl;
58     while (timer_hw->timerawl - start < delay_us) {
59         tight_loop_contents();
60     }
61 }
62
63 void busy_wait_us(uint64_t delay_us) {
64     absolute_time_t t;
65     update_us_since_boot(&t, time_us_64() + delay_us);
66     busy_wait_until(t);
67 }
68
69 void busy_wait_until(absolute_time_t t) {
70     uint64_t target = to_us_since_boot(t);
71     uint32_t hi_target = target >> 32u;
72     uint32_t hi = timer_hw->timerawh;

```

```

73  while (hi < hi_target) {
74      hi = timer_hw->timerawh;
75      tight_loop_contents();
76  }
77  while (hi == hi_target && timer_hw->timerawl < (uint32_t) target) {
78      hi = timer_hw->timerawh;
79      tight_loop_contents();
80  }
81  }

```

4.7.4.4. Complete example using Pico SDK

Pico Examples: https://github.com/raspberrypi/pico-examples/tree/pre_release/timer/hello_timer/hello_timer.c Lines 11 - 57

```

11  volatile bool timer_fired = false;
12
13  int64_t alarm_callback(alarm_id_t id, void *user_data) {
14      printf("Timer %d fired!\n", (int) id);
15      timer_fired = true;
16      // Can return a value here in us to fire in the future
17      return 0;
18  }
19
20  bool repeating_timer_callback(struct repeating_timer *t) {
21      printf("Repeat at %lld\n", time_us_64());
22      return true;
23  }
24
25  int main() {
26      setup_default_uart();
27      printf("Hello Timer!\n");
28
29      // Call alarm_callback in 2 seconds
30      add_alarm_in_ms(2000, alarm_callback, NULL, false);
31
32      // Wait for alarm callback to set timer_fired
33      while (!timer_fired) {
34          tight_loop_contents();
35      }
36
37      // Create a repeating timer that calls repeating_timer_callback.
38      // If the delay is > 0 then this is the delay between the previous callback ending and the
39      // next starting.
40      // If the delay is negative (see below) then the next call to the callback will be exactly
41      // 500ms after the
42      // start of the call to the last callback
43      struct repeating_timer timer;
44      add_repeating_timer_ms(500, repeating_timer_callback, NULL, &timer);
45      sleep_ms(3000);
46      bool cancelled = cancel_repeating_timer(&timer);
47      printf("cancelled... %d\n", cancelled);
48      sleep_ms(2000);
49
50      // Negative delay so means we will call repeating_timer_callback, and call it again
51      // 500ms later regardless of how long the callback took to execute
52      add_repeating_timer_ms(-500, repeating_timer_callback, NULL, &timer);
53      sleep_ms(3000);
54      cancelled = cancel_repeating_timer(&timer);
55      printf("cancelled... %d\n", cancelled);
56      sleep_ms(2000);

```

```

55     printf("Done\n");
56     return 0;
57 }
    
```

4.7.5. List of Registers

Table 555. List of TIMER registers

Offset	Name	Info
0x00	TIMEHW	Write to bits 63:32 of time always write timelw before timehw
0x04	TIMELW	Write to bits 31:0 of time writes do not get copied to time until timehw is written
0x08	TIMEHR	Read from bits 63:32 of time always read timelr before timehr
0x0c	TIMELR	Read from bits 31:0 of time
0x10	ALARM0	Arm alarm 0, and configure the time it will fire. Once armed, the alarm fires when <code>TIMER_ALARM0 == TIMELR</code> . The alarm will disarm itself once it fires, and can be disarmed early using the ARMED status register.
0x14	ALARM1	Arm alarm 1, and configure the time it will fire. Once armed, the alarm fires when <code>TIMER_ALARM1 == TIMELR</code> . The alarm will disarm itself once it fires, and can be disarmed early using the ARMED status register.
0x18	ALARM2	Arm alarm 2, and configure the time it will fire. Once armed, the alarm fires when <code>TIMER_ALARM2 == TIMELR</code> . The alarm will disarm itself once it fires, and can be disarmed early using the ARMED status register.
0x1c	ALARM3	Arm alarm 3, and configure the time it will fire. Once armed, the alarm fires when <code>TIMER_ALARM3 == TIMELR</code> . The alarm will disarm itself once it fires, and can be disarmed early using the ARMED status register.
0x20	ARMED	Indicates the armed/disarmed status of each alarm. A write to the corresponding ALARMx register arms the alarm. Alarms automatically disarm upon firing, but writing ones here will disarm immediately without waiting to fire.
0x24	TIMERAWH	Raw read from bits 63:32 of time (no side effects)
0x28	TIMERAWL	Raw read from bits 31:0 of time (no side effects)
0x2c	DBGPAUSE	Set bits high to enable pause when the corresponding debug ports are active
0x30	PAUSE	Set high to pause the timer
0x34	INTR	Raw Interrupts
0x38	INTE	Interrupt Enable
0x3c	INTF	Interrupt Force
0x40	INTS	Interrupt status after masking & forcing

TIMEHW Register

Description

Write to bits 63:32 of time
always write timelw before timehw

Table 556. TIMEHW Register

Bits	Name	Description	Type	Reset
31:0	NONAME		WF	0x00000000

TIMELW Register**Description**

Write to bits 31:0 of time
writes do not get copied to time until timehw is written

Table 557. TIMELW Register

Bits	Name	Description	Type	Reset
31:0	NONAME		WF	0x00000000

TIMEHR Register**Description**

Read from bits 63:32 of time
always read timelr before timehr

Table 558. TIMEHR Register

Bits	Name	Description	Type	Reset
31:0	NONAME		RO	0x00000000

TIMELR Register**Description**

Read from bits 31:0 of time

Table 559. TIMELR Register

Bits	Name	Description	Type	Reset
31:0	NONAME		RO	0x00000000

ALARM0 Register**Description**

Arm alarm 0, and configure the time it will fire.
Once armed, the alarm fires when `TIMER_ALARM0 == TIMELR`.
The alarm will disarm itself once it fires, and can
be disarmed early using the ARMED status register.

Table 560. ALARM0 Register

Bits	Name	Description	Type	Reset
31:0	NONAME		RW	0x00000000

ALARM1 Register**Description**

Arm alarm 1, and configure the time it will fire.
Once armed, the alarm fires when `TIMER_ALARM1 == TIMELR`.
The alarm will disarm itself once it fires, and can
be disarmed early using the ARMED status register.

Table 561. ALARM1 Register

Bits	Name	Description	Type	Reset
31:0	NONAME		RW	0x00000000

ALARM2 Register

Description

Arm alarm 2, and configure the time it will fire.
 Once armed, the alarm fires when `TIMER_ALARM2 == TIMELR`.
 The alarm will disarm itself once it fires, and can be disarmed early using the ARMED status register.

Table 562. ALARM2 Register

Bits	Name	Description	Type	Reset
31:0	NONAME		RW	0x00000000

ALARM3 Register

Description

Arm alarm 3, and configure the time it will fire.
 Once armed, the alarm fires when `TIMER_ALARM3 == TIMELR`.
 The alarm will disarm itself once it fires, and can be disarmed early using the ARMED status register.

Table 563. ALARM3 Register

Bits	Name	Description	Type	Reset
31:0	NONAME		RW	0x00000000

ARMED Register

Description

Indicates the armed/disarmed status of each alarm.
 A write to the corresponding ALARMx register arms the alarm.
 Alarms automatically disarm upon firing, but writing ones here will disarm immediately without waiting to fire.

Table 564. ARMED Register

Bits	Name	Description	Type	Reset
31:4	Reserved.	-	-	-
3:0	NONAME		WC	0x0

TIMERAWH Register

Description

Raw read from bits 63:32 of time (no side effects)

Table 565. TIMERAWH Register

Bits	Name	Description	Type	Reset
31:0	NONAME		RO	0x00000000

TIMERAWL Register

Description

Raw read from bits 31:0 of time (no side effects)

Table 566. TIMERAWL Register

Bits	Name	Description	Type	Reset
31:0	NONAME		RO	0x00000000

DBGPAUSE Register

Description

Set bits high to enable pause when the corresponding debug ports are active

Table 567. DBGPAUSE Register

Bits	Name	Description	Type	Reset
31:3	Reserved.	-	-	-
2	DBG1	Pause when processor 1 is in debug mode	RW	0x1
1	DBG0	Pause when processor 0 is in debug mode	RW	0x1
0	Reserved.	-	-	-

PAUSE Register

Description

Set high to pause the timer

Table 568. PAUSE Register

Bits	Name	Description	Type	Reset

1	ALARM_1		RO	0x0
0	ALARM_0		RO	0x0

4.8. Watchdog

4.8.1. Overview

The watchdog is a countdown timer that can restart parts of the chip if it reaches zero. This can be used to restart the processor if software gets stuck in an infinite loop. The programmer must periodically write a value to the watchdog to stop it from reaching zero.

The watchdog is reset by `rst_n_run`, which is deasserted as soon as the digital core supply (DVDD) is powered and stable, and the RUN pin is high. This allows the watchdog reset to feed into the power-on state machine (see [Power-On State Machine](#)) and reset controller (see [Subsystem Resets](#)), resetting their dependants if they are selected in the `WDSEL` register. The `WDSEL` register exists in both the power-on state machine and reset controller.

4.8.2. Tick generation

The watchdog reference clock, `clk_tick`, is driven from `clk_ref`. Ideally `clk_ref` will be configured to use the [Crystal Oscillator](#) so that it provides an accurate reference clock. The reference clock is divided internally to generate a tick (nominally 1µs) to use as the watchdog tick. The tick is configured using the `TICK` register.

NOTE

To avoid duplicating logic, this tick is also distributed to the timer (see [Section 4.7](#)) and used as the timer reference.

The Pico SDK starts the watchdog tick at the start of day in `clocks_init`:

Pico SDK: https://github.com/raspberrypi/pico-sdk/tree/pre_release/src/rp2_common/hardware_watchdog/watchdog.c Lines 16 - 19

```
16 void watchdog_start_tick(uint cycles) {
17     // Important: This function also provides a tick reference to the timer
18     watchdog_hw->tick = cycles | WATCHDOG_TICK_ENABLE_BITS;
19 }
```

4.8.3. Watchdog Counter

The watchdog counter is loaded by the `LOAD` register. The current value can be seen in `CTRL.TIME`.

WARNING

Due to a logic error, the watchdog counter is decremented twice per tick. Which means the programmer needs to program double the intended count down value. The Pico SDK examples take this issue into account. See [RP2040-E1](#) for more information.

4.8.4. Scratch Registers

The watchdog contains eight 32-bit scratch registers that can be used to store information between soft resets of the chip. A `rst_n_run` event triggered by toggling the RUN pin or cycling the digital core supply (DVDD) will reset the scratch registers.

The bootrom checks the watchdog scratch registers for a magic number on boot. This can be used to soft reset the chip into some user specified code. See [Section 2.7.2.1](#) for more information.

4.8.5. Programmer's Model

The Pico SDK provides a `hardware_watchdog` driver to control the watchdog.

4.8.5.1. Enabling the watchdog

Pico SDK: https://github.com/raspberrypi/pico-sdk/tree/pre_release/src/rp2_common/hardware_watchdog/watchdog.c Lines 36 - 64

```
36 // Helper function used by both watchdog_enable and watchdog_reboot
37 void _watchdog_enable(uint32_t delay_ms, bool pause_on_debug) {
38     hw_clear_bits(&watchdog_hw->ctrl, WATCHDOG_CTRL_ENABLE_BITS);
39
40     // Reset everything apart from R0SC and X0SC
41     hw_set_bits(&psm_hw->wdsel, PSM_WDSEL_BITS & ~(PSM_WDSEL_ROSC_BITS |
42     PSM_WDSEL_X0SC_BITS));
43     uint32_t dbg_bits = WATCHDOG_CTRL_PAUSE_DBG0_BITS |
44     WATCHDOG_CTRL_PAUSE_DBG1_BITS |
45     WATCHDOG_CTRL_PAUSE_JTAG_BITS;
46
47     if (pause_on_debug) {
```

```

48     hw_set_bits(&watchdog_hw->ctrl, dbg_bits);
49 } else {
50     hw_clear_bits(&watchdog_hw->ctrl, dbg_bits);
51 }
52
53 if (!delay_ms) delay_ms = 50;
54
55 if (delay_ms > 0x7fffff)
56     delay_ms = 0x7fffff;
57
58 // Note, we have x2 here as the watchdog HW currently decrements twice per tick
59 load_value = delay_ms * 1000 * 2;
60
61 watchdog_update();
62
63 hw_set_bits(&watchdog_hw->ctrl, WATCHDOG_CTRL_ENABLE_BITS);
64 }

```

4.8.5.2. Updating the watchdog counter

Pico SDK: https://github.com/raspberrypi/pico-sdk/tree/pre_release/src/rp2_common/hardware_watchdog/watchdog.c Lines 25 - 28

```

25 static uint32_t load_value;
26 void watchdog_update(void) {
27     watchdog_hw->load = load_value;
28 }

```

4.8.5.3. Usage

The Pico Examples repository provides a `hello_watchdog` example that uses the `hardware_watchdog` to demonstrate use of the watchdog.

Pico Examples: https://github.com/raspberrypi/pico-examples/tree/pre_release/watchdog/hello_watchdog/hello_watchdog.c Lines 11 - 33

```

11 int main() {
12     setup_default_uart();
13
14     if (watchdog_caused_reboot()) {
15         printf("Rebooted by Watchdog!\n");
16         return 0;
17     } else {
18         printf("Clean boot\n");
19     }
20
21     // Enable the watchdog, requiring the watchdog to be updated every 100ms or the chip will
    reboot
22     // second arg is pause on debug which means the watchdog will pause when stepping through
    code
23     watchdog_enable(100, 1);
24
25     for (uint i = 0; i < 5; i++) {
26         printf("Updating watchdog %d\n", i);
27         watchdog_update();
28     }
29
30     // Wait in an infinite loop and don't update the watchdog so it reboots us
31     printf("Waiting to be rebooted by watchdog\n");

```

```

32   while(1);
33 }
    
```

4.8.6. List of registers

Table 573. List of WATCHDOG registers

Offset	Name	Info
0x00	CTRL	Watchdog control The rst_wdsel register determines which subsystems are reset when the watchdog is triggered. The watchdog can be triggered in software.
0x04	LOAD	Load the watchdog timer. The maximum setting is 0xfffff which corresponds to 0xfffff / 2 ticks before triggering a watchdog reset (see errata RP2040-E1).
0x08	REASON	Logs the reason for the last reset. Both bits are zero for the case of a hardware reset.
0x0c	SCRATCH0	Scratch register. Information persists through soft reset of the chip.
0x10	SCRATCH1	Scratch register. Information persists through soft reset of the chip.
0x14	SCRATCH2	Scratch register. Information persists through soft reset of the chip.
0x18	SCRATCH3	Scratch register. Information persists through soft reset of the chip.
0x1c	SCRATCH4	Scratch register. Information persists through soft reset of the chip.
0x20	SCRATCH5	Scratch register. Information persists through soft reset of the chip.
0x24	SCRATCH6	Scratch register. Information persists through soft reset of the chip.
0x28	SCRATCH7	Scratch register. Information persists through soft reset of the chip.
0x2c	TICK	Controls the tick generator

CTRL Register

Description

Watchdog control

The rst_wdsel register determines which subsystems are reset when the watchdog is triggered.

The watchdog can be triggered in software.

Table 574. CTRL Register

Bits	Name	Description	Type	Reset
31	TRIGGER	Trigger a watchdog reset	SC	0x0
30	ENABLE	When not enabled the watchdog timer is paused	RW	0x0
29:27	Reserved.	-	-	-

Bits	Name	Description	Type	Reset
26	PAUSE_DBG1	Pause the watchdog timer when processor 1 is in debug mode	RW	0x1
25	PAUSE_DBG0	Pause the watchdog timer when processor 0 is in debug mode	RW	0x1
24	PAUSE_JTAG	Pause the watchdog timer when JTAG is accessing the bus fabric	RW	0x1
23:0	TIME	Indicates the number of ticks / 2 (see errata RP2040-E1) before a watchdog reset will be triggered	RO	0x000000

LOAD Register

Description

Load the watchdog timer. The maximum setting is 0xfffff which corresponds to 0xfffff / 2 ticks before triggering a watchdog reset (see errata RP2040-E1).

Table 575. LOAD Register

Bits	Name	Description	Type	Reset
31:24	Reserved.	-	-	-
23:0	NONAME		WF	0x000000

REASON Register

Description

Logs the reason for the last reset. Both bits are zero for the case of a hardware reset.

Table 576. REASON Register

Bits	Name	Description	Type	Reset
31:2	Reserved.	-	-	-
1	FORCE		RO	0x0
0	TIMER		RO	0x0

SCRATCH0, SCRATCH1, ..., SCRATCH6, SCRATCH7 Registers

Description

Scratch register. Information persists through soft reset of the chip.

Table 577. SCRATCH0, SCRATCH1, ..., SCRATCH6, SCRATCH7 Registers

Bits	Name	Description	Type	Reset
31:0	NONAME		RW	0x00000000

TICK Register

Description

Controls the tick generator

Table 578. TICK Register

Bits	Name	Description	Type	Reset
31:20	Reserved.	-	-	-
19:11	COUNT	Count down timer: the remaining number clk_tick cycles before the next tick is generated.	RO	-
10	RUNNING	Is the tick generator running?	RO	-
9	ENABLE	start / stop tick generation	RW	0x1

Bits	Name	Description	Type	Reset
8:0	CYCLES	Total number of clk_tick cycles before the next tick.	RW	0x000

4.9. RTC

The Real-time Clock (RTC) provides time in human-readable format and can be set to generate events at specific times.

Time is stored in binary, separated in seven fields:

Table 579. RTC storage format

Date/Time Field	Size	Legal values
Year	12 bits	0..4095
Month	4 bits	1..12
Day	5 bits	1..[28,29,30,31], depending on the month
Day of Week	3 bits	0..6. Sunday = 0
Hour	5 bits	0..23
Minute	6 bits	0..59
Seconds	6 bits	0..59

The RTC does not check values. Illegal values may cause unexpected behaviours.

The RTC uses a reference clock `clk_rtc`, which should be set to any integer frequency in the range 1...65536 Hz.

The internal 1 Hz reference is derived internally with an integer divider. Program the desired division value minus 1 through `CLKDIV_M1`.

The `clk_rtc` can be driven either from an internal or external clock source. Those sources can be prescaled, using a fractional divider (see [Clocks](#)).

NOTE

All RTC register reads and writes are done from the processor clock domain `clk_sys`. All data are synchronised back and forth between the domains. Writing to the RTC will take 2 `clk_rtc` clock periods to arrive, additional to the `clk_sys` domain. This should be taken into account especially when the reference is slow (e.g. 1 Hz)

Useful examples:

1. Select XOSC 12MHz, divide externally by 256, set `CLKDIV_M1` = 46874.
2. If the crystal is not exactly 12MHz, but very close, set a fractional value to get `clk_rtc` as close as possible to 46875 Hz.
3. Use an external reference from a GPS, which generates one pulse per second. Bypass the divider external to the rtc and set `CLKDIV_M1` = 0

TO DO: LIAM/ANDRAS: Seems like this would be a good place for some example code

4.9.1. Day of the week

Day of the week is encoded as Sun 0, Mon 1, ..., Sat 6 (i.e. ISO8601 mod 7).

There is no built-in calendar function. The chip will not compute the correct day of the week; it will only increment the existing value.

4.9.2. Leap year

If the current value of `YEAR` in `SETUP_0` is evenly divisible by 4, a leapyear is detected, and Feb 28th is followed by Feb 29th, not March 1st. Since this is not always true (century years for example), the leapyear checking can be forced off by setting the `CTRL.FORCE_NOTLEAPYEAR`. The next occurrence when this should happen is in year 2100.

i NOTE

The leap year check is done only when needed (the second following Feb 28, 23:59:59). The software can set `FORCE_NOTLEAPYEAR` anytime after 2096 Mar 1 00:00:00 as long as it arrives before 2100 Feb 28 23:59:59 (i.e. taking into account the clock domain crossing latency)

4.9.3. Interrupt

One can set up a time in the future, which, when reached, will cause the RTC to generate an interrupt. There is a global bit, `MATCH_ENA` in `IRQ_SETUP_0` to enable this feature, and individual enables for each time field (year, month, day, day-of-the-week, hour, minute, second). The individual enables can be used to implement repeating interrupts at specified times (TO DO: LIAM/ANDRAS: sample code would be a useful illustration of this concept. e.g. to do something every Monday at 11:00 am, enable matching on day of the week, hour, minute, second fields and set those fields to the desired values).

The alarm interrupt is sent to the processors and also to the ROOSC and XOSC to wake them from dormant mode. See Section 4.9.4.6 for more information.

4.9.4. How to use the RTC

There are three setup tasks:

- Set the 1 sec reference
- Set the clock
- Set an alarm

TO DO: LIAM/ANDRAS: sample code for each of these tasks would be awesome. I note sample code is included below in "programmer" section - I'd suggest transferring the following narratives to comments in the code samples and referencing that code. As is, these narratives are confusing.

4.9.4.1. Setup of the 1 second reference:

Select the source for `clk_rtc`. This is done outside the RTC registers.

From XOSC

Set up the clock divider in the `clk_rtc` clock slice to 256. This will give us a `clk_rtc` of 46875Hz. Disable the RTC. Check status, to confirm that RTC is not running. Then load decimal 46874 to `CLKDIV_M1`.

From GPIN

Assume we have an external reference of 32768Hz. Disable the RTC. Check status, to confirm that RTC is not running. Load decimal 32767 to `CLKDIV_M1`.

NOTE

While it is possible to change the `CLKDIV_M1` on the fly, it is not recommended.

4.9.4.2. Setting up the clock

Write a near-future time to RTC setup registers. Write a 1 to the LOAD bit in the `CTRL` register, (this bit is self-clearing). Then, at the appropriate time, enable the RTC using the ENABLE bit in the `CTRL` register. The `RTC_ACTIVE` bit in `CTRL` can be read to confirm the RTC is running.

4.9.4.2.1. Adjusting the clock while running

It is possible to change the current time while the RTC is running. Write the desired values, then set the LOAD bit in the `CTRL` register.

4.9.4.3. Reading the current time

TO DO: LIAM/ANDRAS: Sample code? Not all the time fields fit into one register read. To ensure a consistent value, we need to read register `RTC_0` first and `RTC_1` after, in this order. Reading `RTC_0` will read the live value and save a copy of the data needed for `RTC_1`.

4.9.4.4. One-off alarm

TO DO: LIAM/ANDRAS: Sample code? Let's say we want to set up an alarm for the 2026 solar eclipse (https://moonblink.info/Eclipse/eclipse/2026_08_12). The total eclipse begins at 16:57:54 UT on 12 August, 2026. Write the desired value into the setup_irq registers. No need to write the day of the week, it is redundant in this case. Enable matching on all fields except for the day of the week, and enable global matching. Obviously, the RTC interrupt should be enabled in the processor as well (outside the scope of this note)

Disable matching with an atomic write:

```
IRQ_SETUP_0.MATCH_ENA = 0
```

and wait until the status confirms that the matching became inactive

```
IRQ_SETUP_0.MATCH_ACTIVE = 0
```

Now it is safe to program the registers:

```
IRQ_SETUP_1.DOTW_ENA = 0
IRQ_SETUP_1.HOUR_ENA = 1
IRQ_SETUP_1.MIN_ENA = 1
IRQ_SETUP_1.SEC_ENA = 1
IRQ_SETUP_1.HOUR = 16
IRQ_SETUP_1.MIN = 57
IRQ_SETUP_1.SEC = 54
IRQ_SETUP_0.YEAR_ENA = 1
IRQ_SETUP_0.MONTH_ENA = 1
IRQ_SETUP_0.DAY_ENA = 1
IRQ_SETUP_0.YEAR = 2026
IRQ_SETUP_0.MONTH = 8
IRQ_SETUP_0.DAY = 12
```

Now, enable matching with an atomic write

```
IRQ_SETUP_0.MATCH_ENA = 1
```

and wait until the status confirms that the matching became active

```
IRQ_SETUP_0.MATCH_ACTIVE = 1
```

NOTE

The enable matching step can be done during the write to `IRQ_SETUP_0`, as long as it happens after the write to `IRQ_SETUP_1`

4.9.4.5. Recurring alarm

TO DO: LIAM/ANDRAS: sample code? The interrupt setup registers are used to set a specific date and time for an interrupt to happen.

To set up a recurring alarm for every Monday at 11:00am:

Turn off global matching. `IRQ_SETUP_0`

Disable matching with an atomic write: `IRQ_SETUP_0.MATCH_ENA = 0`

and wait until the status confirms that the matching became inactive

```
IRQ_SETUP_0.MATCH_ACTIVE = 0
```

Now it is safe to program the registers:

```
IRQ_SETUP_1.DOTW_ENA = 1
```

```
IRQ_SETUP_1.HOUR_ENA = 1
```

```
IRQ_SETUP_1.MIN_ENA = 1
```

```
IRQ_SETUP_1.DOTW = 1
```

```
IRQ_SETUP_1.HOUR = 11
```

```
IRQ_SETUP_1.MIN = 0
```

Now, enable matching with an atomic write

```
IRQ_SETUP_0.MATCH_ENA = 1
```

and wait until the status confirms that the matching became active

```
IRQ_SETUP_0.MATCH_ACTIVE = 1
```

4.9.4.6. Interaction with Dormant / Sleep mode

RP2040 supports two power saving levels:

- Sleep mode, where the processors are asleep and the unused clocks in the chip are stopped (see [Section 2.14.3.4](#))
- Dormant mode, where all clocks in the chip are stopped

The RTC can wake the chip up from both of these modes. In sleep mode, RP2040 can be configured such that only `clk_rtc` (a slow RTC reference clock) is running, as well as a small amount of logic that allows the processor to wake back up. The processor is woken from sleep mode when the RTC alarm interrupt fires. See [Section 2.10.5.1](#) for more information.

To wake the chip from dormant mode, the RTC must be configured to use an external reference clock (supplied by a GPIO pin) **TO DO: LIAM/ANDRAS: sample code?** * Set up the RTC to run on an external reference * If the processor is running off the PLL, change it to run from XOSC/ROSC * Turn off the PLLs * Set up the RTC with the desired wake up time (one off, or recurring) * (optionally) power down most memories * Invoke DORMANT mode (see [Crystal Oscillator](#), [Ring Oscillator](#), and [Section 2.10.5.2](#) for more information)

4.9.5. Programmer's Model

4.9.5.1. Initialise the RTC

Pico SDK: https://github.com/raspberrypi/pico-sdk/tree/pre_release/src/rp2_common/hardware_rtc/rtc.c Lines 21 - 43

```

21 int rtc_init(void) {
22     // Get clk_rtc freq and make sure it is running
23     uint rtc_freq = clock_get_hz(clk_rtc);
24     if (rtc_freq == 0) {
25         return -1;
26     }
27
28     // Take rtc out of reset now that we know clk_rtc is running
29     reset_block(RESETS_RESET_RTC_BITS);
30     unreset_block_wait(RESETS_RESET_RTC_BITS);
31
32     // Set up the 1 second divider.
33     // If rtc_freq is 400 then clkdiv_m1 should be 399
34     rtc_freq -= 1;
35
36     // Check the freq is not too big to divide
37     assert(rtc_freq <= RTC_CLKDIV_M1_BITS);
38
39     // Write divide value
40     rtc_hw->clkdiv_m1 = rtc_freq;
41
42     return 0;
43 }

```

4.9.5.2. Set the time

Pico SDK: https://github.com/raspberrypi/pico-sdk/tree/pre_release/src/rp2_common/hardware_rtc/rtc.c Lines 58 - 89

```

58 int rtc_set_datetime(datetime_t *t) {
59     if (!valid_datetime(t)) {
60         return -1;
61     }
62
63     // Disable RTC
64     rtc_hw->ctrl = 0;
65     // Wait while it is still active
66     while (rtc_running()) {
67         tight_loop_contents();
68     }
69
70     // Write to setup registers
71     rtc_hw->setup_0 = (t->year << RTC_SETUP_0_YEAR_LSB) |
72                    (t->month << RTC_SETUP_0_MONTH_LSB) |
73                    (t->day << RTC_SETUP_0_DAY_LSB);
74     rtc_hw->setup_1 = (t->dotw << RTC_SETUP_1_DOTW_LSB) |
75                    (t->hour << RTC_SETUP_1_HOUR_LSB) |
76                    (t->min << RTC_SETUP_1_MIN_LSB) |
77                    (t->sec << RTC_SETUP_1_SEC_LSB);
78
79     // Load setup values into rtc clock domain
80     rtc_hw->ctrl = RTC_CTRL_LOAD_BITS;
81
82     // Enable RTC and wait for it to be running
83     rtc_hw->ctrl = RTC_CTRL_RTC_ENABLE_BITS;
84     while (!rtc_running()) {

```

```

85     tight_loop_contents();
86 }
87
88     return 0;
89 }

```

4.9.5.3. Get the time

Pico SDK: https://github.com/raspberrypi/pico-sdk/tree/pre_release/src/rp2_common/hardware_rtc/rtc.c Lines 91 - 107

```

91 int rtc_get_datetime(datetime_t *t) {
92     // Make sure RTC is running
93     if (!rtc_running()) {
94         return -1;
95     }
96
97     // Note: RTC_0 should be read before RTC_1
98     t->dotw = (rtc_hw->rtc_0 & RTC_RTC_0_DOTW_BITS ) >> RTC_RTC_0_DOTW_LSB;
99     t->hour = (rtc_hw->rtc_0 & RTC_RTC_0_HOUR_BITS ) >> RTC_RTC_0_HOUR_LSB;
100    t->min  = (rtc_hw->rtc_0 & RTC_RTC_0_MIN_BITS  ) >> RTC_RTC_0_MIN_LSB;
101    t->sec   = (rtc_hw->rtc_0 & RTC_RTC_0_SEC_BITS  ) >> RTC_RTC_0_SEC_LSB;
102    t->year  = (rtc_hw->rtc_1 & RTC_RTC_1_YEAR_BITS ) >> RTC_RTC_1_YEAR_LSB;
103    t->month = (rtc_hw->rtc_1 & RTC_RTC_1_MONTH_BITS) >> RTC_RTC_1_MONTH_LSB;
104    t->day   = (rtc_hw->rtc_1 & RTC_RTC_1_DAY_BITS  ) >> RTC_RTC_1_DAY_LSB;
105
106    return 0;
107 }

```

4.9.5.4. Set an alarm

Pico SDK: https://github.com/raspberrypi/pico-sdk/tree/pre_release/src/rp2_common/hardware_rtc/rtc.c Lines 115 - 147

```

115 void rtc_set_alarm(datetime_t *t, rtc_callback_t user_callback) {
116     rtc_disable_alarm();
117
118     rtc_hw->irq_setup_0 = (t->year  << RTC_IRQ_SETUP_0_YEAR_LSB ) |
119                          (t->month << RTC_IRQ_SETUP_0_MONTH_LSB) |
120                          (t->day   << RTC_IRQ_SETUP_0_DAY_LSB);
121     rtc_hw->irq_setup_1 = (t->dotw  << RTC_IRQ_SETUP_1_DOTW_LSB) |
122                          (t->hour  << RTC_IRQ_SETUP_1_HOUR_LSB) |
123                          (t->min   << RTC_IRQ_SETUP_1_MIN_LSB ) |
124                          (t->sec   << RTC_IRQ_SETUP_1_SEC_LSB);
125
126     // Set the match enable bits for things we care about
127     if (t->year  != -1) hw_set_bits(&rtc_hw->irq_setup_0, RTC_IRQ_SETUP_0_YEAR_ENA_BITS);
128     if (t->month != -1) hw_set_bits(&rtc_hw->irq_setup_0, RTC_IRQ_SETUP_0_MONTH_ENA_BITS);
129     if (t->day   != -1) hw_set_bits(&rtc_hw->irq_setup_0, RTC_IRQ_SETUP_0_DAY_ENA_BITS);

4.10. ADC and Temperature Sensor

4.10.1. Features

RP2040 has an internal analogue-digital converter (ADC) with the following features:

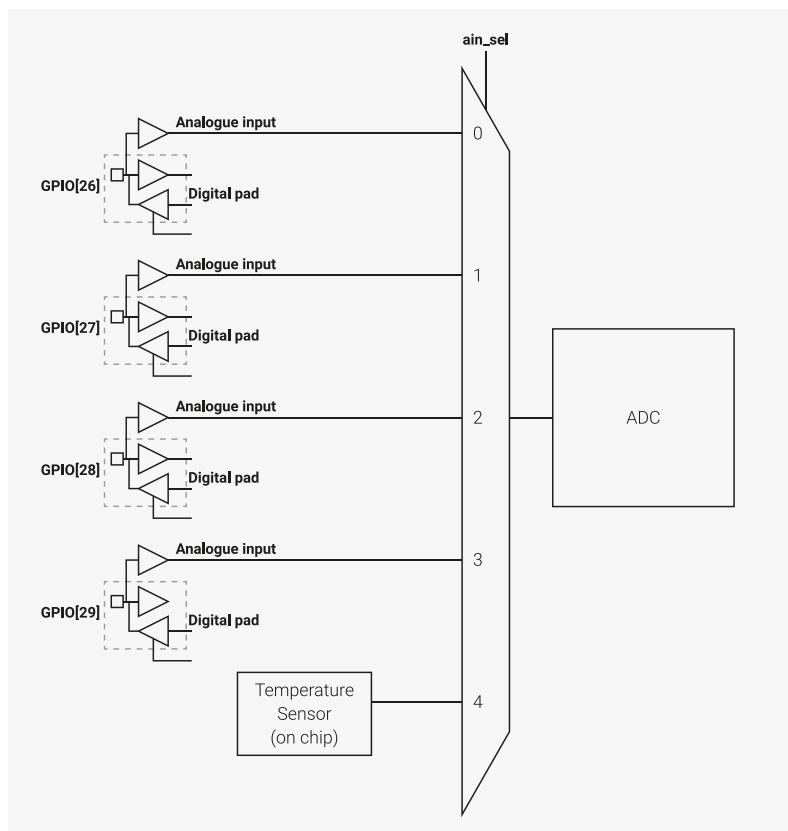

- SAR ADC
- 500 kS/s (Using an independent 48MHz clock)
- 12-bit (9.5 ENOB)
- Five input mux:
 - Four inputs that are available on package pins shared with GPIO[29:26]
 - One input is dedicated to the internal temperature sensor

- Four element receive sample FIFO
- Interrupt generation
- DMA interface

i NOTE

When using an ADC input shared with a GPIO pin, the pin's digital functions must be disabled by setting **IE** low and **OD** high in the pin's pad control register. See [Section 2.18.6.3, "Pad Control - User Bank"](#) for details. The maximum ADC input voltage is determined by the digital IO supply voltage (IOVDD), not the ADC supply voltage (ADC_IOVDD). For example, if IOVDD is powered at 1.8V, the voltage on the ADC inputs should not exceed 1.8V even if ADC_IOVDD is powered at 3.3V. Voltages greater than IOVDD will result in leakage currents through the ESD protection diodes. See [Section 5.2.3, "Pin Specifications"](#) for details.

Figure 112. ADC
Connection Diagram

4.10.2. ADC controller

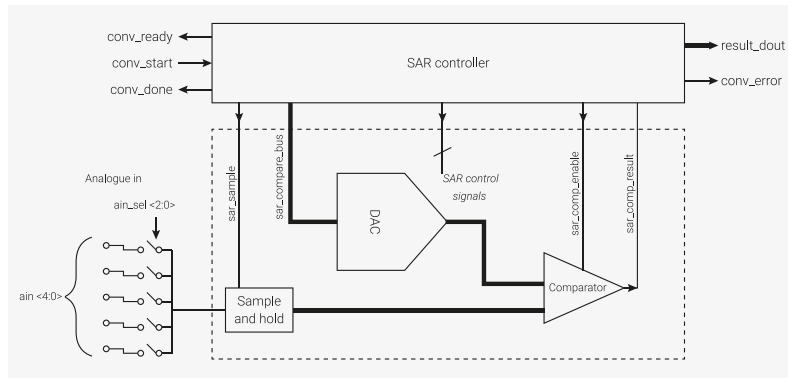

A digital controller manages the details of operating the RP2040 ADC, and provides additional functionality:

- One-shot or free-running capture mode
- Sample FIFO with DMA interface
- Pacing timer (16 integer bits, 8 fractional bits) for setting free-running sample rate
- Round-robin sampling of multiple channels in free-running capture mode
- Optional right-shift to 8 bits in free-running capture mode, so samples can be DMA'd to a byte buffer in system memory

4.10.3. SAR ADC

The SAR ADC (Successive Approximation Register Analogue to Digital Converter) is a combination of digital controller, and analogue circuit as show in Figure 113.

Figure 113. SAR ADC Block diagram

The ADC requires a 48MHz clock (clk_adc), which could come from the USB PLL. Capturing a sample takes 96 clock cycles (96 x 1 / 48MHz) = 2 µs per sample (500kS/s). The clock must be set up correctly before enabling the ADC.

Once the ADC block is provided with a clock, and its reset has been removed, writing a 1 to CS.EN will start a short internal power-up sequence for the ADC’s analogue hardware. After a few clock cycles, CS.READY will go high, indicating the ADC is ready to start its first conversion.

The ADC can be disabled again at any time by clearing CS.EN, to save power. CS.EN does **not** enable the temperature sensor bias source (see Section 4.10.4). This is controlled separately.

4.10.3.1. One-shot Sample

Writing a 1 to CS.START_ONCE will immediately start a new conversion. CS.READY will go low, to show that a conversion is currently in progress. After 96 cycles of clk_adc, CS.READY will go high. The 12-bit conversion result is available in RESULT.

The ADC input to be sampled is selected by writing to CS.AINSEL, any time before the conversion starts. An AINSEL value of 0...3 selects the ADC input on GPIO 26...29. AINSEL of 4 selects the internal temperature sensor.

NOTE

No settling time is required when switching AINSEL.

4.10.3.2. Free-running Sampling

When CS.START_MANY is set,the ADC will automatically start new conversions at regular intervals. The most recent conversion result is always available in RESULT, but for IRQ or DMA driven streaming of samples, the ADC FIFO must be enabled (Section 4.10.3.4).

By default (DIV = 0), new conversions start immediately upon the previous conversion finishing, so a new sample is produced every 96 cycles. At a clock frequency of 48 MHz, this produces 500 kS/s.

Setting DIV.INT to some positive value n will trigger the ADC once per n + 1 cycles, though the ADC ignores this if a conversion is currently in progress, so generally n will be >= 96. For example, setting DIV.INT to 47999 will run the ADC at 1 kS/s, if running from a 48 MHz clock.

The pacing timer supports fractional-rate division (first order delta sigma). When setting DIV.FRAC to a nonzero value, the

ADC will start a new conversion once per $1 + INT + \frac{FRAC}{256}$ cycles on average, by changing the sample interval between INT + 1 and INT + 2.

4.10.3.3. Sampling Multiple Inputs

`CS.RROBIN` allows the ADC to sample multiple inputs, in an interleaved fashion, while performing free-running sampling. Each bit in `RROBIN` corresponds to one of the five possible values of `CS.AINSEL`. When the ADC completes a conversion, `<reg-adc-CS>>.AINSEL` will automatically cycle to the next input whose corresponding bit is set in `RROBIN`.

The round-robin sampling feature is disabled by writing all-zeroes to `CS.RROBIN`.

For example, if `AINSEL` is initially `0`, and `RROBIN` is set to `0x06` (bits 1 and 2 are set), the ADC will sample channels in the following order:

1. Channel 0
2. Channel 1
3. Channel 2
4. Channel 1
5. Channel 2
6. Channel 1...

NOTE

The initial value of `AINSEL` does not need to correspond with a set bit in `RROBIN`.

4.10.3.4. Sample FIFO

The ADC samples can be read directly from the `RESULT` register, or stored in a local 4-entry FIFO and read out from `FIFO`. FIFO operation is controlled by the `FCS` register.

If `FCS.EN` is set, the result of each ADC conversion is written to the FIFO. A software interrupt handler or the RP2040 DMA can read this sample from the FIFO when notified by the ADC's `IRQ` or `DREQ` signals. Alternatively, software can poll the status bits in `FCS` to wait for each sample to become available.

If the FIFO is full when a conversion completes, the sticky error flag `FCS.OVER` is set. The current FIFO contents is not changed by this event, but any conversion that completes whilst the FIFO is full will be lost.

There are two flags that control the data written to the FIFO by the ADC:

- `FCS.SHIFT` will right-shift the FIFO data to eight bits in size (i.e. FIFO bits 7:0 are conversion result bits 11:4). This is suitable for 8-bit DMA transfer to a byte buffer in memory, allowing deeper capture buffers, at the cost of some precision.
- `FCS.ERR` will set a flag at bit 12 of each FIFO entry, showing that a conversion error took place, i.e. the SAR failed to converge **TO DO: this needs a lot more explanation as this isn't typically adc behaviour**

CAUTION

Conversion errors produce undefined results, and the corresponding sample should be discarded.

4.10.3.5. DMA

The ADC can request fetches from the DMA based on FIFO level, and enabled with `FCS.DREQ_EN`.

The DMA interface allows samples to be right-shifted to be one byte in size with `FCS.SHIFT`.

4.10.3.6. Interrupts

An interrupt can be generated when the FIFO level reaches a configurable threshold `FCS.THRESH`. The interrupt output must be enabled via `INTE`.

Status can be read from `INTS`. The interrupt is cleared by draining the FIFO to a level lower than `FCS.THRESH`.

4.10.3.7. Supply

The ADC supply is separated out on its own pin to allow noise filtering.

4.10.4. Temperature Sensor

The temperature sensor measures the V_{be} voltage of a biased bipolar diode, connected to the fifth ADC channel (`AINSEL=4`). Typically, $V_{be} = 0.706V$ at 27 degrees C, with a slope of $-1.721mV$ per degree. Therefore the temperature can be approximated as follows:

$$T = 27 - (ADC_voltage - 0.706)/0.001721$$

As the V_{be} and the V_{be} slope can vary over the temperature range, and from device to device, some user calibration may be required if accurate measurements are required.

The temperature sensor's bias source must be enabled before use, via `CS.TS_EN`. This increases current consumption on `ADC_IOVDD` by approximately $40 \mu A$.

4.10.5. List of Registers

Table 593. List of ADC registers

4.11. SSI

Synopsys Documentation

Synopsys Proprietary. Used with permission.

RP2040 has a Synchronous Serial Interface (SSI) controller which appears on the QSPI pins and is used to communicate with external Flash devices. The SSI forms part of the [XIP](#) block.

The SSI controller is based on a configuration of the Synopsys DW_apb_ssi IP (v4.01a).

4.11.1. Overview

In order for the DW_apb_ssi to connect to a serial-master or serial-slave peripheral device, the peripheral must have a least one of the following interfaces:

Motorola Serial Peripheral Interface (SPI)

A four-wire, full-duplex serial protocol from Motorola. There are four possible combinations for the serial clock phase and polarity. The clock phase (SCPH) determines whether the serial transfer begins with the falling edge of the slave select signal or the first edge of the serial clock. The slave select line is held high when the DW_apb_ssi is idle or disabled.

Texas Instruments Serial Protocol (SSP)

A four-wire, full-duplex serial protocol. The slave select line used for SPI and Microwire protocols doubles as the frame indicator for the SSP protocol.

National Semiconductor Microwire

A half-duplex serial protocol, which uses a control word transmitted from the serial master to the target serial slave.

You can program the FRF (frame format) bit field in the Control Register 0 (CTRLR0) to select which protocol is used.

The serial protocols supported by the DW_apb_ssi allow for serial slaves to be selected or addressed using either hardware or software. When implemented in hardware, serial slaves are selected under the control of dedicated hardware select lines. The number of select lines generated from the serial master is equal to the number of serial slaves present on the bus. The serial-master device asserts the select line of the target serial slave before data transfer begins. This architecture is illustrated in Figure 114.

When implemented in software, the input select line for all serial slave devices should originate from a single slave select output on the serial master. In this mode it is assumed that the serial master has only a single slave select output. If there are multiple serial masters in the system, the slave select output from all masters can be logically ANDed to generate a single slave select input for all serial slave devices. The main program in the software domain controls selection of the target slave device; this architecture is illustrated in Figure 114. Software would use the SSIENR register in all slaves in order to control which slave is to respond to the serial transfer request from the master device.

The DW_apb_ssi does not enforce hardware or software control for serial-slave device selection. You can configure the DW_apb_ssi for either implementation, illustrated in Figure 114.

Figure 114.
Hardware/Software
Slave Selection.

4.11.2. Features

The DW_apb_ssi is a configurable and programmable component that is a full-duplex master serial interface. The host processor accesses data, control, and status information on the DW_apb_ssi through the APB interface. The DW_apb_ssi also interfaces with the DMA Controller for bulk data transfer.

The DW_apb_ssi is configured as a serial master. The DW_apb_ssi can connect to any serial-slave peripheral device using one of the following interfaces:

- Motorola Serial Peripheral Interface (SPI)
- Texas Instruments Serial Protocol (SSP)
- National Semiconductor Microwire

On RP2040, the DW_apb_ssi is a component of the flash execute-in-place subsystem (see [Execute-In-Place](#)), and provides communication with an external SPI, dual-SPI or quad-SPI flash device.

4.11.2.1. IO connections

The SSI controller connects to the following pins:

- **QSPI_SCLK** Connected to output clock *sclk_out*
- **QSPI_SS_N** Connected to chip select *ss_o_n*
- **QSPI_D[3:0]** Connected to data bus *txd* and *rx*

Some pins on the IP are tied off as not used:

- *ss_in_n* is tied high

Clock connections are as follows:

- *pclk* and *sclk* are driven from **clk_sys**

4.11.3. IP Modifications

The following modifications were made to the Synopsys DW_apb_ssi hardware:

1. XIP accesses are byte-swapped, such that the least-addressed byte is in the least-significant position
2. When **SPI_CTRLR0_INST_L** is 0, the XIP instruction field is appended to the end of the address for XIP accesses, rather than prepended to the beginning

The first of these changes allows mixed-size accesses by a little-endian busmaster, such as the RP2040 DMA, or the Cortex-M0+ configuration used on RP2040. Note that this only applies to XIP accesses (RP2040 system addresses in the range **0x10000000** to **0x13ffffff**), not to direct access to the DW_apb_ssi FIFOs. When accessing the SSI directly, it may be necessary for software to swap bytes manually, or to use the RP2040 DMA's byte swap feature.

The second supports issuing of continuation bits following the XIP address, so that command-prefix-free XIP modes can be supported (e.g. **EBh** Quad I/O Fast Read on Winbond devices), for greater performance. For example, the following configuration would be used to issue a standard **03h** serial read command for each access to the XIP address window:

- **SPI_CTRLR0_INST_L** = 8 bits
- **SPI_CTRLR0_ADDR_L** = 24 bits
- **SPI_CTRLR0_XIP_CMD** = **0x03**

This will first issue eight command bits (**0x03**), then issue 24 address bits, then clock in the data bits. The configuration used for **EBh** quad read, after the flash has entered the XIP state, would be:

- **SPI_CTRLR0_INST_L** = 0
- **SPI_CTRLR0_ADDR_L** = 32 bits
- **SPI_CTRLR0_XIP_CMD** = **0xa0** (continuation code on W25Qx devices)

For each XIP access, the DW_apb_ssi will issue 32 "address" bits, consisting of the 24 LSBs of the RP2040 system bus address, followed by the 8-bit continuation code **0xa0**. No command prefix is issued.

4.11.3.1. Example of Target Slave Selection Using Software

The following example is pseudo code that illustrates how to use software to select the target slave.

```

1 int main() {
2     disable_all_serial_devices(); ①
3     initialize_mst(ssi_mst_1); ②
4     initialize_slv(ssi_slv_1); ③
5     start_serial_xfer(ssi_mst_1); ④
6 }

```

① This function sets the SSI_EN bit to logic '0' in the SSIENR register of each device on the serial bus.

② This function initializes the master device for the serial transfer;

1. Write CTRLR0 to match the required transfer
2. If transfer is receive only write number of frames into CTRLR1
3. Write BAUDR to set the transfer baud rate.
4. Write TXFTLR and RXFTLR to set FIFO threshold levels
5. Write IMR register to set interrupt masks
6. Write SER register bit[0] to logic '1'
7. Write SSIENR register bit[0] to logic '1' to enable the master.

③ This function initializes the target slave device (slave 1 in this example) for the serial transfer;

1. Write CTRLR0 to match the required transfer
2. Write TXFTLR and RXFTLR to set FIFO threshold levels
3. Write IMR register to set interrupt masks
4. Write SSIENR register bit[0] to logic '1' to enable the slave.
5. If the slave is to transmit data, write data into TX FIFO Now the slave is enabled and awaiting an active level on its ss_in_n input port. Note all other serial slaves are disabled (SSI_EN=0) and therefore will not respond to an active level on their ss_in_n port.

④ This function begins the serial transfer by writing transmit data into the master's TX FIFO. User can poll the busy status with a function or use an ISR to determine when the serial transfer has completed.

4.11.4. Clock Ratios

The maximum frequency of the bit-rate clock (sclk_out) is one-half the frequency of ssi_clk. This allows the shift control logic to capture data on one clock edge of sclk_out and propagate data on the opposite edge.

Figure 115 illustrates the maximum ratio between sclk_out and ssi_clk.

Figure 115. Maximum $sclk_out/ssi_clk$ Ratio.

The $sclk_out$ line toggles only when an active transfer is in progress. At all other times it is held in an inactive state, as defined by the serial protocol under which it operates.

The frequency of $sclk_out$ can be derived from the following equation:

$$F_{sclk_out} = \frac{F_{ssi_clk}}{SCKDV}$$

SCKDV is a bit field in the programmable register BAUDR, holding any even value in the range 0 to 65,534. If SCKDV is 0, then $sclk_out$ is disabled.

4.11.4.1. Frequency Ratio Summary

A summary of the frequency ratio restrictions between the bit-rate clock ($sclk_out$) and the DW_apb_ssi peripheral clock (ssi_clk) are as follows:

- $F_{ssi_clk} >= 2 \times (\text{maximum } F_{sclk_out})$

4.11.5. Transmit and Receive FIFO Buffers

The FIFO buffers used by the DW_apb_ssi are internal D-type flip-flops that are 16 entries deep. The width of both transmit and receive FIFO buffers is fixed at 32 bits, due to the serial specifications, which state that a serial transfer (data frame) can be 4 to 16/32 bits in length. Data frames that are less than 32 bits must be right-justified when written into the transmit FIFO buffer. The shift control logic automatically right-justifies receive data in the receive FIFO buffer.

Each data entry in the FIFO buffers contains a single data frame. It is impossible to store multiple data frames in a single FIFO location; for example, you may not store two 8-bit data frames in a single FIFO location. If an 8-bit data frame is required, the upper bits of the FIFO entry are ignored or unused when the serial shifter transmits the data.

i NOTE

The transmit and receive FIFO buffers are cleared when the DW_apb_ssi is disabled ($SSI_EN = 0$) or when it is reset (presn).

The transmit FIFO is loaded by APB write commands to the DW_apb_ssi data register (DR). Data are popped (removed) from the transmit FIFO by the shift control logic into the transmit shift register. The transmit FIFO generates a FIFO empty interrupt request (ssi_txe_intr) when the number of entries in the FIFO is less than or equal to the FIFO threshold value. The threshold value, set through the programmable register TXFTLR, determines the level of FIFO entries at which an interrupt is generated. The threshold value allows you to provide early indication to the processor that the transmit FIFO is nearly empty. A transmit FIFO overflow interrupt (ssi_txo_intr) is generated if you attempt to write data into an already full transmit FIFO.

Data are popped from the receive FIFO by APB read commands to the DW_apb_ssi data register (DR). The receive FIFO is loaded from the receive shift register by the shift control logic. The receive FIFO generates a FIFO-full interrupt request (ssi_rxf_intr) when the number of entries in the FIFO is greater than or equal to the FIFO threshold value plus one. The threshold value, set through programmable register RXFTLR, determines the level of FIFO entries at which an interrupt is generated.

The threshold value allows you to provide early indication to the processor that the receive FIFO is nearly full. A receive FIFO overrun interrupt (ssi_rxo_intr) is generated when the receive shift logic attempts to load data into a completely full receive FIFO. However, this newly received data are lost. A receive FIFO underflow interrupt (ssi_rxu_intr) is generated if you attempt to read from an empty receive FIFO. This alerts the processor that the read data are invalid.

Table 603 provides description for different Transmit FIFO Threshold values.

Table 603. Transmit FIFO Threshold (TFT) Decode Values

TFT Value	Description
0000_0000	ssi_txe_intr is asserted when zero data entries are present in transmit FIFO
0000_0001	ssi_txe_intr is asserted when one or less data entry is present in transmit FIFO
0000_0010	ssi_txe_intr is asserted when two or less data entries are present in transmit FIFO
...	...
0000_1101	ssi_txe_intr is asserted when 13 or less data entries are present in transmit FIFO
0000_1110	ssi_txe_intr is asserted when 14 or less data entries are present in transmit FIFO
0000_1111	ssi_txe_intr is asserted when 15 or less data entries are present in transmit FIFO

Table 604 provides description for different Receive FIFO Threshold values.

Table 604. Receive FIFO Threshold (RFT) Decode Values

RFT Value	Description
0000_0000	ssi_rxf_intr is asserted when one or more data entry is present in receive FIFO
0000_0001	ssi_rxf_intr is asserted when two or more data entries are present in receive FIFO
0000_0010	ssi_rxf_intr is asserted when three or more data entries are present in receive FIFO
...	...
0000_1101	ssi_rxf_intr is asserted when 14 or more data entries are present in receive FIFO
0000_1110	ssi_rxf_intr is asserted when 15 or more data entries are present in receive FIFO
0000_1111	ssi_rxf_intr is asserted when 16 data entries are present in receive FIFO

4.11.6. 32-Bit Frame Size Support

The IP is configured to set the maximum programmable value in of data frame size to 32 bits. As a result the following features exist:

- dfs_32 (CTRLR0[20:16]) are valid, which contains the value of data frame size. The new register field holds the values 0 to 31. The dfs (CTRLR0[3:0]) is invalid and writing to this register has no effect.
- The receive and transmit FIFO widths are 32 bits.
- All 32 bits of the data register are valid.

4.11.7. SSI Interrupts

The DW_apb_ssi supports combined and individual interrupt requests, each of which can be masked. The combined interrupt request is the ORed result of all other DW_apb_ssi interrupts after masking. Only the combined interrupt request is routed to the Interrupt Controller. All DW_apb_ssi interrupts are level interrupts and are active high.

The DW_apb_ssi interrupts are described as follows:

Transmit FIFO Empty Interrupt (ssi_txe_intr)

Set when the transmit FIFO is equal to or below its threshold value and requires service to prevent an under-run. The threshold value, set through a software-programmable register, determines the level of transmit FIFO entries at which an interrupt is generated. This interrupt is cleared by hardware when data are written into the transmit FIFO buffer, bringing it over the threshold level.

Transmit FIFO Overflow Interrupt (ssi_txo_intr)

Set when an APB access attempts to write into the transmit FIFO after it has been completely filled. When set, data written from the APB is discarded. This interrupt remains set until you read the transmit FIFO overflow interrupt clear register (TXOICR).

Receive FIFO Full Interrupt (ssi_rxf_intr)

Set when the receive FIFO is equal to or above its threshold value plus 1 and requires service to prevent an overflow. The threshold value, set through a software-programmable register, determines the level of receive FIFO entries at which an interrupt is generated. This interrupt is cleared by hardware when data are read from the receive FIFO buffer, bringing it below the threshold level.

Receive FIFO Overflow Interrupt (ssi_rxo_intr)

Set when the receive logic attempts to place data into the receive FIFO after it has been completely filled. When set, newly received data are discarded. This interrupt remains set until you read the receive FIFO overflow interrupt clear register (RXOICR).

Receive FIFO Underflow Interrupt (ssi_rxu_intr)

Set when an APB access attempts to read from the receive FIFO when it is empty. When set, 0s are read back from the receive FIFO. This interrupt remains set until you read the receive FIFO underflow interrupt clear register (RXUICR).

Multi-Master Contention Interrupt (ssi_mst_intr)

Present only when the DW_apb_ssi component is configured as a serial-master device. The interrupt is set when another serial master on the serial bus selects the DW_apb_ssi master as a serial-slave device and is actively transferring data. This informs the processor of possible contention on the serial bus. This interrupt remains set until you read the multi-master interrupt clear register (MSTICR).

Combined Interrupt Request (ssi_intr)

OR'ed result of all the above interrupt requests after masking. To mask this interrupt signal, you must mask all other DW_apb_ssi interrupt requests.

4.11.8. Transfer Modes

When transferring data on the serial bus, the DW_apb_ssi operates in the modes discussed in this section. The transfer mode (TMOD) is set by writing to control register 0 (CTRLR0).

NOTE

The transfer mode setting does not affect the duplex of the serial transfer. TMOD is ignored for Microwire transfers, which are controlled by the MWCR register.

4.11.8.1. Transmit and Receive

When TMOD = **00b**, both transmit and receive logic are valid. The data transfer occurs as normal according to the selected frame format (serial protocol). Transmit data are popped from the transmit FIFO and sent through the txd line to the target device, which replies with data on the rxd line. The receive data from the target device is moved from the receive shift register into the receive FIFO at the end of each data frame.

4.11.8.2. Transmit Only

When TMOD = **01b**, the receive data are invalid and should not be stored in the receive FIFO. The data transfer occurs as normal, according to the selected frame format (serial protocol). Transmit data are popped from the transmit FIFO and sent through the txd line to the target device, which replies with data on the rxd line. At the end of the data frame, the receive shift register does not load its newly received data into the receive FIFO. The data in the receive shift register is overwritten by the next transfer. You should mask interrupts originating from the receive logic when this mode is entered.

4.11.8.3. Receive Only

When `TMOD = 10b`, the transmit data are invalid. When configured as a slave, the transmit FIFO is never popped in Receive Only mode. The `txd` output remains at a constant logic level during the transmission. The data transfer occurs as normal according to the selected frame format (serial protocol). The receive data from the target device is moved from the receive shift register into the receive FIFO at the end of each data frame. You should mask interrupts originating from the transmit logic when this mode is entered.

4.11.8.4. EEPROM Read

NOTE

This transfer mode is only valid for master configurations.

When `TMOD = 11b`, the transmit data is used to transmit an opcode and/or an address to the EEPROM device. Typically this takes three data frames (8-bit opcode followed by 8-bit upper address and 8-bit lower address). During the transmission of the opcode and address, no data is captured by the receive logic (as long as the `DW_apb_ssi` master is transmitting data on its `txd` line, data on the `rxd` line is ignored). The `DW_apb_ssi` master continues to transmit data until the transmit FIFO is empty. Therefore, you should ONLY have enough data frames in the transmit FIFO to supply the opcode and address to the EEPROM. If more data frames are in the transmit FIFO than are needed, then read data is lost.

When the transmit FIFO becomes empty (all control information has been sent), data on the receive line (`rxd`) is valid and is stored in the receive FIFO; the `txd` output is held at a constant logic level. The serial transfer continues until the number of data frames received by the `DW_apb_ssi` master matches the value of the `NDF` field in the `CTRLR1` register + 1.

NOTE

EEPROM read mode is not supported when the `DW_apb_ssi` is configured to be in the SSP mode.

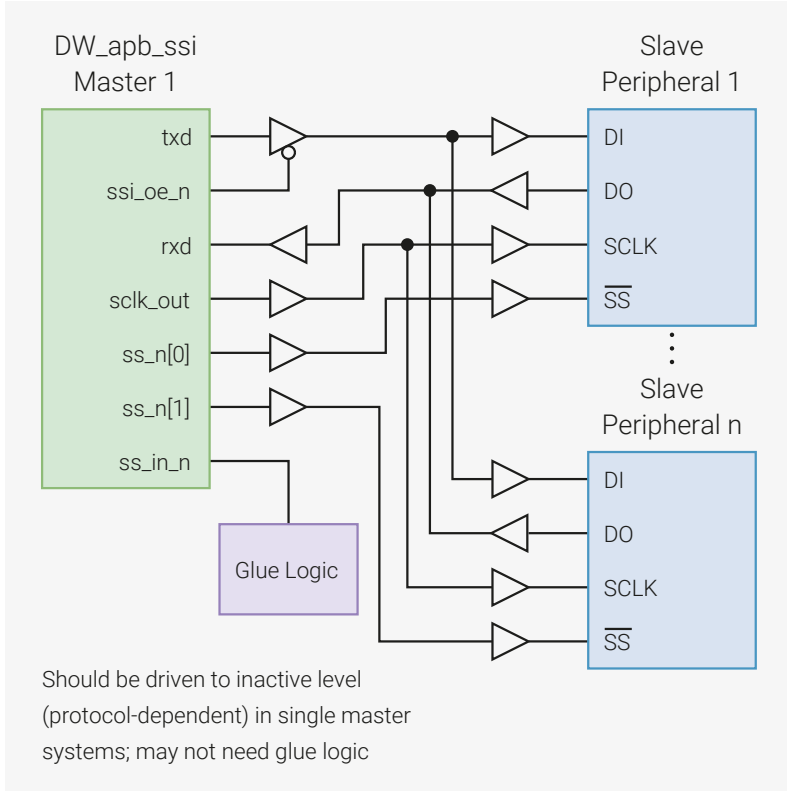

4.11.9. Operation Modes

The `DW_apb_ssi` can be configured in the fundamental modes of operation discussed in this section.

4.11.9.1. Serial Master Mode

This mode enables serial communication with serial-slave peripheral devices. When configured as a serial-master device, the `DW_apb_ssi` initiates and controls all serial transfers. [Figure 116](#) shows an example of the `DW_apb_ssi` configured as a serial master with all other devices on the serial bus configured as serial slaves.

Figure 116.
DW_apb_ssi
Configured as Master
Device

The serial bit-rate clock, generated and controlled by the DW_apb_ssi, is driven out on the sclk_out line. When the DW_apb_ssi is disabled (SSI_EN = 0), no serial transfers can occur and sclk_out is held in “inactive” state, as defined by the serial protocol under which it operates.

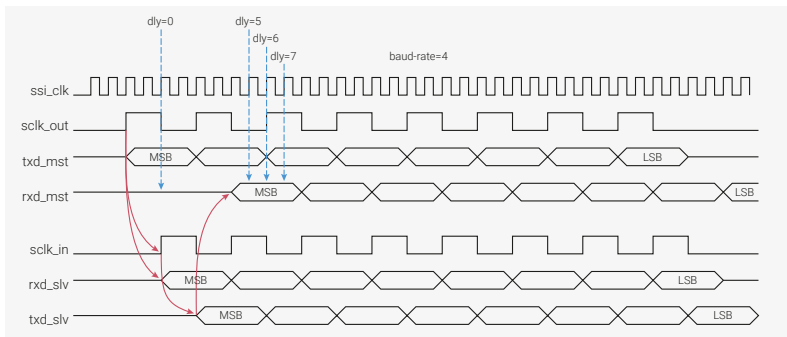

Multiple master configuration is not supported.

4.11.9.1.1. RXD Sample Delay

When the DW_apb_ssi is configured as a master, additional logic can be included in the design in order to delay the default sample time of the rxd signal. This additional logic can help to increase the maximum achievable frequency on the serial bus.

Round trip routing delays on the sclk_out signal from the master and the rxd signal from the slave can mean that the timing of the rxd signal—as seen by the master—has moved away from the normal sampling time. Figure 117 illustrates this situation.

Figure 117. Effects of Round-Trip Routing Delays on sclk_out Signal

The Slave uses the sclk_out signal from the master as a strobe in order to drive rxd signal data onto the serial bus. Routing and sampling delays on the sclk_out signal by the slave device can mean that the rxd bit has not stabilized to the correct value before the master samples the rxd signal. Figure 117 shows an example of how a routing delay on the rxd signal can result in an incorrect rxd value at the default time when the master samples the port.

Without the RXD Sample Delay logic, the user would have to increase the baud-rate for the transfer in order to ensure that

the setup times on the rxd signal are within range; this results in reducing the frequency of the serial interface.

When the RXD Sample Delay logic is included, the user can dynamically program a delay value in order to move the sampling time of the rxd signal equal to a number of ssi_clk cycles from the default.

The sample delay logic has a resolution of one ssi_clk cycle. Software can “train” the serial bus by coding a loop that continually reads from the slave and increments the master’s RXD Sample Delay value until the correct data is received by the master.

4.11.9.1.2. Data Transfers

Data transfers are started by the serial-master device. When the DW_apb_ssi is enabled (SSLEN=1), at least one valid data entry is present in the transmit FIFO and a serial-slave device is selected. When actively transferring data, the busy flag (BUSY) in the status register (SR) is set. You must wait until the busy flag is cleared before attempting a new serial transfer.

i NOTE

The BUSY status is not set when the data are written into the transmit FIFO. This bit gets set only when the target slave has been selected and the transfer is underway. After writing data into the transmit FIFO, the shift logic does not begin the serial transfer until a positive edge of the sclk_out signal is present. The delay in waiting for this positive edge depends on the baud rate of the serial transfer. Before polling the BUSY status, you should first poll the TFE status (waiting for 1) or wait for BAUDR * ssi_clk clock cycles.

4.11.9.1.3. Master SPI and SSP Serial Transfers

When the transfer mode is “transmit and receive” or “transmit only” (TMOD = 00b or TMOD = 01b, respectively), transfers are terminated by the shift control logic when the transmit FIFO is empty. For continuous data transfers, you must ensure that the transmit FIFO buffer does not become empty before all the data have been transmitted. The transmit FIFO threshold level (TXFTLR) can be used to early interrupt (ssi_txe_intr) the processor indicating that the transmit FIFO buffer is nearly empty. When a DMA is used for APB accesses, the transmit data level (DMATDLR) can be used to early request (dma_tx_req) the DMA Controller, indicating that the transmit FIFO is nearly empty. The FIFO can then be refilled with data to continue the serial transfer. The user may also write a block of data (at least two FIFO entries) into the transmit FIFO before enabling a serial slave. This ensures that serial transmission does not begin until the number of data-frames that make up the continuous transfer are present in the transmit FIFO.

When the transfer mode is “receive only” (TMOD = 10b), a serial transfer is started by writing one “dummy” data word into the transmit FIFO when a serial slave is selected. The txd output from the DW_apb_ssi is held at a constant logic level for the duration of the serial transfer. The transmit FIFO is popped only once at the beginning and may remain empty for the duration of the serial transfer. The end of the serial transfer is controlled by the “number of data frames” (NDF) field in control register 1 (CTRLR1).

If, for example, you want to receive 24 data frames from a serial-slave peripheral, you should program the NDF field with the value 23; the receive logic terminates the serial transfer when the number of frames received is equal to the NDF value + 1. This transfer mode increases the bandwidth of the APB bus as the transmit FIFO never needs to be serviced during the transfer. The receive FIFO buffer should be read each time the receive FIFO generates a FIFO full interrupt request to prevent an overflow.

When the transfer mode is “eeprom_read” (TMOD = 11b), a serial transfer is started by writing the opcode and/or address into the transmit FIFO when a serial slave (EEPROM) is selected. The opcode and address are transmitted to the EEPROM device, after which read data is received from the EEPROM device and stored in the receive FIFO. The end of the serial transfer is controlled by the NDF field in the control register 1 (CTRLR1).

NOTE

EEPROM read mode is not supported when the DW_apb_ssi is configured to be in the SSP mode.

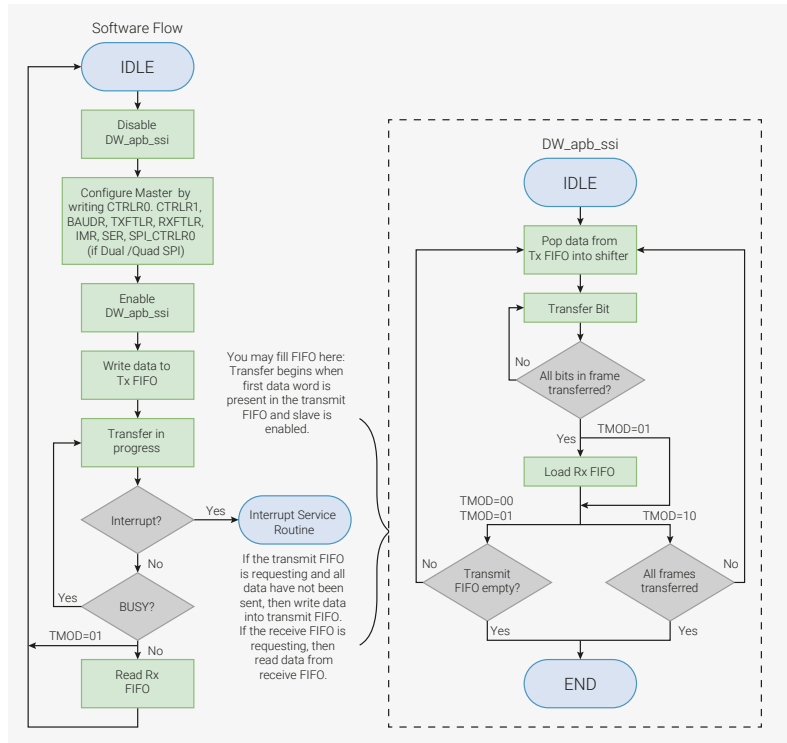

The receive FIFO threshold level (RXFTLR) can be used to give early indication that the receive FIFO is nearly full. When a DMA is used for APB accesses, the receive data level (DMARDLR) can be used to early request (dma_rx_req) the DMA Controller, indicating that the receive FIFO is nearly full.

A typical software flow for completing an SPI or SSP serial transfer from the DW_apb_ssi serial master is outlined as follows:

1. If the DW_apb_ssi is enabled, disable it by writing 0 to the SSI Enable register (SSIENR).
2. Set up the DW_apb_ssi control registers for the transfer; these registers can be set in any order.
 - o Write Control Register 0 (CTRLR0). For SPI transfers, the serial clock polarity and serial clock phase parameters must be set identical to target slave device.
 - o If the transfer mode is receive only, write CTRLR1 (Control Register 1) with the number of frames in the transfer minus 1; for example, if you want to receive four data frames, if you want to receive four data frames, write '3' into CTRLR1.
 - o Write the Baud Rate Select Register (BAUDR) to set the baud rate for the transfer.
 - o Write the Transmit and Receive FIFO Threshold Level registers (TXFTLR and RXFTLR, respectively) to set FIFO threshold levels.
 - o Write the IMR register to set up interrupt masks.
 - o The Slave Enable Register (SER) register can be written here to enable the target slave for selection. If a slave is enabled here, the transfer begins as soon as one valid data entry is present in the transmit FIFO. If no slaves are enabled prior to writing to the Data Register (DR), the transfer does not begin until a slave is enabled.
3. Enable the DW_apb_ssi by writing 1 to the SSIENR register.
4. Write data for transmission to the target slave into the transmit FIFO (write DR). If no slaves were enabled in the SER register at this point, enable it now to begin the transfer.
5. Poll the BUSY status to wait for completion of the transfer. The BUSY status cannot be polled immediately.
6. If a transmit FIFO empty interrupt request is made, write the transmit FIFO (write DR). If a receive FIFO full interrupt request is made, read the receive FIFO (read DR).
7. The transfer is stopped by the shift control logic when the transmit FIFO is empty. If the transfer mode is receive only (TMOD = 10b), the transfer is stopped by the shift control logic when the specified number of frames have been received. When the transfer is done, the BUSY status is reset to 0.
8. If the transfer mode is not transmit only (TMOD != 01b), read the receive FIFO until it is empty.
9. Disable the DW_apb_ssi by writing 0 to SSIENR.

Figure 118 shows a typical software flow for starting a DW_apb_ssi master SPI/SSP serial transfer. The diagram also shows the hardware flow inside the serial-master component.

Figure 118.
DW_apb_ssi Master
SPI/SSP Transfer Flow

4.11.9.1.4. Master Microwire Serial Transfers

Microwire serial transfers from the DW_apb_ssi serial master are controlled by the Microwire Control Register (MWCR). The MWHS bit field enables and disables the Microwire handshaking interface. The MDD bit field controls the direction of the data frame (the control frame is always transmitted by the master and received by the slave). The MWMOD bit field defines whether the transfer is sequential or nonsequential.

All Microwire transfers are started by the DW_apb_ssi serial master when there is at least one control word in the transmit FIFO and a slave is enabled. When the DW_apb_ssi master transmits the data frame (MDD = 1), the transfer is terminated by the shift logic when the transmit FIFO is empty. When the DW_apb_ssi master receives the data frame (MDD = 0), the termination of the transfer depends on the setting of the MWMOD bit field. If the transfer is nonsequential (MWMOD = 0), it is terminated when the transmit FIFO is empty after shifting in the data frame from the slave. When the transfer is sequential (MWMOD = 1), it is terminated by the shift logic when the number of data frames received is equal to the value in the CTRLR1 register + 1.

When the handshaking interface on the DW_apb_ssi master is enabled (MWHS =1), the status of the target slave is polled after transmission. Only when the slave reports a ready status does the DW_apb_ssi master complete the transfer and clear its BUSY status. If the transfer is continuous, the next control/data frame is not sent until the slave device returns a ready status.

A typical software flow for completing a Microwire serial transfer from the DW_apb_ssi serial master is outlined as follows:

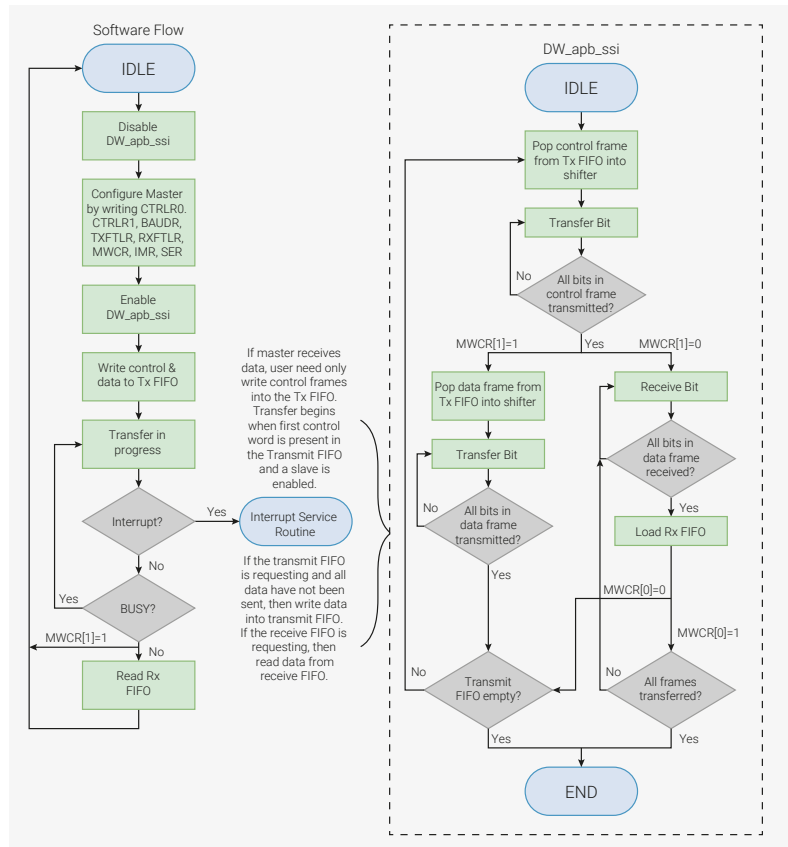

1. If the DW_apb_ssi is enabled, disable it by writing 0 to SSIENR.
2. Set up the DW_apb_ssi control registers for the transfer. These registers can be set in any order. Write CTRLR0 to set transfer parameters.
 - o If the transfer is sequential and the DW_apb_ssi master receives data, write CTRLR1 with the number of frames in the transfer minus 1; for instance, if you want to receive four data frames, write '3' into CTRLR1.
 - o Write BAUDR to set the baud rate for the transfer.
 - o Write TXFTLR and RXFTLR to set FIFO threshold levels.
 - o Write the IMR register to set up interrupt masks.

You can write the SER register to enable the target slave for selection. If a slave is enabled here, the transfer begins as soon as one valid data entry is present in the transmit FIFO. If no slaves are enabled prior to writing to the DR register, the transfer does not begin until a slave is enabled.

3. Enable the DW_apb_ssi by writing 1 to the SSIENR register.
4. If the DW_apb_ssi master transmits data, write the control and data words into the transmit FIFO (write DR). If the DW_apb_ssi master receives data, write the control word(s) into the transmit FIFO.
If no slaves were enabled in the SER register at this point, enable now to begin the transfer.
5. Poll the BUSY status to wait for completion of the transfer. The BUSY status cannot be polled immediately.
6. The transfer is stopped by the shift control logic when the transmit FIFO is empty. If the transfer mode is sequential and the DW_apb_ssi master receives data, the transfer is stopped by the shift control logic when the specified number of data frames is received. When the transfer is done, the BUSY status is reset to 0.
7. If the DW_apb_ssi master receives data, read the receive FIFO until it is empty.
8. Disable the DW_apb_ssi by writing 0 to SSIENR.

Figure 119 shows a typical software flow for starting a DW_apb_ssi master Microwire serial transfer. The diagram also shows the hardware flow inside the serial-master component.

Figure 119.
DW_apb_ssi Master
Microwire Transfer
Flow

4.11.10. Partner Connection Interfaces

The DW_apb_ssi can connect to any serial-slave peripheral device using one of the interfaces discussed in the following sections.

4.11.10.1. Motorola Serial Peripheral Interface (SPI)

With the SPI, the clock polarity (SCPOL) configuration parameter determines whether the inactive state of the serial clock

is high or low. To transmit data, both SPI peripherals must have identical serial clock phase (SCPH) and clock polarity (SCPOL) values. The data frame can be 4 to 16/32 bits (depending upon SSI_MAX_XFER_SIZE) in length.

When the configuration parameter SCPH = 0, data transmission begins on the falling edge of the slave select signal. The first data bit is captured by the master and slave peripherals on the first edge of the serial clock; therefore, valid data must be present on the txd and rxd lines prior to the first serial clock edge.

Figure 120 shows a timing diagram for a single SPI data transfer with SCPH = 0. The serial clock is shown for configuration parameters SCPOL = 0 and SCPOL = 1.

Figure 120. SPI Serial Format (SCPH = 0)

The following signals are illustrated in the timing diagrams in this section:

sclk_out

serial clock from DW_apb_ssi master

ss_0_n

slave select signal from DW_apb_ssi master

ss_in_n

slave select input to the DW_apb_ssi slave

ss_oe_n

output enable for the DW_apb_ssi master

txd

transmit data line for the DW_apb_ssi master

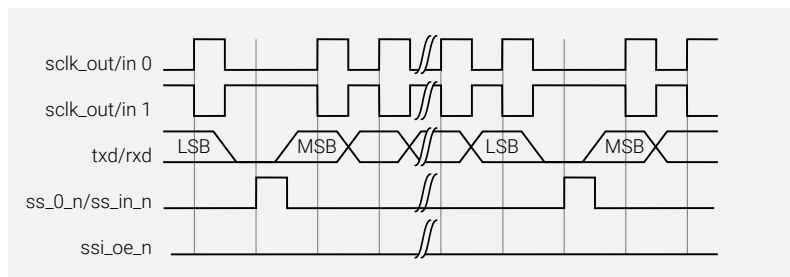

rx

receive data line for the DW_apb_ssi master

Continuous data transfers are supported when SCPH = 0:

- When CTRLR0.SSTE is set to 1, the DW_apb_ssi toggles the slave select signal between frames and the serial clock is held to its default value while the slave select signal is active; this operating mode is illustrated in Figure 121.

Figure 121. Serial Format Continuous Transfers (SCPH = 0)

When the configuration parameter SCPH = 1, master peripherals begin transmitting data on the first serial clock edge after the slave select line is activated. The first data bit is captured on the second (trailing) serial clock edge. Data are propagated by the master peripherals on the leading edge of the serial clock. During continuous data frame transfers, the slave select line may be held active-low until the last bit of the last frame has been captured.

Figure 122 shows the timing diagram for the SPI format when the configuration parameter SCPH = 1.

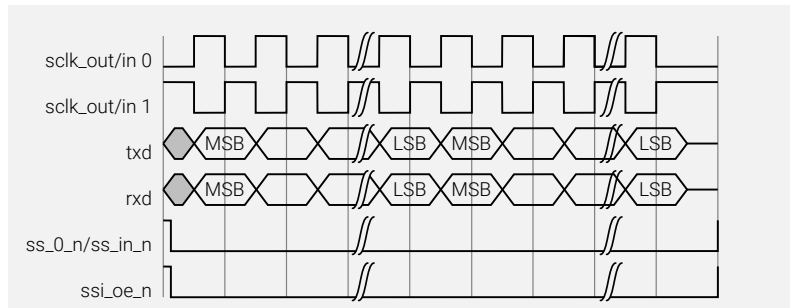

Figure 122. SPI Serial Format (SCPH = 1)

Continuous data frames are transferred in the same way as single frames, with the MSB of the next frame following directly after the LSB of the current frame. The slave select signal is held active for the duration of the transfer.

Figure 123 shows the timing diagram for continuous SPI transfers when the configuration parameter SCPH = 1.

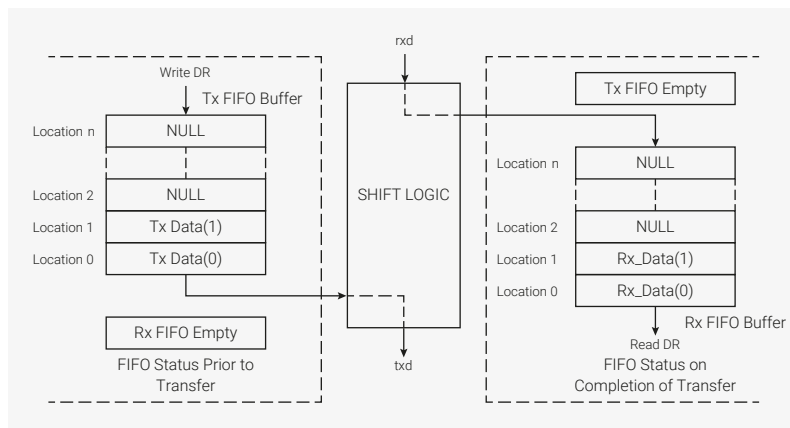

Figure 123. SPI Serial Format Continuous Transfer (SCPH = 1)

There are four possible transfer modes on the DW_apb_ssi for performing SPI serial transactions. For transmit and receive transfers (transfer mode field (9:8) of the Control Register 0 = 00b), data transmitted from the DW_apb_ssi to the external serial device is written into the transmit FIFO. Data received from the external serial device into the DW_apb_ssi is pushed into the receive FIFO.

Figure 124 shows the FIFO levels prior to the beginning of a serial transfer and the FIFO levels on completion of the transfer. In this example, two data words are transmitted from the DW_apb_ssi to the external serial device in a continuous transfer. The external serial device also responds with two data words for the DW_apb_ssi.

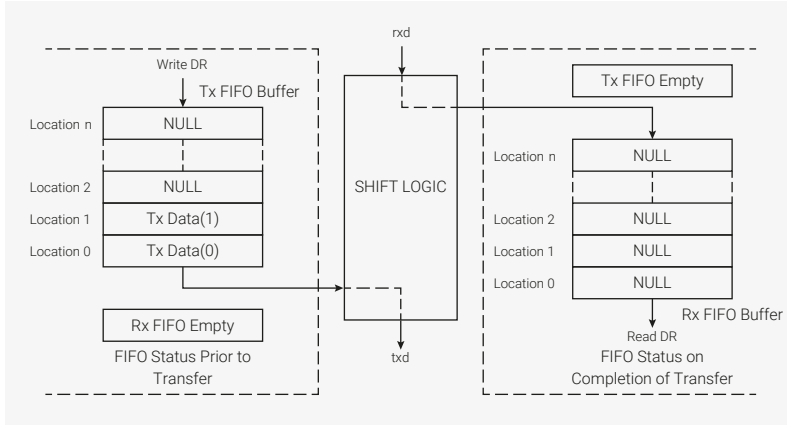

Figure 124. FIFO Status for Transmit & Receive SPI and SSP Transfers

For transmit only transfers (transfer mode field (9:8) of the Control Register 0 = 01b), data transmitted from the DW_apb_ssi to the external serial device is written into the transmit FIFO. As the data received from the external serial device is deemed invalid, it is not stored in the DW_apb_ssi receive FIFO.

Figure 125 shows the FIFO levels prior to the beginning of a serial transfer and the FIFO levels on completion of the transfer. In this example, two data words are transmitted from the DW_apb_ssi to the external serial device in a continuous transfer.

Figure 125. FIFO Status for Transmit Only SPI and SSP Transfers

For receive only transfers (transfer mode field (9:8) of the Control Register 0 = 10b), data transmitted from the DW_apb_ssi to the external serial device is invalid, so a single dummy word is written into the transmit FIFO to begin the serial transfer. The txd output from the DW_apb_ssi is held at a constant logic level for the duration of the serial transfer. Data received from the external serial device into the DW_apb_ssi is pushed into the receive FIFO.

Figure 126 shows the FIFO levels prior to the beginning of a serial transfer and the FIFO levels on completion of the transfer. In this example, two data words are received by the DW_apb_ssi from the external serial device in a continuous transfer.

Figure 126. FIFO Status for Receive Only SPI and SSP Transfers

For eeprom_read transfers (transfer mode field [9:8] of the Control Register 0 = 11b), opcode and/or EEPROM address are written into the transmit FIFO. During transmission of these control frames, received data is not captured by the DW_apb_ssi master. After the control frames have been transmitted, receive data from the EEPROM is stored in the receive FIFO.

Figure 127 shows the FIFO levels prior to the beginning of a serial transfer and the FIFO levels on completion of the transfer. In this example, one opcode and an upper and lower address are transmitted to the EEPROM, and eight data frames are read from the EEPROM and stored in the receive FIFO of the DW_apb_ssi master.

Figure 127. FIFO Status for EEPROM Read Transfer Mode

4.11.10.2. Texas Instruments Synchronous Serial Protocol (SSP)

Data transfers begin by asserting the frame indicator line (ss_0_n/ss_in_n) for one serial clock period. Data to be transmitted are driven onto the txd line one serial clock cycle later; similarly data from the slave are driven onto the rxd line. Data are propagated on the rising edge of the serial clock ($sclk_out/sclk_in$) and captured on the falling edge. The length of the data frame ranges from four to 32 bits.

Figure 128 shows the timing diagram for a single SSP serial transfer.

Figure 128. SSP Serial Format

Continuous data frames are transferred in the same way as single data frames. The frame indicator is asserted for one clock period during the same cycle as the LSB from the current transfer, indicating that another data frame follows.

Figure 129 shows the timing for a continuous SSP transfer.

Figure 129. SSP Serial Format Continuous Transfer

4.11.10.3. National Semiconductor Microwire

Data transmission begins with the falling edge of the slave-select signal (ss_0_n). One-half serial clock ($sclk_out$) period later, the first bit of the control is sent out on the txd line. The length of the control word can be in the range 1 to 16 bits and is set by writing bit field CFS (bits 15:12) in CTRLR0. The remainder of the control word is transmitted (propagated on the falling edge of $sclk_out$) by the DW_app_ssi serial master. During this transmission, no data are present (high impedance) on the serial master's rxd line.

The direction of the data word is controlled by the MDD bit field (bit 1) in the Microwire Control Register (MWCR). When MDD=0, this indicates that the DW_apb_ssi serial master receives data from the external serial slave. One clock cycle after the LSB of the control word is transmitted, the slave peripheral responds with a dummy 0 bit, followed by the data frame, which can be four to 32 bits in length. Data are propagated on the falling edge of the serial clock and captured on the rising edge.

The slave-select signal is held active-low during the transfer and is de-asserted one-half clock cycle later, after the data are transferred. Figure 130 shows the timing diagram for a single DW_apb_ssi serial master read from an external serial slave.

Figure 130. Single DW_apb_ssi Master Microwire Serial Transfer (MDD=0)

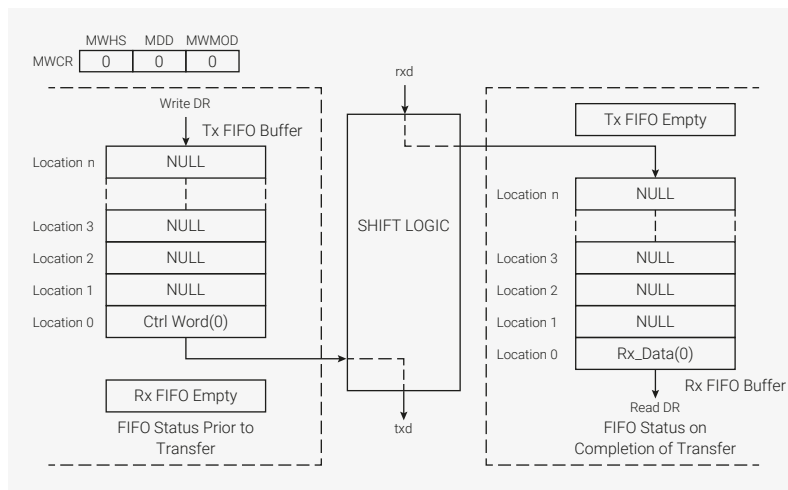

Figure 131 shows how the data and control frames are structured in the transmit FIFO prior to the transfer; the value programmed into the MWCR register is also shown.

Figure 131. FIFO Status for Single Microwire Transfer (receiving data frame)

Continuous transfers for the Microwire protocol can be sequential or nonsequential, and are controlled by the MWMOD bit field (bit 0) in the MWCR register.

Nonsequential continuous transfers occur as illustrated in Figure 132, with the control word for the next transfer following immediately after the LSB of the current data word.

Figure 132. Continuous Nonsequential Microwire Transfer (receiving data frame)

The only modification needed to perform a continuous nonsequential transfer is to write more control words into the transmit FIFO buffer; this is illustrated in Figure 133. In this example, two data words are read from the external serial-slave device.

Figure 133. FIFO Status for Nonsequential Microwire Transfer (receiving data frame)

During sequential continuous transfers, only one control word is transmitted from the DW_apb_ssi master. The transfer is started in the same manner as with nonsequential read operations, but the cycle is continued to read further data. The slave device automatically increments its address pointer to the next location and continues to provide data from that location. Any number of locations can be read in this manner; the DW_apb_ssi master terminates the transfer when the number of words received is equal to the value in the CTRLR1 register plus one.

The timing diagram in Figure 134 and example in Figure 135 show a continuous sequential read of two data frames from the external slave device.

Figure 134. Continuous Sequential Microwire Transfer (receiving data frame)

Figure 135. FIFO Status for Sequential Microwire Transfer (receiving data frame)

When MDD = 1, this indicates that the DW_apb_ssi serial master transmits data to the external serial slave. Immediately after the LSB of the control word is transmitted, the DW_apb_ssi master begins transmitting the data frame to the slave peripheral.

Figure 136 shows the timing diagram for a single DW_apb_ssi serial master write to an external serial slave.

Figure 136. Single Microwire Transfer (transmitting data frame)

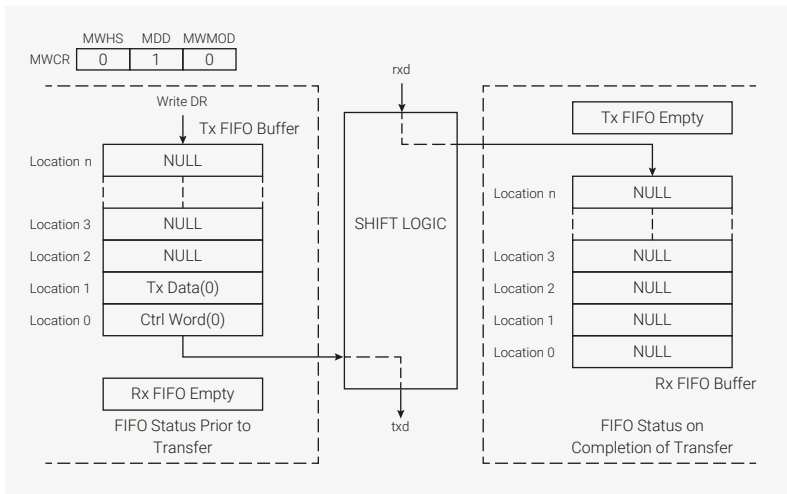

NOTE

The DW_apb_ssi does not support continuous sequential Microwire writes, where MDD = 1 and MWMOD = 1.

Figure 137 shows how the data and control frames are structured in the transmit FIFO prior to the transfer, also shown is the value programmed into the MWCR register.

Figure 137. FIFO Status for Single Microwire Transfer (transmitting data frame)

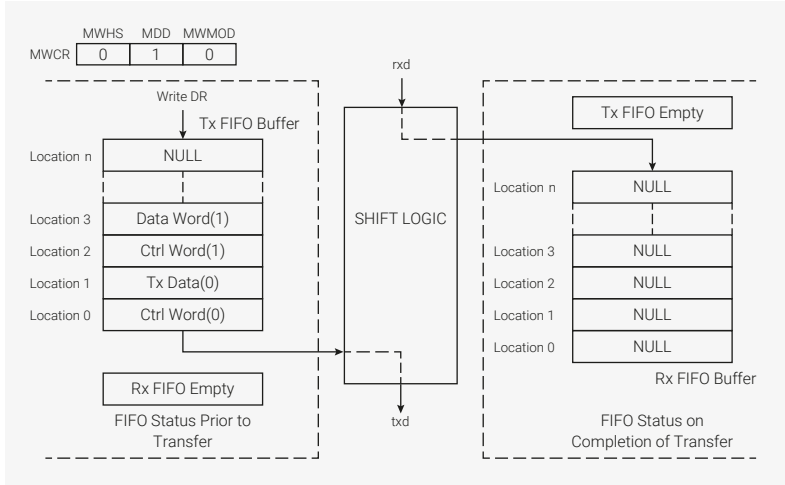

Continuous transfers occur as shown in Figure 138, with the control word for the next transfer following immediately after the LSB of the current data word.

Figure 138. Continuous Microwire Transfer (transmitting data frame)

The only modification you need to make to perform a continuous transfer is to write more control and data words into the transmit FIFO buffer, shown in Figure 139. This example shows two data words are written to the external serial slave device.

Figure 139. FIFO Status for Continuous Microwire Transfer (transmitting data frame)

The Microwire handshaking interface can also be enabled for DW_apb_ssi master write operations to external serial-slave devices. To enable the handshaking interface, you must write 1 into the MHS bit field (bit 2) on the MWCR register. When MHS is set to 1, the DW_apb_ssi serial master checks for a ready status from the slave device before completing the transfer, or transmitting the next control word for continuous transfers.

Figure 140 shows an example of a continuous Microwire transfer with the handshaking interface enabled.

Figure 140. Continuous Microwire Transfer with Handshaking (transmitting data frame)

After the first data word has been transmitted to the serial-slave device, the DW_apb_ssi master polls the rxd input waiting for a ready status from the slave device. Upon reception of the ready status, the DW_apb_ssi master begins transmission of the next control word. After transmission of the last data frame has completed, the DW_apb_ssi master transmits a start bit to clear the ready status of the slave device before completing the transfer. The FIFO status for this transfer is the same as in Figure 139, except that the MWHS bit field is set (1).

To transmit a control word (not followed by data) to a serial-slave device from the DW_apb_ssi master, there must be only one entry in the transmit FIFO buffer. It is impossible to transmit two control words in a continuous transfer, as the shift logic in the DW_apb_ssi treats the second control word as a data word. When the DW_apb_ssi master transmits only a control word, the MDD bit field (bit 1 of MWCR register) must be set (1).

In the example shown in Figure 141 and in the timing diagram in Figure 142, the handshaking interface is enabled. If the handshaking interface is disabled (MHS=0), the transfer is terminated by the DW_apb_ssi master one sclk_out cycle after the LSB of the control word is captured by the slave device.

Figure 141. FIFO Status for Microwire Control Word Transfer

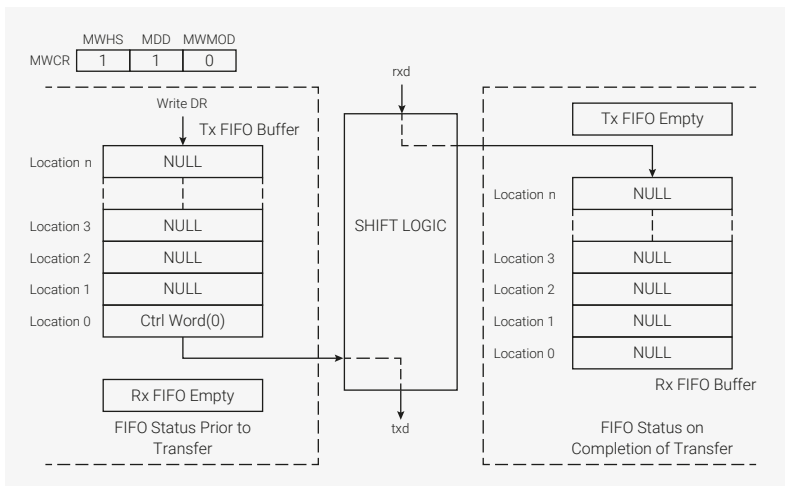

Figure 142. Microwire Control Word

4.11.10.4. Enhanced SPI Modes

DW_apb_ssi supports the dual and quad modes of SPI in RP2040; octal mode is not supported. txd, rxd and ssi_oe_n signals are four bits wide.

Data is shifted out/in on more than one line, increasing the overall throughput. All four combinations of the serial clock's polarity and phase are valid in this mode and work the same as in normal SPI mode. Dual SPI, or Quad SPI modes function similarly except for the width of txd, rxd and ssi_oe_n signals. The mode of operation (write/read) can be selected using the CTRLR0.TMOD field.

4.11.10.4.1. Write Operation in Enhanced SPI Modes

Dual, or Quad, SPI write operations can be divided into three parts:

- Instruction phase
- Address phase
- Data phase

The following register fields are used for a write operation:

- CTRLR0.SPI_FRF - Specifies the format in which the transmission happens for the frame.
- SPI_CTRLR0 (Control Register 0 register) – Specifies length of instruction, address, and data.
- SPI_CTRLR0.INST_L – Specifies length of an instruction (possible values for an instruction are 0, 4, 8, or 16 bits.)
- SPI_CTRLR0.ADDR_L – Specifies address length (See Table 605 for decode values)
- CTRLR0.DFS or CTRLR0.DFS_32 – Specifies data length.

An instruction takes one FIFO location. An address can take more than one FIFO locations.

Both the instruction and address must be programmed in the data register (DR). DW_apb_ssi will wait until both have been programmed to start the write operation.

The instruction, address and data can be programmed to send in dual/quad mode, which can be selected from the SPI_CTRLR0.TRANS_TYPE and CTRLR0.SPI_FRF fields.

NOTE

- If CTRLR0.SPI_FRF is selected to be "Standard SPI Format", everything is sent in Standard SPI mode and SPI_CTRLR0.TRANS_TYPE field is ignored.
- CTRLR0.SPI_FRF is only applicable if CTRLR0.FRF is programmed to 00b.

Figure 143 shows a typical write operation in Dual, or Quad, SPI Mode. The value of N will be: 7 if SSI_SPI_MODE is set to 3, 3 if SSI_SPI_MODE is set to 2, and 1 if SSI_SPI_MODE is set to 1. For 1-write operation, the instruction and address are sent only once followed by data frames programmed in DR until the transmit FIFO becomes empty.

Figure 143. Typical Write Operation Dual/Quad SPI Mode

To initiate a Dual/Quad write operation, CTRLR0.SPI_FRF must be set to 01/10/11, respectively. This will set the transfer type, and for each write command, data will be transferred in the format specified in CTRLR0.SPI_FRF field.

Case A: Instruction and address both transmitted in standard SPI format

For this, SPI_CTRLR0.TRANS_TYPE field must be set to 00b. Figure 144 show the timing diagram when both instruction and address are transmitted in standard SPI format. The value of N will be: 7 if CTRLR0.SPI_FRF is set to 11b, 3 if CTRLR0.SPI_FRF is set to 10b, and 1 if CTRLR0.SPI_FRF is set to 01b.

Figure 144. Instruction and Address Transmitted in Standard SPI Format

Case B: Instruction transmitted in standard and address transmitted in Enhanced SPI format

For this, SPI_CTRLR0.TRANS_TYPE field must be set to one. Figure 145 shows the timing diagram when an instruction is transmitted in standard format and address is transmitted in dual SPI format specified in the CTRLR0.SPI_FRF field. The value of N will be: 7 if CTRLR0.SPI_FRF is set to 11b, 3 if CTRLR0.SPI_FRF is set to 10b, and 1 if CTRLR0.SPI_FRF is set to 01b.

Figure 145. Instruction Transmitted in Standard and Address Transmitted in Enhanced SPI Format

Case C: Instruction and Address both transmitted in Enhanced SPI format

For this, SPI_CTRLR0.TRANS_TYPE field must be set to 10b. Figure 146 shows the timing diagram in which instruction and address are transmitted in SPI format specified in the CTRLR0.SPI_FRF field. The value of N will be: 7 if CTRLR0.SPI_FRF is set to 11b, 3 if CTRLR0.SPI_FRF is set to 10b, and 1 if CTRLR0.SPI_FRF is set to 01b.

Figure 146. Instruction and Address Both Transmitted in Enhanced SPI Format

Case D: Instruction only transfer in enhanced SPI format

For this, SPI_CTRLR0.TRANS_TYPE field must be set to 10b. Figure 147 shows the timing diagram for such a transfer. The value of N will be: 7 if CTRLR0.SPI_FRF is set to 11b, 3 if CTRLR0.SPI_FRF is set to 10b, and 1 if CTRLR0.SPI_FRF is set to 01b.

Figure 147. Instruction only transfer in enhanced SPI Format

4.11.10.4.2. Read Operation in Enhanced SPI Modes

A Dual, or Quad, SPI read operation can be divided into four phases:

- Instruction phase
- Address phase
- Wait cycles
- Data phase

Wait Cycles can be programmed using `SPI_CTRLR0.WAIT_CYCLES` field. The value programmed into `SPI_CTRLR0.WAIT_CYCLES` is mapped directly to `sclk_out` times. For example, `WAIT_CYCLES=0` indicates no Wait, `WAIT_CYCLES=1`, indicates one wait cycle and so on. The wait cycles are introduced for target slave to change their mode from input to output and the wait cycles can vary for different devices.

For a READ operation, `DW_apb_ssi` sends instruction and control data once and waits until it receives NDF (`CTRLR1` register) number of data frames and then de-asserts slave select signal.

Figure 148 shows a typical read operation in dual quad SPI mode. The value of N will be: 3 if `SSI_SPI_MODE` is set to Quad mode, and 1 if `SSI_SPI_MODE` is set to Dual mode.

Figure 148. Typical Read Operation in Enhanced SPI Mode

To initiate a dual/quad read operation, `CTRLR0.SPI_FRF` must be set to 01/10/11 respectively. This will set the transfer type, now for each read command data will be transferred in the format specified in `CTRLR0.SPI_FRF` field.

Following are the possible cases of write operation in enhanced SPI modes:

Case A: Instruction and address both transmitted in standard SPI format

For this, `SPI_CTRLR0.TRANS_TYPE` field should be set to `00b`. Figure 149 shows the timing diagram when both instruction and address are transferred in standard SPI format. The figure also shows WAIT cycles after address, which can be programmed in the `SPI_CTRLR0.WAIT_CYCLES` field. The value of N will be 7 if `CTRLR0.SPI_FRF` is set to `11b`, 3 if `CTRLR0.SPI_FRF` is set to `10b`, and 1 if `CTRLR0.SPI_FRF` is set to `01b`.

Figure 149. Instruction and Address Transmitted in Standard SPI Format

Case B: Instruction transmitted in standard and address transmitted in dual SPI format

For this, `SPI_CTRLR0.TRANS_TYPE` field should be set to `01b`. Figure 150 shows the timing diagram in which instruction is transmitted in standard format and address is transmitted in dual SPI format. The value of N will be 7 if `CTRLR0.SPI_FRF` is set to `11b`, 3 if `CTRLR0.SPI_FRF` is set to `10b`, and 1 if `CTRLR0.SPI_FRF` is set to `01b`.

Figure 150. Instruction Transmitted in Standard and Address Transmitted in Enhanced SPI Format

Case C: Instruction and Address both transmitted in Dual SPI format

For this, SPI_CTRLR0.TRANS_TYPE field must be set to **10b**. Figure 151 shows the timing diagram in which both instruction and address are transmitted in dual SPI format. The value of N will be: 7 if CTRLR0.SPI_FRF is set to **11b**, 3 if CTRLR0.SPI_FRF is set to **10b**, and 1 if CTRLR0.SPI_FRF is set to **01b**.

Figure 151. Instruction and Address Transmitted in Enhanced SPI Format

Case D: No Instruction, No Address READ transfer

For this, SPI_CTRLR0.ADDR_L and SPI_CTRLR0.INST_L must be set to 0 and SPI_CTRLR0.WAIT_CYCLES must be set to a non-zero value. Table 605 lists the ADDR_L decode value and the respective description for enhanced (Dual/Quad) SPI modes.

Table 605. ADDR_L Decode in Enhanced SPI Mode

ADDR_L Decode Value	Description
0000	0-bit Address Width
0001	4-bit Address Width
0010	8-bit Address Width
0011	12-bit Address Width
0100	16-bit Address Width
0101	20-bit Address Width
0110	24-bit Address Width
0111	28-bit Address Width
1000	32-bit Address Width
1001	36-bit Address Width
1010	40-bit Address Width
1011	44-bit Address Width
1100	48-bit Address Width
1101	52-bit Address Width
1110	56-bit Address Width
1111	60-bit Address Width

Figure 152 shows the timing diagram for such type of transfer. The value of N will be: 7 if CTRLR0.SPI_FRF is set to **11b**, 3 if CTRLR0.SPI_FRF is set to **10b**, and 1 if CTRLR0.SPI_FRF is set to **01b**. To initiate this transfer, the software has to perform a dummy write in the data register (DR), DW_apb_ssi will wait for programmed wait cycles and then fetch the amount of data specified in NDF field.

Figure 152. No Instruction and No Address READ Transfer

4.11.10.4.3. Advanced I/O Mapping for Enhanced SPI Modes

The Input/Output mapping for enhanced SPI modes (dual, and quad) is hardcoded inside the DW_apb_ssi. The rxd[1] signal will be used to sample incoming data in standard SPI mode of operation.

For other protocols (such as SSP and Microwire), the I/O mapping remains the same. Therefore, it is easy for other protocols to connect with any device that supports Dual/Quad SPI operation because other protocols do not require a MUX logic to exist outside the design.

Figure 153 shows the I/O mapping of DW_apb_ssi in Quad mode with another SPI device that supports the Quad mode. As illustrated in Figure 153, the IO[1] pin is used as DO in standard SPI mode of operation and it is connected to rxd[1] pin, which will be sampling the input in the standard mode of operation.

Figure 153. Advanced I/O Mapping in Quad SPI Modes

4.11.10.5. Dual Data-Rate (DDR) Support in SPI Operation

In standard operations, data transfer in SPI modes occur on either the positive or negative edge of the clock. For improved throughput, the dual data-rate transfer can be used for reading or writing to the memories.

The DDR mode supports the following modes of SPI protocol:

- SCPH=0 & SCPOL=0 (Mode 0)
- SCPH=1 & SCPOL=1 (Mode 3)

DDR commands enable data to be transferred on both edges of clock. Following are the different types of DDR commands:

- Address and data are transmitted (or received in case of data) in DDR format, while instruction is transmitted in standard format.
- Instruction, address, and data are all transmitted or received in DDR format.

The DDR_EN (SPI_CTRLR0[16]) bit is used to determine if the Address and data have to be transferred in DDR mode and INST_DDR_EN (SPI_CTRLR0[17]) bit is used to determine if Instruction must be transferred in DDR format. These bits are only valid when the CTRLR0.SPLFRF bit is set to be in Dual, or Quad mode.

Figure 154 describes a DDR write transfer where instructions are continued to be transmitted in standard format. In Figure 154, the value of N will be 7 if CTRLR0.SPLFRF is set to 11b, 3 if CTRLR0.SPLFRF is set to 10b, and 1 if CTRLR0.SPLFRF is set to 01b.

Figure 154. DDR Transfer with SCPH=0 and SCPOL=0

Figure 155 describes a DDR write transfer where instruction, address and data all are transferred in DDR format.

Figure 155. DDR Transfer with Instruction, Address and Data Transmitted in DDR Format

NOTE

In the DDR transfer, address and instruction cannot be programmed to a value of 0.

4.11.10.5.1. Transmitting Data in DDR Mode

In DDR mode, data is transmitted on both edges so that it is difficult to sample data correctly. DW_apb_ssi uses an internal register to determine the edge on which the data should be transmitted. This will ensure that the receiver is able to get a stable data while sampling. The internal register (DDR_DRIVE_EDGE) determines the edge on which the data is transmitted. DW_apb_ssi sends data with respect to baud clock, which is an integral multiple of the internal clock ($ssi_clk * BAUDR$). The data needs to be transmitted within half clock cycle ($BAUDR/2$), therefore the maximum value for DDR_DRIVE_EDGE is equal to $[(BAUDR/2)-1]$. If the programmed value of DDR_DRIVE_EDGE is 0 then data is transmitted edge-aligned with respect to sclk_out (baud clock). If the programmed value of DDR_DRIVE_EDGE is one then the data is transmitted one ssi_clk before the edge of sclk_out.

NOTE

If the baud rate is programmed to be two, then the data will always be edge aligned.

Figure 156, Figure 157, and Figure 158 show examples of how data is transmitted using different values of the DDR_DRIVE_EDGE register. The green arrows in these examples represent the points where data is driven. Baud rate used in all these examples is 12. In Figure 156, transmit edge and driving edge of the data are the same. This is default behavior in DDR mode.

Figure 156. Transmit Data With DDR_DRIVE_EDGE = 0

Figure 156 shows the default behavior in which the transmit and driving edge of the data is the same.

Figure 157. Transmit Data With DDR_DRIVE_EDGE = 1

Figure 158. Transmit Data With DDR_DRIVE_EDGE = 2

4.11.10.6. XIP Mode Support in SPI Mode

The eXecute In Place (XIP) mode enables transfer of SPI data directly through the APB interface without writing the data register of DW_apb_ssi. XIP mode is enabled in DW_apb_ssi when the XIP cache is enabled. This control signal indicates whether APB transfers are register read-write or XIP reads. When in XIP mode, DW_apb_ssi expects only read request on the APB interface. This request is translated to SPI read on the serial interface and soon after the data is received, the data is returned to the APB interface in the same transaction.

NOTE

- Only APB reads are supported during an XIP operation

The address length is derived from the SPI_CTRLR0.ADDR_L field, and relevant bits from paddr ((SPI_CTRLR0.ADDR_L-1:0)) are transferred as address to the SPI interface. XIP address is managed by the XIP cache controller.

4.11.10.6.1. Read Operation in XIP Mode

The XIP operation is supported only in enhanced SPI modes (Dual, Quad) of operation. Therefore, the CTRLR0.SPI_FRF bit should not be programmed to 0. An XIP read operation is divided into two phases:

- Address phase
- Data phase

For an XIP read operation

1. Set the SPI frame format and data frame size value in CTRLR0 register. Note that the value of the maximum data frame size is 32.
2. Set the Address length, Wait cycles, and transaction type in the SPI_CTRLR0 register. Note that the maximum address length is 32.

After these settings, a user can initiate a read transaction through the APB interface which will transferred to SPI peripheral using programmed values. Figure 159 shows the typical XIP transfer. The Value of N = 1, 3 and 7 for SPI mode Dual, and Quad modes, respectively.

#TO DO: in the follow diagram should txd and rxd be [N:0] instead of [7:0] #

Figure 159. Typical Read Operation in XIP Mode

4.11.11. DMA Controller Interface

The DW_apb_ssi has built-in DMA capability; it has a handshaking interface to a DMA Controller to request and control transfers. The APB bus is used to perform the data transfer to or from the DMA.

NOTE

When the DW_apb_ssi interfaces to the DMA controller, the DMA controller is always a flow controller; that is, it controls the block size. This must be programmed by software in the DMA controller.

The DW_apb_ssi uses two DMA channels, one for the transmit data and one for the receive data. The DW_apb_ssi has these DMA registers:

DMACR

Control register to enable DMA operation.

DMATDLR

Register to set the transmit the FIFO level at which a DMA request is made.

DMARDLR

Register to set the receive FIFO level at which a DMA request is made.

The DW_apb_ssi uses the following handshaking signals to interface with the DMA controller.

- dma_tx_req
- dma_tx_single
- dma_tx_ack
- dma_rx_req
- dma_tx_req
- dma_tx_single
- dma_tx_ack
- dma_rx_req

To enable the DMA Controller interface on the DW_apb_ssi, you must write the DMA Control Register (DMACR). Writing a 1 into the TDMAE bit field of DMACR register enables the DW_apb_ssi transmit handshaking interface. Writing a 1 into the RDMAE bit field of the DMACR register enables the DW_apb_ssi receive handshaking interface.

Table 606 provides description for different DMA transmit data level values.

Table 606. DMA Transmit Data Level (DMATDL) Decode Value

DMATDL Value	Description
0000_0000	dma_tx_req is asserted when zero data entries are present in the transmit FIFO
0000_0001	dma_tx_req is asserted when one or less data entry is present in the transmit FIFO

0000_0010	dma_tx_req is asserted when two or less data entries are present in the transmit FIFO
...	...
0000_1101	dma_tx_req is asserted when 13 or less data entries are present in the transmit FIFO
0000_1110	dma_tx_req is asserted when 14 or less data entries are present in the transmit FIFO
0000_1111	dma_tx_req is asserted when 15 or less data entries are present in the transmit FIFO

Table 607 provides description for different DMA Receive Data Level values.

Table 607. DMA Receive Data Level (DMARDL) Decode Value

DMARDL Value	Description
0000_0000	dma_rx_req is asserted when one or more data entries are present in the receive FIFO
0000_0001	dma_rx_req is asserted when two or more data entries are present in the receive FIFO
0000_0010	dma_rx_req is asserted when three or more data entries are present in the receive FIFO
...	...
0000_1101	dma_rx_req is asserted when 14 or more data entries are present in the receive FIFO
0000_1110	dma_rx_req is asserted when 15 or more data entries are present in the receive FIFO
0000_1111	dma_rx_req is asserted when 16 data entries are present in the receive FIFO

4.11.11.1. Overview of Operation

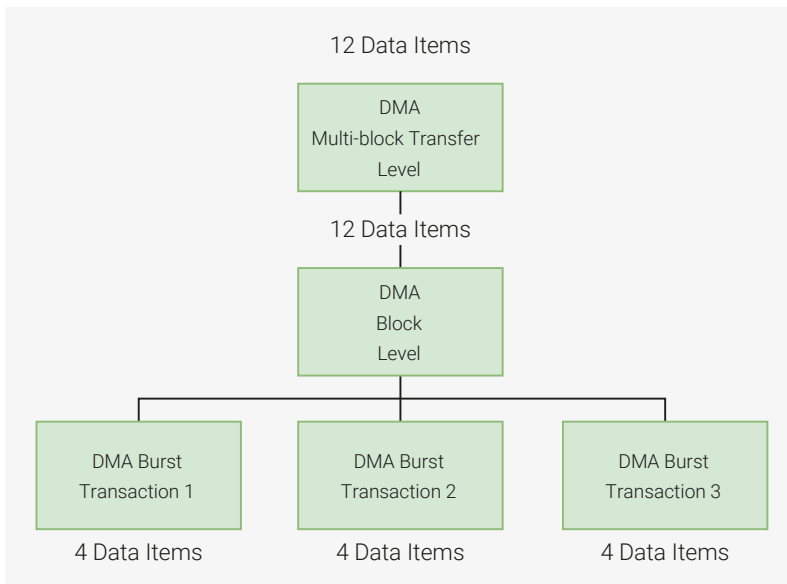

As a block flow control device, the DMA Controller is programmed by the processor with the number of data items (block size) that are to be transmitted or received by the DW_apb_ssi.

The block is broken into a number of transactions, each initiated by a request from the DW_apb_ssi. The DMA Controller must also be programmed with the number of data items (in this case, DW_apb_ssi FIFO entries) to be transferred for each DMA request. This is also known as the burst transaction length.

Figure 160 shows a single block transfer, where the block size programmed into the DMA Controller is 12 and the burst transaction length is set to four. In this case, the block size is a multiple of the burst transaction length; therefore, the DMA block transfer consists of a series of burst transactions.

TO DO: Liam: to check/review/change/remove DMA register settings here

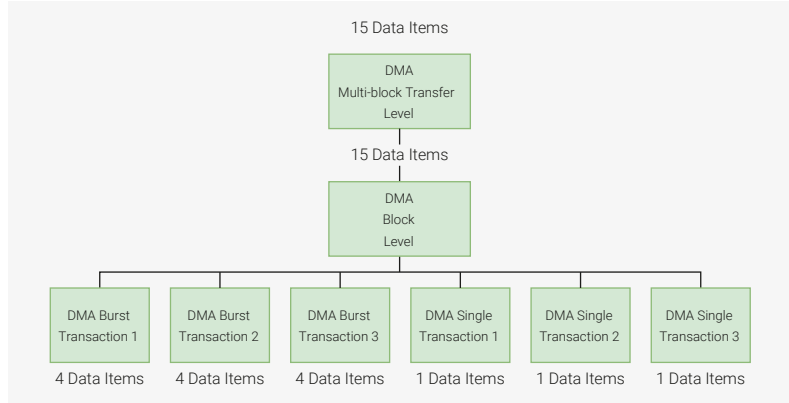

Figure 160. Breakdown of DMA Transfer into Burst Transactions. Block size, DMA.CTLx.BLOCKS_TS = 12. Number of data items per source burst transaction, DMA.CTLx.SRC_MS_IZE = 4. SSI receive FIFO watermark level, SSI.DMARDLR + 1 = DMA.CTLx.SRC_MS_IZE = 4

If the DW_apb_ssi makes a transmit request to this channel, four data items are written to the DW_apb_ssi transmit FIFO. Similarly, if the DW_apb_ssi makes a receive request to this channel, four data items are read from the DW_apb_ssi receive FIFO. Three separate requests must be made to this DMA channel before all 12 data items are written or read.

When the block size programmed into the DMA Controller is not a multiple of the burst transaction length, as shown in Figure 161, a series of burst transactions followed by single transactions are needed to complete the block transfer.

Figure 161. Breakdown of DMA Transfer into Single and Burst Transactions. Block size, DMA.CTLx.BLOCK_TS = 15. Number of data items per burst transaction, DMA.CTLx.DEST_MSIZE = 4. SSI transmit FIFO watermark level, SSI.DMATDLR = DMA.CTLx.DEST_MSIZE = 4

4.11.12. APB Interface

The host processor accesses data, control, and status information on the DW_apb_ssi through the APB interface. APB accesses to the DW_apb_ssi peripheral are described in the following subsections.

4.11.12.1. Control and Status Register APB Access

Control and status registers within the DW_apb_ssi are byte-addressable. The maximum width of the control or status register in the DW_apb_ssi is 16 bits. Therefore all read and write operations to the DW_apb_ssi control and status registers require only one APB access.

4.11.12.2. Data Register APB Access

The data register (DR) within the DW_apb_ssi is 32 bits wide in order to remain consistent with the maximum serial transfer size (data frame). An APB write operation to DR moves data from pwwdata into the transmit FIFO buffer. An APB read operation from DR moves data from the receive FIFO buffer onto prdata.

The DW_apb_ssi DR can be written/read in one APB access.

NOTE

The DR register in the DW_apb_ssi occupies sixty-four 32-bit locations of the memory map to facilitate AHB burst transfers. There are no burst transactions on the APB bus itself, but DW_apb_ssi supports the AHB bursts that happen on the AHB side of the AHB/APB bridge. Writing to any of these address locations has the same effect as pushing the data from the pwwdata bus into the transmit FIFO. Reading from any of these locations has the same effect as popping data from the receive FIFO onto the prdata bus. The FIFO buffers on the DW_apb_ssi are not addressable.

4.11.12.3. APB 3.0 Support

The register interface of DW_apb_ssi is compliant with APB 3.0 specifications. The pready and pslverr signals are included to support the APB 3.0 interface. The pready signal is always kept to its default value (HIGH == 1) for all operations except for XIP operations.

The pslverr signal functionality is disabled.

TO DO: I'm not sure the above section is useful to me a user of the rp2040, if it is what do I do with it

4.11.13. List of Registers

Table 608. List of SSI registers

Offset	Name	Info
0x00	CTRLR0	Control register 0
0x04	CTRLR1	Master Control register 1
0x08	SSIENR	SSI Enable
0x0c	MWCR	Microwire Control
0x10	SER	Slave enable
0x14	BAUDR	Baud rate
0x18	TXFTLR	TX FIFO threshold level
0x1c	RXFTLR	RX FIFO threshold level
0x20	TXFLR	TX FIFO level
0x24	RXFLR	RX FIFO level
0x28	SR	Status register
0x2c	IMR	Interrupt mask
0x30	ISR	Interrupt status
0x34	RISR	Raw interrupt status
0x38	TXOICR	TX FIFO overflow interrupt clear
0x3c	RXOICR	RX FIFO overflow interrupt clear
0x40	RXUICR	RX FIFO underflow interrupt clear
0x44	MSTICR	Multi-master interrupt clear
0x48	ICR	Interrupt clear
0x4c	DMACR	DMA control
0x50	DMATDLR	DMA TX data level
0x54	DMARDLR	DMA RX data level
0x58	IDR	Identification register
0x5c	SSI_VERSION_ID	Version ID
0x60	DR0	Data Register 0 (of 36)
0xf0	RX_SAMPLE_DLY	RX sample delay
0xf4	SPI_CTRLR0	SPI control
0xf8	TXD_DRIVE_EDGE	TX drive edge

CTRLR0 Register

Description

Control register 0

Table 609. CTRLR0 Register

Bits	Name	Description	Type	Reset
31:25	Reserved.	-	-	-
24	SSTE	Slave select toggle enable	RW	0x0
23	Reserved.	-	-	-
22:21	SPI_FRF	SPI frame format 0x0 -> Standard 1-bit SPI frame format; 1 bit per SCK, full-duplex 0x1 -> Dual-SPI frame format; two bits per SCK, half-duplex 0x2 -> Quad-SPI frame format; four bits per SCK, half-duplex	RW	0x0
20:16	DFS_32	Data frame size in 32b transfer mode Value of n -> n+1 clocks per frame.	RW	0x00
15:12	CFS	Control frame size Value of n -> n+1 clocks per frame.	RW	0x0
11	SRL	Shift register loop (test mode)	RW	0x0
10	SLV_OE	Slave output enable	RW	0x0
9:8	TMOD	Transfer mode 0x0 -> Both transmit and receive 0x1 -> Transmit only (not for FRF == 0, standard SPI mode) 0x2 -> Receive only (not for FRF == 0, standard SPI mode) 0x3 -> EEPROM read mode (TX then RX; RX starts after control data TX'd)	RW	0x0
7	SCPOL	Serial clock polarity	RW	0x0
6	SCPH	Serial clock phase	RW	0x0
5:4	FRF	Frame format	RW	0x0
3:0	DFS	Data frame size	RW	0x0

CTRLR1 Register

Description

Master Control register 1

Table 610. CTRLR1 Register

Bits	Name	Description	Type	Reset

Chapter 5. Electrical and Mechanical

Physical and electrical details of the RP2040 chip.

5.1. Package

Figure 162. Top down view (left, top) and side view (right, top), along with bottom view (left, bottom) of the RP2040 QFN-56 package

NOTE

There is no standard size for the central GND pad (or ePad) with QFNs. However, the one on RP2040 is smaller than most. This means that standard 0.4mm QFN-56 footprints provided with CAD tools may need adjusting. This gives the opportunity to route between the central pad and the ones on the periphery, which can help with maintaining power and ground integrity on cheaper PCBs. See [Minimal Design Example](#) for an example.

5.1.1. Recommended PCB Footprint

Figure 163. Recommended PCB Footprint for the RP2040 QFN-56 package

5.2. Pinout

5.2.1. Pin Locations

Figure 164. RP2040 QFN-56 package pinout

5.2.2. Pin Definitions

5.2.2.1. Pin Types

In the following [GPIO Pin table](#), the pin types are defined as shown below.

Table 637. Pin Types

Pin Type	Direction	Description
Digital In	Input only	Standard Digital. Programmable Pull-Up, Pull-Down, Slew Rate, Schmitt Trigger and Drive Strength. Default Drive Strength is 4mA.
Digital IO	Bi-directional	
Digital In (FT)	Input only	Fault Tolerant Digital. These pins are described as Fault Tolerant, which in this case means that very little current flows into the pin whilst it is below 3.63V and IOVDD is 0V. There is also enhanced ESD protection on these pins. Programmable Pull-Up, Pull-Down, Slew Rate, Schmitt Trigger and Drive Strength. Default Drive Strength is 4mA.
Digital IO (FT)	Bi-directional	
Digital IO / Analogue	Bi-directional (digital), Input (Analogue)	Standard Digital and ADC input. Programmable Pull-Up, Pull-Down, Slew Rate, Schmitt Trigger and Drive Strength. Default Drive Strength is 4mA.
USB IO	Bi-directional	These pins are for USB use, and contain internal pull-up and pull-down resistors, as per the USB specification. Note that external 27 Ω series resistors are required for USB operation.
Analogue (XOSC)		Oscillator input pins for attaching a 12MHz crystal. Alternatively, XIN may be driven by a square wave.

5.2.2.2. Pin List

Table 638. GPIO pins

Name	Number	Type	Power Domain	Reset State	Description
<i>GPIO0</i>	2	Digital IO (FT)	IOVDD	Pull-Down	User IO
<i>GPIO1</i>	3	Digital IO (FT)	IOVDD	Pull-Down	User IO
<i>GPIO2</i>	4	Digital IO (FT)	IOVDD	Pull-Down	User IO
<i>GPIO3</i>	5	Digital IO (FT)	IOVDD	Pull-Down	User IO
<i>GPIO4</i>	6	Digital IO (FT)	IOVDD	Pull-Down	User IO
<i>GPIO5</i>	7	Digital IO (FT)	IOVDD	Pull-Down	User IO
<i>GPIO6</i>	8	Digital IO (FT)	IOVDD	Pull-Down	User IO
<i>GPIO7</i>	9	Digital IO (FT)	IOVDD	Pull-Down	User IO
<i>GPIO8</i>	11	Digital IO (FT)	IOVDD	Pull-Down	User IO
<i>GPIO9</i>	12	Digital IO (FT)	IOVDD	Pull-Down	User IO
<i>GPIO10</i>	13	Digital IO (FT)	IOVDD	Pull-Down	User IO
<i>GPIO11</i>	14	Digital IO (FT)	IOVDD	Pull-Down	User IO
<i>GPIO12</i>	15	Digital IO (FT)	IOVDD	Pull-Down	User IO
<i>GPIO13</i>	16	Digital IO (FT)	IOVDD	Pull-Down	User IO
<i>GPIO14</i>	17	Digital IO (FT)	IOVDD	Pull-Down	User IO
<i>GPIO15</i>	18	Digital IO (FT)	IOVDD	Pull-Down	User IO

Name	Number	Type	Power Domain	Reset State	Description
<i>GPIO16</i>	27	Digital IO (FT)	IOVDD	Pull-Down	User IO
<i>GPIO17</i>	28	Digital IO (FT)	IOVDD	Pull-Down	User IO
<i>GPIO18</i>	29	Digital IO (FT)	IOVDD	Pull-Down	User IO
<i>GPIO19</i>	30	Digital IO (FT)	IOVDD	Pull-Down	User IO
<i>GPIO20</i>	31	Digital IO (FT)	IOVDD	Pull-Down	User IO
<i>GPIO21</i>	32	Digital IO (FT)	IOVDD	Pull-Down	User IO
<i>GPIO22</i>	34	Digital IO (FT)	IOVDD	Pull-Down	User IO
<i>GPIO23</i>	35	Digital IO (FT)	IOVDD	Pull-Down	User IO
<i>GPIO24</i>	36	Digital IO (FT)	IOVDD	Pull-Down	User IO
<i>GPIO25</i>	37	Digital IO (FT)	IOVDD	Pull-Down	User IO
<i>GPIO26 / ADC0</i>	38	Digital IO / Analogue	IOVDD / ADC_IOVDD	Pull-Down	User IO or ADC input
<i>GPIO27 / ADC1</i>	39	Digital IO / Analogue	IOVDD / ADC_IOVDD	Pull-Down	User IO or ADC input
<i>GPIO28 / ADC2</i>	40	Digital IO / Analogue	IOVDD / ADC_IOVDD	Pull-Down	User IO or ADC input
<i>GPIO29 / ADC3</i>	41	Digital IO / Analogue	IOVDD / ADC_IOVDD	Pull-Down	User IO or ADC input

Table 639. QSPI pins

Name	Number	Type	Power Domain	Reset State	Description
<i>QSPI_SD3</i>	51	Digital IO	IOVDD		QSPI data
<i>QSPI_SCLK</i>	52	Digital IO	IOVDD	Pull-Down	QSPI clock
<i>QSPI_SD0</i>	53	Digital IO	IOVDD		QSPI data
<i>QSPI_SD2</i>	54	Digital IO	IOVDD		QSPI data
<i>QSPI_SD1</i>	55	Digital IO	IOVDD		QSPI data

Table 643. USB pins

Name	Number	Type	Power Domain	Description
USB_DP	47	USB IO	USB_IOVDD	USB Data +ve. 27Ω series resistor required for USB operation
USB_DM	46	USB IO	USB_IOVDD	USB Data -ve. 27Ω series resistor required for USB operation

Table 644. Power supply pins

Name	Number(s)	Description
IOVDD	1, 10, 22, 33, 42, 49	IO supply
DVDD	23, 50	Core supply
VREG_IOVDD	44	Voltage regulator input supply
VREG_VOUT	45	Voltage regulator output
USB_IOVDD	48	USB supply
ADC_IOVDD	43	ADC supply
GND	57	Common ground connection via central pad

5.2.3. Pin Specifications

The following electrical specifications are obtained from characterisation over the specified temperature and voltage ranges, as well as process variation, unless the specification is marked as 'Simulated'. In this case, the data is for information purposes only, and is not guaranteed.

5.2.3.1. Absolute Maximum Ratings

Table 645. Absolute maximum ratings for digital IO (Standard and Fault Tolerant)

Parameter	Symbol	Minimum	Maximum	Units	Comment
I/O Supply Voltage	IOVDD	-0.5	3.63	V	
Voltage at IO	V _{PIN}	-0.5	IOVDD + 0.5	V	

5.2.3.2. ESD Performance

Table 646. ESD performance for all pins, unless otherwise stated

Parameter	Symbol	Maximum	Units	Comment
Human Body Model	HBM	2	kV	Compliant with JEDEC specification JS-001-2012 (April 2012)
Human Body Model Digital (FT) pins only	HBM	4	kV	Compliant with JEDEC specification JS-001-2012 (April 2012)
Charged Device Model	CDM	500	V	Compliant with JESD22-C101E (December 2009)

5.2.3.3. Thermal Performance

Table 647. Thermal Performance

Parameter	Symbol	Minimum	Typical	Maximum	Units	Comment
Case Temperature	T _C	-20		85	°C	

5.2.3.4. IO Electrical Characteristics

Table 648. Digital IO characteristics - Standard and FT unless otherwise stated

Parameter	Symbol	Minimum	Maximum	Units	Comment
Pin Input Leakage Current	I _{IN}		1	µA	
Input Voltage High @ IOVDD=1.8V	V _{IH}	0.65 * IOVDD	IOVDD + 0.3	V	
Input Voltage High @ IOVDD=2.5V	V _{IH}	1.7	IOVDD + 0.3	V	
Input Voltage High @ IOVDD=3.3V	V _{IH}	2	IOVDD + 0.3	V	
Input Voltage Low @ IOVDD=1.8V	V _{IL}	-0.3	0.35 * IOVDD	V	
Input Voltage Low @ IOVDD=2.5V	V _{IL}	-0.3	0.7	V	
Input Voltage Low @ IOVDD=3.3V	V _{IL}	-0.3	0.8	V	
Input Hysteresis Voltage @ IOVDD=1.8V	V _{HYS}	0.1 * IOVDD		V	Schmitt Trigger enabled
Input Hysteresis Voltage @ IOVDD=2.5V	V _{HYS}	0.2		V	Schmitt Trigger enabled
Input Hysteresis Voltage @ IOVDD=3.3V	V _{HYS}	0.2		V	Schmitt Trigger enabled

Parameter	Symbol	Minimum	Maximum	Units	Comment
Output Voltage High @ IOVDD=1.8V	V_{OH}	1.24	IOVDD	V	$I_{OH} = 2, 4, 8$ or 12mA depending on setting
Output Voltage High @ IOVDD=2.5V	V_{OH}	1.78	IOVDD	V	$I_{OH} = 2, 4, 8$ or 12mA depending on setting
Output Voltage High @ IOVDD=3.3V	V_{OH}	2.62	IOVDD	V	$I_{OH} = 2, 4, 8$ or 12mA depending on setting
Output Voltage Low @ IOVDD=1.8V	V_{OL}	0	0.3	V	$I_{OL} = 2, 4, 8$ or 12mA depending on setting
Output Voltage Low @ IOVDD=2.5V	V_{OL}	0	0.4	V	$I_{OL} = 2, 4, 8$ or 12mA depending on setting
Output Voltage Low @ IOVDD=3.3V	V_{OL}	0	0.5	V	$I_{OL} = 2, 4, 8$ or 12mA depending on setting
Pull-Up Resistance	R_{PU}	50	80	k Ω	
Pull-Down Resistance	R_{PD}	50	80	k Ω	

Table 649. USB IO characteristics

Parameter	Symbol	Minimum	Maximum	Units	Comment
Pin Input Leakage Current	I_{IN}		1	μ A	
Single Ended Input Voltage High	V_{IHSE}	2		V	
Single Ended Input Voltage Low	V_{ILSE}		0.8	V	
Differential Input Voltage High	V_{IHDIFF}	0.2		V	
Differential Input Voltage Low	V_{ILDIFF}		-0.2	V	
Output Voltage High	V_{OH}	2.8	USB_IOVDD	V	
Output Voltage Low	V_{OL}	0	0.3	V	
Pull-Up Resistance - RPU2	R_{PU2}	0.873	1.548	k Ω	
Pull-Up Resistance - RPU1&2	$R_{PU1\&2}$	1.398	3.063	k Ω	
Pull-Down Resistance	R_{PD}	14.25	15.75	k Ω	

Table 650. ADC characteristics

Parameter	Symbol	Minimum	Maximum	Units	Comment
ADC Input Voltage Range	V_{PIN_ADC}	0	ADC_IOVDD	V	
Effective Number of Bits	ENOB	9		bits	Simulated
Resolved Bits			12	bits	

Table 651. Oscillator pin characteristics when using a Square Wave input

Parameter	Symbol	Minimum	Maximum	Units	Comment
Input Voltage High	V_{IH}	$0.65 \cdot IOVDD$	$IOVDD + 0.3$	V	XIN only. XOUT floating
Input Voltage Low	V_{IL}	0	$0.35 \cdot IOVDD$	V	XIN only. XOUT floating

See [Crystal Oscillator](#) for more details on the Oscillator, and [Minimal Design Example](#) for information on crystal usage.

5.2.3.5. Interpreting GPIO output voltage specifications

The GPIOs on RP2040 have four different output drive strengths, which are nominally called 2, 4, 8 and 12mA modes. These are not hard limits, nor do they mean that they will always be sourcing (or sinking) the selected amount of milliamps. The amount of current a GPIO sources or sinks is dependant on the load attached to it. It will attempt to drive the output to the IOVDD level (or 0V in the case of a logic 0), but the amount of current it is able to source is limited, which will be dependant on the selected drive strength. Therefore the higher the current load is, the lower the voltage will be at the pin. At some point, the GPIO will be sourcing so much current, that the voltage is so low, it won't be recognised as a logic 1 by the input of a connected device. The purpose of the output specifications in [Table 648](#) are to try and quantify how much lower the voltage can be expected to be, when drawing specified amounts of current from the pin.

The Output High Voltage (V_{OH}) is defined as the lowest voltage the output pin can be when driven to a logic 1 with a particular selected drive strength; e.g., 4mA being sourced by the pin whilst in 4mA drive strength mode. The Output Low Voltage is similar, but with a logic 0 being driven.

Figure 165. Typical Current vs Voltage curves of a GPIO output.

Figure 165 shows the effect on the output voltage as the current load on the pin increases. You can clearly see the effect of the different drive strengths; the higher the drive strength, the closer the output voltage is to IOVDD (or 0V) for a given current. The minimum V_{OH} and maximum V_{OL} limits are shown in red. You can see that at the specified current for each drive strength, the voltage is well within the allowed limits, meaning that this particular device could drive a lot more current and still be within V_{OH}/V_{OL} specification. This is a typical part at room temperature, there will be a spread of other devices which will have voltages much closer to this limit. Of course, if your application doesn't need such tightly controlled voltages, then you can source or sink more current from the GPIO than the selected drive strength setting, but experimentation will be required to determine if it indeed safe to do so in your application, as it will be outside the scope of this specification.

5.3. Power Supplies

Table 652. Power Supply Specifications

Power Supply	Supplies	Min	Typ	Max	Units
IOVDD ^a	Digital IO	1.62	1.8 / 3.3	3.63	V
DVDD	Digital core	0.99	1.1	1.21	V
VREG_IOVDD	Voltage regulator	1.62	1.8 / 3.3	3.63	V
USB_IOVDD	USB PHY	3.135	3.3	3.63	V
ADC_IOVDD ^b	ADC	1.62	3.3	3.63	V

^a If IOVDD < 2.5V, GPIO VOLTAGE_SELECT registers should be adjusted accordingly. See Power Supplies for details.

^b ADC performance will be compromised at voltages below 2.97V

5.4. Power Consumption

The following data shows the current consumption of various power supplies on 3 each of typical (tt), fast (ff) and slow (ss) corner RP2040 devices, with four different software use-cases.

NOTE

For power consumption of the Raspberry Pi Pico, please see the [Raspberry Pi Pico Datasheet](#).

Firstly, 'Popcorn' (Media player demo) using the VGA, SD Card, and Audio board. This demo uses VGA video, I2S audio and 4-bit SD Card access, with a system clock frequency of 48MHz.

NOTE

For more details of the VGA board see the [Hardware design with the RP2040](#) book.

Secondly, the USB Boot mode of RP2040. These measurements are made both with and without USB activity on the bus, using a Raspberry Pi 4 as a host.

The third use-case uses the `hello_dormant` binary which puts RP2040 into a low power state, `DORMANT` mode.

The final use-case uses the `hello_sleep` binary code which puts RP2040 into a low power state, `SLEEP` mode.

Table 653 has two columns per power supply, 'Typical Average Current' and 'Maximum Average Current'. The former is the current averaged over several seconds that you might expect a typical RP2040 to consume at room temperature and nominal voltage (e.g., DVDD=1.1V, IOVDD=3.3V, etc). The 'Maximum Average Current' is the maximum current consumption (again averaged over several seconds) you might expect to see on a worst-case RP2040 device, across the temperature extremes, and maximum voltage (e.g., DVDD=1.21V, etc).

NOTE

The 'Popcorn' consumption measurements are heavily dependant on the video being displayed at the time. The 'Typical' values are obtained over several seconds of video, with varied colour and intensity. The 'Maximum' values are measured during periods of white video, when the required current is at its highest.

Table 653. Power Consumption

Software Use-case	Typical Average DVDD Current	Max. Average DVDD current	Typical Average IOVDD Current	Max. Average IOVDD current	Typical Average USB_IOVDD Current	Max. Average USB_IOVDD current	Units
Popcorn	10.9	16.6	24.8	35.5	-	-	mA
USB Boot Mode - Active	9.4	14.7	1.2	4.3	1.4	2.0	mA
USB Boot Mode - Idle	9.0	14.3	1.2	4.3	0.2	0.6	mA
Dormant	0.18	4.2	-	-	-	-	mA
Sleep	0.39	4.5	-	-	-	-	mA

5.4.1. Power Consumption versus frequency

To give an indication of the relationship between the core frequency that RP2040 is operating at, and the current consumed by the DVDD supply, Figure 166 shows the measured results of a typical RP2040 device, continuously running FFT calculations on both cores, at various core clock frequencies. Figure 166 also shows the effects of case temperature, and DVDD voltage upon the current consumption.

Figure 166. DVDD Current vs Core Frequency of a typical RP2040 device, whilst running FFT calculations

Appendix A: Register Field Types

Standard types

RW

The processor can write to this field and read the value back.

RO

The processor can only read this field.

WO

The processor can only write to this field.

Clear types

SC

This is a single bit that is written to by the processor and then cleared on the next clock cycle. An example use of this would be a start bit that triggers an event, and then clears again so the event doesn't keep triggering.

WC

This is a single bit that is typically set by a piece of hardware and then written to by the processor to clear the bit. The bit is cleared by writing a **1**, using either a normal write or the clear alias. See [Section 2.1.2](#) for more information about the clear alias.

FIFO types

These fields are implementation specific.

RF

Implementation defined read from the hardware.

WF

Implementation defined write to the hardware.

RWF

Implementation defined read to, and write from the hardware.

Appendix B: Errata

Watchdog

RP2040-E1

Reference	RP2040-E1
Summary	Watchdog count is decremented twice per tick.
Description	The watchdog (Section 4.8) has a 24 bit counter, that decrements every tick, starting from a user defined value set in LOAD register. There is a logic error which means the counter is decremented twice per tick, instead of once per tick. In a recommended setup where the tick occurs at 1µs intervals, this halves the maximum time between resetting the watchdog counter from ~16.7 seconds to ~8.3 seconds.
Workaround	Use double the desired value in LOAD .
Affects	RP2040B0, RP2040B1
Fixed by	Documentation, Software

USB

RP2040-E2

Reference	RP2040-E2
Summary	USB device endpoint abort is not cleared.
Description	The USB device controller (Section 4.1) has the ability to abort any pending transactions on an endpoint by setting that endpoint's bit in the EP_ABORT register. Due to a logic error, the USB device controller will reply with NAKs forever on all endpoints if a transaction is initiated for any endpoint with the EP_ABORT bit set.
Workaround	Do not use the EP_ABORT bits.
Affects	RP2040B0, RP2040B1
Fixed by	Not fixed, do not use

RP2040-E3

Reference	RP2040-E3
Summary	USB host: interrupt endpoint buffer done flag can be set with incorrect buffer select.

Description	The USB host has two types of transactions: normal software initiated transfer, and interrupt transfers, where the host polls an interrupt endpoint after a specific amount of time. For example, polling a mouse every 1ms to check for movement. Interrupt transfer are single buffered, but the controller doesn't reset the buffer selector to zero. This means that if a software initiated transfer happened then the interrupt transfer can potentially raise the buffer done flag with BUF1 selected instead of BUF0 . The fix is to ignore the BUFF_CPU_SHOULD_HANDLE register for interrupt endpoints.
Workaround	
Affects	RP2040B0, RP2040B1
Fixed by	Software

RP2040-E4

Reference	RP2040-E4
Summary	USB host writes to upper half of buffer status in single buffered mode.
Description	The USB host maintains a buffer selector which switches between BUF0 and BUF1 . This should only be toggled in double buffered mode but is toggled in single buffered mode too. For a transaction lasting multiple packets (i.e. length more than 8 bytes in low speed mode, and length more than 64 bytes in full speed mode), the buffer status can be written back to the BUF1 half of the status register when the buffer select is incorrectly set to BUF1 . Note this does not affect reading new buffer information from the buffer control register, as the controller ignores the buffer selector in single buffered mode when reading the buffer control register.
Workaround	Shift endpoint control register to the right by 16 bits if the buffer selector is BUF1 . You can use BUFF_CPU_SHOULD_HANDLE find the value of the buffer selector when the bufer was marked as done.
Affects	RP2040B0, RP2040B1
Fixed by	Software

RP2040-E5

Reference	RP2040-E5
Summary	USB device fails to exit RESET state on busy USB bus.

Description	<p>The USB bus RESET state is triggered by the host sending SE0 for 10ms to the device. The USB device controller requires 800µs of idle (J-state) after a bus reset before moving to the CONNECTED state. Without this idle time, the USB device does not connect and will not receive any packets from the host, and so does not enumerate.</p> <p>A device reset happens just after the device is plugged in. Although a host will wait before talking to a reset device, other devices attached to the same USB hub may also be communicating with the host.</p> <p>USB 2.0 and USB 3.0 hubs have one or more transaction translators, which facilitate low speed and full speed transactions on a higher speed bus. It depends on the hub design, but a transaction translator is usually shared between a few ports.</p> <p>As the RP2040 USB device is full speed, its traffic when connected to a hub will come via a transaction translator. This means that if you have another device plugged in next to an RP2040, the RP2040 is likely to see some messages from the host addressed to the other device. If the device is not very active, for example, a mouse that is polled every 8ms, this is not a problem. However some devices, such as a USB serial port, are polled every 30-50µs. In this case the bus is very active, and will cause the RP2040 to never exit RESET state and not connect.</p> <p>There is a software workaround for this issue (see workaround section). A user can also work around this by closing the USB serial port or any other offending devices while connecting their RP2040 and then re opening their USB serial port.</p> <p>On a larger hub, the problem may be fixed by moving the RP2040 far away (onto a different transaction translator) from the offending device. For example, connecting the RP2040 to port 1 of a 7 port hub, and connecting the USB serial console to port 7, may solve the issue. Connecting the RP2040 to a separate USB hub to any busy devices will also fix the problem.</p>
Workaround	Use software to force USB device controller to see idle USB bus for 800µs to move the device from the RESET state to the CONNECTED state. This fix uses internal debug logic that is connected to GPIO15 for a short amount of time (~800µs). This forces the controller to see DP as a logical 1 (and DM and logical 0) to make the USB Device controller believe there is a J-state on the USB bus. GPIO15 does not need to be tied in any particular way for this fix to work. Instead, we can force the input path in software using the Section 2.18 input override feature. See https://github.com/raspberrypi/pico-sdk/tree/pre_release/src/rp2_common/pico_fix/rp2040_usb_device_enumeration/rp2040_usb_device_enumeration.c .
Affects	RP2040B0, RP2040B1
Fixed by	Not fixed. Software workaround on RP2040B0, RP2040B1. The workaround isn't present in the USB mass storage code in the bootrom. The software workaround requires use of GPIO15 during USB bus reset.

GPIO / ADC

RP2040-E6

Reference	RP2040-E6
Summary	GPIO digital inputs not disabled for ADC pins by default
Description	GPIO26-29 are shared with ADC inputs AIN0-3. The GPIO digital input is enabled after RUN is released. If the pins are connected to an analogue signal to measure, there could be unexpected signal levels on these pads. This is unlikely to cause a problem as the digital inputs have hysteresis enabled by default.
Workaround	If analogue inputs are used, the digital input should be disabled as early as possible after startup.

Affects	RP2040B0, RP2040B1
Fixed by	Software. Fixed in Pico SDK, custom user code will need to take note.
