

# Managed Switch with 24 FE Ports + 4-GbE Interface

## GENERAL DESCRIPTION

The BCM53262M is a ninth-generation RoboSwitch™ design based on the field-proven BCM5324 device. This integrated 0.13 $\mu$ -CMOS device combines all the functions of a high-speed switch system including packet buffers, PHY transceivers, Media Access Controllers (MACs), address management, and a nonblocking switch fabric. It is designed to be fully compliant with the IEEE 802.3 and IEEE 802.3x specifications, including the MAC control PAUSE frame, auto-negotiation and with all industry-standard Ethernet and Fast Ethernet devices.

The BCM53262M contains 24 full-duplex 10Base-T/100Base-TX Fast Ethernet transceivers with Advanced Cable Diagnostics support. Each performs all physical layer interface functions for 10Base-T Ethernet on Category 3, 4, or 5 Unshielded Twisted Pair (UTP) cable and 100Base-TX Fast Ethernet on Category 5 UTP cable. The BCM53262M has four SGMII interfaces that provide flexible 10/100/1000Base-TX/FX connectivity. An additional MAC is included for CPU connection via RvMII/MII (Rev. A)/GMII (Rev. B) interface.

The BCM53262M has a rich feature set suitable for streaming VoIP, video, and data traffic for multimedia applications. The BCM53262M supports up to four QoS queues per port. Traffic QoS can be assigned based on Port-ID, MAC Address, 802.1p or DiffServ. Together with 4K entries, 802.1Q VLAN, 802.1x EAPOL protocol filtering, MAC-based link aggregation with dynamic failover, per-port bandwidth/rate control, MAC address locking, and IGMP snooping at Layer 3 allow system vendors to build advanced L2+ switch systems for the Multitenant/Multidweller Unit (MTU/MDU) markets. The BCM53262M provides 70+ on-chip MIB counters to collect receive and transmit statistics for each port.

## FEATURES

- Ninth-generation L2+ Fast Ethernet switch with four SGMII interfaces.
  - 24-port 10/100 transceivers for TX/EFX.
  - Advanced Cable Diagnostic support.
  - 25 10/100 MACs.
  - Four Gigabit MACs.
  - 3-Mbit (384 KB) packet buffer and control memory.
  - Management Port with RvMII/MII interface (Rev. A).
  - Management Port with RvMII/MII/GMII interface (Rev. B).
- Nonblocking switch fabric for 24 FE + 4 GbE ports.
- Jumbo frame support up to 2048 bytes.
- Flexible TCAM-based Compact Field Processor for packet classification and filtering.
- Packet Remarking, VID Replacement.
  - 802.1p PCP, DSCP remarking.
- Optimized for managed switch design.
- 802.1p, Port, MAC, Protocol, Customer\_VID, and DiffServ (IPv4/IPv6) based QoS packet classification with four priority queues.
- Port-based VLAN.
- 802.1Q-based VLAN with 4K entries.
- MAC-based VLAN with 512 entries.
- Protocol-based VLAN with 16 entries.
- VLAN Translation.
- Double tagging.
  - UNI/NNI configuration per port for edge access application.
  - QinQ packet transmission through NNI port.
  - Programmable global SP\_TPID.
  - Programmable SP\_VID through flexible mapping.
- Link Aggregation support with automatic link fail-over.
- Programmable per-port Bandwidth/Rate control.
- Protected port security feature.
- Port mirroring (Ingress/Egress), IGMP Layer 3. snooping and MLD snooping.
- Spanning Tree support (802.1d/1s/1w).
- Supports 802.1x EAPOL higher layer protocol.
- Programmable Broadcast, Multicast, and Unknown Unicast storm control. 8K MAC addresses with automatic learning and aging.
- MDC/MDIO and SPI interfaces.
- 4K-entry Multicast Address table.
- Hardware supports SNMP, RMON.
- Internal oscillator simplifies design and reduces cost.
- JTAG.
- 2.5V and 1.2V, typical power consumption: ~ 4.3W.
- 676-pin PBGA package.

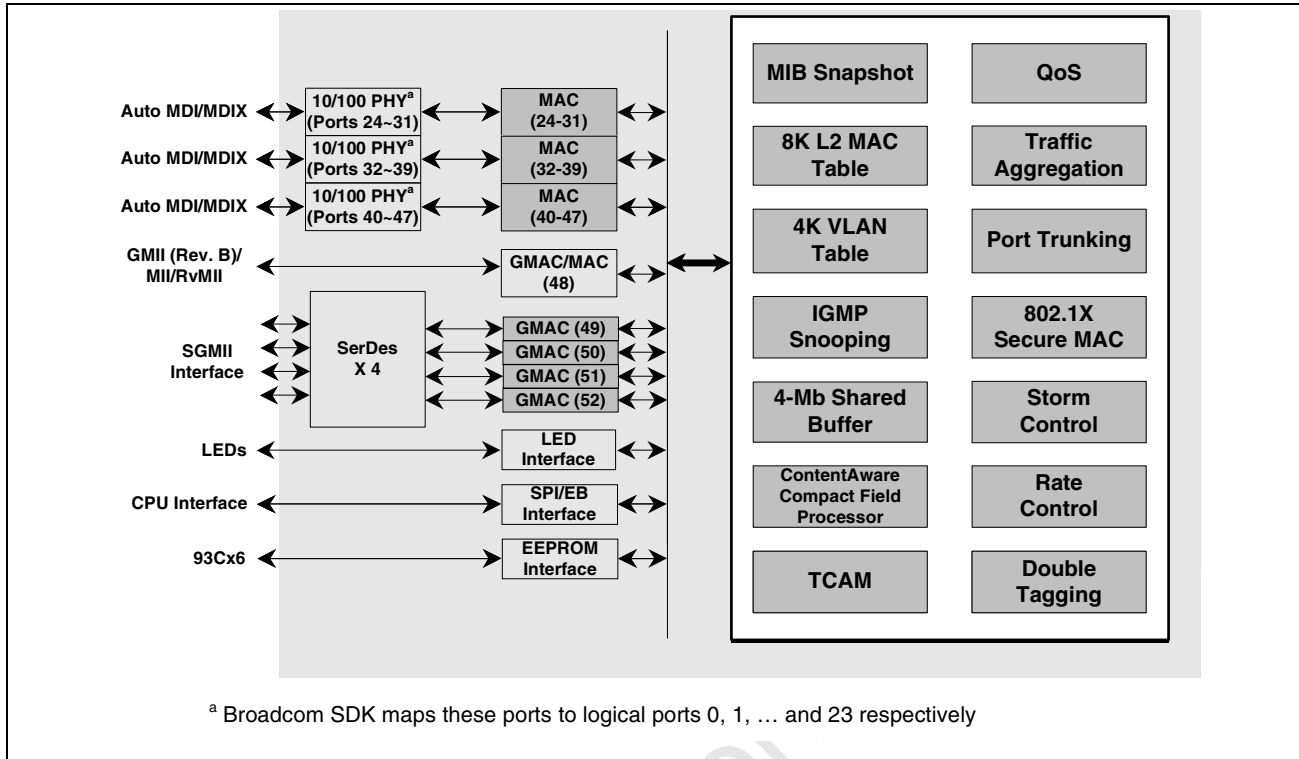

Figure 1: Functional Block Diagram

## REVISION HISTORY

## About This Document

### Purpose and Audience

This document provides details of the functional, operational, and electrical characteristics of the Broadcom<sup>®</sup> BCM53262M. It is intended for hardware design, application, and OEM engineers.

### Acronyms and Abbreviations

In most cases, acronyms and abbreviations are defined on first use.

For a comprehensive list of acronyms and other terms used in Broadcom documents, go to:  
<http://www.broadcom.com/press/glossary.php>.

### Document Conventions

The following conventions may be used in this document:

<i>Convention</i>	<i>Description</i>
<b>Bold</b>	User input and actions: for example, type <b>exit</b> , click <b>OK</b> , press <b>Alt+C</b>
Monospace	Code: <code>#include &lt;iostream&gt;</code> HTML: <code>&lt;td rowspan = 3&gt;</code> Command line commands and parameters: <code>wl [-1] &lt;command&gt;</code>
< >	Placeholders for <i>required</i> elements: enter your <code>&lt;username&gt;</code> or <code>wl &lt;command&gt;</code>
[ ]	Indicates <i>optional</i> command-line parameters: <code>wl [-1]</code> Indicates bit and byte ranges (inclusive): <code>[0:3]</code> or <code>[7:0]</code>

## Technical Support

Broadcom provides customer access to a wide range of information, including technical documentation, schematic diagrams, product bill of materials, PCB layout information, and software updates through its customer support portal (<https://support.broadcom.com>). For a CSP account, contact your Sales or Engineering support representative.

In addition, Broadcom provides other product support through its Downloads & Support site (<http://www.broadcom.com/support/>).

# Section 1: Introduction

---

## Overview

The Broadcom® BCM53262M is a single-chip, 24-port 10/100Base-TX and 4-port 10/100/1000Base-T SGMII switch device. This device integrates the following functions:

- 24 fully integrated 10/100Base-TX/EFX compatible PHY transceivers
- Four-port 10/100/1000 SGMII interface
- 25 integrated 10/100 MACs
- Management Port with RvMII/MII interface (Rev. A)
- Management Port with RvMII/MII/GMII interface (Rev. B)
- A Serial Peripheral Interface (SPI) and MDC/MDIO Interface allowing the device to be custom-configured
- Flexible TCAM-based Compact Field Processor
- High speed management EB Bus for register access
- High-performance integrated packet buffer memory
- An address resolution engine
- Nonblocking switch controller
- Set of Management Information Base (MIB) statistics registers

The Serial Peripheral Interface allows the device to be custom-configured and bridge management to be implemented.

The integrated 10/100Base-TX transceivers perform all the physical layer interface functions for 100Base-TX full-duplex or half-duplex Ethernet on CAT-5 twisted pair cable and 10Base-T full-duplex or half-duplex Ethernet on CAT-3, -4, or -5 cable. Each of the integrated transceiver ports of the BCM53262M connects directly to the network media through isolation transformers. The integrated transceiver is fully compliant with the IEEE 802.3 and 802.3u standards.

Each MAC supports full and half-duplex for 10 Mbps and 100 Mbps and the Gigabit MACs additional support full-duplex operation at 1 Gbps. Flow control is provided in half-duplex mode with backpressure. In full-duplex mode, 802.3x frame-based flow control is provided. The MAC is 802.3 compliant and supports a maximum frame size of 2048 bytes.

The BCM53262M supports advanced ContentAware™ processing via a Compact Fast Field Processor (CFP). Up to three intelligent ContentAware processes are performed in parallel for every packet. This flexible engine uses a TCAM-based architecture with wildcard capabilities; specific areas of the incoming packet to be masked and matched can be defined. Furthermore, multiple actions can be performed per packet as a result of a match. Action examples include dropping, changing of the port forwarding map, changing priority of frame, etc. These advanced ContentAware processes are well suited for both Access Control List and Security protection, for example, DOS prevention.

An integrated address management engine provides address learning and recognition functions at maximum frame rates. The address table provides capacity for up to 8K unicast and multicast addresses. Addresses are added to the table after receiving an error-free packet. Broadcast and multicast frames are forwarded to all ports within the VLAN domain except the port where it was received.

The MIB statistics registers collect receive and transmit statistics for each port, and provide direct hardware support for the Etherlike MIB, Bridge MIB, MIB II (Interfaces), and the first four groups of the RMON MIB. All nine groups of RMON can be supported by using additional capabilities, such as port mirroring/snooping, together with an external microcontroller to process some MIB attributes. The MIB registers can be accessed through the Serial Peripheral Interface Port by an external microcontroller.

---

## Audience

This document is for designers interested in integrating the BCM53262M switch into their hardware designs, and others who need specific data about the physical characteristics and operation of the BCM53262M switch.

---

## Data Sheet Information

The following notational conventions are used in this document:

- Signal names are shown in UPPERCASE letters. For example: DATA
- A bar over a signal name indicates that it is active low. For example:  $\overline{CE}$ .
- In register and signal descriptions, [n:m] indicates a range from bit n to bit m. For example: [7:0] indicates bits 7 through 0, inclusive.
- The use of R or RESERVED indicates that a bit or field is reserved by Broadcom for future use. Typically R is used for individual bits and RESERVED is used for fields.
- Numerical modifiers such as K or M follow traditional usage. For example, 1 KB means 1,024 bytes, 100 Mbps (referring to Fast Ethernet speed) means 100,000,000 bits per second, and 133 MHz means 133,000,000 Hertz.

Where it seems helpful, cross-reference links have been incorporated in the data sheet. The cross-reference is denoted in blue text. When using a PDF version of the data sheet, jump to other sections of the data sheet by clicking on the blue text using the PDF hand tool.

**Example:** Clicking on the text: [“Features and Operation” on page 36](#) jumps to the next section. To return, press the left-arrow key while holding down the alt key. It returns to the previous view. Likewise, pressing the right-arrow key while holding down the alt key jumps to next view.

As always, every effort is made to improve the data sheet and other documentation. To submit suggestions, send e-mail to [RoboDocs@broadcom.com](mailto:RoboDocs@broadcom.com). For technical questions, please contact your local sales representative.

## Section 2: Features and Operation

---

### Overview

The BCM53262M includes the following features:

- “Quality of Service” on page 37
- “Port-Based VLANs” on page 42
- “802.1Q VLANs” on page 43
- “MAC-based VLANs” on page 43
- “Protocol-based VLANs” on page 43
- “Customer-Tag-Based VLANs” on page 43
- “Double Tagging” on page 45
- “Link Aggregation” on page 51
- “Rate Control” on page 52
- “Protected Ports” on page 54
- “Port Mirroring” on page 55
- “IGMP and MLD Snooping” on page 56
- “Jumbo Frame Support” on page 56
- “802.1x Port-Based Security” on page 56
- “Dynamic Secure MAC Mode” on page 57
- “Address Management” on page 57
- “Bridge Management” on page 63
- “Compact Field Processor” on page 65
- “Packet Remarking” on page 73
- “VID Replacement” on page 74

Each topic is discussed in more detail in the following sections.

---

## Quality of Service

The Quality of Service (QoS) feature provides up to four internal queues per port to support four different traffic priorities. These priorities can be programmed in such a way that higher-priority traffic experiences less delay in the switch under congested conditions than the latency of lower-priority traffic. This can be important in minimizing latency for delay-sensitive traffic. The BCM53262M can assign the packet to one of the four egress transmit queues according to information in:

- [“Port-Based QoS” on page 38](#) (ingress port ID)
- [“802.1p QoS” on page 38](#)
- [“Protocol-Based QoS” on page 39](#)
- [“MAC SA-Based QoS” on page 39](#)
- [“DiffServ Based QoS” on page 40](#)
- [“Reason Code Based QoS” on page 41](#)

**Note:** Only 1Q or 4Q mode is supported

**Note:** As a part of the QoS discussion, it is important to understand the BCM53262M Egress port Queue structure.

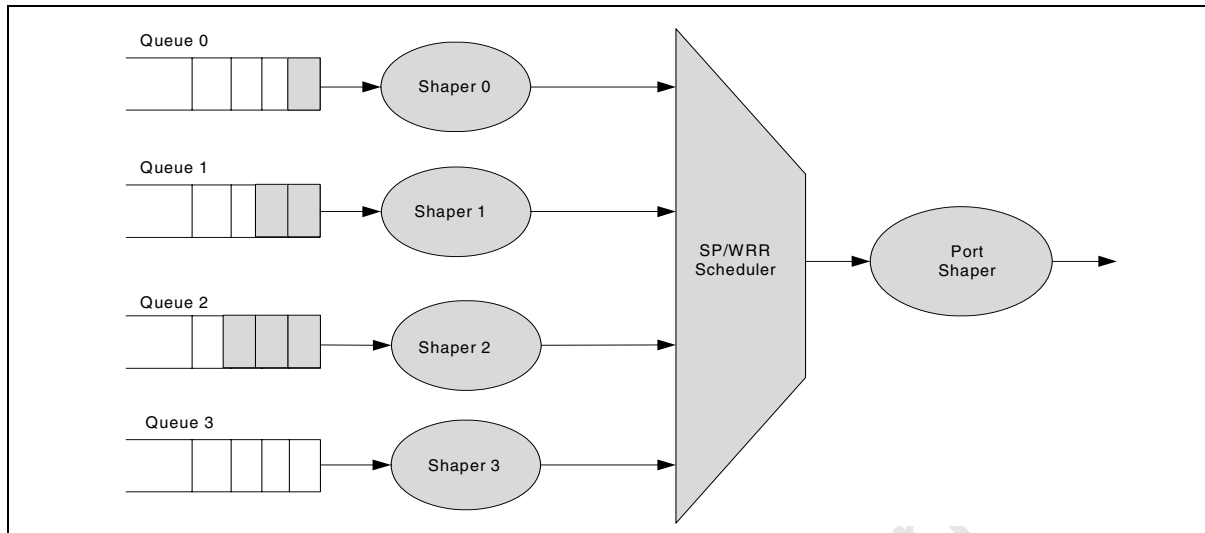

## Egress Transmit Queues

Each egress port can support up to four transmit queues. Each egress transmit queue contains a list specifying the packet transmission order. Every incoming frame is forwarded to one of the four egress transmit queues of the assigned egress port, based on its priority. The egress port transmits packets from each of the four transmit queues according to a configurable scheduling algorithm, which can be a combination of Strict Priority (SP) and/or Weighted Round Robin (WRR). The following scheduling algorithm combinations are available in the BCM53262M:

- Four Strict Priority queues
- Four Weighted Round Robin queues
- One Strict Priority and three Weighted Round Robin queues
- Two Strict Priority and two Weighted Round Robin queues

When a queue is designated as the strict-priority queue, all other lower-priority queues are prevented from transmitting packets until the strict-priority queue is empty. Furthermore, the traffic at each egress port is gated by a Shaper, so that the aggregated output from the queues can be scheduled by a programmable Egress Rate Control, with a granularity of 64 Kbps. Egress Rate Control details are further described within this data sheet.

[Figure 2](#) shows the Shaping-Scheduling structure of each Egress port.

**Figure 2: Shaping-Scheduling Structure of Each Egress port**

## Port-Based QoS

When using the port-based priority mechanism, the port-based priority of each ingress port determines the egress queue assigned to frames arriving via the associated ingress port. The frames will be assigned to the priority queue based on the upper 3-bit per port COS value programmed in the 802.1Q Default Port Tag.

Follow the sequence below to enable Port-Based QoS:

- 1). Enable bit[63], as shown in [Table 238: “QoS Control Register \(Pages: 30h, Address 10h–17h\),” on page 287](#).
- 2). Enable bits[59:58] of QoS Control register.
- 3). Program the upper 3-bit of per-port COS value as shown in [Table 258: “802.1Q Default Port Tag Register \(Page: 34h, Address 40h–79h\),” on page 307](#).
- 4). To select the desired queue, program the register shown in [Table 242: “Priority Threshold Register \(Page 30h: Address 30h–31h\),” on page 290](#).

## 802.1p QoS

When using 802.1p priority mechanism, the packet is examined for the presence of a valid 802.1p priority tag. If the tag is present, the packet is assigned to a programmable egress queue based on the value of the tagged priority. The tagged priority can be designated to any of the available queues.

Follow the sequence below to enable 802.1p QoS:

- 1). Enable bit[63], as shown in [Table 238: “QoS Control Register \(Pages: 30h, Address 10h–17h\),” on page 287](#).
- 2). Enable bits[59:58] of QoS Control register.

3). To select the desired queue, program the register shown in [Table 242: “Priority Threshold Register \(Page 30h: Address 30h–31h\),” on page 290](#).

## Protocol-Based QoS

When using Protocol Based QoS, the EtherType field carried with the incoming packet is used to map the packet to one of the available output queues at the destination port. Protocol-based QoS shares the same control bit and 16-entry Protocol to VLAN mapping table with Protocol-based VLAN. The upper 3-bit in the Protocol to VLAN mapping table is used to program the Protocol-Based priority select field. This mapping can be enabled/disabled per port, but the mapping table is configured globally.

Follow the sequence below to enable Protocol-Based QoS:

1. Enable bit[63], of the QoS Control register (see [Table 238: “QoS Control Register \(Pages: 30h, Address 10h–17h\),” on page 287](#)).
2. Enable bits[59:58] of the QoS Control register.
3. Program the 3-bits of the per-port COS value in the Protocol to VLAN mapping table. (see TBL\_DATA\_0[30:28] of [Table 135: “Multitable Data 0 Register \(Page 05h: Address 38h–3Fh\),” on page 231](#)
4. To select the desired queue, program the Priority Threshold Register (see [Table 242: “Priority Threshold Register \(Page 30h: Address 30h–31h\),” on page 290](#)).
5. Program the Protocol to VLAN Control register (see [Table 264: “Protocol To VLAN Control Register \(Pages: 34h, Address B0h–B7h\),” on page 313](#)) to enable/disable per-port Protocol-Based QoS.

## MAC SA-Based QoS

When using MAC SA-Based QoS, the source address field carried with the incoming packet is used to map the packet to one of the available output queues at the destination port. MAC-Based QoS shares the same control bit and 512-entry MAC to VLAN mapping table with MAC-Based VLAN. The upper 3-bits in the MAC to VLAN mapping table is used to program the MAC-Based priority select field. This mapping can be enabled/disabled per port, but the mapping table is configured globally.

Follow the sequence below to enable MAC SA-Based QoS:

1. Enable bit[63], of the QoS Control register (see [Table 238: “QoS Control Register \(Pages: 30h, Address 10h–17h\),” on page 287](#)).
2. Enable bits[59:58] of the QoS Control register.
3. Program the 3-bits of the per-port COS value in the MAC to VLAN mapping table. (see TBL\_DATA\_0[62:60] of [Table 135: “Multitable Data 0 Register \(Page 05h: Address 38h–3Fh\),” on page 231](#)
4. To select the desired queue, program the Priority Threshold Register (see [Table 242: “Priority Threshold Register \(Page 30h: Address 30h–31h\),” on page 290](#)).
5. Program MAC to VLAN Control register. See [Table 263: “MAC To VLAN Control Register \(Pages: 34h, Address A8h–AFh\),” on page 312](#)) to enable/disable per port MAC-Based QoS.

## DiffServ Based QoS

When using the DiffServ priority mechanism, the packet is classified based on the DSCP field in the IP header. If the tag is present, the packet is assigned to a programmable egress queue based on the value of the tagged priority. The tagged priority can be designated to any of the available queues.

Follow the sequence below to enable DiffServ-Based QoS:

1. Enable bit[63], of the QoS Control register (see [Table 238: “QoS Control Register \(Pages: 30h, Address 10h–17h\),” on page 287](#)).
2. Enable bits[59:58] of the QoS Control register.
3. To select the desired queue, program the [Table 243: “DiffServ DSCP Priority Register 1 \(Page 30h: Address 40h–47h\),” on page 291](#) and [Table 244: “DiffServ DSCP Priority Register 2 \(Page 30h: Address 48h–4Fh\),” on page 291](#).

## QoS Resolution Tree

The resolution tree shown in the next figure determines which priority based QoS is used. There are two levels of determining which queue of egress port the packet is going to be assigned. The first level of how incoming packet QoS is determined is shown in [Figure 3](#), the QoS value from the first level QoS resolution is then muxed with the QoS value from the Compact Field Processor to be the final QoS value for the egress queue. The second level QoS resolution tree is shown in [Figure 4 on page 42](#).

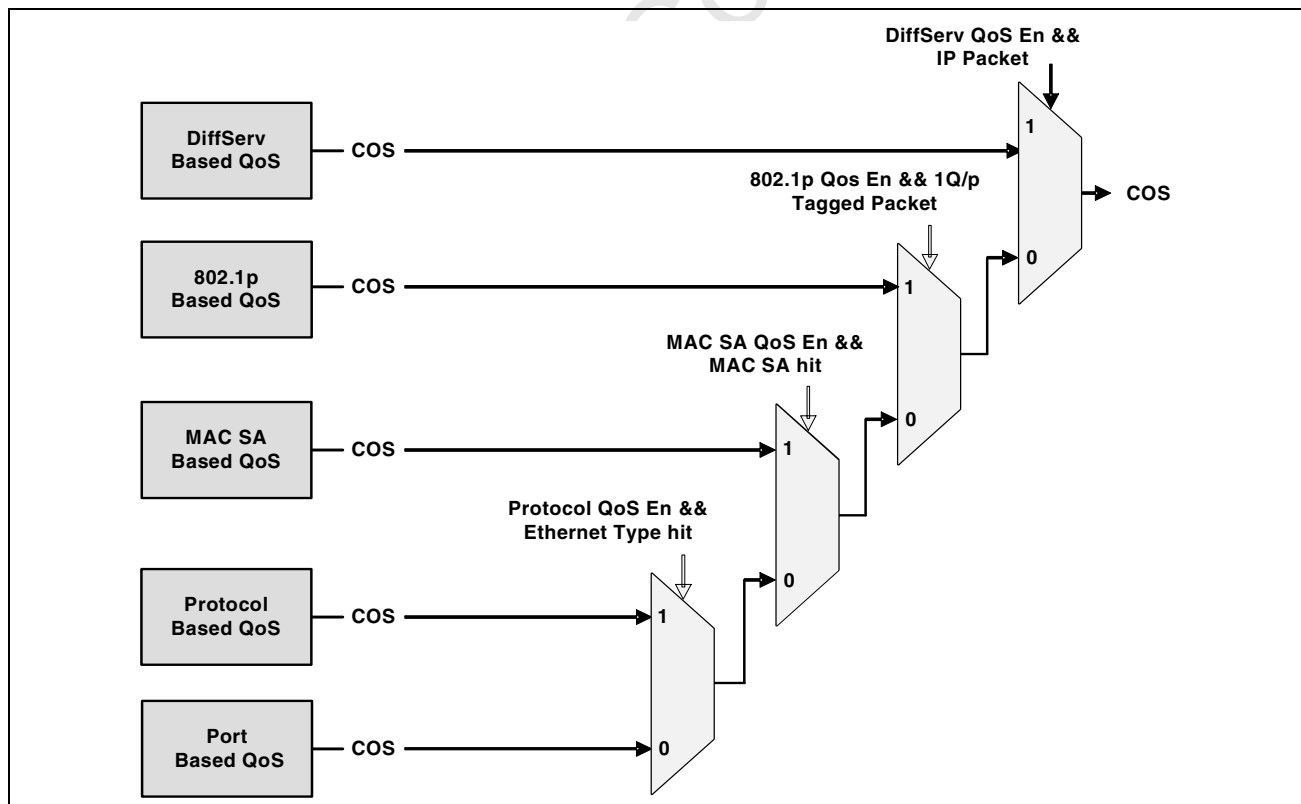

Figure 3: First Level QoS Resolution Tree

## Reason Code Based QoS

When the IMP port is configured as the management port, the BCM53262M provides a Reason Code Based QoS for packets being forwarded to the CPU through the IMP port. When the IMP port is configured as a regular data port, the packets are forwarded based on the QoS schemes mentioned above.

Table 1 lists the conditions where packets can be forwarded to the CPU, descriptions, and their default QoS levels. Note that the default QoS values are configurable (see Table 245: “QoS Reason Code Enable Register (Page 30h: Address 58h–59h),” on page 292). The QoS value for Mirroring and SA Learning conditions must be programmed with a lower, or equal value, compared to the other conditions. This prevents out-of-order flow delivery of identical packets to the CPU.

**Table 1: Reasons and QoS for CPU Traffic**

<b>Condition</b>	<b>Description</b>	<b>Default QoS level</b>
<b>Mirroring</b>	The packet is forwarded (copied) through the IMP port because it needs to be mirrored to the CPU as the capturing port.	0
<b>SA learning</b>	The packet is forwarded through the IMP port because the SA must be learned by the CPU.	0
<b>Switching</b>	The packet is forwarded through the IMP port, either because the CPU is one of the intended destination hosts of the packet, or because the switch logic determines to flood the packet to all potential destinations.	2
<b>Protocol Termination</b>	The packet is forwarded through the IMP port because it implies an IEEE 802.1 defined L2 protocol that needs to be terminated by the CPU.	3
<b>Protocol Snooping</b>	The packet is forwarded through the IMP port because it implies an L3 or application level protocol that needs to be monitored by the CPU for network security or operation efficiency.	2
<b>Exception Processing/ Flooding</b>	The packet is forwarded through the IMP port for some special processing even though the CPU is not the intended destination or because the switch makes the flooding decision to reach all potential destinations.	1

The Figure 4 shows the complete QoS Resolution tree structure.

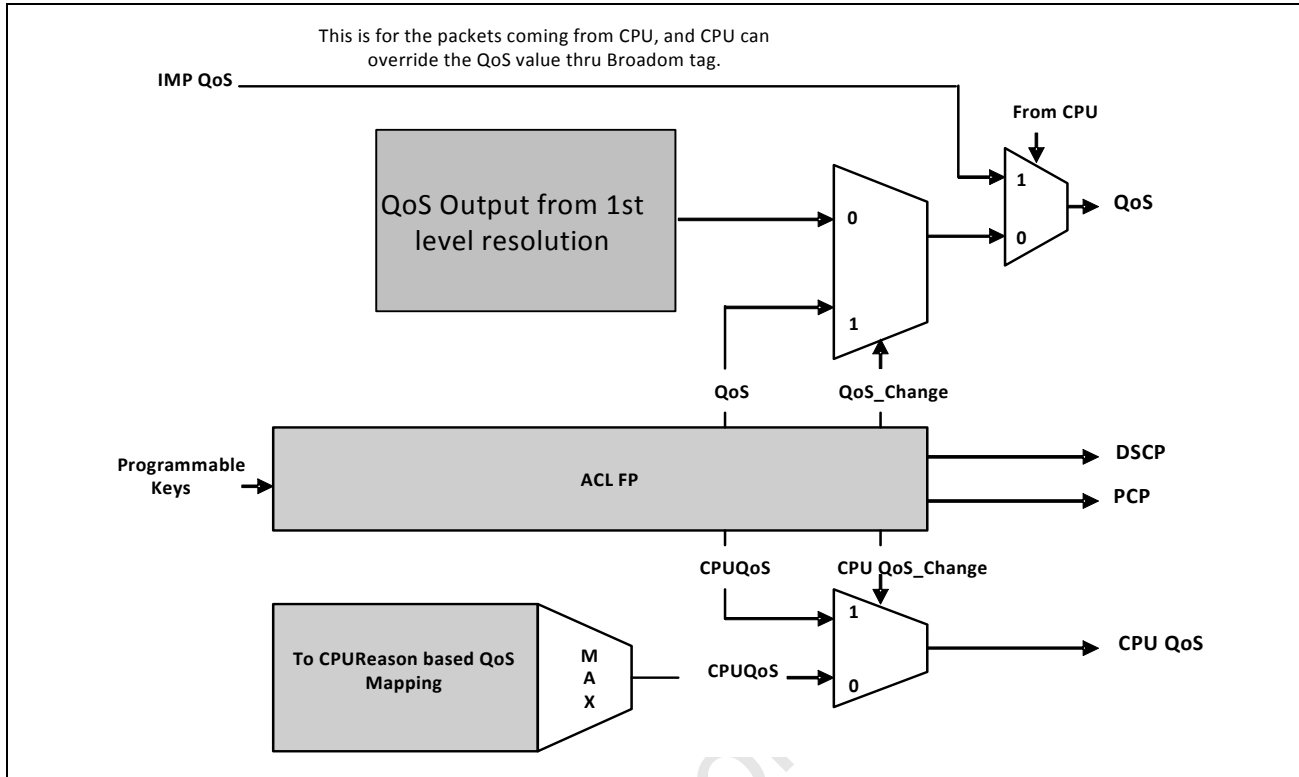

Figure 4: Final level QoS Resolution Tree

## Port-Based VLANs

The port-based virtual LAN (VLAN) feature partitions the switching ports into virtual private domains designated on a per port basis. Data switching outside of the port’s private domain is not allowed. The BCM53262M provides flexible VLAN configuration for each ingress (receiving) port.

The port-based VLAN feature works as a filter, filtering out traffic destined to nonprivate domain ports. The private domain ports are selected for each ingress port. Because the port selection is individual to each ingress port, it is possible for two ingress ports to not be granted bi-directional access. For each received packet, the ARL resolves the DA and obtains a forwarding vector (list of ports to which the frame shall be forwarded). The ARL then applies the VLAN filter to the forwarding vector, effectively masking out the nonprivate domain ports. The frame is only forwarded to those ports that meet the ARL table criteria, as well as the port-based VLAN criteria.

---

## 802.1Q VLANs

The BCM53262M supports IEEE 802.1Q VLAN and up to approximately 4K VLAN table entries that reside in the internal embedded memory. Once the VLAN table is programmed and maintained by the CPU, the BCM53262M will autonomously handle all protocol operations. These actions include the stripping or adding of the 802.1Q tag depending on the requirements of the individual transmitting port. It also performs all VLAN and MAC L2 lookups necessary to determine the correct packet routing.

---

## MAC-based VLANs

The BCM53262M supports MAC-based VLAN and up to 512 VLAN table entries that reside in the internal embedded memory. When the MAC-based VLAN is enabled, the VID is derived through the mapping table indexed by the MAC Source Address field embedded in the incoming packet. This mapping can be enabled/disabled per port, but the mapping table is configured globally. Once the VLAN mapping table is programmed and maintained by the CPU, the BCM53262M will autonomously handle all operations of the protocol.

---

## Protocol-based VLANs

The BCM53262M supports Protocol-based VLAN and up to 16 VLAN table entries that reside in the internal embedded memory. When Protocol-based VLAN is enabled, the VID is derived through the mapping table indexed by the EtherType field embedded in the incoming packet. This mapping can be enabled/disabled per port, but the mapping table is configured globally. Once the VLAN mapping table is programmed and maintained by the CPU, the BCM53262M will autonomously handle all operations of the protocol.

---

## Flow-based VLANs

The BCM53262M supports Flow-based VLAN. For more details, see [“VID Replacement” on page 74](#).

---

## Customer-Tag-Based VLANs

The BCM53262M supports customer-tag-based VLANs and up to 4K VLAN table entries that reside in the internal embedded memory. When customer-tag-based VLAN is enabled, the VID is derived through the mapping table indexed by the customer-tag VID embedded in the incoming packet. Each mapping entry may be configured for VLAN appending (Double Tagging) or VLAN replacement (VLAN Translation) operation. Once the VLAN mapping table is programmed and maintained by the CPU, the BCM53262M will autonomously handle all operations.

The [Figure 5](#) shows the VLAN resolution tree.

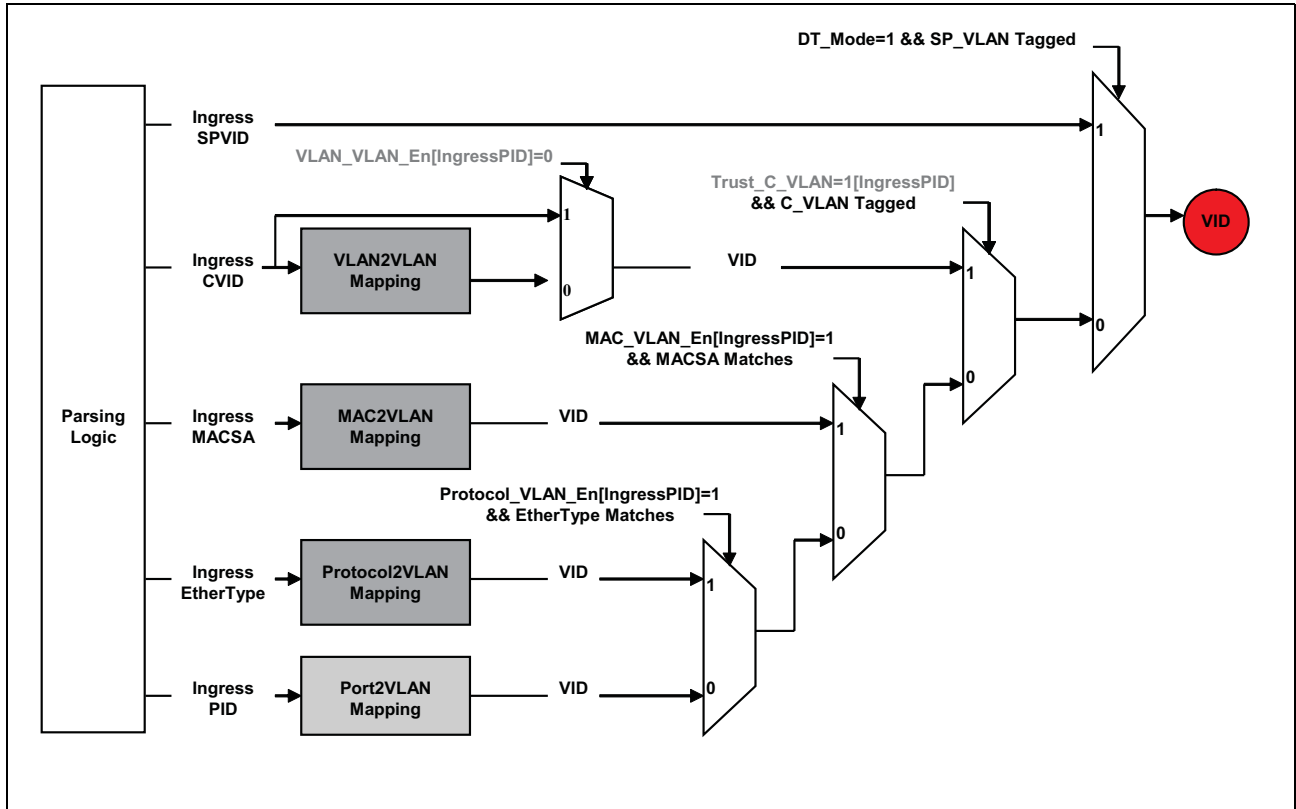

Figure 5: VLAN Resolution Tree

Broadcom

---

## Double Tagging

BCM53262M can be configured to operate either in Double Tagging mode for Edge Access Network Switching applications, or in Nondouble Tagging mode for traditional Local Area Network Switching applications. The Double Tagging mode is also referred as QinQ.

In **Double Tagging** mode,

- An Ethernet port can be configured either as a Network-Network Interface (NNI) port or as a User-Network Interface (UNI) port.
- There are four possible traffic profiles. Each possible traffic profile is described below, and illustrated in diagrams.
  - Incoming packets from NNI, and being forwarded to NNI (applies to Edge Access application)
  - Incoming packets from UNI, and being forwarded to NNI (applies to Edge Access application)
  - Incoming packets from NNI, and being forwarded to UNI
  - Incoming packets from UNI, and being forwarded to UNI

### NNI to NNI

The numbered process described below corresponds to the number in the diagram.

1. Over a NNI/NNI link, all incoming packets are expected to have a Service Provider (SP) Tag for normal switching traffic forwarding or untagged for peer CPU communication across the NNI link. (C-tagged (customer) or Priority-tagged packets are not supposed to be forwarded across a NNI link.
2. VLAN table is dedicated for Service Provider domain VLAN control. (The VID used to index the VLAN table is Service Provider Control for packet forwarding and learning operation, and the untag control can strip SP\_Tag only.)
3. With the Double Tagging (QinQ) process being performed, the VLAN translation operations are performed concurrently, either through the ingress VLAN remapping operations, or through the CFP action with the egress VLAN remapping operations.
4. Local CPU generated packets (incoming packets through IMP port with Broadcom tag) have options to preserve the untagged status or to be processed as normal input packets.

[Figure 6](#) shows how the extra (SP) tag is added to the incoming packets (tagged or untagged), and how the added tag can be output as is or be replaced.

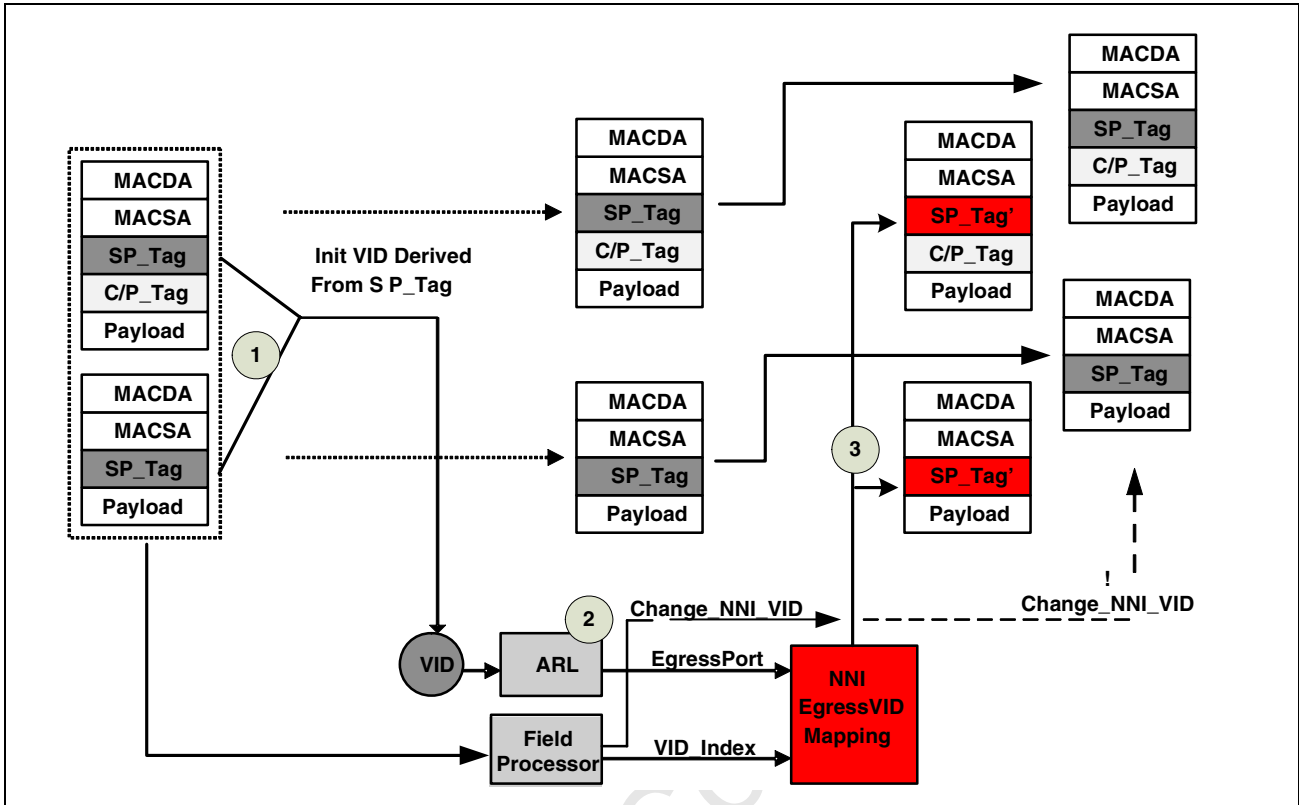

Figure 6: NNI to NNI Tag Handling

## UNI to NNI

The numbered process described below corresponds to the number in the diagram.

1. Over a UNI/NNI link, incoming packets can be Untagged, Priority tagged, or C tagged. (SP-tagged packets should not be forwarded across an UNI link.)
2. When an incoming packet from a UNI (customer) port is received, the packet is processed through the initial VID generation process (Port/ Protocol/ MACSA/ C\_VID-based mapping) to generate an SP tag and the SP tag is used to access the ARL table.
3. If the process is QinQ (double tagging or VLAN translation), the SP tag can be added as an outer tag, or the SP tag can be used to replace the original customer tag.
4. With the Double Tagging (QinQ) process being performed, the VLAN translation operations are performed through the CFP action with the egress VLAN remapping operations. If the matched rule indicates VID is present, the SP tag is replaced with the newly mapped SP tag at the NNI port for transmission.
5. Local CPU generated packets (incoming packets through IMP port with Broadcom tag) have options to preserve the untagged status or to be processed as normal input packets.

Figure 7 shows how the extra (SP) tag is added to the incoming packets (tagged or untagged), and how the added tag can be output as is or be replaced.

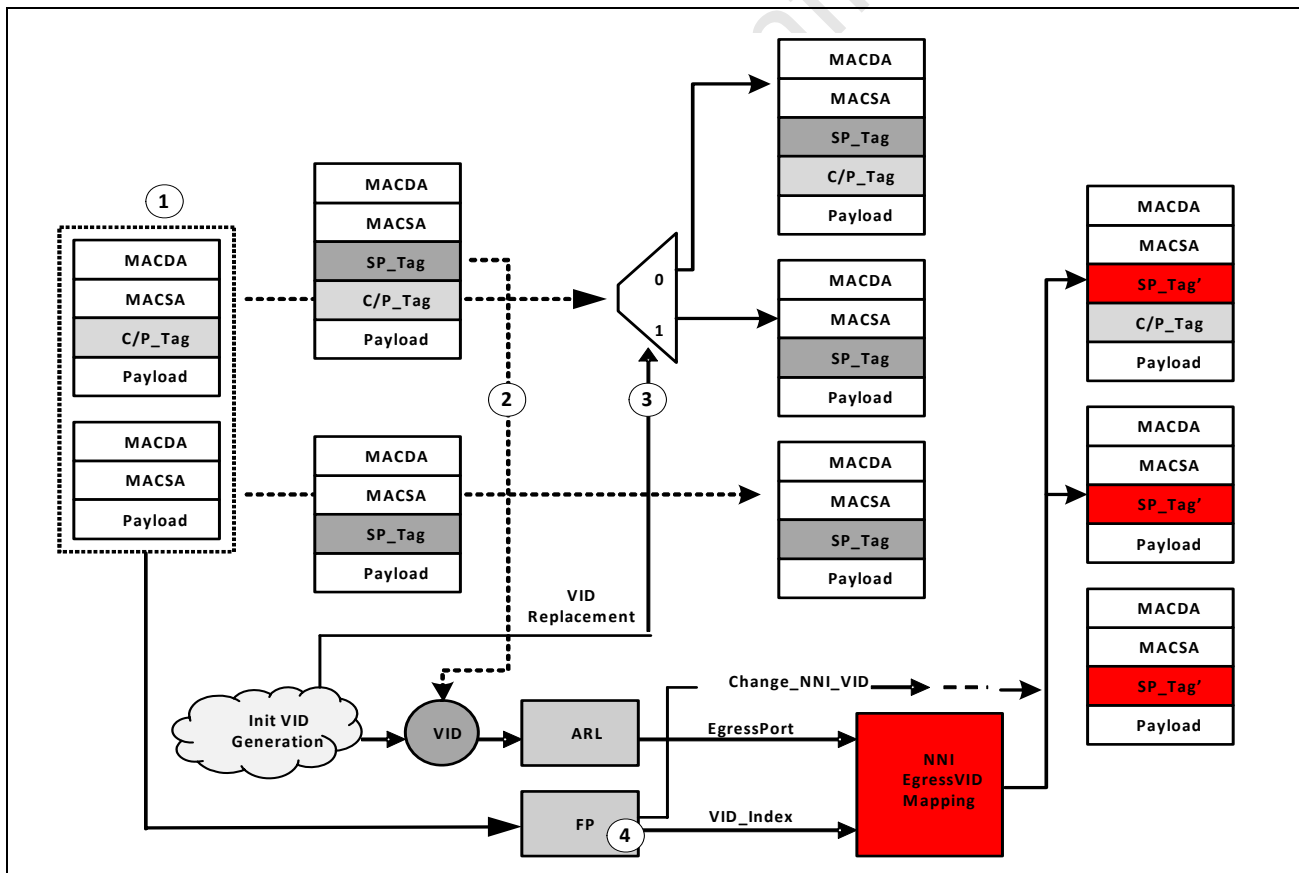

Figure 7: UNI to NNI

## NNI to UNI

The numbered process described below corresponds to the number in the diagram.

1. Over a NNI/UNI link, all incoming packets are expected to have a Service Provider (SP) Tag for normal switching traffic forwarding or untagged for peer CPU communication across the NNI link. (C-tagged (customer) or Priority-tagged packets are not supposed to be forwarded across a NNI link).
2. VLAN table is dedicated for Service Provider domain VLAN control. The VID used to index the VLAN table is Service Provider Control for packet forwarding and learning operation, and the untag control can strip SP\_Tag only.
3. With the Double Tagging (QinQ) process being performed, the VLAN translation operations are performed concurrently, either through the ingress VLAN remapping operations, or through the CFP action with the egress VLAN remapping operations.
4. Local CPU generated packets (incoming packets through the IMP port with a Broadcom tag) have options to preserve the untagged status or to be processed as normal input packets.

Figure 8 shows how the extra (SP) tag is added to the incoming packets (tagged or untagged), and how the added tag can be output as is or be replaced.

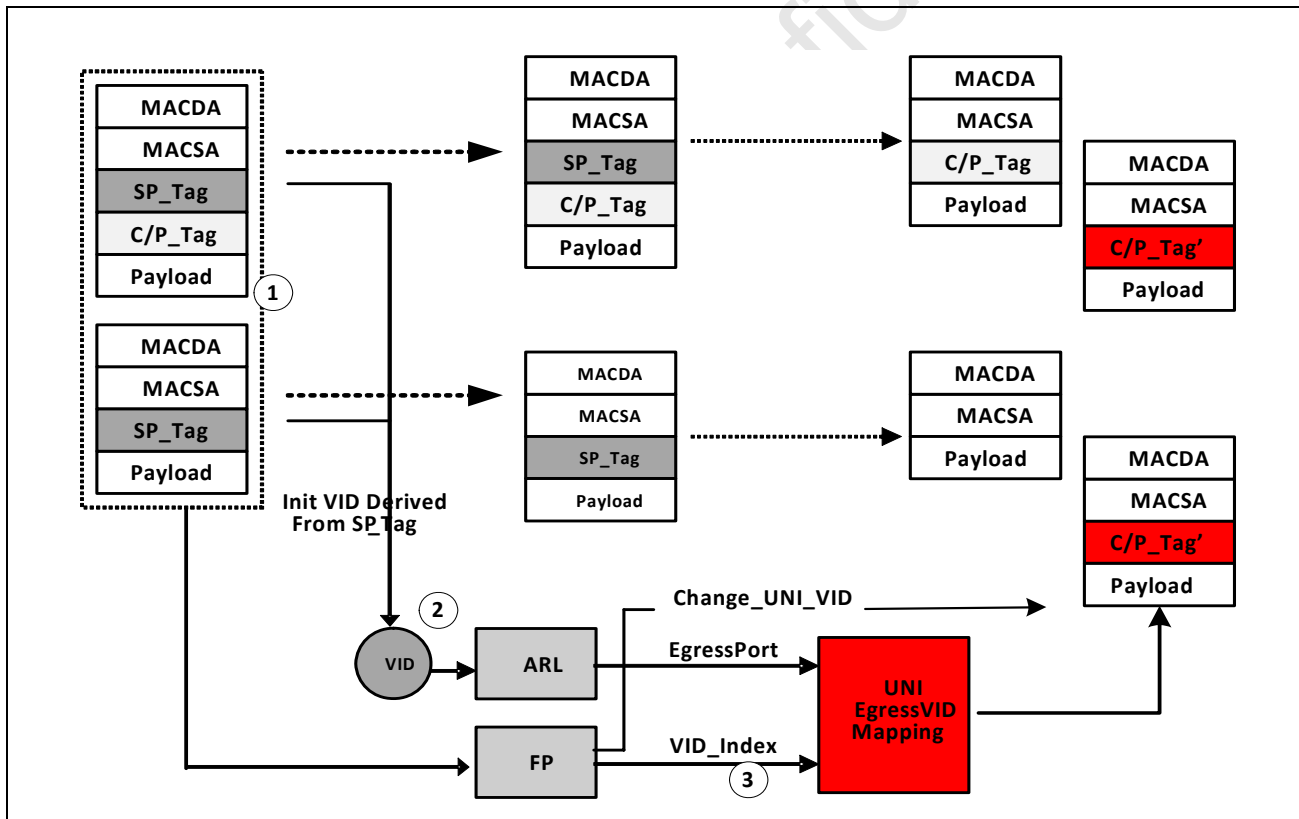

Figure 8: NNI to UNI

## UNI to UNI

The numbered process described below corresponds to the number in the diagram.

1. Over a UNI/UNI link, incoming packets can be Untagged, Priority tagged, or C tagged. (SP-tagged packets are not supposed to be forwarded across a UNI link.)
2. VLAN table is dedicated for Service Provider domain VLAN control. (The VID used to index the VLAN table is Service Provider Control for packet forwarding and learning operation, and the untag control can strip SP\_Tag only.)
3. With the Double Tagging (QinQ) process being performed, the VLAN translation operations are performed concurrently, either through the ingress VLAN remapping operations, or through the CFP action with the egress VLAN remapping operations.
4. Local CPU generated packets (incoming packets through IMP port with Broadcom tag) have options to preserve the untagged status or to be processed as normal input packets.

Figure 9 shows how the extra (SP) tag is added to the incoming packets (tagged or untagged), and how the added tag can be output as is or be replaced.

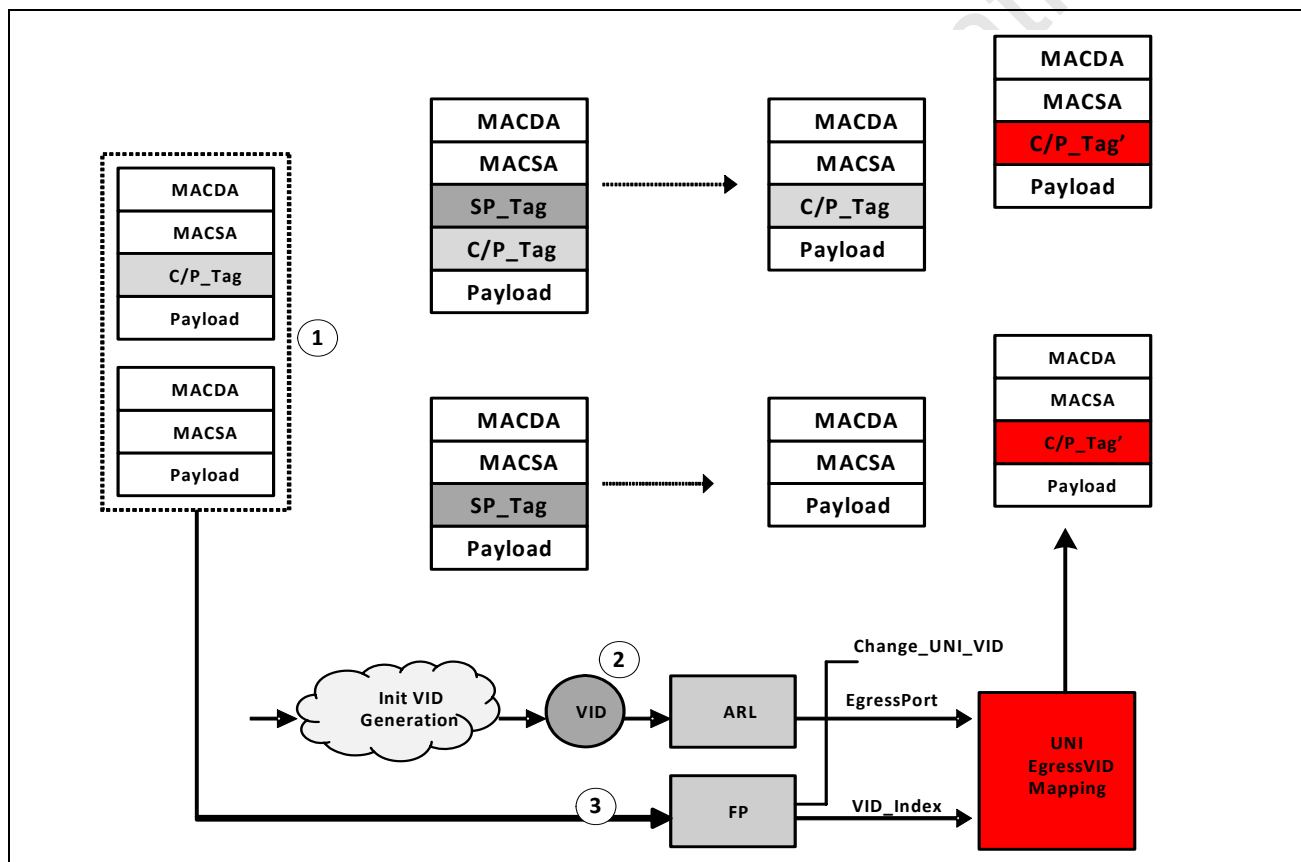

Figure 9: UNI to UNI

In **Non\_Double Tagging** mode, the following definitions will be used throughout the description of the Non-Double Tagging operation. See Figure 10.

- All Ethernet ports are treated same (as if they are all UNI ports).
- Incoming packets can be Untagged, Priority tagged, or C tagged. (SP-tagged packets are not supposed to be forwarded across an UNI link.)

- The VLAN Table is dedicated for Customer domain VLAN control. (The VID used to index the VLAN Table is Customer’s property for packet forwarding and learning operations)
- Local CPU-generated packets have option to preserve the CPU intended untag status.
- The VLAN translation operation may be performed, either through the ingress VLAN remapping operations or through the CFP action with the egress VLAN remapping operations.

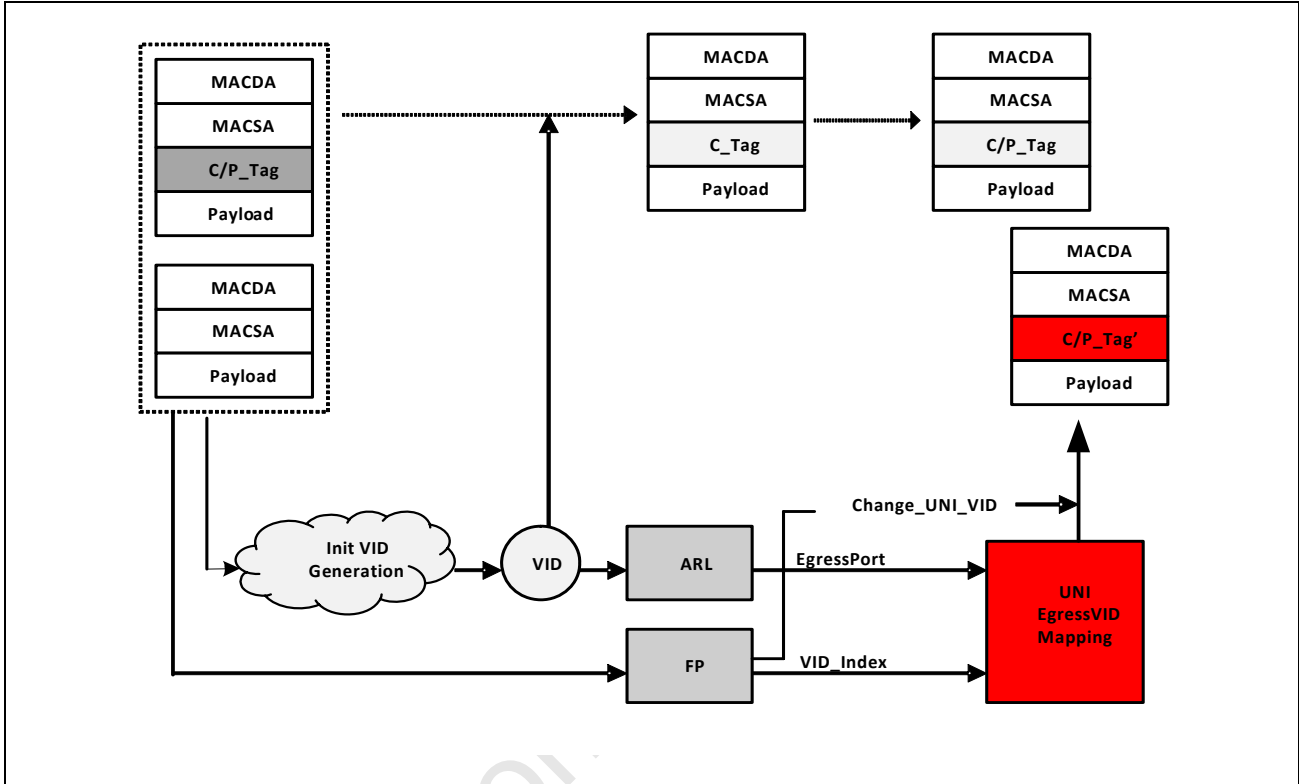

Figure 10: Non\_Double Tagging Mode UNI to UNI

## Link Aggregation

The BCM53262M supports MAC-based aggregation. The aggregation feature allows up to eight ports to be grouped together as a single-link connection between two switch devices. This increases the effective bandwidth through a link and provides redundancy. BCM53262M allows up to 14 aggregation groups. Aggregations are composed of predetermined ports and can be enabled via a register. Ports within an aggregation group must be of the same linked speed. By performing a dynamic hashing algorithm on the MAC address, each packet destined for the aggregation is forwarded to one of the valid ports within the aggregation group. This method has several key advantages. By dynamically performing this function, the traffic patterns can be more balanced across the ports within an aggregation. In addition, the MAC-based algorithm provides dynamic failover. If a port within an aggregation group fails, the other ports within the aggregation automatically assume all traffic designated for the aggregation. It allows for a seamless, automatic redundancy scheme. This hashing function can be performed on either the DA, SA, IPv4DA, IPv4SA, or any combination of four depending on the Aggregation Hash Selector bit.

Figure 11: Link Aggregation

---

## Rate Control

Forwarding broadcast traffic consumes switch resources, which can negatively impact the forwarding of other traffic. The rate-based broadcast storm suppression mechanism is used to protect regular traffic from an over abundance of broadcast or multicast traffic. This feature monitors the rate of ingressed traffic of programmable packet types. If the rates of these packet types exceed the programmable maximum rate, the packets are dropped or flow control is activated.

The broadcast storm mechanism works on a credit-based rate system that figuratively uses a bucket to track the bandwidth of each port (see [Figure 12 on page 53](#)) on the basis of egress or ingress data flow. Credit is continually added to the bucket at a programmable Bucket Bit Rate. Credit is decremented from the bucket whenever one of the programmable packet types is ingressed at the port. If no packets are ingressed for a considerable length of time, the bucket credit will continue to increase up to a programmable maximum bucket size. If a heavy burst of traffic is suddenly ingressed at the port, the bucket credit will become drained. When the bucket is emptied, incoming traffic will be constrained to the Bucket Bit Rate, the rate at which credit is added to the bucket. At this point, excess packets will be either dropped or deterred via flow control.

## Egress Rate Control

The egress rate control employs a single bucket system to track the bandwidth usage of all egressed packets. Each port has the queue structure as shown in [Figure 2 on page 38](#), each queue has a shaper can control the egress rate, and each port has a shaper can control the egress rate per port basis. The simple but effective method can be enabled on a per-port and per queue basis with a granularity of 64Kbps.

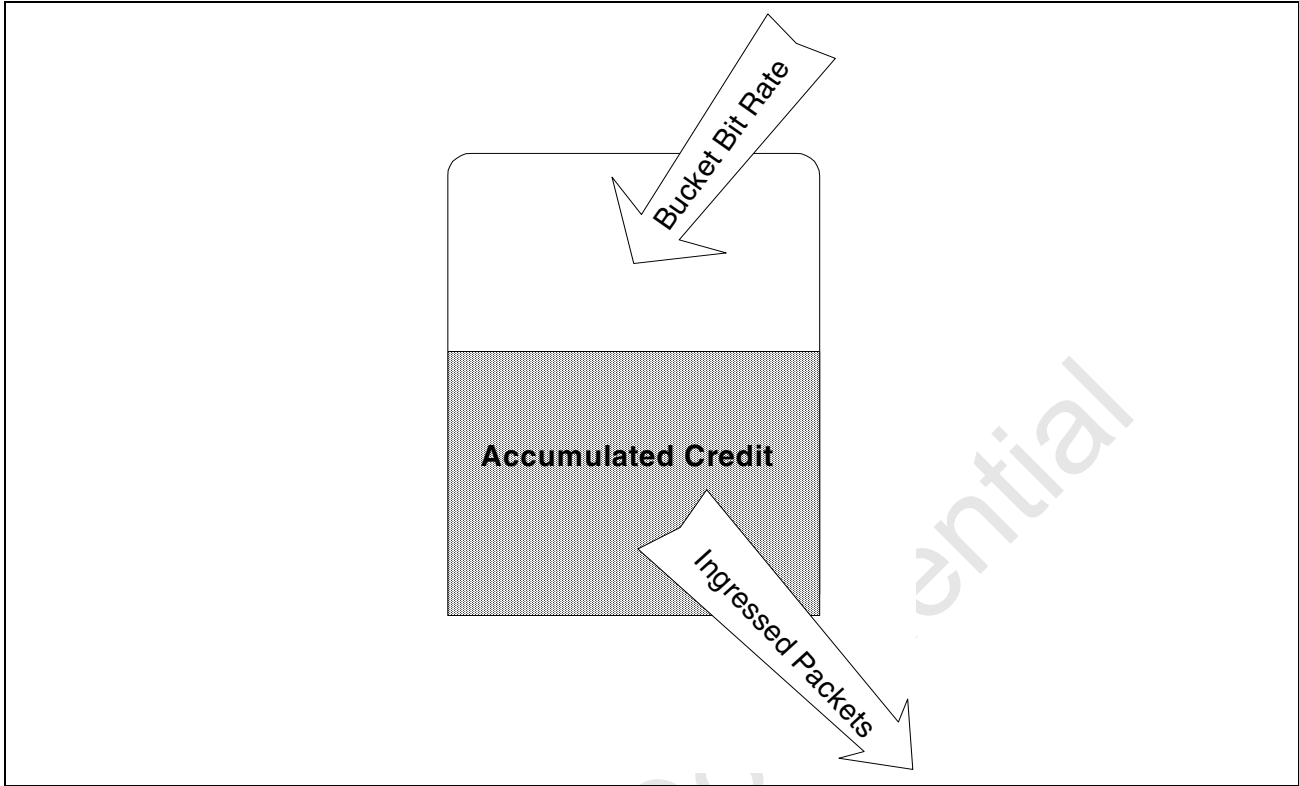

Figure 12: Ingress Bucket Flow

## Ingress Rate Control: The Three-Bucket System

For added flexibility, the BCM53262M ingress rate control employs three buckets to track the rate of ingressed packets. Each of the three buckets, Bucket 0, Bucket 1, and Bucket 2, can be programmed to monitor different packet types. For example, Bucket 0 could monitor broadcast packets, while Bucket 1 and Bucket 2 monitor other types of packets. Multiple packet types can be monitored by each bucket, and a packet type can be monitored by both buckets.

The rates of each bucket can be programmed individually. For example, the broadcast packets of Bucket 0 could have a maximum rate of 3 Mbps, whereas the multicast packets of Bucket 1 could be allowed up to 80 Mbps, with the granularity of each bucket at 64 Kbps. The size of each bucket can be programmed individually as well. This determines the maximum credit that can accumulate in each bucket. The bucket rate can be specified as an absolute rate or a normalized rate, which is scaled to the link speed of the given ingress port. The rate control can be enabled or disabled on a per-port basis.

---

## Protected Ports

The Protected Ports feature allows certain ports to be designated as protected. All other ports are unprotected. Traffic between protected port group members is blocked. However, protected ports are able to send traffic to unprotected ports. Unprotected ports can send traffic to any port. There are the following application benefits:

- **Aggregator:** All of the available ports are designated as protected ports, except a single aggregator port. All traffic incoming to the protected ports will not be sent within the protected ports group. Any flooded traffic is forwarded only to the aggregator port.
- To prevent unsecured ports from monitoring important information on a server port, the server port and unsecured ports are designated as protected. The unsecured ports will not be able to receive traffic from the server port.

## Port Mirroring

The BCM53262M supports port mirroring, allowing ingress and/or egress traffic to be monitored by a single port that is defined as mirror capture port. The mirror capture port can be any 10/100 port, 10/100/1000 port or the Management port. The BCM53262M can be configured to mirror the ingress traffic and/or egress traffic of any other port(s). Mirroring multiple ports is possible, but can create congestion at the mirror capture port. Filtering can be used to decrease the port congestion. In addition, each ingress port can be configured to randomly pick the received packets and send to the CPU for Sflow packet sampling purpose.

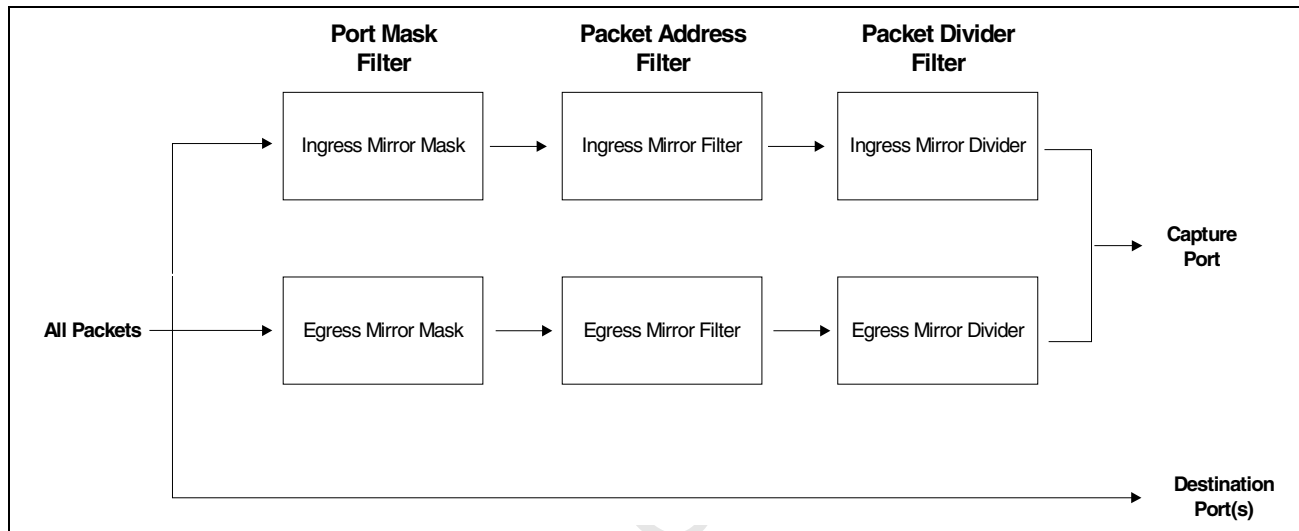

Figure 13: Mirror Filter Flow

## Mirror Filtering Rules

Mirror Filtering Rules consist of a set of three filter operations

- “Port Mask Filter”
- “Packet Address Filter”
- “Packet Divider Filter” on page 56

### Port Mask Filter

The most basic of filtering, the Port Mask filter, allows for the selection of a limited number of ports to be monitored based on egress or ingress packet flow. Any number of ingress/egress ports can be programmed to be mirrored, but bandwidth restrictions on the one mirror capture port should be taken under advisement, so as not to cause congestion or packet loss.

### Packet Address Filter

The Packet Address filter further filters the mirrored ingress/egress frames based on the following criteria:

- Mirror all received frames

- Mirror received frames with DA = x
- Mirror received frames with SA = x

Where x is programmed 48-bit MAC address.

## Packet Divider Filter

The Packet Divider filter allows further statistical sampling to be performed. Only one out of every n ingress/ egress frames is forwarded to the mirror capture port, where n is a programmable integer. Combined with the packet address filter it allows the following capabilities:

- Mirror every n<sup>th</sup> received frame
- Mirror every n<sup>th</sup> received frame with DA = x
- Mirror every n<sup>th</sup> received frame with SA = x

---

## IGMP and MLD Snooping

The BCM53262M supports IP layer IGMP and MLD Snooping. When IGMP and MLD is enabled, the BCM53262M forwards IGMP and MLD frames to the frame management port. The external management entity programs the multicast membership information to the ARL table.

When the IP layer IGMP and MLD snooping is enabled, a frame with a value of 2 in the IP header protocol field and not a IGMP query will be forwarded to the CPU port. The Management CPU can then determine, from the IGMP control packets, which port should participate in the multi group session. The management CPU proactively programs the multicast address in the ARL table or the Multiport Address Entries.

---

## Jumbo Frame Support

The BCM53262M can receive and transmit frames of extended length on all linked ports. Referred to as jumbo frames, these packets may be longer than 1518 bytes (when untagged), up to 2048 bytes. This feature is automatically enabled upon power up.

---

## 802.1x Port-Based Security

IEEE 802.1x is a port-based authentication protocol based on the exchange of Extensive Authentication Protocol over LAN (EAPOL) packets. When enabled the BCM53262M 802.1x feature forwards these packet types to the management CPU. Based on the receipt of these packets, the management CPU has the prerogative to modify per-port 802.1x-based security status.

When 802.1x feature is enabled, all traffic is blocked except EAPOL and ARP frames. The default state for all switch ports is a nonforwarding state. As ports become authenticated via the management CPU, these port states are modified via the CPU. Thus packet forwarding can commence.

---

## Dynamic Secure MAC Mode

Another security feature that can be used in with the 802.1x feature, the Dynamic Secure MAC Mode allows the management CPU control of the dynamic Source Address (SA) learning process. When enabled, the maximum number of learned SA ARL entries is set. When this maximum has been reached, the learning process is no longer active. Incoming frames with an unknown source address will be dropped without dynamically learning them into the ARL table. The learning process will continue when the aging process removes existing learned entries from the ARL table. This feature does not account for statically programmed ARL entries via the management CPU.

---

## Address Management

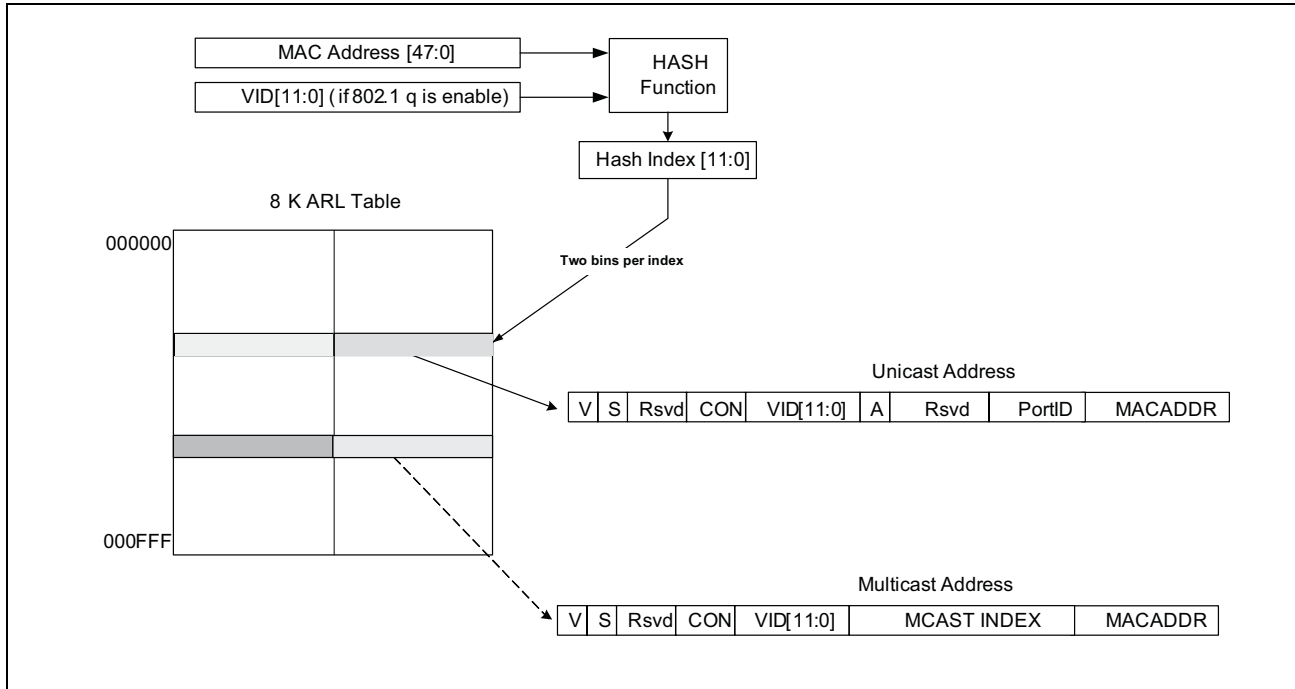

The BCM53262M Address Resolution Logic contains the following features:

- Two bins per bucket address table configuration.
- Hashing of the MAC/VID address to generate the address table pointer.

The address management unit of the BCM53262M provides wire-speed learning and recognition functions. The address table supports 8K unicast/multicast addresses using on-chip memory.

## Address Table Organization

The MAC addresses are stored in embedded SRAM. Each bucket contains two entries (or bins). The address table has 4K buckets.

**Figure 14: BCM53262M Address Table Organization**

The index to the address table is computed using a hash algorithm based on the MAC address and the VLAN ID (VID) if enabled. The hash algorithm uses the CRC-CCITT polynomial. The input to the hash is reduced to a 16-bit CRC hash value. Bits 11:0 of the hash are used as an index to the 4K buckets of the address table.

The CRC-CCITT polynomial is:

$$x^{16} + x^{12} + x^5 + 1$$

## Address Learning

Information is gathered from received unicast packets, and learned or stored for the future purpose of forwarding frames addressed to the receiving port. During the receive process the frame information, such as the source address (SA) and VID, is saved until completion of the packet. An entry is created in the ARL table memory if the following conditions are met:

- The packet has been received without error
- The packet is of legal length
- The packet has a unicast SA
- If using 802.1Q VLAN, the packet is from a SA that belongs to the indicated VLAN domain
- The packet does not have a reserved multicast destination address
- There is free space available in memory to which the hashed index points.

When unicast packets are dynamically learned, the VALID bit is set, the AGE bit is set, and the STATIC bit is cleared in the entry.

## Reserved Addresses

The BCM53262M treats certain of the 802.1 administered reserved multicast destination addresses in specific ways, dependent on the mode of operation. Packets identified with these destination addresses are handled uniquely since they are designed for special functions.

**Table 2: Behavior for Reserved Multicast Addresses**

<b>MAC Address</b>	<b>Function</b>	<b>802.1 Specified Action</b>	<b>Unmanaged Mode Action (Note 1)</b>	<b>Managed Mode Action</b>
01-80-C2-00-00-00	Bridge Group Address	Drop Frame	Forward Frame	Forward Frame to Frame Management Port Only (Note 2)
01-80-C2-00-00-01	IEEE Std 802.3x MAC Control Frame	Drop Frame	Receive MAC Determines if Valid PAUSE Frame and acts accordingly	Receive MAC Determines if Valid PAUSE Frame and acts accordingly
01-80-C2-00-00-02	RESERVED	Drop Frame	Drop Frame	Forward Frame to Management Port Only
01-80-C2-00-00-03	RESERVED	Drop Frame	Drop Frame	Forward Frame to Management Port Only
01-80-C2-00-00-04~ 01-80-C2-00-00-0F	RESERVED	Drop Frame	Drop Frame	Forward Frame to Management Port Only
01-80-C2-00-00-10	All LANs Bridge Management Group Address	Forward Frame	Forward Frame	Forward Frame to all Ports Including Frame Management Port
01-80-C2-00-00-20	GMRP address	Forward Frame	Forward Frame	Forward Frame to all Ports Except Frame Management Port (Note 3)
01-80-C2-00-00-21	GVRP address	Forward Frame	Forward Frame	Forward Frame to all Ports Except Frame Management Port (Note 3)
01-80-C2-00-00-22~ 01-80-C2-00-00-2F	RESERVED	Forward Frame	Forward Frame	Forward Frame to all Ports Except Frame Management Port

**Table 2: Behavior for Reserved Multicast Addresses (Cont.)**

<b>MAC Address</b>	<b>Function</b>	<b>802.1 Specified Action</b>	<b>Unmanaged Mode Action (Note 1)</b>	<b>Managed Mode Action</b>
Note:				
1. Unmanaged Mode disables the frame management port option. The IMP does not receive frame data when in this mode. The MII port will be treated as a normal network port and have frames forwarded to it in accordance with the entries in the address table.				
2. Frames with the reserved multicast address corresponding to the BridgeGroup Address (01-80-C2-00-00-00) are forwarded to the programmed Frame Management Port based on the contents of the BPDU Multicast Address Register (in the ARL Control Register Page). Changing this register from the default value causes frames with the new address to be forwarded to the Frame Management Port, and BPDUs are flooded to all ports except the Frame Management Port. The RX_BPDU_EN bit of Management Configuration Register must be enabled.				
3. Frames with the reserved multicast address corresponding to the GMRP or GVRP Addresses (01-80-C2-00-00-20 or 01-80-C2-00-00-21) are forwarded to all ports except the source and Frame Management Ports. If the switch product implements either of these protocols, then the BCM53262M should be programmed to use the Managed Mode, and the multicast address should be instantiated in the address table, with a Port ID that forwards the frame to the chip and port with the defined Frame Management Port.				

## Learning

During the receive process the source address (SA) of the packet is saved until completion of the packet. The address is stored in the address table memory if the following conditions are met:

- The packet is not from the Management port.
- The packet has been received without error.
- The packet is of legal length.
- The packet has a unicast address.
- There is a free space available in one of the two entries (STATIC=0 and VALID=0) in the bucket that the hashed address indexes to. If there is no free space available in the bucket, the address is not learned.

When learning, the MAC address and the source port ID is stored into the address table. The VALID bit is set, the AGE bit is set, and the STATIC bit is reset in the entry.

## Static Address

The BCM53262M supports static filtering entries that are created and updated by software through the Serial Management Port. Bridge management software can create these entries by directly writing the entry location of the buffer memory, and setting the STATIC bit of the entry. Static entries do not have new MAC addresses or port associations learned automatically, and are not aged out by the automatic internal aging process (i.e., the AGE bit is subject to aging and refreshing processes, however, the entry can only be invalidated by CPU.).

For instance, addresses associated with a switch's network ports and the management port should be instantiated as Static entries in the address table by the management processor, with the source port ID and as the physical management port. All the specific register information is temporary and subject to be change in the final version of the data sheet.

## Resolution

The destination address (DA) of the received packet is used by the address resolution function to search the address table and assign a destination port for the packet. The destination port is assigned by locating a matching address in the address table and selecting the source port identifier field as the destination port. The search for a matching address occurs only for unicast packets. The address resolution function for unicast packets proceeds as follows:

- The lower 12 bits of the DA are used as a pointer into the address table memory and both entries in the bucket are retrieved. The address resolution logic processes the two entries in parallel.
- If the valid indicator is set and the address stored at one of the locations matches the DA of the packet received, the port identifier is assigned to be the destination port of the packet.
- If the destination port matches the source port, the packet is not forwarded.
- If the valid indicator is not set or the address stored does not match the DA address of the packet, the packet is forwarded as a broadcast packet and will be transmitted to all other ports.

If SW\_FWDG\_MODE is Unmanaged, packets with the group address bit set in the DA are handled as follows:

- If the DA matches the globally assigned multicast address of the 802.3x MAC Control PAUSE frame of 01-80-C2-00-00-01, the packet is not forwarded.
- If the DA matches the Bridge Group Address, the packet is forwarded to all ports except the source port.
- If the DA matches one of the other globally assigned reserved address (between 01-80-C2-00-00-02 and 01-80-C2-00-00-0F), the packet is not forwarded.
- All other multicast and broadcast packets are forwarded to all ports except the source port and the Management Port.

If SW\_FWDG\_MODE is Managed, packets with the group address bit set in the DA are handled as follows:

- If the DA matches the globally assigned multicast address of the 802.3x MAC control PAUSE frame of 01-80-C2-00-00-01, the packet is not forwarded.
- If the DA matches one of the globally assigned reserved address (between 01-80-C2-00-00-00 and 01-80-C2-00-00-0F excluding 802.3x MAC Control PAUSE frame address), the packet is forwarded to the Management port.
- If the DA matches the All LANs Bridge Management Group Address of 01-80-C2-00-00-10, or the GARP addresses of 01-80-C2-00-00-20 to 01-80-C2-00-00-2F, the packet is forwarded to all ports except the source port and the Management Port.
- All other multicast and broadcast packets are forwarded to all ports except the source port. The Management Port can selectively have broadcast packets and/or multicast packets individually disabled based on the RX\_MCST\_DISABLE and RX\_BCST\_DISABLE bits in the Port Control Register for the IMP (MII).

## Hash Function

The address resolution logic incorporates a hash function to randomize storage location for the MAC address.

## ARL Mishs Options

When an ARL miss occurs, the BCM53262M allows for the programming of two registers to decide what to do with the ARL missed packet:

- MLF\_FWD\_MAP is for Multicast packet
- ULF\_FWD\_MAP is for unicast packet

When a unicast ARL miss occurs, the BCM53262M forwards it according to the ULF\_FWD\_MAP value. When a Multicast ARL miss occurs, the BCM53262M forwards it according to the MLF\_FWD\_MAP value.

---

## Bridge Management

BCM53262M provides the following services:

- 802.1D—Spanning Tree Protocol
- 802.1s—Multiple Spanning Trees
- 802.1W—Rapid Reconfiguration of Spanning Tree
- Bridge Management state register access through the CPU interface
- Bridge Protocol Data Unit (BPDU) frame forwarding through the CPU interface or the MII interface

## Spanning Tree Port State

The BCM53262M device supports the Spanning Tree Protocol (STP) by providing the spanning tree state in the Port Control Register for each of the network ports. Each Port Control Register (PCR) contains three bits dedicated to STP state (STP\_STATE[2:0]) as well as additional bits to control the operation of the MAC port.

In the unmanaged compatible mode of operation (SW\_FWDG\_MODE = Unmanaged), the default state of the STP\_STATE[2:0] bits are all 0s, and no spanning tree state is maintained. Write operations to the spanning tree state bits are ignored. Frames are forwarded based only on their DA. Known unicast address frames are forwarded to their single defined destination port, and unknown unicast, as well as all multicast/broadcast addressed frames, are flooded to all ports, with the exception of the management port, providing SW\_FWDG\_EN = 1. BPDU frames, are one of the 802.1 reserved multicast addresses that the unmanaged mode floods.

The BCM53262M reacts to the STP state bits as written by the management CPU, as described in the following sections (providing SW\_FWDG\_EN = 1).

### Disable

In this state, all frames received by the port are discarded. The port also does not forward any transmit frames, queued by either BCM53262M receive network ports, or frames cast by the management entity via the IMP. Addresses are not learned by ports in the Disabled state. This is the default state that the BCM53262M will power up in when SW\_FWDG\_MODE = Managed.

### Blocking

In this state, the MAC port forwards received BPDUs to the designated Management port (IMP). All other frames received by the port are discarded and the addresses are not learned. The port will also not forward any transmit frames, queued by other BCM53262M receive network ports.

## Listening

In this state, the MAC port forwards received BPDUs to the designated Management port (IMP). All other frames received by the port are discarded and the addresses are not learned. The port also does not forward any transmit frames, queued by other BCM53262M receive network ports, but transmits frames cast by the management entity, via the MSP or IMP, as expected (such as BPDUs). Note that the Learning and Listening states of all BCM53262M ports are identical. The external management processor running the STP algorithm must distinguish these two states using the STP algorithm, but is able to store the Learning and Listening state information into the BCM53262M for consistency.

## Learning

In this state the MAC port forwards received BPDUs to the Management port, transmits BPDUs sent into the Management port, and learns MAC addresses. All other frames received by the port are discarded.

## Forwarding

In this state the MAC port forwards received BPDUs to the Management port, transmits BPDUs sent into the Management port, forwards all other frames and learns all incoming frame's MAC addresses.

**Table 3: Spanning Tree State**

<b>Spanning Tree State</b>	<b>Receive BPDU</b>	<b>Transmit BPDU</b>	<b>Normal Frame</b>	<b>Learning State</b>	<b>STP_State</b>
No Spanning Tree OR Spanning Tree Disable	Treated as Multicast	Flood to all ports	Forward	Learn	000
Disable State	Disabled	Disabled	Don't Forward	Don't Learn	001
Blocking State	Forward to Management	Disabled	Don't Forward	Don't Learn	010
Listening State	Forward to Management	Enabled	Don't Forward	Don't Learn	011
Learning State	Forward to Management	Enabled	Don't Forward	Learn	100
Forwarding State	Forward to Management	Enabled	Forward	Learn	101

The Multiple Spanning Tree Protocol (MSTP), which uses the Rapid Spanning Tree protocol (RSTP) to provide rapid convergence, enables VLANs to be grouped into a spanning-tree instance, provides for multiple forwarding paths for data traffic, and enables load balancing. It improves the fault tolerance of the network because a failure in one instance (forwarding path) does not affect other instances (forwarding paths). The most common initial deployment of MSTP and RSTP is in the backbone and distribution layers of a Layer 2 switched network; this deployment provides the highly-available network required in a service-provider environment. Both RSTP and MSTP improve the operation of the spanning tree while maintaining backward compatibility with equipment that is based on the (original) 802.1D spanning tree. The BCM53262M can support up to 256 Spanning Trees.

The BCM53262M also supports per-port aging.

## Management Frames

Management frames received by the BCM53262M are forwarded to the Bridge Management entity (an external CPU or microcontroller) through the GMII/MII Port. When the GMII/MII is used as the interface to the external management subsystem the port is referred to as the In-band Management Port (IMP). When operating in the unmanaged mode, management frames are treated differently. The following frames are forwarded to the Bridge Management entity in the BCM53262M mode:

- **BPDU Frames**—BPDUs are identified by the Bridge Group Address (01-80-C2-00-00-00) in the destination address field of a frame. The STP\_STATE bits in the Port Control Register must be configured to permit BPDU reception on a particular port. A BPDU received on such a port will be forwarded, with the Port ID of the receiving port, to the port configured in the Management Port ID register.
- **Reserved Multicast Addressed Frames**—Frames with 802.1 administered Reserved Multicast Addresses (between 01-80-C2-00-00-02 and 01-80-C2-00-00-0F in their DA field) are forwarded only to the Management Port, with a header which includes the Port ID of the port from which the frame was received. Frames with the All LANs Bridge Management Group Address (01-80-C2-00-00-10) as the DA are forwarded to all ports, with the Management Port again receiving the header information to identify the Port ID from which the frame was received.
- **Directed Management Agent Frames**—Packets with the DA equal to one of the MAC addresses associated with the Management Port. These addresses are generally entered as Static addresses by the management entity itself.
- **Mirrored Frames**—Ingress or egress port frames that have been assigned to be mirrored to the management port.

---

## Compact Field Processor

BCM53262M provides a TCAM based Compact Field Processor (CFP) to support ACL implementation and packet classification. CFP is a versatile filter and classification processor.

There are three CFP slices running in parallel in BCM53262M as shown in [Figure 15 on page 66](#). As a result, multiple ContentAware processing can be executed per packet. The each CFP slice consists of Parser, Lookup Engine, Policy Engine, Metering/Statistic Engine, and Action Resolution Logic.

The input (key) to the CFP includes the predefined fields from the packet header, and/or user-defined fields within a packet. All these inputs are gathered at the receive port through the parser.

Up to 1K rules can be set for the parallel engines to search and assign the action to be taken when a match has been discovered. These rules can be distributed over the input ports in any combination. The actions supported by the BCM53262M are flooding, dropping, copying, changing the forward port map, adding forward port, and changing the priority, VID, and DSCP of a frame. The details of the actions are described in later paragraph.

Each CFP Engine (slice) consists of a Parser, a Lookup engine, a Policy engine, a Metering and Statistic engine and an Action Resolution engine.

- **Parser** assembles and extracts specified Ethernet standard field data and/or user-configurable UDF field data. Then, the Parser makes the assembled key available to the lookup engine. BCM53262M has

predefined key fields for each of three slices as shown in [Table 4 on page 70](#), [Table 5 on page 70](#), [Table 6 on page 72](#), and [Table 7 on page 72](#). The most well known packet header fields may be selected, as well as any field in the packet through User-Defined Field (UDF).

- Lookup engine, which performs lookup and outputs the address of the matched location. Lookup engine compares the input (combination of fields defined in each slice) with all the entries in the TCAM memory. The result of the comparison is the address for the entry that is 100 percent matched. If there is more than one matching entry, the entry with the lowest physical address is returned. In addition, the lookup engine also has a mask per entry that selects specific bits of each memory entry that are required to be an exact match with the incoming bits from the input. This provides flexibility by allowing the Don't Care fields in the input.
- Policy engine, which contains a list of actions for the matching rule in the ContentAware lookup engine. There are as many actions as rules. Each matching index from the Lookup Engine is mapped to an action in the Policy engine.
- Metering and Statistics engines, which perform policing and statistics collection.
- Action resolution engine, which resolves multiple/conflict matches. Based on the matching results from the Lookup Engine, three possible actions from each slice are input to the Action Resolution Logic. The priority of each slice can be configured. The Action Resolution Logic sorts out the each action from each slice, and implements all the non conflicting actions. For the conflicting actions, the Action Resolution Logic picks an action from the high-priority slices.

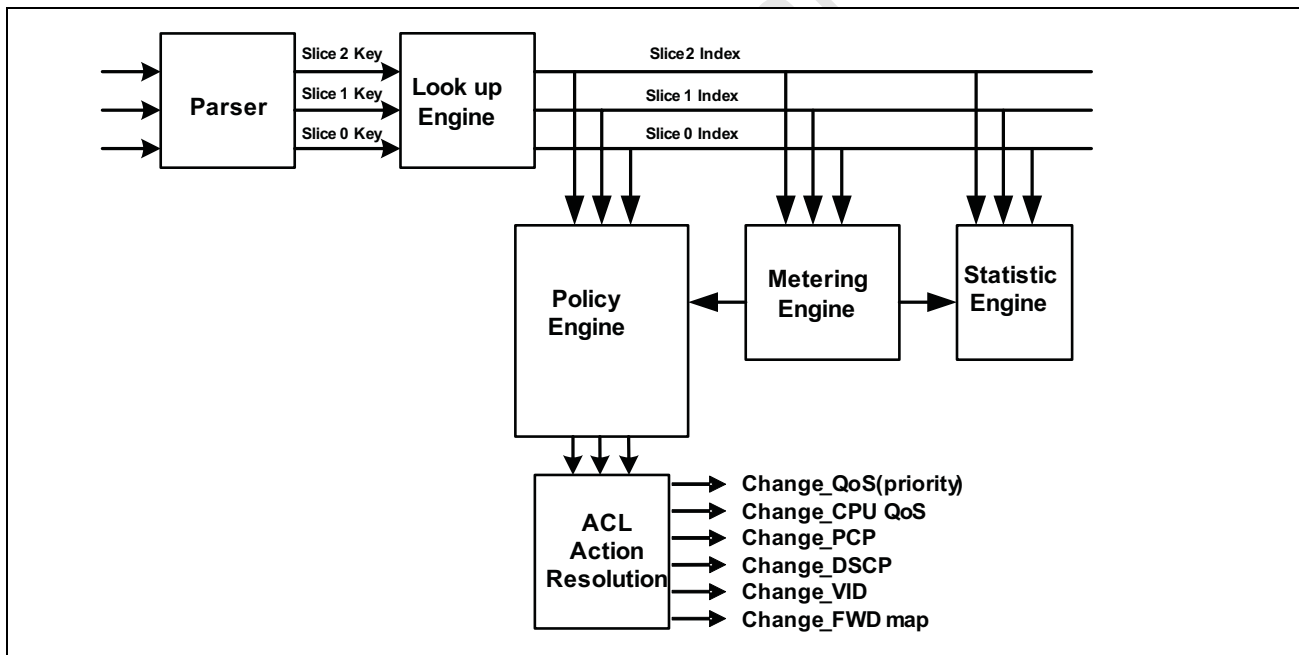

Figure 15: CFP Engines

## Parser

The parser parses for standard Ethernet fields, as well as, user-defined fields. [Figure 16](#) shows standard packet format. The parser recognizes the following predefined fields:

- EtherType (ETYPE, 16 bits)

- L2 Known Field
  - Destination MAC address (MAC\_DA, 48 bits)
  - Source MAC address (MAC\_SA, 48 bits)
  - Outer (Service Provider) Tag (TPID 1, 16 bits)
  - Inner (Customer) Tag (TPID2, 16 bits)
- L3 Known Field (IPv4)
  - Destination IP address (IP\_DA, 32 bits)
  - Source IP address (IP\_SA, 32 bits)
  - DSCP field (DSCP [6 bits] and CU [2 bits])
  - IP protocol field (IP\_PROTOCOL, 8 bits)
  - TTL Range (2 bits)
  - Same IP address (Same\_IPAddr, 1 bit)
- L3 Known Field (IPv6)
  - Flow ID (FlowID, 20 bits)
  - Source IP address (IP\_SA, 32 bits)
  - Traffic Class (8 bits)
  - Next Header (8 bits)
  - Hop Limit Range (HopLimit\_Range, 2bits)
  - Same IP address (Same\_IPAddr, 1 bit)
- L4 Known Field (TCP/UDP)
  - Destination Port (DST\_port, 16 bits)
  - Source Port (SRC\_Port, 16 bits)
  - TCP flags (TCP\_FLAG, 6 bits)  
SYN, FIN, ACK, FRAG, RST, PSH
  - Same L4 Port (Same\_L4Port, 1 bit)
  - L4 Source less than 1024 (L4SRC\_Less1024, 1 bit)
  - TCP Sequence number zero (TCP\_Seq\_Zero, 1 bit)
  - The length of TCP Header is less than min (MIN\_TCP\_Header, 1 bit)
- L4 Known Fields (ICMP/IGMP)
  - Type (8 bits)
  - Code (8 bits)
  - Max\_ICMP (1 bit)
- Range Field
  - BCM53262M supports eight ranger mechanism: four rangers are used to detect the range of C-VID of received packets, and four rangers are used to detect the rage of TCP/UDP port of received packets. All rangers are globally configurable in terms of range setting and DST/SRC checking.
    - C\_VLAN Range (4 bits): Each bit indicates whether the C\_VID of the received packet falls into the corresponding range.
    - L4\_Port Range (4 bits): Each bit indicates whether the L4 (DST/SRC) port of the received TCP/UDP packet falls into the corresponding range.

- User-Defined Field
  - User-define field A0 ... A2 (UDF A, 16-bits wide) used for slice 0
  - User-define field B0 ... B10 (UDF B, 16-bits wide) used for slice 1
  - User-define field C0 ... C2 (UDF C, 16-bits wide) used for slice 2
  - User-define field D0 ... D7 (UDF D, 32-bits wide) used for slice 2
  - The four Offset parameters are used to define the location of particular UDF field within the packet. They are defined in the UDF definition registers.
  - End of Tag
  - End of EtherType
  - End of IP Header

## Lookup Engine

The lookup engine is a highly flexible TCAM. This table contains fully user-programmable entries. Each entry has its individual corresponding mask. CFP implements three fixed rule templates, which are called Slice 0, Slice 1 and Slice 2. [Table 4 on page 70](#), [Table 5 on page 70](#), [Table 6 on page 72](#), and [Table 7 on page 72](#) show the slice key field description.

**Table 4: Slice Key Common Fields**

<b>Field</b>	<b>Width (bits)</b>	<b>Bit Position</b>	<b>Description</b>
Slice ID	2	1:0	Indicates the search slice number
Ingress Port Map	29	30:2	Indicates which ingress port(s) the associated ACL rule will apply
SP Tagged	1	31	Indicates whether the received packet is Service Provider tagged.
C Tagged	1	32	Indicates whether the received packet is Customer tagged.
L2 Format	2	34:33	Indicates L2 encapsulation of the received packets: <ul style="list-style-type: none"> <li>• 00: L2_Others</li> <li>• 01: Ethernet_II</li> <li>• 10: IEEE_802_2_SNAP</li> </ul>

## Policy Engine

Table 4 on page 70, Table 5 on page 70, Table 6 on page 72, and Table 7 on page 72 contain one entry per lookup engine entry and the actions/policies that should be taken for the lookup engine entry. The policy entry also indicates which metering and counter entries should be used.

There are six types of actions in CFP policy.

1. The forwarding-related action. Change the destination port or add destination port. It can also drop a frame by making new\_dest to 6'b11\_1111 and enable change destination.
2. To change the priority of the frame. The priority queue can be specified to use by setting PRI\_MAP accordingly.
3. To change the QoS of the outgoing packets.
4. To change the QoS of the CPU originated packets.
5. To change the DSCP tag of the outgoing packets.
6. To change the VID of the outgoing packets.

All six operations can be asserted in parallel, so it is possible that in the end of ContentAware processing, assign to a specific priority and also copy to CPU port and update the corresponding counter.

## Packet Remarking

BCM53262M supports Packet Remarking. Remarks can be made on the PCP field of the outmost VLAN tag of the outgoing packet, or remarks can be made on the DSCP field if the outgoing packet is an IP packet. The remarking process is a part of the ChangePCP, and the ChangeDSCP actions from the CFP, and carried over through the MMU as a part of the packet descriptor information. Based on the new DSCP value, the corresponding IP checksum is also re calculated. The Remarking information is applied globally, independent to the Egress port.

## VID Replacement

BCM53262M supports VID Replacement. The VID field of the outmost VLAN tag of the outgoing packet can be replaced. The Replacement feature is port dependent, each port can be setup differently. Each Egress port supports a 16 entry FLOW to VID mapping table which is indexed by the FlowID. This is derived as a part of the ChangeVID action from the CFP, and is carried through the MMU as a part of the packet descriptor information.

One of the applications for this feature is in the IPTV distribution where the common Multicast VLAN can be dynamically associated with different subscriber's VLANs.

## Metering Engine

Metering engine provides the ability to control ingress bandwidth based on packet classification. Metering determines whether a packet is inband or outband. The results of the metering engine is fed back to the policy engine for determining which actions should be processed.

## Statistic Engine

The Statistics engine increments the counters based on the metering results. For each rule, there are in-profile and out-profile counters counting packets (not bytes).

## ACL Action Resolution Block

The Action Resolution engine collects the information (action and metering results) from the hit entries: if more than one rule matches, the actions and meter/counters are taken from the policy associated with the matched rule with highest priority.

## Section 3: System Functional Blocks

---

### Overview

The BCM53262M includes the following functional blocks:

- “Media Access Controller”
- “Integrated PHY” on page 77
- “Frame Management” on page 88
- “Switch Controller” on page 93
- “Integrated High-Performance Memory” on page 94
- “Clocking” on page 94
- “MIB Engine” on page 94

Each are discussed in more detail in the following sections.

---

### Media Access Controller

The MAC automatically selects the appropriate speed, CSMA/CD or Full-duplex, based on the PHY auto-negotiation result. In FDX mode, 802.3x PAUSE-frame-based flow control is also determined through auto-negotiation. The MAC is IEEE 802.3, 802.3u, and 802.3x compliant.

### Receive Function

The MAC initiates frame reception following the assertion of receive data valid indication from the physical layer. The MAC monitors the frame for the following error conditions:

- Receive error indication from the PHY
- Runt frame error if frame is fewer than 64 bytes
- CRC error
- Long frame error if frame is greater than 2048 bytes (Rev. A silicon)
- For revision B silicon, long frame error if frame is greater than MAX\_RX\_LIMIT, which is defined in “[New Control Register \(Page 00h/Addr 03h\)](#)” on page 167.

If no errors are detected, the frame is processed by the switch controller. Frames with errors are discarded. Receive functions can be disabled.

## Transmit Function

Frame transmission begins with the switch controller queuing a frame to the MAC transmitter. The frame data is transmitted as received from the switch controller. The transmit controller is responsible for preamble insertion, carrier deferral, collision backoff, and inter-packet gap enforcement.

In 10/100 half-duplex mode, when a frame is queued for transmission, the transmit controller behaves as specified by the 802.3 requirements for frame deferral. Following deferral, the transmitter adds 8 bytes of preamble and SFD to the frame data received from the switch controller. If, during frame transmission, a collision is observed and the collision window timer has not expired, the transmit controller asserts jam and then executes the backoff algorithm. The frame is retransmitted when appropriate. On the sixteenth consecutive collision, the backoff algorithm starts over at the initial state, the collision counter is reset and attempts to transmit the current frame continue. Following a late collision, the frame is aborted and the switch controller is allowed to queue the next frame for transmission.

While in full-duplex mode, the transmit controller ignores carrier activity and collision indication. Transmission begins after the switch controller queues the frame and the 96 bit-times of IPG have been observed. Transmit functions can be disabled.

## Flow Control

The BCM53262M implements an intelligent flow control algorithm to minimize the system impact resulting from traffic congestion. Buffer memory allocation is adaptive to the status of each port's speed and Duplex mode, providing an optimal balance between flow management and per-port memory depth. The BCM53262M initiates flow control in response to buffer memory conditions on a per-port basis.

The MACs are capable of flow control in both full-and half-duplex modes.

### 10/100 Mbps Half-Duplex

In 10/100 Half-duplex mode, the MAC backpressures a receiving port by transmitting a 96-bit time-jam packet to the port. A single jam packet is asserted for each received packet for the duration of the time the port is in the flow control state.

### 10/100/1000 Mbps Full-Duplex

Flow control in full-duplex mode functions as specified by the IEEE 802.3x requirements. In the receiver, MAC flow control frames are recognized and, when properly received, set the flow control pause time for the transmit controller. The pause time is assigned from the 2-byte pause time field following the pause opcode. MAC control PAUSE frames are not forwarded from the receiver to the switch controller.

When the switch controller requests flow control, the transmit controller transmits a MAC control PAUSE frame with the pause time set to maximum. When the condition that caused the flow control state is no longer present, a second MAC control PAUSE frame is sent with the pause time field set to 0.

The flow control capabilities of the BCM53262M are enabled based on the results of auto-negotiation and the state of the ENFDXFLOW and ENHDXFLOW control signals loaded during reset. Flow control in half-duplex mode is independent of the state of the link partner's flow control (802.3x) capability. See [Table 8](#) for more information.

**Table 8: Flow Control Modes**

<b>Link Partner Flow Control (802.3x)</b>	<b>Control Input ENFDXFLOW</b>	<b>Control Input ENHDXFLOW</b>	<b>Auto-Negotiated Link Speed</b>	<b>Flow Control Mode</b>
X	X	0	Half-Duplex	Disabled
X	X	1	Half-Duplex	Jam Pattern
0	0	X	Full-Duplex	Disabled
0	1	X	Full-Duplex	Disabled
1	0	X	Full-Duplex	Disabled
1	1	X	Full-Duplex	IEEE 802.3x Flow Control

## Integrated PHY

The PHY is the ethernet transceiver that appropriately processes data presented by the MAC into an analog data stream to be transmitted at the MDI interface, and performs the reverse process on data received at the MDI interface. The registers of the PHY are read/written to via the programming interface. The following sections describe the operations of the internal PHY block.

**Note:** The 24 integrated transceivers are referred to in this document as ports 24, 25 ... and 47. Broadcom SDK maps these ports to logical ports 0, 1 ... 23 respectively.

## Encoder

In 10Base-T mode, Manchester encoding is performed on the data stream that is transmitted on the twisted-pair cable. The multimode transmit digital-to-analog converter (DAC) performs pre-equalization for 100m of Category-3 cabling.

In 100Base-TX mode, the PHY transmits a continuous data stream over the twisted-pair cable. The transmit packet is encapsulated by replacing the first 2 nibbles of preamble with a start-of-stream delimiter (/J/K/ codes) and appending an end-of-stream delimiter (/T/R/ codes) to the end of the packet. The transmitter repeatedly sends the idle (/i/ code) between packets. The encoded data stream is serialized and then scrambled by the stream cipher block. The scrambled data is then encoded into MLT3 signal levels.

## Decoder

In 10Base-T mode, Manchester decoding is performed on the data stream.

In 100Base-TX mode, following equalization and clock recovery, the receive data stream is converted from MLT3 to serial nonreturn to zero (NRZ) data. The NRZ data is descrambled by the stream cipher block, as described later in this document. The descrambled data is then deserialized and aligned into 5-bit code groups. The 5-bit code groups are decoded into 4-bit data nibbles. The start-of-stream delimiter is replaced with preamble nibbles, and the end-of-stream delimiter and idle codes are replaced with 0h. The decoded data is driven onto the internal MAC interface. When an invalid code group is detected in the data stream, the PHY asserts the internal MII receive error signal. This signal is also asserted when the link fails or when the descrambler loses lock during packet reception.

## Link Monitor

In 10Base-T mode, a link-pulse detection circuit constantly monitors the TRD± pins for the presence of valid link pulses.

In 100Base-TX mode, receive signal energy is detected by monitoring the receive pair for transitions in the signal level. Signal levels are qualified using squelch detect circuits. When no signal is detected on the receive pair, the link monitor enters the Link Fail state and the transmission and reception of data packets is disabled. When a valid signal is detected on the receive pair for a minimum of 1 ms, the link monitor enters link-pass state and the transmit and receive functions are enabled.

## Digital Adaptive Equalizer

The digital adaptive equalizer removes intersymbol interference (ISI) created by the transmission channel media. The equalizer accepts sampled unequalized data from the analog-to-digital converter (ADC) on each channel and produces equalized data. The PHY achieves optimum signal-to-noise ratio by using a combination of feed forward equalization (FFE) and decision feedback equalization (DFE) techniques. Under harsh noise environments, these powerful techniques achieve a bit error rate (BER) of less than  $1 \times 10^{-12}$  for transmissions up to 100m on Category-5 twisted-pair cabling (100m on Category-3 UTP cable for 10Base-T mode). The all-digital nature of the design drives high noise-tolerant performance. The filter coefficients are self-adapting to accommodate varying conditions of cable quality and cable length.

## Analog-to-Digital Converter

Each receive channel has its own 125-MHz analog-to-digital converter (ADC) that samples the incoming data and feeds the output to the digital adaptive equalizer. Advanced analog circuit techniques achieve the following results:

- Low offset
- High power-supply noise-rejection
- Fast settling time
- Low bit-error-rate

## Clock Recovery/Generator

The clock recovery and generator block creates the transmit and receive clocks for 100Base-TX and 10Base-T operation.

In 10Base-T or 100Base-TX mode, the transmit clock is locked to the 25-MHz crystal input, and the receive clock is locked to the incoming data stream.

## Baseline Wander Correction

100Base-TX data streams are not always DC-balanced. Because the receive signal must pass through a transformer, the DC offset of the differential receive input can vary with data content. This effect, which is known as baseline wander, can greatly reduce the noise immunity of the receiver. The PHY automatically compensates for baseline wander by removing the DC offset from the input signal, thereby significantly reducing the probability of a receive symbol error.

In 10Base-T mode, baseline wander correction is not performed because the Manchester coding provides perfect DC balance.

## Multimode TX Digital-to-Analog Converter

The multimode transmit digital-to-analog converter (DAC) transmits PAM5, MLT3, and Manchester coded symbols. The transmit DAC performs signal wave shaping that decreases the unwanted high-frequency signal components, reducing electromagnetic interference (EMI). The transmit DAC uses a current drive output that is well-balanced, and therefore, produces very low noise transmit signals.

## Stream Cipher

In 100Base-TX mode, the transmit data stream is scrambled to reduce radiated emissions and to ensure that there are adequate transitions within the data stream. The scrambler reduces peak emissions by randomly spreading the signal energy over the transmit frequency range and eliminating peaks at certain frequencies. The randomization of the data stream also assists the digital adaptive equalizers and echo/crosstalk cancelers. The algorithms in these circuits require there to be no sequential or cross-channel correlation among symbols in the various data streams.

In 100Base-TX mode, the transmit data stream is scrambled by exclusive ORing the encoded serial data stream. This is done with the output of an 11-bit wide linear feedback shift register (LFSR), producing a 2047-bit nonrepeating sequence.

The receiver descrambles the incoming data stream by exclusive ORing it with the same sequence generated at the transmitter. The descrambler detects the state of the transmit LFSR by looking for a sequence representing consecutive idle code groups. The descrambler locks to the scrambler state after detecting a sufficient number of consecutive idle codes. The BCM53262M enables transmission and reception of packet data only when the descrambler is locked. The receiver continually monitors the input data stream to ensure that it has not lost synchronization by checking that inter-packet gaps containing idles or frame extensions are received at expected intervals.

In 10Base-T mode, scrambling is not required to reduce radiated emissions.

## Wire Map and Pair Skew Correction

During 10/100-Mbps operation, pair swaps are corrected. Delay skew is not an issue though, because only one pair of wires is used in each direction.

## Internal Loopback Mode

When enabled in this mode, all packets egressed to the integrated PHY ports are looped back internally from the TXD signals to the RXD signals. The transmitter outputs TRD± are set to high impedance, and incoming packets on the cable are ignored.

## Isolate Mode

The PHY can be isolated from the internal MAC interface. When the transceiver is put into Isolate mode, all inputs from the MAC block are ignored, and all outputs to the MAC block are tristated. While in Isolate mode, the PHY still sends out link pulses or FLPs, depending on whether the PHY was configured for Forced or Auto-negotiation mode. A link is established if the link partner is forced or is advertising the same technologies. Clearing the same bit removes the device from Isolate mode.

## PHY Registers

Each transceiver within the BCM53262M contains a complete set of PHY registers. The 5-bit transceiver address is assigned correspondingly to the internal port ID. All PHY registers can be accessed through the MDC and MDIO signals, or through the Serial Peripheral Interface.

## 100Base-FX Fiber Mode

The 10/100 port can be configured to operate in 100Base-FX compatible mode. The following sequence is required for configuring the preferred PHY ports to 100Base-FX-compatible operation using register write from the CPU. Each port's register can be programmed through page A0h-B7h, respectively.

1. Write 2100h to register (Pages A0h-B7h, Address 00h-01h). This forces the port to 100M full-duplex without auto-negotiation. Most FX applications require configuration for full-duplex.
2. Set bits 9 and 5 of register (Pages A0h-B7h, Address 20h-21h). This bypasses the scrambler and descrambler blocks (i.e., these scrambling functions are not required for 100Base-FX operation). Other bits within this register may be set, so it is best to perform a read-modified write to ensure proper setting of this register.
3. Set bit 5 of hidden register (Page A0h-B7h, Address 2Eh-2Fh). This changes the three-level MLT-3 code transmitted by the PHY to two-level binary, suitable for driving standard fiber transceivers. Additionally, the PHY receiver is configured to recognize binary signaling. This register access must also be in the form of a read-modified write.
4. Enable Internal EFX Signal Detect Function:
  - a. Write 008Bh to register (Pages A0h-B7h, Address 3Eh-3Fh).
  - b. Write 0200h to register (Pages A0h-B7h, Address 32h-33h).
  - c. Write 0084h to register (Pages A0h-B7h, Address 3Ah-3Bh).

- d. Write 000Bh to register (Pages A0h-B7h, Address 3Eh–3Fh).
5. Configure Full-duplex Pause Capability by setting bit 63 and relevant port bits[47:24] of the Software Flow Control registers (Page 00H, Address 48h).

Refer to the *Enhanced-FX-AN1XX 100Base-FX-Compatibility Application Note* for the FX termination requirement.

## Cable Analyzer Registers and Programming

Cable diagnostics can be initiated at any time by entering certain parameters in the required register bits and then setting the *start* bit. Once the start bit is set, the PHY starts the cable diagnostics and looks for opens, shorts, cable lengths on pair-A and pair-B. When this analysis is completed, it records the results and resets the start bit.

### Shadow Register Description

All of the required bits for the cable analyzer are located in the shadow registers, in particular shadow registers (Pages A0h-B7h, addresses 26h and 28h). Within address 26h, there are eight subregisters 0x26-0, 0x26-1, 0x26-2, 0x26-3, 0x26-4, 0x26-5, 0x26-6, and 0x26-7.

Shadow register 0x26-n is accessed by writing an index value (n = 000b to 111b) to the shadow register at address 28h. To access shadow register 0x26-1, the index value in shadow register 28h must be set to 1. Whenever an access is made (either a read or a write) to shadow register 26h, the index value in the shadow register 28h is automatically incremented.

When changing a bit within any register, preserve the existing values of reserved bits by performing a 'read modify' write.

The following tables shows the cable analyzer registers and their contents.

**Table 9: Shadow Register 28h (Pages A0h-B7h, Address 28h)**

Address	15–11	10–8	7–0	Default
0x28	Reserved	0x26 index	Reserved	0x0000

### 0x26 Index [10:8]

To access shadow register 26h, first an index value from 0(000b) to 7(111b) must be written to these bits. When an access (either read or write) is made to shadow register 26h, this value automatically increments by 1 (111b after the increment, it becomes 000b).

**Table 10: Shadow Register 0x26–0 (Pages A0h-B7h, Address 26h)**

Address	15–14	13–12	11–10	9–8	7–6	9–3	2	1	0	Default
0x26-0	Reserved	Pair-B State	Pair-A State	Pass	Error	Reserved	Start	MP	Reserved	0x0000

## Pair-B State[13:12]

After the completion of cable analyzer, these bits indicate the status of pair-B of the cable (see [Table 11](#) for details). Pair-B of the cable is the pair that is connected to RD± of the device.

**Table 11: Pair-B State**

Value	Result for Pair-B
00b	No fault detected
01b	Pair is open
10b	Pair is short
11b	Reserved

**Note:** When the cable analyzer function returns a value of 00 (No fault detected), then the attached cable is good. If the device is unable to establish a valid link, the problem is not related to the cable.

## Pair-A State[11:10]

After the completion of cable analyzer, these bits indicate the status of pair-A of the cable (see [Table 12](#) for details). Pair-A of the cable is the pair that is connected to TD± of the device.

**Table 12: Pair-A State**

Value	Result for Pair-A
00b	No fault detected
01b	Pair is open
10b	Pair is short
11b	Reserved

**Note:** When the cable analyzer function returns a value of 00 (No fault detected), then the attached cable is good. If the device is unable to establish a valid link, the problem is not related to the cable.

## Start [2]

Setting this bit to a 1 starts the cable diagnostics function in the BCM5325EBCM5325F. This should be the last bit that is set after programming the required values in shadow registers 0x26-0, 0x26-1, 0x26-2, 0x26-3, 0x26-4, 0x26-5, 0x26-6 and 0x26-7. This bit is cleared when the cable analyzer function is complete. Once this bit is set, it is reset in approximately 5 ms.

## MP [1] = 1

This is an internal variable required to be set before starting the cable analyzer. Set this bit to a 1.

## Pass [9:8]

These bits are 11b when reading the results of the cable analyzer.

## Error [7:6]

These bits must be 00b when reading the results of the cable analyzer.

**Table 13: Shadow Register 0x26-1 (Pages A0h-B7h, Address 26h)**

Address	15–8	7–0	Default
0x26-1	Pair-B length	Pair-A length	0x0000

## Pair-B Length [15:8]

These bits indicate the length of pair-B once the cable analyzer is completed. To convert this value to meters, multiply the value by 0.8. This value should be used in combination with the result posted on the condition of pair-B in bits [13:12] of shadow register 0x26-0.

**Table 14: Pair-B Cable Diagnostics Result**

Pair-B state [13:12] (shadow register 0x26-0)	Pair-B length [15:8] (shadow register 0x26-1)
01b	Distance at which an open is detected in pair-B
10b	Distance at which a short is detected in pair-B

## Pair-A Length [7:0]

These bits indicate the length of pair-A once the cable analyzer is completed. To obtain the value in meters, multiply this value by 0.8. This value should be used in combination with the result posted on the condition of pair-A in bits [11:10] of shadow register 0x26-0.

**Table 15: Pair-A Cable Diagnostics Result**

Pair-A state [11:10] (shadow register 0x26-0)	Pair-A length [7:0] (shadow register 0x26-1)
01b	Distance at which an open is detected in pair-A
10b	Distance at which a short is detected in pair-A

**Table 16: Shadow Register 0x26-2 (Pages A0h-B7h, Address 26h)**

Address	15–14	13–12	11–10	9–6	5	4–0	Default
0x26-2	GainA	Reserved	TypeA	Reserved	HP	ThresholdA	0x0000

## GainA [15:14] = 01b

This is an internal variable required to be set before starting the cable analyzer. Set these bits to 01b.

**TypeA [11:10] = 10b**

This is an internal variable required to be set before starting the cable analyzer. Set these bits to 10b.

**HP [5] = 1**

This is an internal variable required to be set before starting the cable analyzer. Set these bits to a 1.

**ThresholdA [4:0] = 00100b**

This is an internal variable required to be set before setting the start bit in shadow register 0x26-0 to start the cable analyzer. Set these bits to 00100b.

*Table 17: Shadow Register 0x26-3 (Pages A0h-B7h, Address 26h)*

Address	15–8	7–0	Default
0x26-3	SourceA	Reserved	0x0000

**SourceA [13:8] = 00100000b**

This is an internal variable required to be set before setting the start bit in shadow register 0x26-0 to start the cable analyzer. Set these bits to 00100000b.

*Table 18: Shadow Register 0x26-4 S (Pages A0h-B7h, Address 26h)*

Address	15–11	10	9	8–6	5–0	Default
0x26-4	Reserved	TypeB	Reserved	TPG	Reserved	0x0000

**TypeB [10]**

This is an internal variable required to be set before starting the cable analyzer. Set this bit to a 1.

**TPG [8:6]**

This is an internal variable required to be set before starting the cable analyzer. Set this bit to 100b.

*Table 19: Shadow Register 0x26-5 (Pages A0h-B7h, Address 26h)*

Address	15–14	13–5	4–2	1–0	Default
0x26-5	GainB	Reserved	ThresholdB	Reserved	0x0400

**GainB [15:14 = 11b]**

This is an internal variable required to be set before starting the cable analyzer. Set these bits to 11b.

## ThresholdB [4:2] = 001b

This is an internal variable required to be set before setting the start bit in shadow register 0x26-0 to start the cable analyzer. Set these bits to 001b.

**Table 20: Shadow Register 0x26-6 (Pages A0h-B7h, Address 26h)**

Address	15–14	13–8	7–0	Default
0x26-6	Reserved	SourceB	Reserved	0x0000

## SourceB [13:8] = 000001b

This is an internal variable required to be set before setting the start bit in shadow register 0x26-0 to start the cable analyzer. Set these bits to 000001b.

**Table 21: Shadow Register 0x26-7 (Pages A0h-B7h, Address 26h)**

Address	15–9	8–6	5	4–0	Default
0x26-7	Reserved	PGWB	Reserved	AmpB	0x0000

## PGWB [8:6] = 001b

This is an internal variable required to be set before setting the start bit in shadow register 0x26-0 to start the cable analyzer. Set this bit to a 001b

## AmpB [4:0] = 01100b

This is an internal variable required to be set before setting the start bit in shadow register 0x26-0 to start the cable analyzer. Set this bit to a 01100b.

## Programming Example

The following example of code shows a general flow of completing the cable analyzer in the PHY.

Cable Analyzer programming

```

-----
Start
Write register (Pages A0h-B7h, address 3Eh) = 0x008BEnable shadow register
Wait1
Read (Pages A0h-B7h, address 28h) ; Wait here for at least 2 seconds of bit 6 for address 28h to be
at 0. This ensures that there is no energy from the link partner.
Write (Pages A0h-B7h, address 28h) -0x0000
End Wait1
Write register (Pages A0h-B7h, address 26h) = 0x0000
Write register (Pages A0h-B7h, address 28h) = 0x0200;Set access shadow register 26h to 0x26-2
Write (Pages A0h-B7h, address 26h) = 0x4824; 0x26-2
Write (Pages A0h-B7h, address 26h) = 0x4000; 0x26-3
Write (Pages A0h-B7h, address 26h) = 0x0500; 0x26-4
Write (Pages A0h-B7h, address 26h) = 0xC404; 0x26-5
Write (Pages A0h-B7h, address 26h) = 0x0100; 0x26-6
Write (Pages A0h-B7h, address 26h) = 0x004C; 0x26-7
Write (Pages A0h-B7h, address 26h) = 0x8006; 0x26-0 (Start cable diagnostics)
Wait2
    Write (Pages A0h-B7h, address 28h) = 0x0000; Set access to 0x26-0
    Read (Pages A0h-B7h, 1 address 26h) ; Read 0x26-0
    If register 0x26-0 bit [2] = 1 then go to Wait2
Result
Pair-A status = 0x26-0 bit [11:10]
Pair-B status = 0x26-0 bit [13:12]

Read (Pages A0h-B7h, 19h, address 26h) ; Read 0x26-1
Pair-A length = bit [7:0] X 0.8 meters
Pair-B length = bit [15:8] X 0.8 meters

Write register (Pages A0h-B7h, 1address 3Eh) = 0x000BEnable default MII register access
End

```

**Note:** If a port is connected to a link partner with a good cable (no short or no open on either pair) and the link partner is not powered up, then the cable status bits are valid, but the length bits are invalid.

### Cable Analyzer Flow Chart

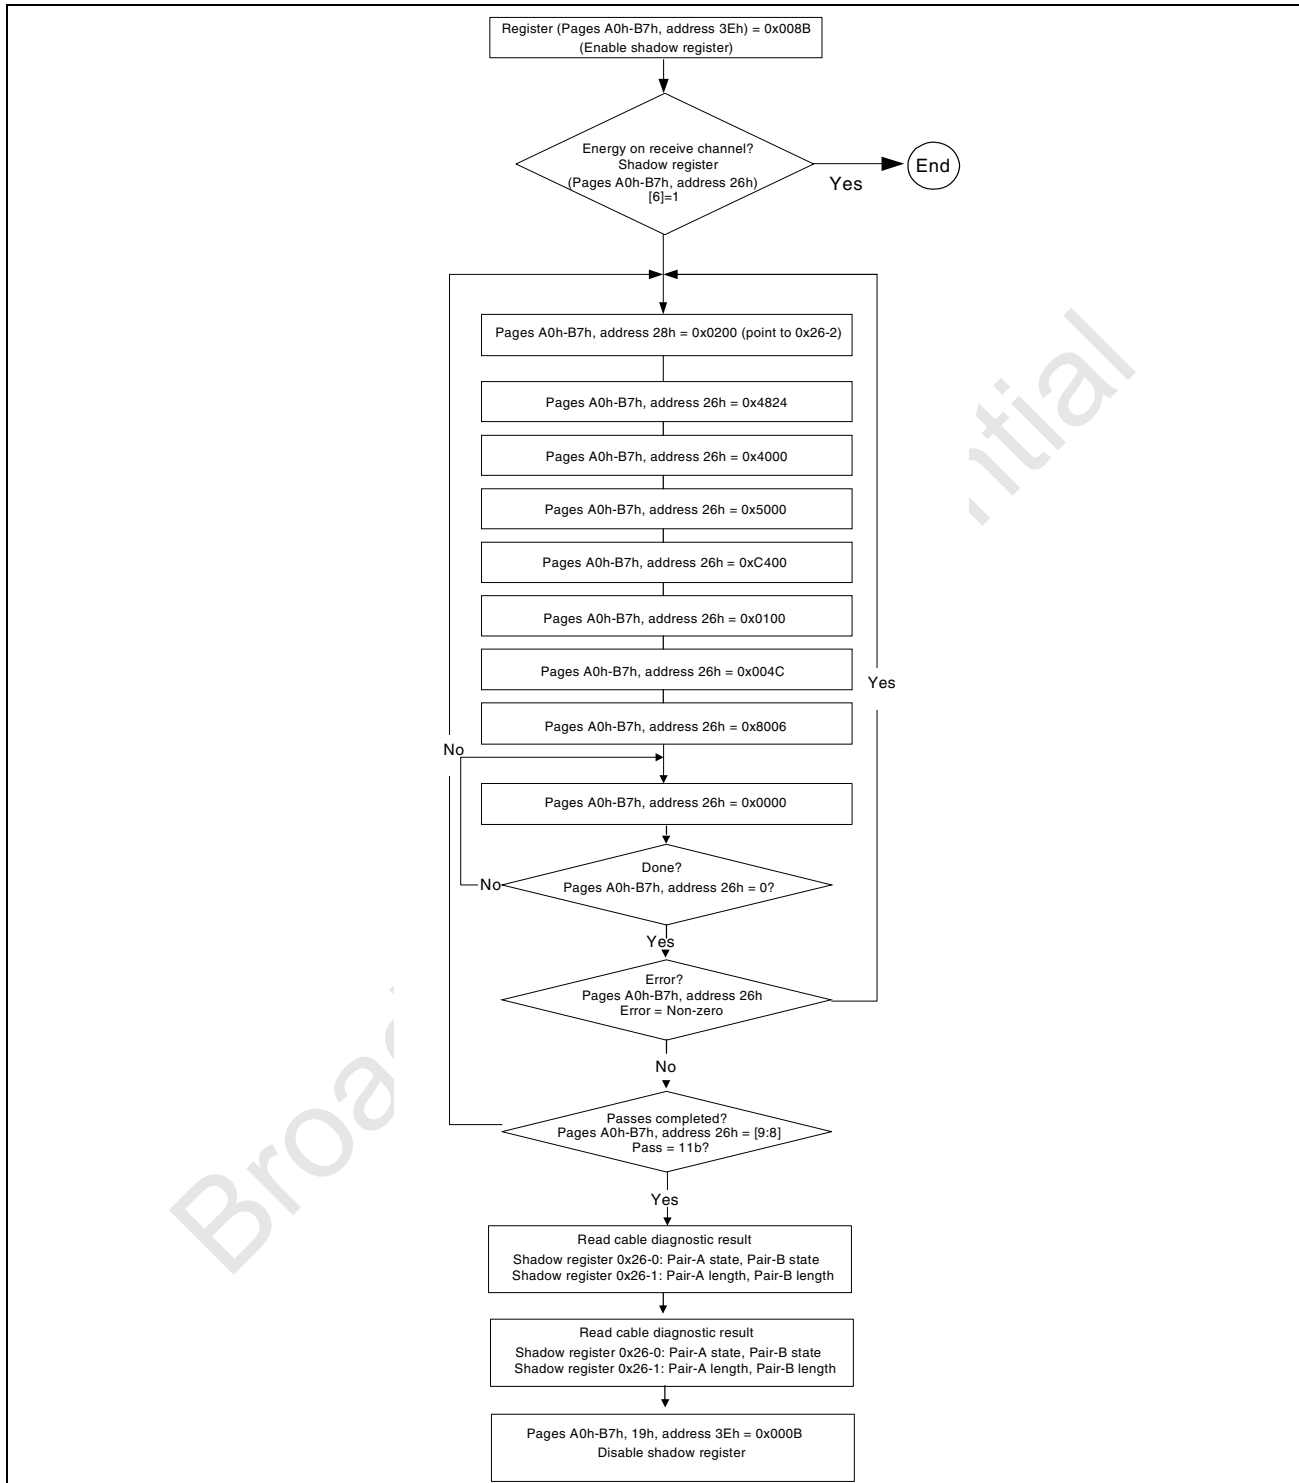

Figure 17: Cable Analyzer Flow Chart

---

## Frame Management

The BCM53262M provides a frame management block that works in conjunction with a selectable port interface to receive forwarded management frames directed to the switch.

The frame management block is configured via the FRM\_MNGT\_PORT bits of the Global Management Configuration register as shown in [Table 99: "Global Management Configuration Register \(Page 03h: Address 00h\)," on page 205](#).

An external CPU connects via the selected port interface to process the forwarded frames and respond appropriately. When the selected port is defined as the Frame Management Port, it is referred to as the In-band Management Port (IMP).

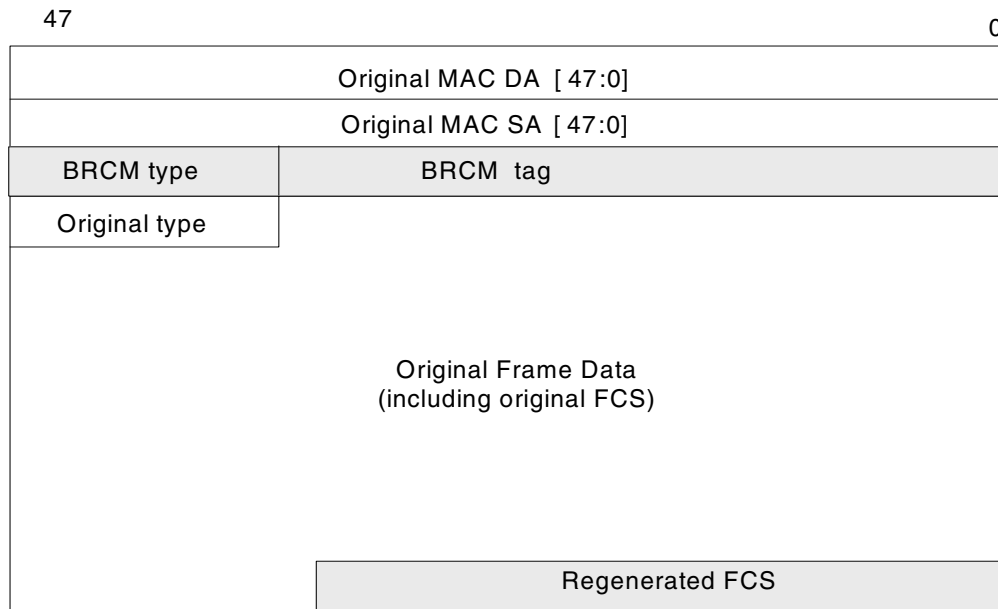

### In Band Management Port

The IMP can be used as a full-duplex port, which can be used to forward management information to the external management agent, such as BPDUs, mirrored frames, or frames addressed to other Static address entries that have been identified as of special interest to the management system.

As IMP is defined as the Frame Management Port, normal frame data is forwarded to the port based on the state of the RX\_UCST\_EN, RX\_MCST\_EN and RX\_BCST\_EN bits in the associated IMP Port Control Register. If these bits are cleared, no frame data will be forwarded to the Frame Management Port, with the exception that frames meeting the Mirror Ingress/Egress Rules criteria, will always be forwarded to the designated Frame Management Port.

The BCM53262M device intrusively tags frames destined to the management entity to allow the identity of the originating ingress port of a frame to be retained. Additional header information is inserted into the original frame, between the original SA field and Type/Length fields, see [Figure 18 on page 89](#). The tag includes the BRCM Type field and the BRCM Tag field. The Broadcom tag type is 0x8874, the alignment of the regenerated FCS may vary depending on the original frame length, and the regenerated FCS covers from the whole frame, including the BRCM Type and BRCM tag. A recalculated FCS is appended to the resultant frame, before the frame is forwarded.

**Figure 18: Broadcom-Tagged Packet Encapsulation Format**

The Broadcom Tag is designed for asymmetric operation across the IMP port. The information carried from the BCM53262M to the external CPU (IMP Egress) is different from the information carried from the external CPU to BCM53262M (IMP Ingress).

Similarly, the host system must insert the BRCM Type/Length and Tag fields into frames it wishes to send into the management port, to be routed to specific egress ports. The OPCODE within the Tag field determines how the frame will be handled, and allows frames to be forwarded using the normal address lookup or via a Port ID designation within the Tag.

**Note:** The FCS (outer) is ignored by the BCM53262M device. However, the management entity is still intended to provide 4 bytes of any data as a place holder. Only the final outgoing FCS (inner) is required.

The BRCM Tag and BRCM Type/Length fields are transmitted with the convention of highest significant octet first, followed by next lowest significant octet, etc., and with the least significant bit of each octet transmitted out from the MAC first. So for the BRCM Type/Length field in [Table 22 on page 90](#), the most significant octet would be transmitted first (bits 24:31), with bit 24 being the first bit transmitted.

## IMP Ingress

[Table 22](#) shows the format of the IMP Ingress BRCM Tag field. The OPCODE field slightly modifies the use and validity of some fields in the Tag. [Table 23](#) defines the supported OPCODEs.

**Table 22: BRCM Header Tag Format (CPU to IMP)**

31-29	28,27	26,25	24 - 6	5-0
Opcode = (000) Unicast/Multicast/ Broadcast	TQ[1:0]	TE[1:0]	Reserved	Reserved
Opcode = (010) Egress Directed	TQ[1:0]	TE[1:0]	Reserved	Dest Portid Indicates the destination Port ID for Egress Directed frames. <b>Note:</b> Setting Dest Portid = 0x30 allows egress directed frame to loopback to CPU. This is for testing purpose.
Opcode = (100) Multicast Egress Directed to 10/100 Ports	TQ[1:0]	TE[1:0]	Dest Port Vector [Port 47~Port 24] Defines the destination Port IDs for Multicast Egress Directed frames. <b>Note:</b> Bit 24 is not used	
Opcode = (101) Multicast Egress Directed to GigaPorts	TQ[1:0]	TE[1:0]		Dest Port Vector [G3, G2, G1, G0, IMP] Defines the destination GigaPort IDs for Multicast Egress direct frames. <b>Note:</b> For testing purpose, setting bit[0] = 1 allows the CPU to loop back the frame at the IMP port.

**Table 23: OPCODE Field in BRCM Tag for Management Port Frame**

OpCodes	Name	Description
0 0 0	Unicast/Multicast Broadcast	Normal unicast and multicast frames are forwarded using the address table lookup of the DA contained in the frame. Broadcast frames sent by the host management system into IMP port are forwarded based on the broadcast rule that is in effect.
0 1 0	Egress Directed	An Egress Directed frame is sent by the host management system into the IMP port, and is forwarded to the Egress Port specified in the Destination Port ID fields in the BRCM Tag.
1 0 0	Multicast Egress Directed	A Multicast Egress Directed frame is sent by the host management system into the IMP port and is forwarded to multiple 10/100 Egress Ports specified in the Dest Port Vector field in <a href="#">Table 22 on page 90</a> .
1 0 1	Multicast Egress Directed	A multicast Egress Directed frame is sent by the host management system into the IMP port and is forwarded to multiple Egress ports specified in the Dest Port Vector field in <a href="#">Table 22 on page 90</a> .

**Table 24: TQ and TE Fields in BRCM Tag for Management Port Frame**

Field	Name	Description
TQ[1:0]	Traffic Class Queue	Uses by the host CPU to assign a traffic class queue for forwarding the packet. <ul style="list-style-type: none"> <li>11: Highest queue</li> <li>10: 3rd queue</li> <li>01: 2nd queue</li> <li>00: Lowest queue</li> </ul>
TE[1:0]	Tag Enforcement	Used by the host CPU to enforce the 802.1Q/1p tagging/untagging encapsulation of the packet at the egress forwarding of the packet. <ul style="list-style-type: none"> <li>11: Reserved</li> <li>10: Enforces tagging regardless of the 802.1Q VLAN untag mask</li> <li>01: Enforces untagging regardless of the 802.1Q VLAN untag mask</li> <li>00: No enforcement. Follows the 802.1Q VLAN untag mask</li> </ul>

## IMP Egress

Table 25 shows the format of the IMP Egress BRCM Tag field. The OPCODE field slightly modifies the use and validity of some fields in the Tag. Table 26 defines the supported OPCODEs.

**Table 25: BRCM Header Tag Format (IMP to CPU)**

31-29	28-17	16	15-14	13 - 8	7,6	5 - 0
Opcode = (000) Unicast Multicast/ Broadcast	Frame Oct Count[11:0] This 11-bit field incorporates the Octet Count of the entire Ethernet frame octet count starting at the DA field and inclusive of CRC, but not including the BRCM Type, BRCM Tag, and recalculated FCS.	RSVD	QoS: Indicates the traffic class queue used in forwarding the packet to CPU	Reason Code[5:0]: Indicates the reason code for the packet to be forwarded to CPU.	ERMON 7: Extended RMON for Ingress ERMON 6: Extended RMON for Egress	SRC_PID: Indicates the source Port ID for ingress directed frames.

**Table 26: OPCODE Field in BRCM Tag for Management Port Frame**

OpCodes	Name	Description
0 0 0	Unicast/ Multicast/ Broadcast	Unicast, multicast, reserved multicast and broadcast frames from a network port destined to the host management system are forwarded using the address table lookup of the DA contained in the frames. All frames are automatically inserted a BRCM Tag that includes the Frame Oct Count and Source Port ID fields.

**Table 27: Reason Code Field in BRCM Tag for Management Port Frame**

<b>Reason Code</b>	<b>Name</b>	<b>Description</b>
0	Mirroring	The packet is mirrored to the CPU as the capture port.
1	SA Learning	The packet is forwarded to the CPU for controlled MAC SA learning.
2	Switching/Flooding	The packet is forwarded to the CPU either because of flooding or the CPU is the intended receive host.
3	Protocol Termination	The packet is trapped by the CPU because an IEEE 802.1-defined L2 protocol must be terminated by the CPU.
4	Protocol Snooping	The packet is copied to the CPU because an L3 or application level protocol must be monitored by the CPU for network security or operation efficiency.
5	Exception Processing/Flooding	The packet is trapped and forwarded to the CPU either because of flooding or for some special processing, even though the CPU is not the intended receive host.

---

## Switch Controller

The core of the BCM53262M device is a cost-effective and high-performance switch controller. The controller manages packet forwarding between the MAC receive and transmit ports through the frame buffer memory with a store and forward architecture. The switch controller encompasses the functions of buffer management, memory arbitration and transmit descriptor queuing.

### Buffer Management

The frame buffer memory is divided into 256 bytes per page. Each packet received may allocated more than one page, of which, six pages are required for storing maximum 1536B frame data. Frame data is stored to the memory block as the packet is received. After reception, the frame is queued to the egress port(s) transmit queue. For unicast frames, following transmission of a packet from the frame buffer memory, the block of memory for the frame is released to the free buffer pool. If the frame is destined to multiple ports, the memory block is not released until all ports complete transmission of the frame.

### Memory Arbitration

Processes requesting access to the internal memory include the receive and transmit frame data handlers, address resolution, learning and aging functions, and output port queue managers. These processes are arbitrated to provide fair access to the memory and minimize latency of critical processes to provide a fully nonblocking solution.

### Transmit Output Port Queues

When the Quality of Service (QoS) function is turned off, the switch controller maintains an output port queue for each port. The queue depth becomes smaller for each output port when the QoS function is on. Transmit descriptors are updated after the packet has been received and the destination port resolved. One or two transmit descriptors are assigned to each destination port queue linking the destination with the frame data. For packets which have frame sizes larger than 512 bytes, two transmit descriptors are required. In the case of multicast and broadcast packets, a transmit descriptor for the packet is assigned to the transmit descriptor queues of multiple ports.

For each port, frames are initiated for transmission with minimum IPG until the transmit descriptor queue of the port is empty.

When the QoS is turned on, the single queue is split into four different-sized priority queues. These four queues are maintained by the switch controller for each transmit port. The weighted fair scheduling is applied to the queues to select frames from all queues and prevent starvation.

## Integrated High-Performance Memory

The BCM53262M includes 4 Mb of integrated, high-performance RAM which stores all packet buffer and address table information; and eliminates the need for external memory. This allows for the implementation of extremely low-cost systems.

## Clocking

The BCM53262M uses a single 25-MHz clock input to derive the device's internal clocks to operate at 100 MHz, which affect the operation of the system logic and internal RAM. This allows for the best trade-offs with respect to performance, cost, and power.

## MIB Engine

The MIB Engine is responsible for processing status words received from each port. Based on whether it is a receive status or transmit status, appropriate MIB counters are updated. The BCM53262M implements 70 plus MIB counters on a per-port basis. MIB counters can be categorized into three groups:

- Receive only counters
- Transmit only counters
- Receive or transmit counters

The receive or transmit counters group can, as a group, be selectively steered to the receive or transmit process on a per-port basis. The following section describes each individual counter.

## MIB Counters Per Port

**Table 28: Receive Only Counters (17)**

<b>Counters</b>	<b>Description</b>
RxDropPkts (32 bit)	The number of packets received by a port that were dropped due to security conflict when MAC address security Control is enabled.
RxOctets (64 bit)	The number of bytes of data received by a port (excluding preamble but including FCS), including bad packets.
RxBroadcastPkts (32 bit)	The number of good packets received by a port that are directed to the broadcast address. This counter does not include errored broadcast packets or valid multicast packets.
RxMulticastPkts (32 bit)	The number of good packets received by a port that are directed to a multicast address. This counter does not include errored multicast packets or valid broadcast packets.
RxSACHanges (32 bit)	The number of times the SA of good receive packets has changed from the previous value. A count greater than 1 generally indicates the port is connected to a repeater based network.

**Table 28: Receive Only Counters (17) (Cont.)**

<b>Counters</b>	<b>Description</b>
RxUndersizePkts (32 bit)	The number of good packets received by a port that are less than 64 bytes long (excluding framing bits but including the FCS).
RxOversizePkts (32 bit)	The number of good packets received by a port that are greater than MAX_RX_LIMIT (excluding framing bits but including the FCS). This counter alone is incremented for packets in the range MAX_RX_LIMIT–2048 bytes inclusive, whereas both this counter and the RxExcessSizeDisc counter is incremented for packets of 2049 bytes and higher. (Revision B silicon.) See Bit 2:1 at <a href="#">Table 56: “New Control Register (Page 00h: Address 03h),” on page 167.</a> The number of good packets received by a port that are greater than 1518 (excluding framing bits but including the FCS). This counter alone is incremented for packets in the range 1518–2048 bytes inclusive, whereas both this counter and the RxExcessSizeDisc counter is incremented for packets of 2049 bytes and higher. (Revision A silicon)
RxFragments (32 bit)	The number of packets received by a port that are less than 64 bytes (excluding framing bits) and have either an FCS error or an alignment error.
RxJabbers (32 bit)	The number of packets received by a port that are longer than MAX_RX_LIMIT bytes and have either an FCS error or an alignment error (Revision B silicon). See Bit 2:1 at <a href="#">Table 56: “New Control Register (Page 00h: Address 03h),” on page 167.</a> The number of packets received by a port that are longer than 1522 bytes and have either an FCS error or an alignment error (Revision A silicon).
RxUnicastPkts (32 bit)	The number of good packets received by a port that are addressed to a unicast address.
RxAlignmentErrors (32 bit)	The number of packets received by a port that have a length (excluding framing bits but including FCS) between 64 and 1522 bytes, inclusive, and have a bad FCS with a nonintegral number of bytes.
RxFCSErrors (32 bit)	The number of packets received by a port that have a length (excluding framing bits but including FCS) between 64 and 1522 bytes inclusive, and have a bad FCS with an integral number of bytes.
RxGoodOctets (64 bit)	The total number of bytes in all good packets received by a port (excluding framing bits, but including FCS).
RxExcessSizeDisc (32 bit)	The number of good packets received by a port that are greater than 2048 bytes (excluding framing bits but including the FCS) and were discarded due to excessive length.
RxPausePkts (32 bit)	The number of PAUSE frames received by a port. The PAUSE frame must have a valid MAC Control Frame EtherType field (88-08h), have a destination MAC address of either the MAC Control frame reserved multicast address (01-80-C2-00-00-01) or the unique MAC address associated with the specific port, a valid PAUSE Opcode (00-01), be a minimum of 64 bytes in length (excluding preamble but including FCS), and have a valid CRC. Although an 802.3-compliant MAC is only permitted to transmit PAUSE frames when in full duplex mode, with flow control enabled, and with the transfer of PAUSE frames determined by the result of auto-negotiation, an 802.3-MAC receiver is required to count all received PAUSE frames, regardless of its half/full-duplex status. An indication that a MAC is in half-duplex with the RxPausePkts incrementing indicates a noncompliant transmitting device on the network.

**Table 28: Receive Only Counters (17) (Cont.)**

<b>Counters</b>	<b>Description</b>
RxSymbolErrors (32 bit)	The total number of times a valid length packet was received at a port and at least one invalid data symbol was detected. Counter only increment once per carrier event and does not increment on detection of collision during the carrier event.
RxDiscPkts (32 bit)	<p>The number of good packets received by a port that are discarded by the forwarding processes. This counter increments each time a good packet received by a port is discarded due to a final egress forwarding decision produced by the following processes:</p> <ul style="list-style-type: none"> <li>• ARL DA</li> <li>• VLAN</li> <li>• Spanning tree</li> <li>• EAP</li> <li>• CFP</li> <li>• Protected port</li> <li>• WAN port</li> <li>• VPN port</li> <li>• Link down status</li> <li>• Rate control</li> <li>• Flow control</li> </ul> <p>This counter does not include packets dropped due to Rx-based flow control process.</p>

**Table 29: Transmit Counters Only (21)**

<b>Counters</b>	<b>Description</b>
TxDropPkts (32 bit)	This counter is incremented every time a transmit packet is dropped due to lack of resources (e.g., transmit FIFO underflow), or an internal MAC sublayer transmit error not counted by either the TxLateCollision or the TxExcessiveCollision counters.
TxOctets (64 bit)	The total number of good bytes of data transmitted by a port (excluding preamble but including FCS).
TxBroadcastPkts (32 bit)	The number of good packets transmitted by a port that are directed to a broadcast address. This counter does not include errored broadcast packets or valid multicast packets.
TxMulticastPkts (32 bit)	The number of good packets transmitted by a port that are directed to a multicast address. This counter does not include errored multicast packets or valid broadcast packets.
TxCollisions (32 bit)	The number of collisions experienced by a port during packet transmissions.
TxUnicastPkts (32 bit)	The number of good packets transmitted by a port that are addressed to a unicast address.
TxSingleCollision (32 bit)	The number of packets successfully transmitted by a port that experienced exactly one collision.
TxMultipleCollision (32 bit)	The number of packets successfully transmitted by a port that experienced more than one collision.

**Table 29: Transmit Counters Only (21) (Cont.)**

<b>Counters</b>	<b>Description</b>
TxDeferredTransmit (32 bit)	The number of packets transmitted by a port for which the first transmission attempt is delayed because the medium is busy.
TxLateCollision (32 bit)	The number of times that a collision is detected later than 512 bit-times into the transmission of a packet.
TxExcessiveCollision (32 bit)	The number of packets that are not transmitted from a port because the packet experienced 16 transmission attempts.
TxPausePkts (32 bit)	The number of PAUSE frames transmitted by a port. The MAC resolve to full duplex mode, with 802.3x flow control PAUSE frame exchange enabled at the completion of auto-negotiation.
TxFrameInDisc (32 bit)	The number of valid packets received which are discarded by the forwarding process due to lack of space on an output queue. Not maintained or reported in the MIB counters. Located in the Congestion Management registers (Page 0Ah). This attribute only increments if a network device is not acting in compliance with a flow control request, or the BCM53262M internal flow control/buffering scheme has been misconfigured.
TxQoS0Pkts (32 bit)	The total number of good packets transmitted on queue 0 when QoS is enabled.
TxQoS0Octets (64 bit)	The total number of good bytes transmitted on queue 0 when QoS is enabled.
TxQoS1Pkts (32 bit)	The total number of good packets transmitted on queue 1 when QoS is enabled.
TxQoS1Octets (64 bit)	The total number of good bytes transmitted on queue 1 when QoS is enabled.
TxQoS2Pkts (32 bit)	The total number of good packets transmitted on queue 2 when QoS is enabled.
TxQoS2Octets (64 bit)	The total number of good bytes transmitted on queue 2 when QoS is enabled.
TxQoS3Pkts (32 bit)	The total number of good packets transmitted on queue 3 when QoS is enabled.
TxQoS3Octets (64 bit)	The total number of good bytes transmitted on queue 3 when QoS is enabled.

**Table 30: Transmit or Receive Counters (6)**

<b>Counters</b>	<b>Description</b>
Pkts64Octets (32 bit)	The number of packets (including error packets) that are 64 bytes long.
Pkts65to127Octets (32 bit)	The number of packets (including error packets) that are between 65 and 127 bytes long.
Pkts128to255Octets (32 bit)	The number of packets (including error packets) that are between 128 and 255 bytes long.
Pkts256to511Octets (32 bit)	The number of packets (including error packets) that are between 256 and 511 bytes long.
Pkts512to1023Octets (32 bit)	The number of packets (including error packets) that are between 512 and 1023 bytes long.
Pkts1024toMaxOctets (32 bit) (Revision B silicon)	The number of packets (including error packets) that are between 1024 and MAX_RX_LIMIT bytes long. See Bit 2:1 at <a href="#">Table 56: "New Control Register (Page 00h: Address 03h),"</a> on page 167.
Pkts1024to1522Octets (32 bit) (Revision A silicon)	The number of packets (including error packets) that are between 1024 and 1522 bytes long.

## Total Number of Counters Per Port: 35

Table 31 identifies the mapping of the BCM53262M MIB counters and their generic mnemonics, to the specific counters and mnemonics for each of the key IETF MIBs which are supported (this is defined where there is a direct mapping). However, there are several additional statistics counters that are indirectly supported, which make up the full complement of the counters required to fully support each MIB. These are shown in Table 32 on page 100. Finally, Table 33 on page 100 identifies the additional counters supported by the BCM53262M, and references the specific standard or reason for the inclusion of the counter.

Note 1: Derived by summing two or more of the supported counters. See [Table 32 on page 100](#) for specific details.

Note 2: Extensions required by recent Standards developments or BCM53262M operation specifics.

Note 3: The MIB II Interfaces specification for if OutOctets includes preamble/SFD and errored bytes. Because 802.3 compliant MACs have no requirement to keep track of the number of transmit bytes in an errored frame, this count is impossible to maintain. The TxOctets maintained by the BCM53262M is consistent with good bytes transmitted, excluding preamble but including FCS. The count can be adjusted to more closely match the if OutOctets definition by adding the preamble for TxGoodPkts, and possibly an estimate of the octets involved in TxCollisions and TxLateCollision.

Note 4: The attributes TxCarrierSenseErrors and TxSQETestErrors are not supported in the BCM53262M. These attributes were originally defined to support coax based AUJ transceivers. The BCM53262M's integrated transceiver design means these error conditions are eliminated. MIBs intending to support such counters should return a value of 0 or not supported.

**Table 32: Indirectly Supported MIB Counters**

## Section 4: System Interfaces

---

### Overview

The BCM53262M includes the following interfaces.

Each of these is discussed in more detail in the following sections.

- [“MII Port” on page 102](#)
- [“10/100 Mbps Copper Interface” on page 106](#)
- [“Configuration Pins” on page 107](#)
- [“Programming Interfaces” on page 107](#)
- [“EEPROM Interface” on page 112](#)
- [“Extended Bus Interface” on page 113](#)
- [“MDC/MDIO Interface” on page 118](#)
- [“LED Interfaces” on page 127](#)
- [“JTAG Interface” on page 136](#)

---

### MII Port

The BCM53262M provides a fully 802.3u compatible MII interface as a twenty-fifth network port (port 48). The port can be configured to operate differently dependent on the programming of the internal registers.

### Network Port

In unmanaged mode after power-up, the MII operates as a normal MAC-based MII port, capable of interfacing directly to an external TX or FX transceiver. The port incorporates an internal MAC, and functions identically to the integrated 10/100 ports. Frames are forwarded to the port under control of the forwarding model.

Predecessors of the BCM53262M device allowed the MII management signals (MDC/MDIO) to interrogate the internal MII registers associated with the integrated 10/100 Mbps PHYs. The BCM53262M can still support this mode, in which case, configuration of the integrated PHYs requires the 2.5-MHz clock to be supplied to the BCM53262M MDC pin and any external MII-connected transceiver, and the external management device controls MDIO to select and configure all the PHYs appropriately. To operate in this mode, the external transceiver needs to support some signals in addition to the standard MII signals, so that the state of the external transceiver can be monitored by the BCM53262M. Individual active-low Link, Speed (100 Mbps), Duplex, and link partner Flow Control mode signals from the transceiver should be provided. An MII-based single 10/100 Mbps PHY, such as the BCM5202, provides these additional signals. With these additional signals, the BCM53262M generates port LEDs for the external MII-based PHY, equivalent to the LEDs of the internal transceivers.

The more typical use of the MII in a BCM53262M implementation is that the device is accessed via the SPI. In this case, on sensing activity of the SPI, the BCM53262M takes control of the MII management pins, and sources the 2.5-MHz clock signal for MDC. The external PHY can be accessed by the management entity, since its MII registers are aliased to the Port 48 ([Table 327: “External Port MII Registers Page Versus PHY,” on page 374](#)). Access to MII registers in this page in the register map automatically generates an MDIO/MDC request to the external MII-based transceiver, allowing configuration control and status monitoring of the off-chip PHY port. The MII port uses the unique PHY address of 18h. The external PHY must be programmed/strapped to respond to the PHY address of 18h. See [“MDC/MDIO Interface” on page 118](#) for additional detail on internal and external PHY address values.

When an external transceiver is connected to the BCM53262M MII port and managed by the MDC/MDIO lines, the state of the link, speed, full/half-duplex and link partner flow control capabilities (among many others) can all be accessed via software, and need not be provided as hardware pins. In order to preserve LED display capabilities for the MII port, an additional alias register is provided in the Control registers (Page 0h). All the specific register information is temporary and subject to be change in the final version of the data sheet. This allows the state of the aforementioned status bits to be read from the external PHY and then written to this register, so that consistent LED status information for all 10/100 ports can be preserved.

If no MII-based external transceiver is present, page 28h of the register space is not present, and returns indeterminate data when read.

## Reverse MII Port

BCM53262M device includes an enhanced MII mode that supports direct MAC-to-MAC connectivity. The BCM53262M device supports a strap option selectable Reverse MII (RvMII) mode, which makes the BCM53262M MII interface appear as a 100-Mbps full-duplex PHY MII, as seen by the external MAC.

To support this RvMII mode, the clock-to-data timing has been modified. The TXC/RXC input clocks become 25-MHz clock outputs (identical to those of a PHY MII) that only support a 100-Mbps MII interface.

Rv MII mode is enabled by selecting the strap pin RvMII.

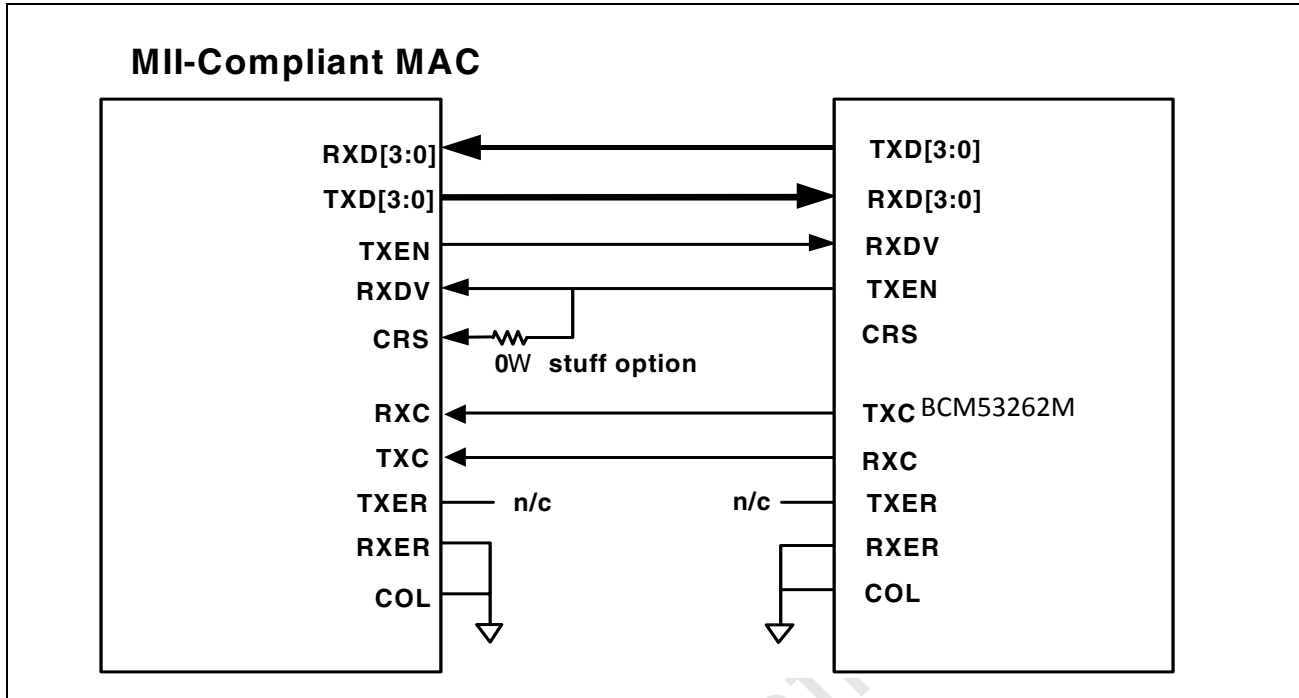

Figure 19: MAC-to-MAC MII Connection

### Management Port (IMP)

The dedicated port can be used as a high-speed connection to transfer management packets to the external management agent. For more information, see ["Frame Management" on page 88](#)

## Serial Interface

Each LVDS-compatible serial port can be configured in SGMII or SerDes mode.

### SGMII Mode

The SGMII interface transmits serial data differentially at 1.25 Gbaud via the (SD\_TXDN, SD\_TXDP) pins, and receives serial data differentially via the (SD\_RXDN, SD\_RXDP) pins. Transmit data timing is recovered from the incoming data signal and the attached link partner does so, likewise. The SGMII interface pins are shared with the SerDes interface pins.

The data signals operate at 1.25 Gbaud. Each of these signals is realized as a differential pair because of the speed of operation, providing signal integrity while minimizing system noise. The SGMII signals use LVDS voltage levels. Both the data and clock signals are DC-balanced; therefore, implementations that meet the AC parameters, but fail to meet the DC parameters, can be AC-coupled.

The 1.25-Gbaud transfer rate of the SGMII is greater than required for the BCM53262M transceiver operating at 10 Mbps or 100 Mbps. When these situations occur, the BCM53262M elongates the frame by replicating each frame byte 10 times for 100 Mbps and 100 times for 10 Mbps. This frame elongation takes place above the IEEE Standard 802.3z PCS layer, making the start-frame delimiter appear only once per frame.

When the device operates at 10 Mbps or 100 Mbps, the SGMII differential pair replicates the data 100 and 10 times, respectively.

### SerDes Mode

The SerDes interface operates via 1000Base-X and complies with IEEE 802.3, Clauses 36 and 37. The interface shares differential data pins with the SGMII interface. The BCM53262M SerDes can be used in various applications as listed below.

- The SerDes interface can be connected to SerDes fiber modules creating switched fiber ports.
- The SerDes interface can be connected to a SerDes-to-copper PHY creating switched copper ports.
- The SerDes interface can be connected to a SerDes MAC or switch for a SerDes switch-to-switch application.

The SerDes auto-negotiation is similar to the SGMII except for the link timer. [Table 34](#) summarizes the differences between the two interfaces. The differential pair runs at 1.25 Gbps. The data is 8b/10b encoded, and the decoded data throughput is 1 Gbps.

**Table 34: SGMII and SerDes Auto-Negotiation**

	<i>Link Timer</i>	<i>Remote Fault</i>	<i>PAUSE Frame</i>	<i>Speed Bit</i>	<i>Link Status</i>	<i>Duplex Bit</i>
SGMII	1.6 ms	Not Supported	Not Supported	Supported	Supported	Supported
SerDes	10 ms	Supported	Supported	Not Supported (always 1000Base-X)	Not Supported	Supported

## SerDes/SGMII Auto-Negotiation

It is necessary to pass control information to the link partner when establishing a link. The link partner receives and decodes the sent control information and also begins auto-negotiation. The link partner acknowledges the update of the link status and visa versa. Upon receiving proper acknowledgement, the BCM53262M completes auto-negotiation and returns to normal data mode. The included control information for SerDes and SGMII is compared in [Table 34](#).

---

## 10/100 Mbps Copper Interface

The internal PHYs transmit and receive data via the digiPHY. This section discusses the following topics:

- [“Auto-Negotiation”](#)
- [“Automatic MDI Crossover”](#)
- [“10/100Base-T Forced Mode Auto-MDIX”](#)

For more information on the integrated PHY block, see [“Integrated PHY”](#) on page 77.

## Auto-Negotiation

The BCM53262M negotiates its mode of operation over the copper media using the auto-negotiation mechanism defined in the IEEE 802.3u specifications. When the auto-negotiation function is enabled, the BCM53262M automatically chooses the mode of operation by advertising its abilities and comparing them with those received from its link partner. The BCM53262M can be configured to advertise the following modes:

- 100Base-TX full-duplex and/or half-duplex
- 10Base-T full-duplex and/or half-duplex

The transceiver negotiates with its link partner and chooses the highest common operating speed and duplex mode, commonly referred to as highest common denominator (HCD).

## Automatic MDI Crossover

During auto-negotiation, one end of the link needs to perform an MDI crossover so that each transceiver's transmitter is connected to the other receiver. The BCM53262M internal PHY can perform an automatic media dependent interface (MDI) crossover, eliminating the need for crossover cables or cross-wired (MDIX) ports.

During auto-negotiation, the BCM53262M internal PHY normally transmits on the TD± pin and receives on the RD± pin. When connecting to another device that does not perform MDI crossover, the BCM53262M internal PHY automatically switches its RD±/TD± pin pairs, when necessary, to communicate with the remote device. When connecting to another device that does have MDI crossover capability, an algorithm determines which end performs the crossover function. During 100Base-TX operation, pair swaps automatically occur within the device and do not require user intervention.

## 10/100Base-T Forced Mode Auto-MDIX

The Forced Mode Auto-MDIX feature allows the copper auto-negotiation to be disabled in either 10Base-T or 100Base-T and still take advantage of the automatic MDI crossover function. Whenever the forced link is down for at least four seconds, then auto-negotiation is internally enabled with its automatic MDI crossover function until link pulses or 100Base-Tx idles are detected. Once detected, the internal PHY returns to forced mode operation.

---

## Configuration Pins

Initial configuration of the BCM53262M takes place during power-on/reset by loading internal control values from hardware strap pins. The value of the pin is loaded when the reset sequence completes and the pin transitions to normal operation. Pull-up or pull-down resistors can be added to these pins to control the device configuration. If the pins are left floating, the default value is determined based on the internal pull-up or pull-down configuration.

---

## Programming Interfaces

The BCM53262M can be programmed via the SPI Interface, EEPROM Interface, or Extended Bus. The SPI interface provides access for a general purpose microcontroller, allowing read and write access to the internal BCM53262M register space. It is configured to be compatible with the Motorola® Serial Peripheral Interface (SPI) protocol. Alternatively, the EEPROM interface can be connected to an external EEPROM for writing register values upon power-up initialization.

A 16-bit or 8-bit extended bus interface on the BCM53262M is designed to provide connection to an external processor, allowing read and write accesses to the internal BCM53262M registers.

The internal address space of the BCM53262M device is broken into a number of pages. Each page groups a logical set of registers associated with a specific function. Each page provides a logical address space of 256 bytes, although, in general, only a small portion of the address space in each page is utilized.

### SPI Interface

The BCM53262M can be controlled over a serial interface that is compatible with a subset of the Motorola Synchronous Serial Peripheral Interconnect (SPI) bus. The microcontroller interface consists of four signals: serial clock (SCK), slave select (SS/CS), master-in/slave-out (MISO/DO) and master-out/slave-in (MOSI/DI). The BCM53262M always operates as an SPI slave device, in that it never initiates a transfer on the SPI and only responds to the read and write requests issued from a master device.

A layer of protocol is added to the basic SPI definition to facilitate transfers from the BCM53262M. This protocol establishes the definition of the first two bytes issued by the master to the BCM53262M slave during an SPI transfer. The first byte issued from the SPI master in any transaction is defined as a command byte, which is always followed by a register address byte, and any additional bytes are data bytes.

The SPI mode supports normal SPI determined by the content of the command byte. [Table 35](#) shows the normal SPI command byte.

**Table 35: Normal SPI Command Byte**

0	1	1	MODE = 0	CHIP ID 2 (MSB)	CHIP ID 1	CHIP ID 0 (LSB)	Read/Write (0/1)
---	---	---	----------	-----------------	-----------	-----------------	------------------

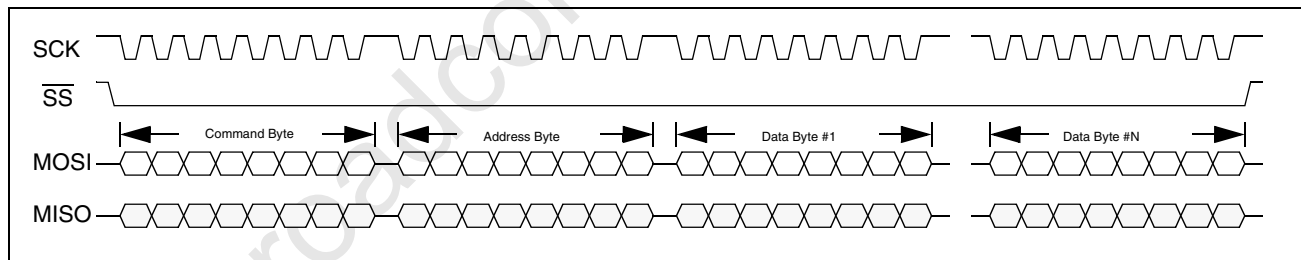

The MODE bit (bit 4) of the command byte determines the meaning of bits 7:5. If bit 4 is a 0, it is a normal SPI command byte, and bits 7:5 should be defined as 011b.

In command bytes, bits[3:1] indicate the CHIP ID to be accessed. Because the BCM53262M operates as a single-chip system, the CHIP ID will be 000. Note that the SS# signal must also be active for any BCM53262M device to recognize that it is being accessed.

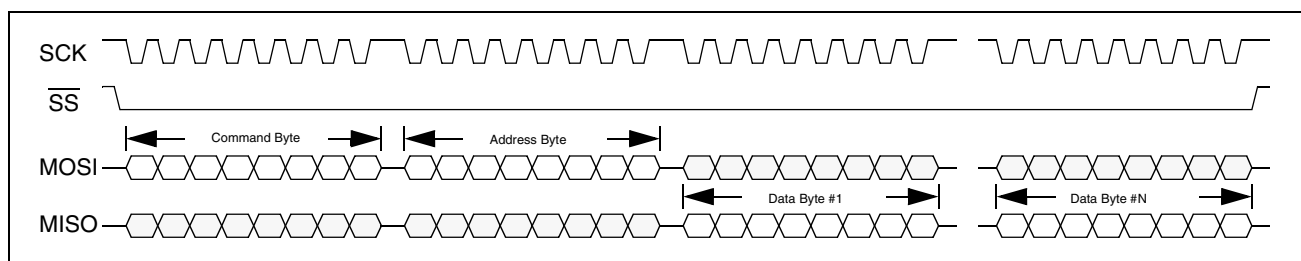

Bit 0 of the command byte is the R/W signal (0 = Read, 1 = Write) and determines the transmission direction of the data.

The byte following the command byte is an 8-bit register address. Initially, this sets the page address, followed by another command byte that contains the register base address in that page, which is used as the location to store the next byte of data received in the case of a write operation, or the next address from which to retrieve data in the case of a read operation. This base address increments as each byte of data is transmitted/received, allowing a contiguous block data from a register to be stored/read in a single transmission.

Noncontiguous blocks are also stored/read through the use of multiple transmissions, which allow a new command byte and register base address to be specified. The SS signal must remain low for the entire read or write transaction, as shown in [Figure 20 on page 108](#) and [Figure 21 on page 108](#), with the transaction terminated by the deassertion of the SS line by the master.

**Figure 20: SPI Serial Interface Write Operation**

**Figure 21: SPI Serial Interface Read Operation**

The Serial Interface supports operation up to 2 MHz in SPI mode.

## Normal SPI Mode

Normal SPI mode allows single-byte read and multibyte string write operations, with the CPU polling to monitor progress. Read operations are performed using the SPI Status Register and SPI Data I/O Register. All read operations take the form:

<CMD, CHIP ID, R><REG ADDR>

where the first byte is the command byte with the appropriate CHIP ID and Read bits set, and the second byte is the register address.

All write operations are of the form:

<CMD, CHIP ID, W><REG ADDR><DATA0>...<DATAn>

where the first byte is the command byte with the appropriate CHIP ID and Write bits set, the second byte is the register address, and the remaining bytes are the exact number of data bytes appropriate for the selected register follow. Failure to provide the correct number of data bytes means the register write operation does not occur.

A simple flow chart for the read process is shown in [Figure 22 on page 110](#).

To read a register, first the Page Register is written (<CMD, CHIP ID, W><REG ADDR = FFh><DATA = NEW PAGE>). It is only necessary to write the page register when moving to a new page. Once in the correct page, a read operation is performed on the appropriate register (<CMD, CHIP ID, R><REG ADDR>). Once the SPI Status Register indicates that the data is available (RACK = 1), the data can be read. Data is read from the SPI Data I/O Register, located at F0h–F7h on every page (so no page swap is necessary to read the data on any page). A read operation can access any or all of the bytes on a specific register, including the ability to start at any offset. For instance, reading from SPI Data I/O Register [0], reads the least significant byte of the register, and successive reads to SPI Data I/O Register [0] read the remaining bytes. However, reading the first byte from SPI Data I/O Register [2] reads the third byte of the register, and successive reads to SPI Data I/O Register [2] reads the remaining bytes of the register up to the most significant byte of the register. It is not necessary to read all bytes of a registers, only the bytes of interest. The SPI master can then move on to perform another read or write operation.

A flow chart for the write process is shown in [Figure 23 on page 111](#). To write a register, the Page Register is written if necessary (<CMD, CHIP ID, W><REG ADDR = FFh><DATA = NEW PAGE>), then data is written to the selected register (<CMD, CHIP ID, W><REG ADDR><DATA0>...<DATAn>), where DATA0 is the least significant byte of the register, and DATAn is the most significant byte of the register, and the exact number of bytes is present as defined by the register width. No byte offset is provided for write operations, and all bytes must be present to activate the write process internal to the BCM53262M.

The following simple rules apply to the normal SPI mode:

- A write to the page register at any time causes the SPI state machine to reset.
- A read operation can access any number of bytes at any offset using the SPI Data I/O Register.
- A write operation must write the exact number of bytes to the register being accessed.
- The RXRDY/TXRDY flags in SPI Status Register must be checked after each 8-byte string has been read/written to ensure the next string is ready and can be accepted (since the largest internal register is 8

bytes, this restriction only applies to reading and writing frames via the SPI).

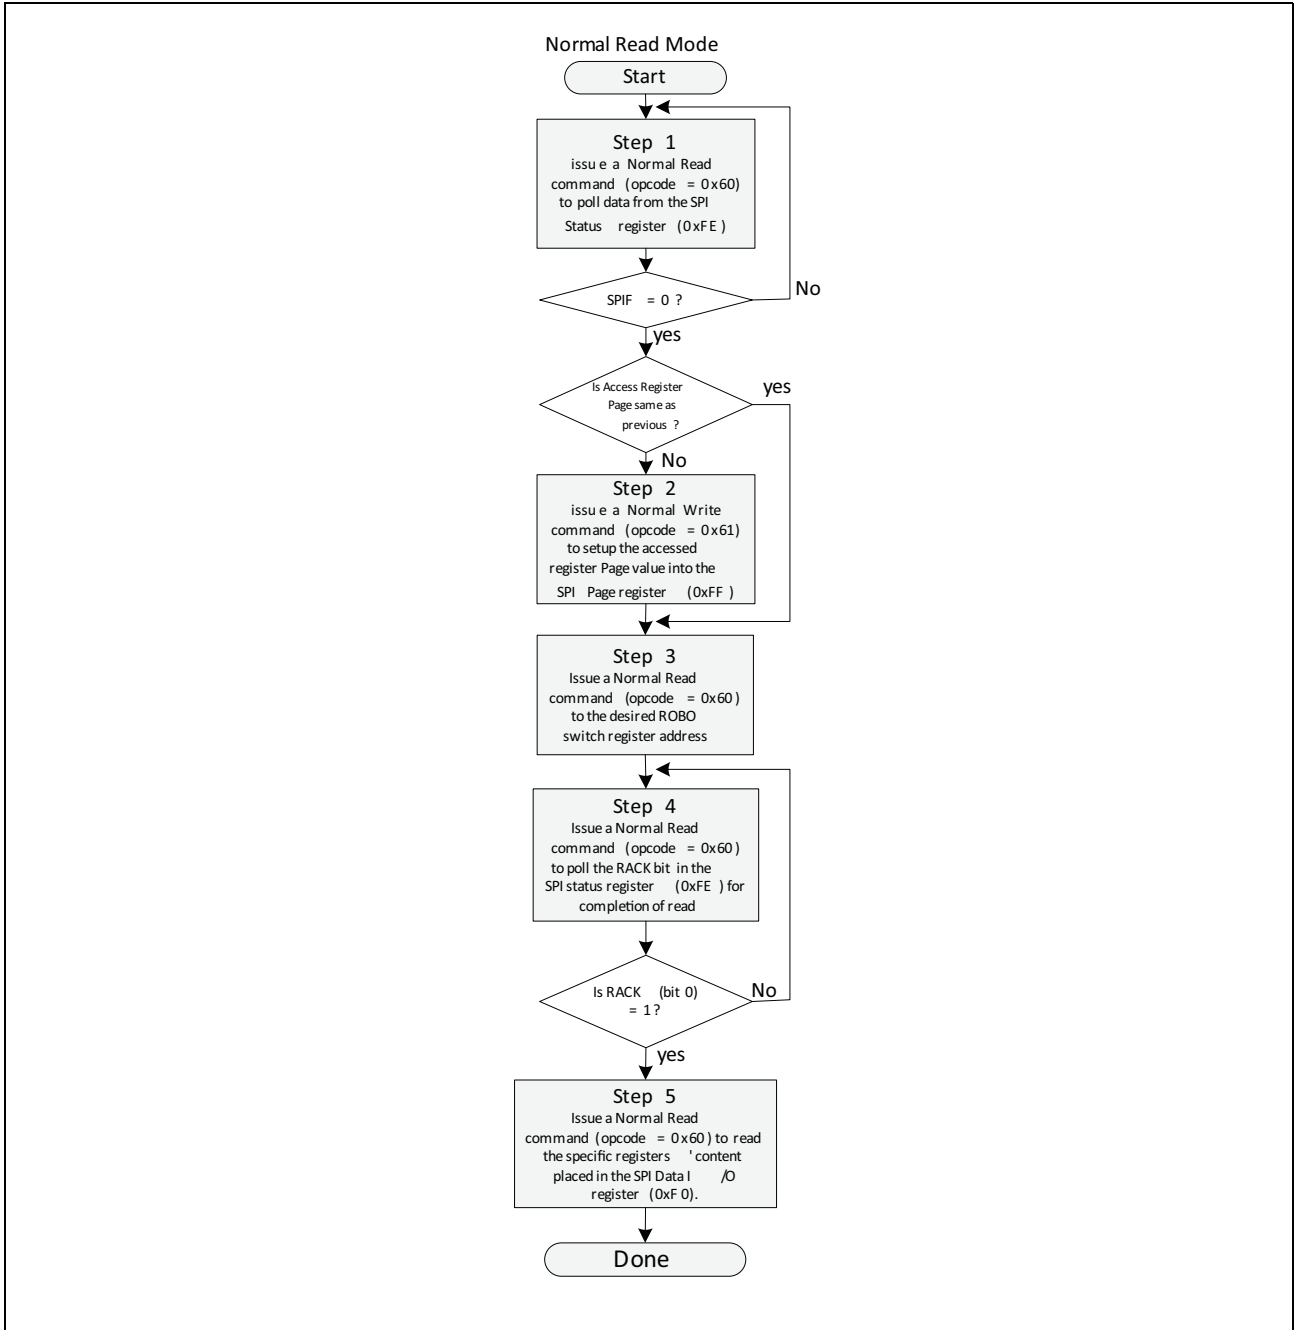

Figure 22: Normal SPI Mode Read Flow Chrt

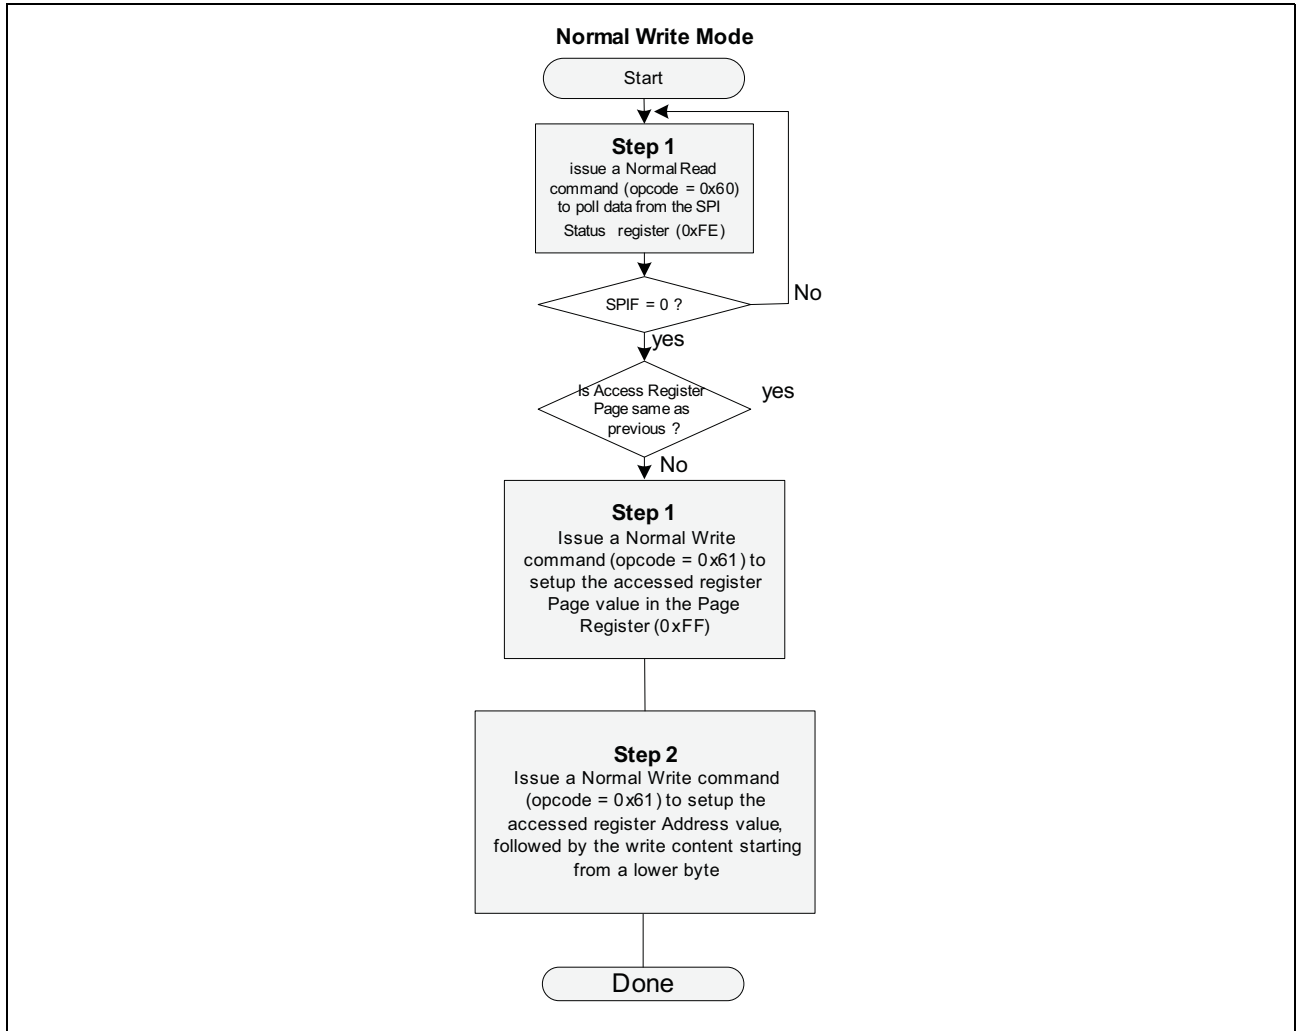

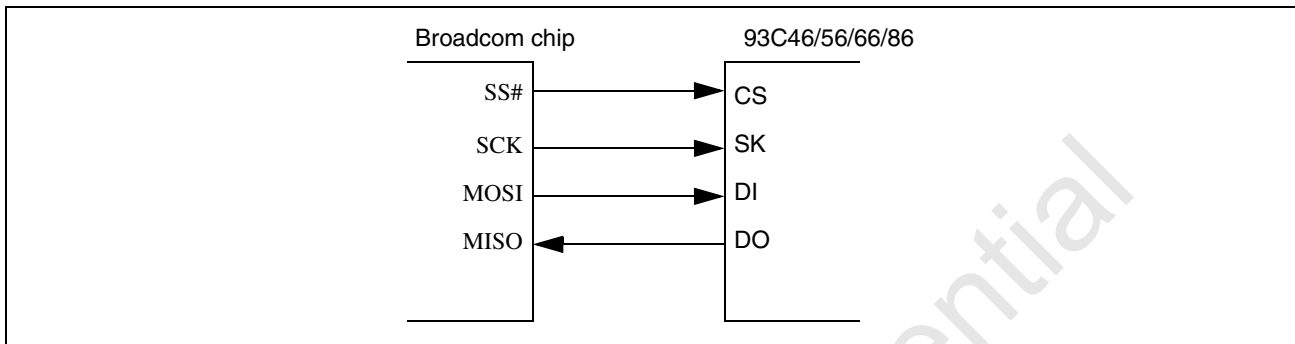

Figure 23: Normal SPI Mode Write Flow Chart

## EEPROM Interface

The BCM53262M can be connected via the Serial Interface to a low-cost external serial EEPROM, enabling it to download register programming instructions during power-on initialization. For each programming instruction fetched from the EEPROM, the instruction executes immediately and affects the register file.

**Figure 24: Serial EEPROM Connection**

During the chip initialization phase, the data is sequentially read-in from the EEPROM after the internal memory has been cleared. The first data read-in is the HEADER and matches a predefined magic code. In the case where the HEADER data does not match the instruction fetch, the process stops, and the EEPROM controller treats it as if no EEPROM exists. If the magic code matches, the fetch instruction process continues until it reaches the instruction length defined in the HEADER.

The BCM53262M supports EEPROMs with varying capacities. These include the 93C46, 93C56, 93C66 and 93C86. The BCM53262M implements the automatic detection of EEPROM types. The two EEPROM\_TYPE[1:0] strap pins are designated as “don't cares” and “can be ignored”.

### EEPROM Format

The EEPROM should be configured to x16 word format. The header contains a key and length information as in [Table 36](#).

- Upper 5 bits are magic code 15h, which indicates valid data follows.
- Bit 10 is for speed indication. A 0 means normal speed. A 1 indicates speed up. The default is 0.
- Lower 10 bits indicate the total length of all entries. For example:
  - 93C46 up to 64 words
  - 93C56 up to 128 words
  - 93C66 up to 256 words
  - 93C86 up to 1024 words

**Table 36: EEPROM Header Format**

15:11	10	9:0
Magic code, 15h	Speed	Total Entry Number <ul style="list-style-type: none"> <li>• 93C46: 0–63</li> <li>• 93C56: 0–127</li> <li>• 93C66: 0–255</li> <li>• 93C86: 0–1023</li> </ul>

After chip initialization, the header is read from the EEPROM and used to compare to the pre-defined magic code. When the fetched data does not match the predefined magic code, the EEPROM instruction fetch process is stopped. If the magic code is matched, fetching instructions continues until the instruction length as defined in the HEADER.

The EEPROM Port shares pins with the SPI port. Either the SPI port or the EEPROM can be selected by using the strap pin, CPU\_EEPROM\_SEL. The register space for the EEPROM port is the same as for the SPI port.

Contact your local Broadcom FAE for EEPROM Programming Guide for more details on EEPROM data format.

## Extended Bus Interface

The Extended Bus (EB) interface is an asynchronous bus designed for the host CPU to access the internal BCM53262M register space indirectly through a register map. The EB interface operates based on 100 MHz internal system clock. The EB interface consists of: Address bus (EB\_ADDR[3:0]), Data bus (EB\_DATA[15:0]), Chip Select (EB\_CS), Output Enable (EB\_OE), Write Enable (EB\_WE). The data bus can be configured as 8-bit or 16-bit modes and is selected by strap pin EB\_16BITMODE. In 8-bit mode, address is byte-aligned. In 16-bit mode, address is 2-byte aligned.

**Table 37: Interface Signals**

Signal Name	Direction	Description
EB_ADDR[3:0]	I	Address of register to be accessed in the register map.
EB_DATA[15:0]	I/O	Data value to be written into the register specified by EB_ADDR for a write operation or data read from the register specified by EB_ADDR for a read operation.
EB_CS	I	<b>Chip Select.</b> Selects the EB Bus operation.
EB_OE	I	<b>Output Enable.</b> Enables the output drivers of the EB_DATA bus.
EB_WE	I	<b>Write Enable.</b> Enables the register write function.
EB_16BITMODE	I	<b>Strap pin.</b> <ul style="list-style-type: none"> <li>• 1 = Indicates the EB Bus operates in 16-bit mode.</li> <li>• 0 = Indicates the EB Bus operates in 8-bit mode.</li> </ul>

## Register Map

All read and write accesses to the internal BCM53262M register space are conducted indirectly through a set of registers as outlined in the following maps.

**Table 38: Register Map In 8-bit Mode**

Address	Bit	Register Name	Description
0000	[7:0]	Data Byte 0	Store data read from or write to byte 0
0001	[7:0]	Data Byte 1	Store data read from or write to byte 1
0010	[7:0]	Data Byte 2	Store data read from or write to byte 2
0011	[7:0]	Data Byte 3	Store data read from or write to byte 3
0100	[7:0]	Data Byte 4	Store data read from or write to byte 4
0101	[7:0]	Data Byte 5	Store data read from or write to byte 5
0110	[7:0]	Data Byte 6	Store data read from or write to byte 6
0111	[7:0]	Data Byte 7	Store data read from or write to byte 7
1000	[7:0]	Page Address	Store BCM53262M internal register page address to be accessed
1001	[7:0]	Offset Address	Store BCM53262M internal register offset address to be accessed
1010	[7:0]	Command	<ul style="list-style-type: none"> <li>• Bits[7:2]: Reserved.</li> <li>• Bit[1]: Write Command. When set, enable write operation.</li> <li>• Bit[0]: Read Command. When set, enable read operation.</li> </ul> <p><b>Note:</b> Either bit [1] or bit [0] should be set, but not simultaneously. These bits are self-clear after the operation is completed.</p>
1011	[7:0]	Status	<ul style="list-style-type: none"> <li>• Bits[7:1]: Reserved.</li> <li>• Bit[0]: When set, indicating a read or write operation is still busy. This bit is self-clear after the operation is complete.</li> </ul> <p><b>Note:</b> When accidentally accessing to the reserved addresses, this bit will always be asserted, due to no register acknowledgement.</p>
1100	[7:0]	Byte Count	<p>This register records the byte count that had been successfully read from or write to the accessed register.</p> <ul style="list-style-type: none"> <li>• Bit[7] = 1: 8 bytes.</li> <li>• Bit[6] = 1: 7 bytes.</li> <li>• Bit[5] = 1: 6 bytes.</li> <li>• Bit[4] = 1: 5 bytes.</li> <li>• Bit[3] = 1: 4 bytes.</li> <li>• Bit[2] = 1: 3 bytes.</li> <li>• Bit[1] = 1: 2 bytes.</li> <li>• Bit[0] = 1: 1 byte.</li> </ul>
Others	[7:0]	Reserved	Unmapped area.

**Table 39: Register Map In 16-bit Mode**

Addresses	Bit	Register Name	Description
0000	[15:0]	Data Bytes 1, 0	Store data read from or write to bytes 1 and 0
0010	[15:0]	Data Bytes 3, 2	Store data read from or write to bytes 3 and 2
0100	[15:0]	Data Bytes 5, 4	Store data read from or write to bytes 5 and 4
0110	[15:0]	Data Bytes 7, 6	Store data read from or write to bytes 7 and 6
1000	[15:0]	Page Address, Offset Address	Store BCM53262M internal register Page and Offset addresses to be accessed
1010	[15:0]	Status, Command	<ul style="list-style-type: none"> <li>• Bits[15:9]: Reserved.</li> <li>• Bit[8]: When set, indicating a read or write operation is still busy. This bit is self-clear after the operation is complete.</li> </ul> <p><b>Note:</b> When accidentally accessing to the reserved addresses, this bit will always be asserted, due to no register acknowledgement.</p> <ul style="list-style-type: none"> <li>• Bits[7:2]: Reserved.</li> <li>• Bit[1]: Write Command. When set, enable write operation.</li> <li>• Bit[0]: Read Command. When set, enable read operation.</li> </ul> <p><b>Note:</b> Either bit [1] or bit [0] should be set, but not simultaneously. These bits are self-clear after the operation is completed.</p>

## EB Interface Read Cycle

The host CPU starts an EB read cycle by asserting an address on EB\_ADDR followed by the chip select  $\overline{\text{EB\_CS}}$ . Read data is available on EB\_DATA on the falling edge of EB\_OE. The EB\_OE signal must be active for at least 4 internal system clock cycle, which is running at 100 Mhz. The cycle is terminated at the rising edges of both EB\_OE and EB\_CS.

Figure 25: ED Read Cycle

### EB Interface Write Cycle

The host CPU starts an EB write cycle by asserting an address on EB\_ADDR followed by the chip select EB\_CS. Ensure that write data is available on EB\_DATA before the falling edge of EB\_WE. The EB\_WE signal must be active for at least 4 internal system clock cycle, which is running at 100 MHz. The cycle is terminated at the rising edges of both EB\_WE and EB\_CS.

Figure 26: ED Write Cycle

## Programming Sequence

Use the following sequence to read from or write to any internal BCM53262M register.

### Read Operation

- Program Page Address Register and Offset Address Register to point to BCM53262M internal register
- Set bit[0] of Command Register to 1 to issue a read operation
- Polling Status Register until the Busy bit is 0, which indicates the operation is complete
- Read Byte Count Information Register to learn how many bytes are valid for this read operation (optional)
- Read Data Byte 0 ~ Data Byte 7 Register for the read data.

### Write Operation

- Program Page Address Register and Offset Address Register to point to BCM53262M internal register
- Program Data Byte 0 ~ Data Byte 7 Register with the write data.
- Set bit[1] of Command Register to 1 to issue a write operation
- Polling Status Register until the Busy bit is 0, which indicates the operation is complete
- Read Byte Count Information Register to learn how many bytes are successfully written for this operation (optional)

---

## MDC/MDIO Interface

### MDC/MDIO Master Interface

Each of the external transceivers can be daisy-chained to the MDC and MDIO pins of the BCM53262M. The BCM53262M uses the MDC/MDIO interface to read/write the register information of the external transceivers.

The BCM53262M initiates a master MII access cycle when:

- Automatically polling the external PHY MII registers, unless the PHY\_POLL\_DIS strap pin is deliberately pulled high
- Any SCK activity is detected on the SPI interface to access the external PHY MII registers

Each external transceiver is assigned a unique hardware PHY address for MII management. The IMP port hardware PHY address is 18h. Gigabit ports G0, G1, G2 and G3 have hardware PHY addresses 19h, ..., 1Ch respectively.

Each time a master MII write or read operation is executed, the transceiver compares the PHY address with its own PHY address definition. The operation is executed only when the addresses match.

**Note:** When a master MII access cycle is executed, the BCM53262M sources a 2.5 MHz clock on the MDC pin.

### MDC/MDIO Slave Interface

The BCM53262M executes a MII slave access cycle, when the CPU initiates a read/write access to either the switch registers or the internal transceiver MII registers.

### Switch Register Access Through Pseudo-PHY Interface

The switch registers are organized into pages, each of which contains a defined register set. To access any switch register, both the page number and register address must be specified.

The CPU can access the BCM53262M switch registers through the MDC and MDIO interface. The switch registers are accessed through a pseudo-PHY (PHY Address = 01E), which is not used by any of the physical transceivers on the BCM53262M MDC/MDIO path. Page number, register address and the read/write data are encapsulated in the MII management frame format.

The algorithm for read access to the switch registers is shown in [Figure 35 on page 125](#). The algorithm for write access is shown in [Figure 36 on page 126](#). The pseudo-PHY MDC/MDIO interface has an address space of 32, as shown in [Figure 28 on page 122](#). The first 16 registers are reserved by IEEE. Only addresses 16-31 can be used to access the switch registers. The switch register page number, register address, and access type are determined by registers 16 and 17. The data read from or written to a switch register is stored in registers 24 to 27 (64 bits total).

## MDC/MDIO Slave Interface Register Programming

Each internal transceiver in the BCM53262M is assigned a unique hardware PHY address.

Transceiver 24 has address 00000. Transceivers 25-47 have addresses 1 through 17h, respectively.

Each internal PHY checks that the PHY address of the initiated command matches that of its own before executing the command.

The BCM53262M fully complies with the IEEE 802.3u Media Independent Interface (MII) specification. The MII management interface registers of each internal transceiver are serially written-to and read-from using a common set of MDIO and MDC pins. A single clock must be provided to the BCM53262M at a rate of 0-12.5 MHz through the MDC pin.

The serial data is communicated on the MDIO pin. Every MDIO bit must have the same period as the MDC clock. The MDIO bits are latched on the rising edge of the MDC clock. MDC may be stopped between frames provided no timing requirements are violated. MDC must be active during each valid bit of every frame, including preamble, instruction, address, data, and at least one idle bit. Every MII read or write instruction frame contains the fields shown in [Table 40](#).

**Table 40: MII Management Frame Format**

<i>Operation</i>	<i>PRE</i>	<i>ST</i>	<i>OP</i>	<i>PHYAD</i>	<i>REGAD</i>	<i>TA</i>	<i>DATA</i>	<i>IDle</i>	<i>Direction</i>
Read	1 ... 1	01	10	AAAAA	RRRRR	ZZ Z0	Z ... Z D ... D	Z Z	Driven to BCM53262M Driven by BCM53262M
Write	1 ... 1	01	01	AAAAA	RRRRR	10	D ... D	Z	Driven to BCM53262M

### Preamble (PRE)

32 consecutive 1 bits must be sent through the MDIO pin to the BCM53262M to signal the beginning of an MII instruction. Fewer than 32 1 bits will cause the remainder of the instruction to be ignored. In preamble suppression mode, only two preamble bits are required between frames.

### Start of Frame (ST)

A 01 pattern indicates that the start of the instruction follows.

### Operation Code (OP)

A read instruction is indicated by 10, while a WRITE instruction is indicated by 01.

### PHY Address (PHYAD)

A 5-bit PHY address follows next, with the MSB transmitted first. The PHY address allows a single MDIO bus to access multiple PHY chips.

## Register Address (REGAD)

A 5-bit Register Address follows, with the MSB transmitted first. The register map of the BCM53262M, containing register addresses and bit definitions, are provided on the following pages.

## Turnaround (TA)

The next two bit times are used to avoid contention on the MDIO pin when a read operation is performed. For a Write operation, 10 must be sent to the BCM53262M chip during these two bit times. For a read operation, the MDIO pin must be placed into high-impedance during these two bit times. The chip drives the MDIO pin to 0 during the second bit time.

## Data

The last 16 bits of the frame are the actual data bits. For a write operation, these bits are sent to the BCM53262M, whereas, for a read operation, these bits are driven by the BCM53262M. In either case, the MSB is transmitted first. When writing to the BCM53262M, the data field bits must be stable during the rising edge of MDC. When reading from the BCM53262M, the data field bits are valid after the rising-edge of MDC until the next rising-edge of MDC.

## Idle

A high impedance state of the MDIO line. All tri-state drivers are disabled and an external pull-up resistor pulls the MDIO line to logic 1. At least one or more clocked idle states are required between frames.

Following are two examples of MII write and read instructions:

To put a transceiver with PHY address 00001 into Loopback mode, the following MII write instruction must be issued:

- 1111 1111 1111 1111 1111 1111 1111 1111 0101 00001 00000 10 0100 0000 0000 0000

To determine if a PHY is in the link pass state, the following MII read instruction must be issued:

- 1111 1111 1111 1111 1111 1111 1111 1111 0110 00001 00001 ZZ ZZZZ ZZZZ ZZZZ ZZZZ

For the MII read operation, the BCM53262M will drive the MDIO line during the second half of the TA field and the Data field (the last 17 bit times).

## LED Interfaces

The BCM53262M provides visibility for up to four status indications per port. Both serial and matrix interfaces are supplied to drive the status to the LEDs. The matrix interface provides a cost effective solution for implementing LED in a high port count system. Both interfaces provide per port of link status, port speed, duplex mode, combined transmit and receive activity, and collision. During power-on and reset, the serial interface shifts a continuous low value for 1.34s.

### Serial LED Interface

A two-pin serial interface, LEDDATA and LEDCLK, provides data and clock to enable external shift registers to capture the LED status indications from the BCM53262M for each port. The status encapsulated within the shift sequence is configured by the LEDMODE configuration signals. The configuration signals select both the number of status bits per port and the status type of each bit. Refer to [Table 42 on page 129](#) for LED mode shift sequence.

The LEDCLK is generated by dividing the 25 MHz input clock by 8, providing a 320 ns clock period. The LEDDATA outputs are generated on the falling edge of the LEDCLK, and have adequate setup and hold time to be clocked externally on the rising edge of LEDCLK.

The shift sequence is per port status words. Each port status word contains up to 4-bit for the designated LED status type as mentioned above. Port G3 status word is shifted out first, followed by Port G2, ..., Port IMP and Port 47, ..., and Port 24 status words, where Port IMP is configured as a regular network port with the PHY connected. When the Port IMP is configured as a management port connected to the host CPU, there is no LED status to be reported. The shift sequence is repeated every 42 ms.

See [Figure 37](#) for an illustration of the serial LED shift sequence, and [Table 41: "LED Status Types," on page 128](#) for LED status Type.

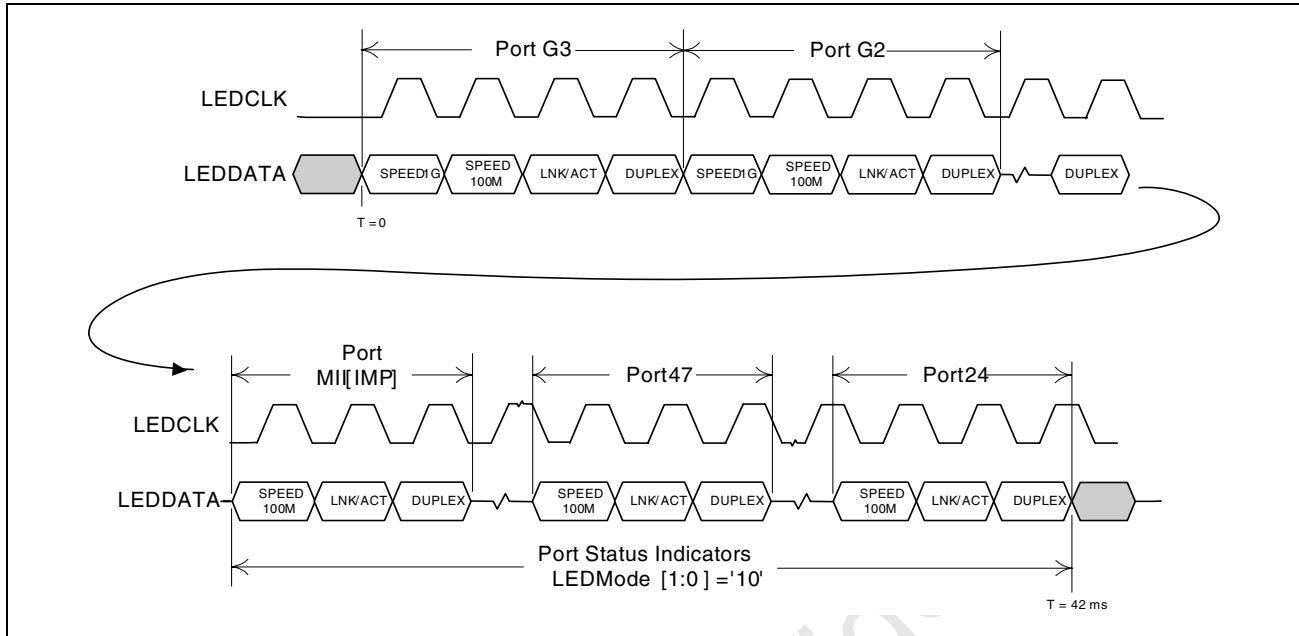

Figure 37: Serial LED Shift Sequence LEDMODE[1:0] = '10'

**Note:** LED status is only reported for the MII port when that port is connected to the external PHY with polling enabled.

Table 41: LED Status Types

Name	Description
LNK	<b>Link status indicator.</b> Low when link is established.High when link is off.
DUPLEX	<b>Duplex mode indicator.</b> High for half-duplex or no link, and low for full-duplex and link.
LNK/ACT	<b>Link and Activity status indicator.</b> Low when link is established. Blinking at 12 Hz when link is up and port is transmitting and receiving.
SPEED100M	<b>Speed indicator and Activity.</b> High for 10 Mbps or no link. Low for 100 Mbps and link
SPEED1G	<b>Speed indicator.</b> Low for link at 1000 Mbps. High for all other conditions.
DUPLEX/COL	<b>Duplex and Collision indicator.</b> Blinking when collision is detected. Low for full-duplex and link.
SPEED1G/ACT	<b>Speed 1G and Activity Indicator.</b> Low when linked at 1000 Mbps. Blinking at 12 Hz when link is up and port is transmitting and receiving.
SPEED100M/ACT	<b>Speed 100M and Activity Indicator.</b> Low when linked at 100 Mbps. Blinking at 12 Hz when link is up and port is transmitting and receiving.
SPEED10M/ACT	<b>Speed 10M and Activity Indicator.</b> Low when linked at 10 Mbps. Blinking at 12 Hz when link is up and port is transmitting and receiving.
SPEED10M/ SPEED100M/ACT	<b>Speed 10M, Speed 100M and Activity Indicator.</b> Low when linked at 10 Mbps/100 Mbps. Blinking at 12 Hz when link is up and port is transmitting and receiving.

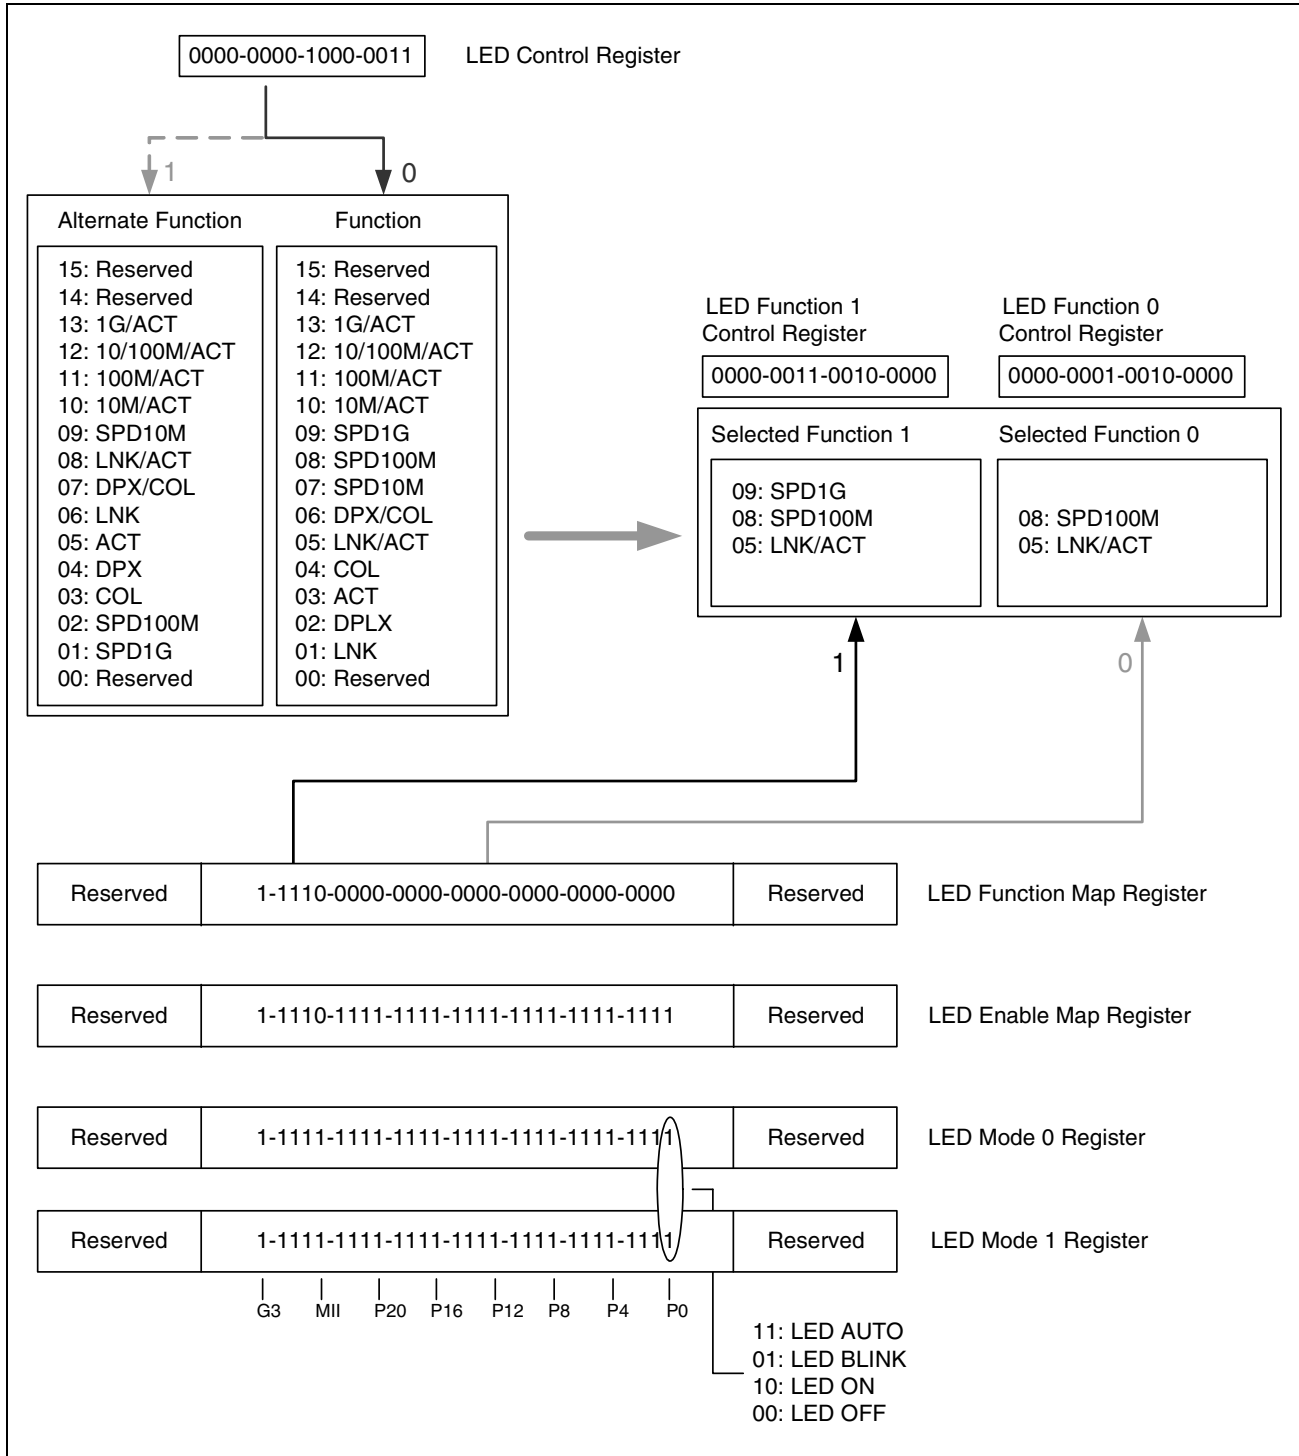

Figure 39: BCM53262 LED Register Structure Diagram

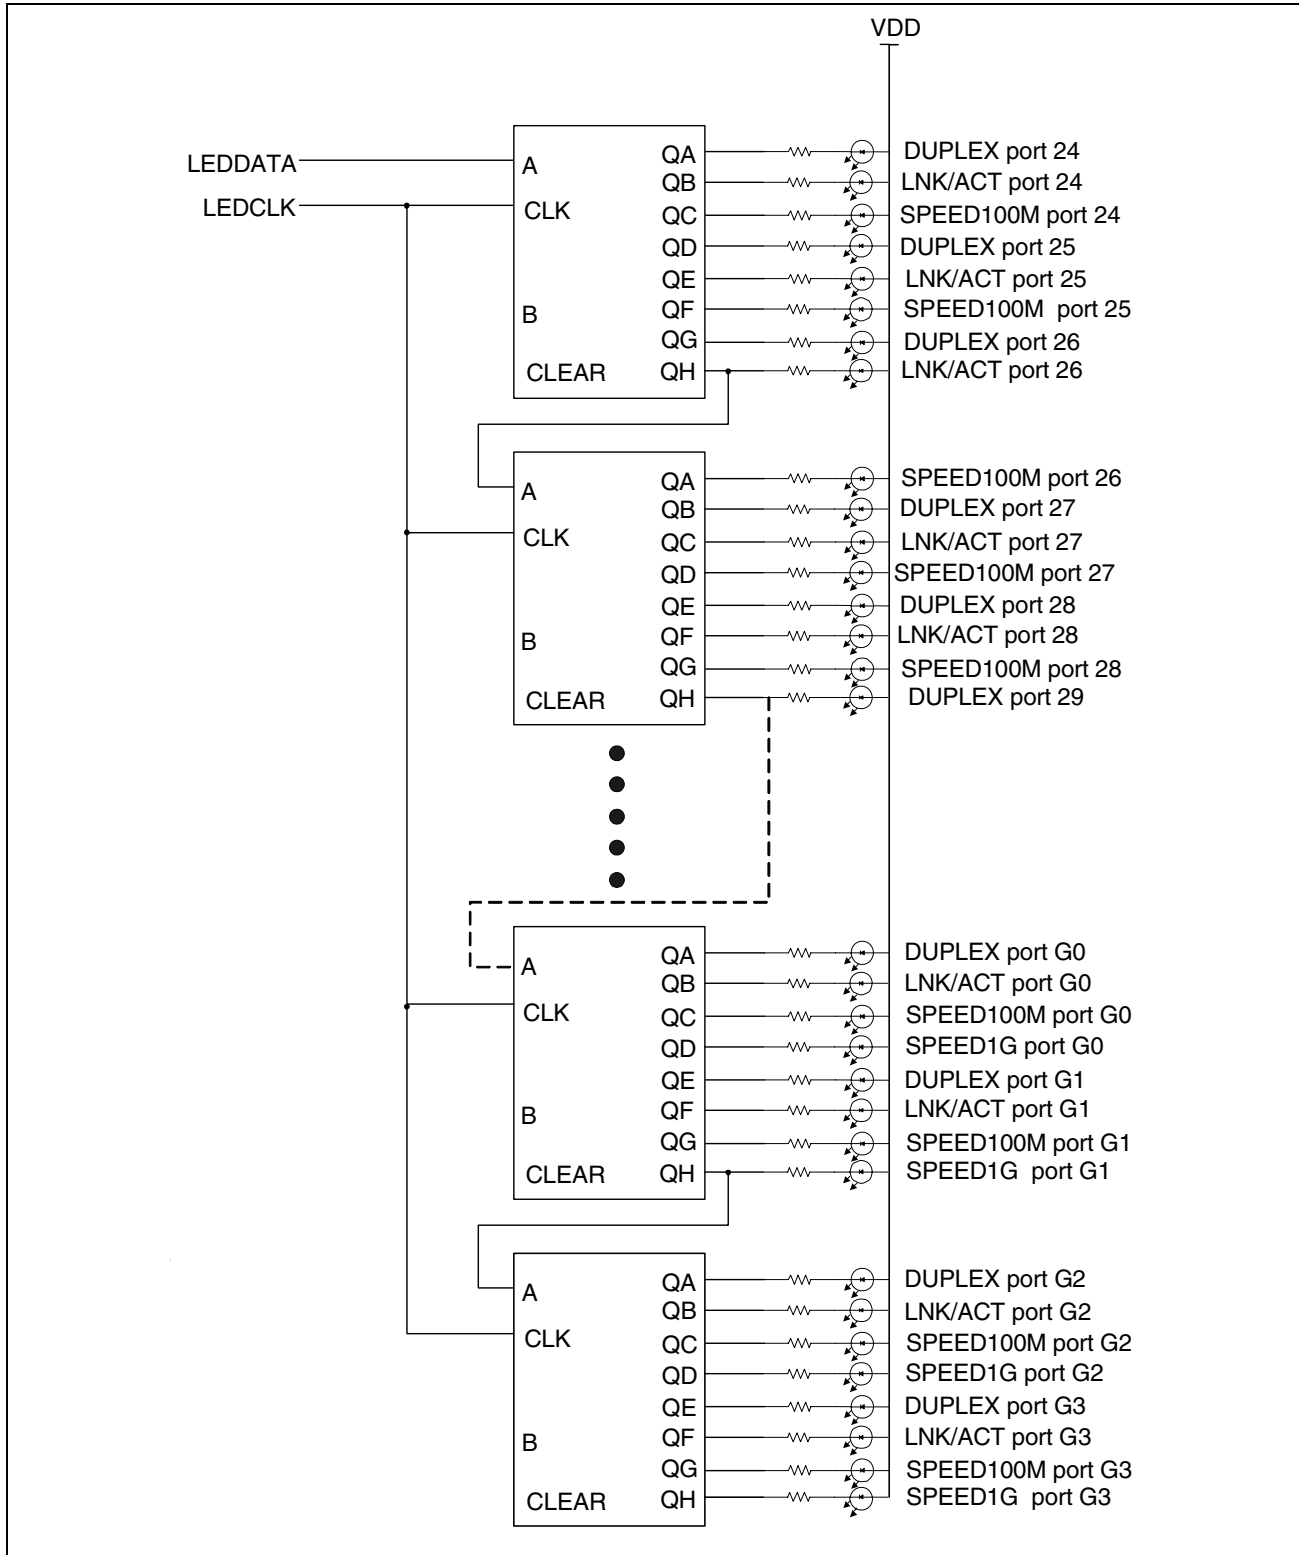

Figure 40: Partial Example External Circuit for Serial LED Mode (LEDMODE[1:0]='00')

## Matrix LED Interface

A three-pin matrix interface, MLEDCOL, MLEDROW and MLEDCLK enable external shift registers to form a 32 by 8 matrix to capture the LED status indications for each port of the BCM53262M. The status encapsulated within the shift sequence is configured by the LEDMODE configuration signals. The configuration signals select both the number of status bits per port and the status type of each bit. Refer to [Table 42 on page 129](#) for LED mode shift sequence.

The MLEDCLK is generated by dividing the 25 MHz input clock by 8, providing a 320 ns clock period. The MLEDCOL and MLEDROW outputs are generated on the falling edge of the MLEDCLK, and have adequate setup and hold time to be clocked externally on the rising edge of MLEDCLK. Refer to [Figure 41](#) for an illustration of a typical Matrix LED circuit for a column.

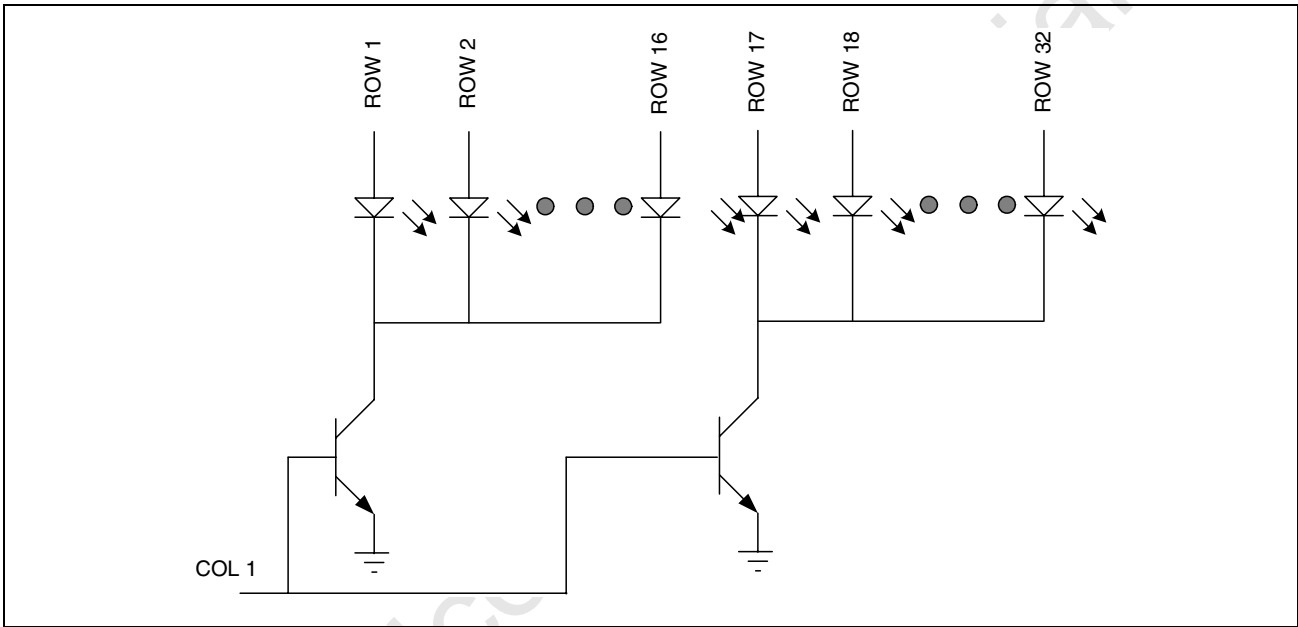

Figure 41: Typical Matrix LED Circuit

Figure 42 shows the decoding of the column and row for the matrix shift sequences.

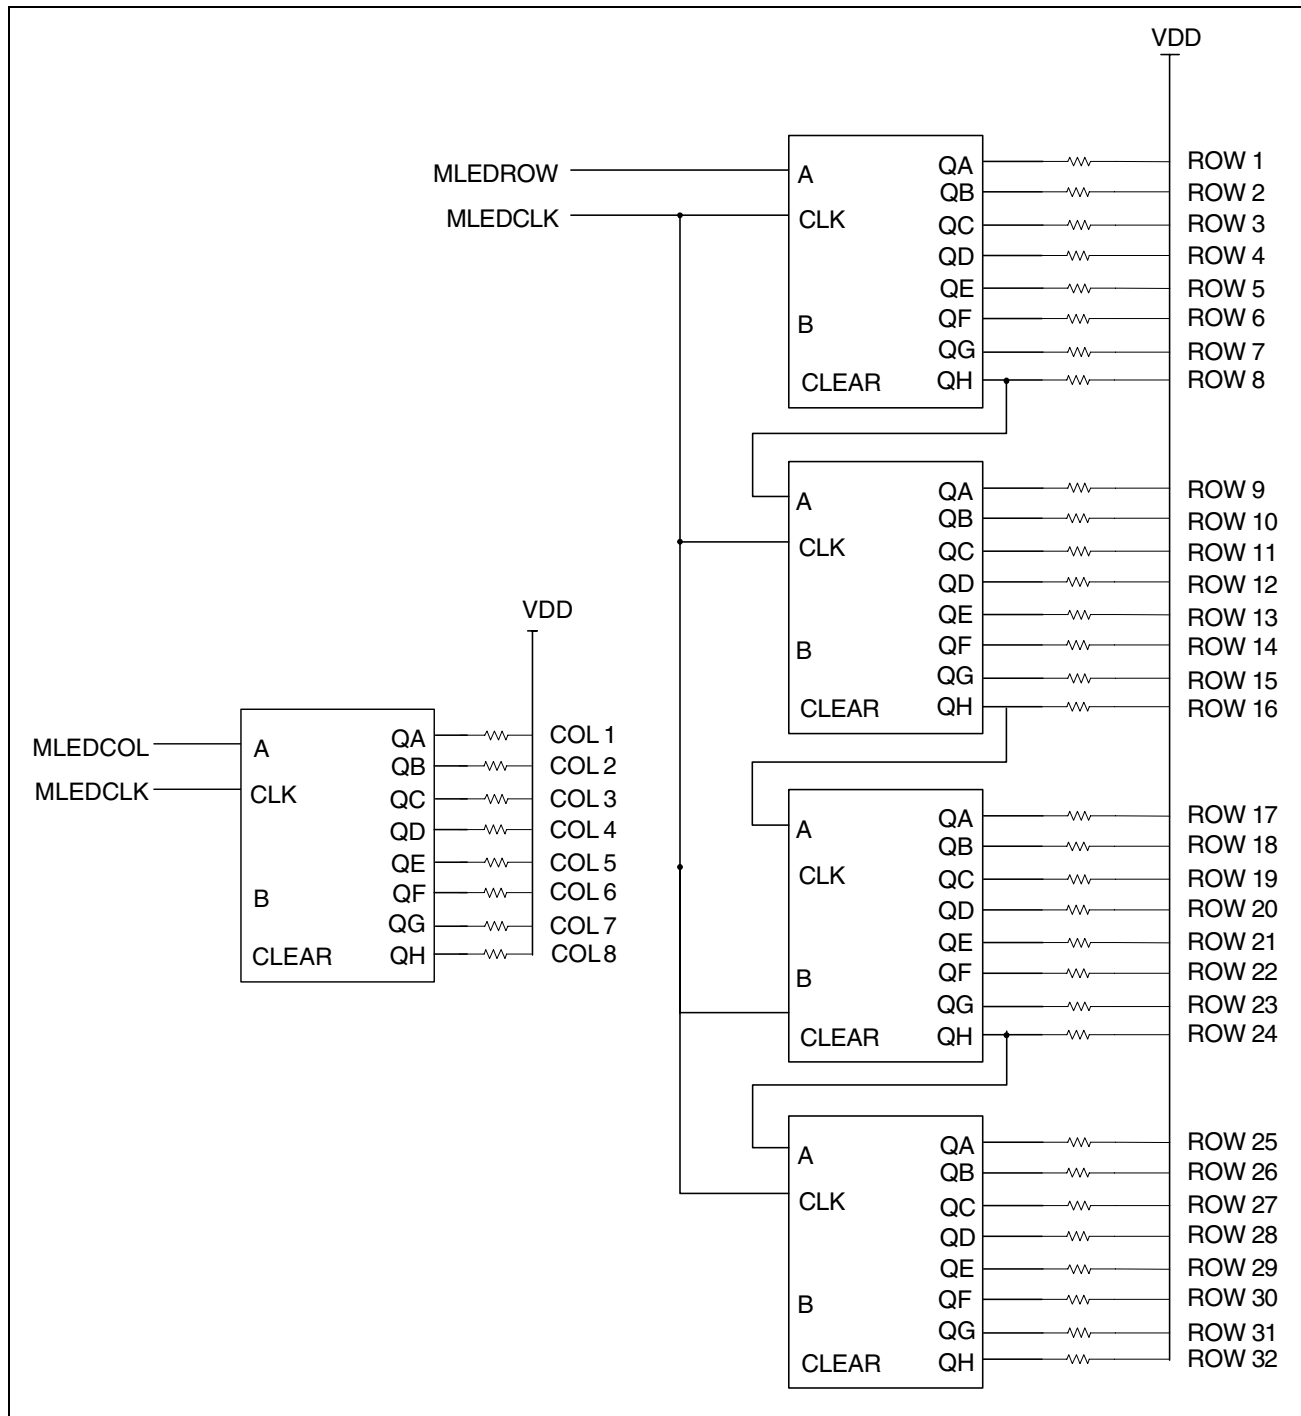

Figure 42: Matrix Row And Column Shift Sequences

Table 44 shows the relative location of per port Matrix LED status. Each port has up to 4 status words. Each status word is designated as Px-1, Px-2, Px-3 and Px-4, where x is the port number.

**Table 44: Matrix Port LED Status And Sequence Map**

## JTAG Interface

A standard JTAG interface is provided for boundary scan operations. This interface uses the standard five-pin interface, and supports operation at speeds up to 20 MHz.

## Section 5: BCM53262M Hardware Signal Definitions

Table 47 lists the conventions are used to identify the I/O types in Table 48.

**Table 47: I/O Signal Type Definitions**

<i>Type</i>	<i>Description</i>	<i>Type</i>	<i>Description</i>
I	Input	O	Output
I/O	Bi-directional	O <sub>OD</sub>	Open drain output
I <sub>PD</sub>	Input with internal pull-down	O <sub>ODPM</sub>	Open drain power management output
I <sub>PU</sub>	Input with internal pull-up	O <sub>3S</sub>	Tristated signal
I <sub>S</sub>	Input with Schmidt Trigger	B	Bias
GND	Ground	A	Analog
PWR	Power supply	OVERLINE	Active low signal

Pin number in *Italic* font indicates pin is shared with multiple functions.

Configuration of the BCM53262M takes place during reset by loading device control values from hardware strapping pins. Some of the strapping pin are I/O pins and have secondary function during normal device operation. They should be configured with external pull-up or pull-down resistors. The strapping value is loaded during the reset sequence and the I/O pin returns to output operation after the completion of reset. Installing a pull-up or pull-down resistor to these pins other than the intended default value can have adverse affect on the function of the device.

TDN_47/TDP_47	U25/T25			

Table 48: Hardware Signal Descriptions (Cont.)

Signal Name	Ball #	Type	Drive (mA)	Description
<b>Clock/Reset</b>				
RESET	D10	I <sub>S,PU</sub>	–	<b>Reset.</b> Active-low. Resets the BCM53262M.
XTALI	P21	I	–	<b>25-MHz Crystal/Clock Input.</b> For a single-ended clock signal input, connect a 25.000 (±50 ppm) MHz reference clock to the XTALI pin. This pin must be driven with a continuous clock. Leave XTALO unconnected for this mode of operation.  Alternatively, a 25.000 MHz parallel-resonant crystal can be connected between the XTALI/XTALO pins, with a 22 pF capacitor from each pin to GND.
XTALO	P22			
XTALI_CK25	AA20	I	–	<b>Additional 25-MHz Crystal/Clock.</b> The signal pins when selected, CK25_SRC_SEL = 0, provide a 25 MHz clock to on-chip integrated PHY. Similarly, these inputs can be driven by a single-ended clock or connected to parallel-resonant crystal. <ul style="list-style-type: none"> <li>For a single-ended clock signal input, connect a 25.000 (±50 ppm) MHz reference clock to the XTALI_CK25 pin. This pin must be driven with a continuous clock. Leave XTALO_CK25 unconnected for this mode of operation.</li> <li>Alternatively, a 25.000 MHz parallel-resonant crystal can be connected between the XTALI_CK25/XTALO_CK25 pins, with a 27 pF capacitor from each pin to GND.</li> </ul>
XTALO_CK25	AB21			
CK25_SRC_SEL	Y7	I <sub>PU</sub>	–	<b>EPHY Clock Source Select</b> <ul style="list-style-type: none"> <li>1 = Select clock source derived from internal to the device.</li> <li>0 = Select clock source from XTALI_CK25/XTALO_CK25.</li> </ul>
CLK25_OUT	E22	O		<b>25-MHz Clock Output.</b> A single-ended 25 MHz clock output for use to connect to external GPHY.
<b>SGMII/SerDes Interface</b>				
SD_TXDN_G0	N23	O	–	<b>G0 SerDes Transmit pairs.</b> Differential SerDes output data pairs.
SD_TXDP_G0	N24			
SD_TXDN_G1	L23	O	–	<b>G1 SerDes Transmit pairs.</b> Differential SerDes output data pairs.
SD_TXDP_G1	L24			
SD_TXDN_G2	J23	O	–	<b>G2 SerDes Transmit pairs.</b> Differential SerDes output data pairs.
SD_TXDP_G2	J24			
SD_TXDN_G3	G23	O	–	<b>G3 SerDes Transmit pairs.</b> Differential SerDes output data pairs.
SD_TXDP_G3	G24			
SD_RXDN_G0	M25	I	–	<b>G0 SerDes Receive pairs.</b> Differential SerDes input data pairs.
SD_RXDP_G0	M26			

**Table 48: Hardware Signal Descriptions (Cont.)**

<b>Signal Name</b>	<b>Ball #</b>	<b>Type</b>	<b>Drive (mA)</b>	<b>Description</b>
SD_RXDN_G1	K25	I	–	<b>G1 SerDes Receive pairs.</b> Differential SerDes input data pairs.
SD_RXDP_G1	K26			
SD_RXDN_G2	H25	I	–	<b>G2 SerDes Receive pairs.</b> Differential SerDes input data pairs.
SD_RXDP_G2	H26			
SD_RXDN_G3	F25	I	–	<b>G3 SerDes Receive pairs.</b> Differential SerDes input data pairs.
SD_RXDP_G3	F26			
SD_G0	C23	I	–	<b>Fiber Signal Detect.</b> Single-ended input reference signal from fiber optic module.
SD_G1	B24			
SD_G2	A24			
SD_G3	E23			
<b>IMP Interface</b>				
IMP_GTXCLK (Revision B only)	C20	0	–	<b>IMP GMII Transmit Clock.</b> 125 MHz clock is driven to synchronize the data in GMII mode. <b>Note:</b> When the IMP Interface is configured to GMII mode, IMP_TXCLK must also be connected to a clock source (such as 25 MHz) for this port to receive/transmit packets.
IMP_TXCLK	C22	I	–	<b>IMP MII Receive Clock.</b> Synchronizes the TXD[3:0] in MII mode. In 100-Mbps mode, this input is 25 MHz. In 10-Mbps mode this input is 2.5 MHz.
		O	–	<b>IMP RvMII Receive Clock.</b> Synchronizes the TXD[3:0] in RvMII mode and connects to the MAC/management entity RXC. In 100-Mbps mode, this output is 25 MHz. In 10-Mbps mode this output is 2.5 MHz.
IMP_TXD[7:4] (Revision B only)	A23, D21, A22, E20	O	–	<b>IMP GMII Transmit Data Output.</b> Data bits TXD[7:0] are clocked on the rising edge of GTXCLK. TXD[7] is the most significant bit.
IMP_TXD[3:0]	D20, B21, A21, D19	O	–	<b>IMP MII Transmit Data Output.</b> Data bits TXD[3:0] are clocked on the rising edge of TXCLK supplied by MAC/management entity. TXD[3] is the most significant bit. <b>IMP RvMII Receive Data Output.</b> Data bits TXD[3:0] are clocked on the rising edge of TXCLK and connected to the RXD pins of the external MAC/management entity.
IMP_TXEN	E21	O	–	<b>IMP GMII/MII Transmit Enable.</b> Active-high. TXEN indicates the data is valid on TXD pins. <b>IMP RvMII Receive Data Valid.</b> Active high. Connected to RXDV pin of MAC/management entity. Indicates that a receive frame is in progress, and the data present on the TXD output pins is valid.
IMP_TXER	D22	O	–	<b>IMP GMII/MII Transmit Error.</b> Active-high. Asserts TXER when TXEN is high to force a bad code into the transmit data stream.

**Table 48: Hardware Signal Descriptions (Cont.)**

<b>Signal Name</b>	<b>Ball #</b>	<b>Type</b>	<b>Drive (mA)</b>	<b>Description</b>
IMP_RXCLK	C18	I	–	<b>IMP GMII Receive Clock.</b> (Revision B only) 125 MHz for 1000-Mbps operation.
		I	–	<b>IMP MII Receive Clock.</b> 25 MHz for 100-Mbps operation, and 2.5 MHz for 10-Mbps operation.
		O	–	<b>IMP RvMII Receive Clock.</b> RvMII Transmit Clock. Synchronizes the RXD[3:0] in RvMII mode and connects to the MAC/management entity TXC. 25 MHz for 100-Mbps mode.
IMP_RXD[7:4] (Revision B only)	A20, D18, E19, B19	I	–	<b>IMP GMII Receive Data Input.</b> Data bits RXD[7:0] are clocked on the rising edge of RXCLK. RXD[7] is the most significant bit.
IMP_RXD[3:0]	E18, D17, A19, A18	I	–	<b>IMP MII Receive Data Input.</b> Data bits RXD[3:0] are clocked on the rising edge of RXCLK. RXD[3] is the most significant bit. <b>IMP RvMII Transmit Data Input.</b> Clocked on the rising edge of RXCLK and connected to the TXD pins of the external MAC/management entity.
IMP_RXDV	B17	I	–	<b>IMP GMII/MII Receive Data Valid.</b> Active high. RXDV indicates that a receive frame is in progress, and the data present on the RXD output pins is valid. <b>IMP RvMII Transmit Enable.</b> Active-high. Indicates the data on the RXD[3:0] pins is encoded and transmitted. Connects to the TXEN of the external MAC/management entity.
IMP_RXER	E17	I	–	<b>IMP GMII/MII Receive Error.</b> Indicates an error during the receive frame.
IMP_COL	E16	I <sub>PD</sub>	–	<b>Collision Detect.</b> In half-duplex mode, active-high input indicates that a collision has occurred. In full-duplex mode, COL remains low. COL is an asynchronous input signal.
IMP_CRS	A17	I <sub>PD</sub>	–	<b>Carrier Sense.</b> Active-high. Indicates traffic on link.
<b>EB Bus Interface</b>				
EB_ADDR[3:0]	E15, A16, C16, D16	I		<b>Extended Bus Address.</b> Specify address of register to be accessed. EB_ADDR3 is the MSB. EB_ADDR0 is shared with SPI's MISO and EEPROM's DO.
EB_DATA[15:0]	E11, A12, C12, D12, E12, A13, B13, D13, E13, A14, C14, D14, E14, A15, B15, D15	I/O		<b>Extended Bus Data.</b> Data value to be written into EB_ADDR for a write operation or data read from the register specified by EB_ADDR for a read operation. Depending on the EB_16BITMODE setting, this will either be an 8 or 16 bit operation EB_DATA0 is Shared with SPI's MOSI and EEPROM's DI

**Table 48: Hardware Signal Descriptions (Cont.)**

<b>Signal Name</b>	<b>Ball #</b>	<b>Type</b>	<b>Drive (mA)</b>	<b>Description</b>
EB_CS	D11	I		<b>Extended Bus Chip Select.</b> Selects the BCM53262M for an EB Bus operation Shared with SPI's SS and EEPROM's CS.
EB_OE	B11	I		<b>Extended Bus Output Enable.</b> Used to enable the output drivers within the BCM53262M for the EB_DATA bus.
EB_WE	A11	I		<b>Expansion Bus Write Enable.</b> Used to write a register within the BCM53262M Shared with SPI's SCK and EEPROM's CK
EB_16BITMODE	D5	I <sub>PU</sub>		<b>Strap Pin.</b> <ul style="list-style-type: none"> <li>• 1 = Indicates the EB Bus operates in 16 bit mode. EB_DATA15 is the MSB. (Default)</li> <li>• 0 = Indicates the EB Bus operates in 16 bit mode. EB_DATA7 is the MSB.</li> </ul>
<b>MII Interface</b>				
MDIO	C10	I/O <sub>PD</sub>	8	<b>Management Data I/O.</b> This serial input/output bit is used to read from and write to the MII registers of both the internal and external transceivers. The input data value on the MDIO pin is valid and latched on the rising edge of MDC.
MDC	A10	I/O <sub>PD</sub>	8	<b>Management Data Clock.</b> For a slave-driven access, MDC must be provided to the BCM53262M as an input to allow MII management functions. Clock frequencies up to 12.5 MHz are supported.  During master mode access. As in auto-polling or when any SCK activity is detected on the SPI Interface, the BCM53262M sources a 2.5-MHz clock to the external PHY device.
<b>Bias</b>				
RDAC2	AA22	B	–	<b>DAC Bias Resistor.</b> Adjusts the drive level of the transmit DAC. Three separate 1percent precision resistors must be connected between the RDAC pins and GND. See <a href="#">“Recommended Operating Conditions” on page 377</a> for the required value.
RDAC1	Y21			
RDAC0	AB14			
<b>LEDs</b>				
LEDMODE1	D24	I <sub>PD</sub>	–	<b>LED Mode.</b> See <a href="#">Table 42: “LED Mode Shift Sequence,” on page 129</a> for details.
LEDMODE0	B26	I <sub>PD</sub>		
LEDCLK	D9	O	8	<b>LED Shift Clock.</b> Periodically active to enable the shift of LEDDATA into external registers.

**Table 48: Hardware Signal Descriptions (Cont.)**

<b>Signal Name</b>	<b>Ball #</b>	<b>Type</b>	<b>Drive (mA)</b>	<b>Description</b>
LEDDATA	A9	O	8	<b>LED Data Output.</b> Serial LED data is shifted out when LEDCLK is active. Refer to <a href="#">Table 41: “LED Status Types,” on page 128</a> and <a href="#">Table 42: “LED Mode Shift Sequence,” on page 129</a> for a functional description of these signals.
MLEDCLK	B9	O		<b>Matrix LED Shift Clock.</b> Periodically active to enable the shift of both MLEDCOL and MLEDROW data into external registers.
MLEDCOL	E10	O		<b>Matrix LED Column Data Output.</b> Serial LED data is shifted out when MLEDCLK is active.
MLEDROW	A8	O		<b>Matrix LED Row Data Output.</b> Serial LED data is shifted out when MLEDCLK is active.
<b>SPI</b>				
MISO	D16	O <sub>3S</sub>	8	<b>Master-In/Slave-Out.</b> Output signal from the BCM53262M driven with serial data during a Serial Management Port Read operation. Shared with EEPROM’s DO and EB_ADDR0.
MOSI	D15	I <sub>PU</sub>	–	<b>Master-Out/Slave-In.</b> Input signal which receives control and address information for the Serial Management Port, as well as serial data during Write operations. Shared with EEPROM’s DI and EB_DATA0.
SCK	A11	I/O <sub>PD</sub>	8	<b>Serial Clock.</b> Clock input to the Serial Management Port supplied by the SPI master. Supports up to 2 MHz. Shared with EEPROM’s CK and EB_WE.
$\overline{SS}$	D11	I/O <sub>PU</sub>	8	<b>Slave Select.</b> Active-low signal which enables a Serial Management Port Read or Write operation. Shared with EEPROM’s CS and EB_CS.
<b>EEPROM</b>				
CS	D11	O <sub>PU</sub>	8	<b>Chip Select.</b> Active-high signal which enables an EEPROM read operation. Shared with SPI’s $\overline{SS}$ and EB_CS.
DI	D15	O <sub>PU</sub>	8	<b>Data In.</b> Serial data input to the external EEPROM. Shared with SPI’s MOSI and EB_DATA0.
DO	D16	I <sub>PU</sub>	–	<b>Data Out.</b> Serial data output from the external EEPROM. Shared with SPI’s MISO and EB_ADDR0.
CK	A11	O <sub>PD</sub>	8	<b>Serial Data Clock.</b> Clock output to the EEPROM supplied by the BCM53262M. Shared with SPI’s SCK and EB_WE.

**Table 48: Hardware Signal Descriptions (Cont.)**

<b>Signal Name</b>	<b>Ball #</b>	<b>Type</b>	<b>Drive (mA)</b>	<b>Description</b>
<b>Test Interface</b>				
TCK	E5	I <sub>PU</sub>	–	<b>JTAG Test Clock Input.</b> Clock input used to synchronize JTAG control and data transfers. If unused, may be left unconnected.
TDI	F5	I <sub>PU</sub>	–	<b>JTAG Test Data Input.</b> Serial data input to the JTAG TAP Controller. Sampled on the rising edge of TCK. If unused, may be left unconnected.
TDO	C2	O <sub>3S</sub>	8	<b>JTAG Test Data Output.</b> Serial data output from the JTAG TAP Controller. Updated on the falling edge of TCK. Actively driven both high and low when enabled; high impedance otherwise.
TMS	A1	I <sub>PU</sub>	–	<b>JTAG Mode Select Input.</b> Single control input to the JTAG TAP Controller used to traverse the test-logic state machine. Sampled on the rising edge of TCK. If unused, may be left unconnected.
TRST	B2	I <sub>PU</sub>	–	<b>JTAG Test Reset.</b> Asynchronous active-low reset input to the JTAG TAP Controller. The TRST input must be driven low to insure the TAP controller initializes to the proper state. <b>Note:</b> A 4.7K external pull-down resistor is required on this pin to ensure proper initialization.
<b>Strap Configuration</b>				
CPU_EEPROM_SEL1	F10	I/O <sub>PD</sub>	–	<b>CPU Interface Selection.</b> <ul style="list-style-type: none"> <li>CPU_EEPROM_SEL[1:0] = 00: EEPROM interface.</li> <li>CPU_EEPROM_SEL[1:0] = 01: SPI interface. (Default)</li> <li>CPU_EEPROM_SEL[1:0] = 10: Reserved.</li> <li>CPU_EEPROM_SEL[1:0] = 11: EB Bus interface.</li> </ul>
CPU_EEPROM_SELO	B8	I/O <sub>PU</sub>	–	
EEPROM_TYPE1	C24	I/O <sub>PD</sub>	–	EEPROM Type Select. The EEPROM type is automatically detected by the BCM53262M. These two strap pins are essentially don't cares and can be ignored. See <a href="#">“EEPROM Interface” on page 112</a> for more information.
EEPROM_TYPE0	G21	I/O <sub>PD</sub>	–	
ENFDXFLOW	D26	I/O <sub>PU</sub>	–	<b>Enable Automatic Full Duplex Flow Control.</b> In combination with the results of auto-negotiation, sets the flow control mode. Refer to <a href="#">Table 8: “Flow Control Modes,” on page 77</a> for more information.
ENHDXFLOW	D25	I/O <sub>PU</sub>	–	<b>Enable Automatic Backpressure.</b> <ul style="list-style-type: none"> <li>ENHDXFLOW = 0: 10/100 ports half-duplex flow control is disabled.</li> <li>ENHDXFLOW = 1: 10/100 ports half-duplex flow control is enabled.</li> </ul> See <a href="#">Table 8: “Flow Control Modes,” on page 77</a> for more information.

**Table 48: Hardware Signal Descriptions (Cont.)**

<b>Signal Name</b>	<b>Ball #</b>	<b>Type</b>	<b>Drive (mA)</b>	<b>Description</b>
EN_GRX_FLOW	B25	I/O <sub>PU</sub>	–	<b>Enable Gigabit Receive Flow Control.</b> <ul style="list-style-type: none"> <li>EN_GRX_FLOW = 0: Gigabit ports Half-duplex flow control is disabled.</li> <li>EN_GRX_FLOW = 1: Gigabit ports Half-duplex flow control is enabled.</li> </ul>
HW_FWDG_EN	C25	I/O <sub>PU</sub>	–	<b>Forwarding Enable.</b> <ul style="list-style-type: none"> <li>HW_FWDG_EN = 0: Frame forwarding is disabled at power-up. Typically implemented to support compliant 802.1 Spanning Tree Protocol in a managed application.</li> <li>HW_FWDG_EN = 1: Frame forwarding is enabled (typical for unmanaged applications).</li> </ul>
MDIX_DIS	AF1	I/O <sub>PD</sub>	–	<b>HP Auto-MDIX Disable.</b> <ul style="list-style-type: none"> <li>MDIX_DIS = 0: Automatic TX cable swap detection enabled.</li> <li>MDIX_DIS = 1: Automatic TX cable swap detection disabled.</li> </ul>
GIGA_IMP_IFSEL1	E9	I <sub>PD</sub>	–	<b>IMP-Port Interface Select.</b> <ul style="list-style-type: none"> <li>GIGA_IMP_IFSEL[1:0] = 11: Reserved (Revision A)</li> <li>GIGA_IMP_IFSEL[1:0] = 11: GMII (Revision B)</li> <li>GIGA_IMP_IFSEL[1:0] = 10: RvMII (Recommended)</li> <li>GIGA_IMP_IFSEL[1:0] = 01: MII</li> <li>GIGA_IMP_IFSEL[1:0] = 00: Reserved (Default).</li> </ul> <b>Note:</b> RvMII when selected enables the interface to appear as a 100 Mbps full duplex PHY MII, as seen by external MAC. Under this mode the TXCLK/RXCLK become 25 MHz clock outputs.
GIGA_IMP_IFSEL0	A7			
PHY_POLL_DIS	C9	I <sub>PD</sub>	–	<b>PHY Polling Disable.</b> <ul style="list-style-type: none"> <li>1 = Disable External EPHY/EGPHY Polling</li> <li>0 = Enable External EPHY/EGPHY Polling</li> </ul>
CFP_ENABLE	F6	I <sub>PD</sub>	–	<b>CFP Function Enable.</b> <ul style="list-style-type: none"> <li>1 = Enable.</li> <li>0 = Disable.</li> </ul>
<b>Power</b>				
AVDD	AA19	PWR	–	<b>2.5V Internal 25-MHz Clock VDD.</b>
AVDD2	R20	PWR	–	1.2V XTALI_CK25 and XTALO_CK25 Circuit VDD.

**Table 48: Hardware Signal Descriptions (Cont.)**

<b>Signal Name</b>	<b>Ball #</b>	<b>Type</b>	<b>Drive (mA)</b>	<b>Description</b>
AVDDL	AA7, AA9, AA11, AA13, AA15, AA17, AA25, AB11, AC21, AD6, AD9, AD13, AD18, AD25, AE7, AE11, AE16, AE20, AF5, T20, U20, U21, V20, V21, W19, W20, W21, W24, Y10, Y11, Y12, Y13, Y14, Y15, Y16, Y17, Y18, Y19	PWR	–	<b>1.2V Analog VDD.</b>
AVSS	AA8, AA10, AA112, AA14, AA16, AA18, AA21, AB6, AB20, AB24, AC6, AC22, AD10, AD14, AD17, AE5, AE8, AE12, AE15, AE19, AE25, P18, T19, U19, U22, U23, V19, V23, W10, W11, W12, W13, W14, W15, W16, W18, Y20, Y25	GND	–	<b>Analog GND.</b>
DVDD	H9, H10, H11, H12, H13, H14, H15, H16, H17, H18, H19, J8, J19, K8, K19, L8, L19, M8, M19, N8, P8, R8, R19, T8, U8, V8, V14, W9, W17	PWR	–	<b>1.2V Digital Core VDD.</b>

**Table 48: Hardware Signal Descriptions (Cont.)**

<b>Signal Name</b>	<b>Ball #</b>	<b>Type</b>	<b>Drive (mA)</b>	<b>Description</b>
OVDD	AB1, AB3, C4, C7, C11, C13, F12, F14, G8, G9, G10, G11, G12, G13, G14, H1, H3, H6, H7, H8, H20, H21, J6, J7, J20, J21, K6, K7, K20, K21, L6, L7, L20, L21, M6, M7, N6, N7, P6, P7, R1, R3, R6, R7, T6, T7, U6, U7, V6, V7, W6, W7, W8, Y8, Y9	PWR	–	<b>2.5V</b>
OVDD2	B18, B20, B22, C15, C17, F15, F17, F19, F21, G15, G16, G17, G18, G19, G20	PWR	–	<b>2.5V/3.3V</b> <ul style="list-style-type: none"> <li>• GMII = 3.3V</li> <li>• MII = 2.5V or 3.3V</li> <li>• RvMII 2.5V or 3.3V</li> </ul>
SAVDD	E25, F23, G25, H23, J25, K23, L25, M23, N19, N25, P19, P23, R25, T23	PWR	–	<b>1.2V SerDes VDD</b>
BIASVDD0	AB15	PWR	–	<b>2.5V Bias Circuit VDD.</b>
BIASVDD1	AB22			
BIASVDD2	Y22			
XTALVDD	N21	PWR	–	<b>2.5V XTAL Circuit VDD.</b>
SAVSS	E26, F24, G22, G26, H24, J22, J26, K22, K24, L22, L26, M20, M24, N20, N22, N26, P20, P24, R26, T24	PWR	–	<b>Ground</b>
PLLAVDD	M21, M22	PWR	–	<b>1.2V PLL</b>
PLL2AVDD	H22	PWR	–	<b>1.2V PLL</b>
PLLAVSS	R21, R22, T22	PWR	–	<b>Ground</b>
PLL2AVSS	F22	PWR	–	<b>Ground</b>

**Table 48: Hardware Signal Descriptions (Cont.)**

## Section 8: Register Definitions

### Register Notations

In the register description tables, the following notation in the R/W column is used to describe the ability to read or write:

- R/W = Read or write
- RO = Read only
- LH = Latched high. Clear after read operation
- LL = Latched low. Clear after read operation
- H = Fixed high
- L = Fixed low
- SC = Self clear after read

Reserved bits must be written as the default value and ignored when read.

### Register Definition

The BCM53262 series consists of several devices with differing port configurations. Except as noted in [Table 51](#), all switching features are identical within each of the devices. The register definition described hereunder is in the highest port count configuration. Refer to [Table 51](#) for the valid port configuration and feature difference for the specific device.

**Table 51: Valid Port Map and Feature Difference**

<i>Device</i>	<i>FE Ports</i>	<i>GE Ports</i>	<i>CFP Rules</i>	<i>MAC-Based QoS/VLAN</i>	<i>Protocol-Based QoS/VLAN</i>	<i>QinQ</i>	<i>VLAN Translation</i>
BCM53262M	P24 ~ P47	G0, G1, G2, G3	1K	Y	Y	Y	Y
BCM53262S	P24 ~ P47	G0, G1, G2, G3	512	N	N	N	N

The BCM53262M's registers set can be accessed through the SPI Port or EB bus. The register space is organized into pages, each contains a certain set of registers. The following table lists the pages defined in the BCM53262M. In addition to access via the SPI port, registers can be accessed via the MDC/MDIO path via pseudo MII mode. The per-port MII registers are still accessible via the MDC/MDIO path of the external MII, compatible with the BCM53xx device mode.

To access a page, the page register (0xFF) is written with the page value. The registers contained in the page can then be accessed by their address.

## Switch Mode Register (Page 00h/Addr 00h)

**Table 54: Switch Mode Register (Page 00h: Address 00h)**

Bit	Name	R/W	Description	Default
7:6	RSVD	–	Reserved. Write as default. Ignore on read.	10
5:4	IPG	R/W	Programmable Inter-Packet-Gap. For 10/100 speed: <ul style="list-style-type: none"> <li>11 = 96-bit time</li> <li>10 = 92-bit time</li> <li>0x = Reserved</li> </ul>	11
3	NOBLKCD	R/W	When the bit is set, it does not block the carrier detected signal. <ul style="list-style-type: none"> <li>1 = Does not block, and txport always defers to CRS.</li> <li>0 = Block CD</li> </ul>	0
2	RSVD	R/W	Reserved. Write as default. Ignore on read.	1
1	SW_FWDG_EN	R/W	Software Forwarding Enable. <ul style="list-style-type: none"> <li>SW_FWDG_EN=1: Frame forwarding is enabled.</li> <li>SW_FWDG_EN=0: Frame forwarding is disabled.</li> </ul> Read from HW_FWDG_EN pin on power-on. Can be overwritten subsequently. For managed switch implementations (BCM53262M mode), the switch should be configured to disable forwarding on power-on, to allow the processor to configure the internal address table and other parameters, before frame forwarding is enabled.	HW_FWDG_EN strap pin state
0	SW_FWDG_MODE	R/W	Software Forwarding Mode. Programmed from the inverse of the HW_FWDG_EN pin at power-on. Can be overwritten subsequently. <ul style="list-style-type: none"> <li>1 = Managed Mode.</li> <li>0 = Unmanaged Mode.</li> </ul>	inverted HW_FWDG_EN strap pin state

## PHY Scan Control Register (Page 00h/Addr 02h)

**Table 55: PHY Scan Control Register (Page 00h: Address 02h)**

Bit	Name	R/W	Description	Default
7	RSVD	RO	Reserved. Write default. Ignore on read.	0
6:2	RSVD	RO	Reserved. Write default. Ignore on read.	0

**Table 55: PHY Scan Control Register (Page 00h: Address 02h)**

Bit	Name	R/W	Description	Default
1	EN_PHY_SCAN	R/W	<p>Enable Global External PHY Scanning Function</p> <p>Programmed from the inverse of the PHY_POLL_DIS pin at power-on reset. Can be overwritten subsequently. When enabled, the BCM53262M will poll externally at addresses 18h, 19h, 1Ah, 1Bh and 1Ch to read the PHY status.</p> <ul style="list-style-type: none"> <li>• 1 = Enable PHY scanning</li> <li>• 0 = Disable PHY scanning</li> </ul>	1 Inverse of PHY_POLL_DIS Strap Pin State
0	EN_INIT_CFG	R/W	Enable.	1

## New Control Register (Page 00h/Addr 03h)

**Table 56: New Control Register (Page 00h: Address 03h)**

Bit	Name	R/W	Description	Default
7:6	MLF_FM_EN	R/W	<p>Multicast Lookup Fail Forward Map Enable.</p> <ul style="list-style-type: none"> <li>• 00: Any incoming packets with multicast DA not in ARL table are flooded.</li> <li>• 01: Any incoming packets with multicast DA not in ARL table are forwarded according to the <a href="#">“Multicast Lookup Fail Forward Map Register (Page 00h/Addr 38h)”</a> on page 170.</li> <li>• 10: IPMC lookup fail packets are forwarded according to <a href="#">“IPMC Lookup Fail Forward Map Register (Page 00h/Addr 28h)”</a> on page 169.</li> <li>• 11: Reserved.</li> </ul>	0
5	ULF_FM_EN	R/W	<p>Unicast Lookup Fail Forward Map Enable.</p> <p>When set to 1, any incoming packets with unicast DA not in ARL table are forwarded according to the <a href="#">“Unicast Lookup Fail Forward Map Register (Page 00h/Addr 30h)”</a> on page 169.</p>	0
4	CLK25	R/W	<ul style="list-style-type: none"> <li>• 1 = Enable 25-MHz clock output.</li> <li>• 0 = Disable 25-MHz clock output.</li> </ul>	1

Bit	Name	R/W	Description	Default
7	PHY_Scan Enable	R/W	PHY Scan Control on IMP(MII) port: <ul style="list-style-type: none"> <li>0 = Use MII Software Override</li> <li>1 = PHY scan enabled.</li> </ul>	1
6	MII_SW_OR	R/W	MII Software Override: <ul style="list-style-type: none"> <li>0 = Use MII hardware pin status</li> <li>1 = Use contents of this register</li> </ul>	0
5	SW_FC_En	R/W	Software Flow Control Enable	0
4:3	RSVD	RO	Reserved Write default. Ignore on read	0
2	SPEED	R/W	Software Port Speed Setting: <ul style="list-style-type: none"> <li>1 = 100 Mbps</li> <li>0 = 10 Mbps.</li> </ul>	1
1	FDX	R/W	Full-duplex: <ul style="list-style-type: none"> <li>1 = Full-duplex</li> <li>0 = Half-duplex</li> </ul>	1
0	LINK	R/W	Link State. <ul style="list-style-type: none"> <li>1 = Link pass (up)</li> <li>0 = Link fail</li> </ul>	1

## MII GigaPort State Override Registers (Page 01h/Addr 41-44h)

**Table 78: MII GigaPort State Override Registers (Page 01h/Addr 41-44h)**

Address	Bits	Register Name
40h	8	IMP Port (Rev. B silicon only) (see Table 79: “MII GigaPort State Override Registers,” on page 188)
41h	8	GE port 0 (see Table 79: “MII GigaPort State Override Registers,” on page 188)
42h	8	GE port 1 (see Table 79: “MII GigaPort State Override Registers,” on page 188)
43h	8	GE port 2 (see Table 79: “MII GigaPort State Override Registers,” on page 188)
44h	8	GE port 3 (see Table 79: “MII GigaPort State Override Registers,” on page 188)

**Table 79: MII GigaPort State Override Registers**

Bit	Name	R/W	Description	Default
7	GPHY_Scan Enable	R/W	Allows per port control for the BCM53262M to scan the external GPHY.	1
6	MII_SW_OR	R/W	MII Software Override. <ul style="list-style-type: none"> <li>0 = Use GMII hardware pin status.</li> <li>1 = Use contents of this register.</li> </ul>	0
5	TX Flow Control	R/W	Software Tx Flow Control Enable. Link Partner Flow Control Capability. <ul style="list-style-type: none"> <li>0 = Not PAUSE capable.</li> <li>1 = PAUSE capable.</li> </ul>	0
4	RX Flow Control	R/W	Software Rx Flow Control Enable. Link Partner Flow Control Capability. <ul style="list-style-type: none"> <li>0 = Not PAUSE capable.</li> <li>1 = PAUSE capable.</li> </ul>	0
3:2	SPEED	R/W	Speed. <ul style="list-style-type: none"> <li>10 = 1000 Mbps.</li> <li>01 = 100 Mbps.</li> <li>00 = 10 Mbps.</li> </ul>	10
1	FDX	R/W	Full-duplex. <ul style="list-style-type: none"> <li>1 = Full-duplex.</li> <li>0 = Half-duplex.</li> </ul>	1
0	LINK	R/W	Link State. <ul style="list-style-type: none"> <li>1 = Link pass.</li> <li>0 = Link fail.</li> </ul>	1

## IMP Port PHY Scan Result Registers (Page 01H/Addr 68h)

**Note:** This register is in Rev. A silicon only.

**Table 80: IMP Port PHY Scan Result Registers (Page 01H/Addr 68h)**

Bit	Name	R/W	Description	Default
7	RSVD	RO	Reserved Write default. Ignore on read	0
6	TIMEOUT	RO	PHY Register Scan Timeout Error	0
5	Flow Control	RO	Software Flow Control Enable Link Partner Flow Control Capability <ul style="list-style-type: none"> <li>• 0 = Not PAUSE capable</li> <li>• 1 = PAUSE capable</li> </ul>	0
4:3	RSVD	RO	Reserved Write default. Ignore on read	0
2	SPEED	RO	Speed status <ul style="list-style-type: none"> <li>• 1 = 100 Mbps</li> <li>• 0 = 10 Mbps</li> </ul>	0
1	FDX	RO	Duplex status <ul style="list-style-type: none"> <li>• 1 = Full-duplex</li> <li>• 0 = Half-duplex</li> </ul>	0
0	LINK	RO	Link status <ul style="list-style-type: none"> <li>• 1 = Link pass</li> <li>• 0 = Link fail</li> </ul>	0

## IMP GigaPort PHY Scan Result Register (Page 01h/Addr 68h)

**Note:** This register is in Rev. B silicon only.

**Table 81: IMP GigaPort PHY Scan Result Register (Page 01h/Addr 68h)**

Address	Bits	Register Name
68h	8	IMP GigaPort (see <a href="#">Table 83: "GigaPorts PHY Scan Result Registers," on page 190</a> )

## G0–G3 GigaPorts PHY Scan Result Registers (Page 01h/Addr 69h–72h)

**Table 82: G0–G3 GigaPorts PHY Scan Result Registers (Page 01h/Addr 69h–72h)**

Address	Bits	Register Name
69h	8	GE port 0 (see <a href="#">Table 83: “GigaPorts PHY Scan Result Registers,” on page 190</a> )
70h	8	GE port 1 (see <a href="#">Table 83: “GigaPorts PHY Scan Result Registers,” on page 190</a> )
71h	8	GE port 2 (see <a href="#">Table 83: “GigaPorts PHY Scan Result Registers,” on page 190</a> )
72h	8	GE port 3 (see <a href="#">Table 83: “GigaPorts PHY Scan Result Registers,” on page 190</a> )

**Table 83: GigaPorts PHY Scan Result Registers**

Bit	Name	R/W	Description	Default
7	RSVD	RO	Reserved Write default. Ignore on read	0
6	TIMEOUT	RO	PHY Register Scan Timeout Error	0
5	TX Flow Control	RO	Software Tx Flow Control Enable. Link Partner Flow Control Capability. <ul style="list-style-type: none"> <li>0 = Not PAUSE capable.</li> <li>1 = PAUSE capable.</li> </ul>	0
4	RX Flow Control	RO	Software Rx Flow Control Enable. Link Partner Flow Control Capability. <ul style="list-style-type: none"> <li>0 = Not PAUSE capable.</li> <li>1 = PAUSE capable.</li> </ul>	0
3:2	SPEED	RO	Speed Status. <ul style="list-style-type: none"> <li>10 = 1000 Mbps.</li> <li>01 = 100 Mbps.</li> <li>00 = 10 Mbps.</li> </ul>	0

## Global Management Configuration Register (Page 03h/Addr 00h)

**Table 99: Global Management Configuration Register (Page 03h: Address 00h)**

Bit	Name	R/W	Description	Default
7:6	FRM_MNGT_PORT	R/W	Frame Management Port. Defines the physical port used to forward management frames directed to the switch. <ul style="list-style-type: none"> <li>• 00 = No Management Port</li> <li>• 01 = Reserved</li> <li>• 10 = IMP (In-band Management Port)</li> <li>• 11 = Reserved</li> </ul> These bits are ignored when SW_FWD_MODE = 0 (unmanaged) in the Switch Mode register Page 00h, Address 00h.	00
5	RSVD	RO	Reserved Write default. Ignore on read	0
4:3	IGMP_MLD_CHK	R/W	<ul style="list-style-type: none"> <li>• 11 = IGMP/MLD snooping is enabled. IGMP/MLD packet is forwarded according to its original port forwarding map from DA/VID look-up in addition to IMP port.</li> <li>• 01 = IGMP/MLD snooping is enabled. IGMP/MLD packet is forwarded to IMP port only.</li> <li>• 00 = IGMP/MLD snooping is disabled.</li> </ul>	0
2	RSVD	RO	Reserved Write default. Ignore on read	0
1	RX_BPDU_EN	R/W	Receive BPDU Enable. Enables all ports to receive BPDUs and forward to the defined Physical Management Port. Management CPU must set this bit to globally allow BPDUs to be received.	0
0	RSVD	–	Reserved	0

## Table Memory Reset Control Register (Page 03h/Addr 01h)

**Table 100: Table Memory Reset Control Register (Page 03h/Addr 01h)**

Bit	Name	R/W	Description	Default
7:5	RSVD	R/W	Reserved	00
4	RST_MSPT	SC	Reset Multiple Spanning Tree Table Setting bit = 1 sets the table content to zero, and the bit resets to 0 when the operation is done.	0
3	RST_IPMC	SC	Reset L2 Multicast Table Setting bit = 1 sets the table content to zero, and the bit resets to 0 when the operation is done.	0

**Table 100: Table Memory Reset Control Register (Page 03h/Addr 01h)**

<b>Bit</b>	<b>Name</b>	<b>R/W</b>	<b>Description</b>	<b>Default</b>
2	RST_VT	SC	Reset VLAN Table Setting bit = 1 sets the table content to zero, and the bit resets to 0 when the operation is done.	0
1	RST_ARL	SC	Reset ARL Table Setting bit = 1 sets the table content to zero, and the bit resets to 0 when the operation is done.	0
0	RST_MIB_CNTR	SC	Reset MIB counters Setting bit = 1 sets the table content to zero, and the bit resets to 0 when the operation is done.	0

## Management Port ID Register (Page 03h/Addr 02h)

**Table 101: Management Port ID Register (Page 03h: Address 02h)**

<b>Bit</b>	<b>Name</b>	<b>R/W</b>	<b>Description</b>	<b>Default</b>
7:6	RSVD	RO	Reserved Write default. Ignore on read	0
5:0	PORT ID	R/W	Port ID where Management Port is located. This must be programmed consistent with the Frame Management Port in the Global Management Configuration register. <b>Note:</b> Only IMP port (Port 48 [30h]) is legal value (i.e., not to be set to any other value).	0x30

## Reset Table Memory Register (Page 03h: Address 03h)

**Table 102: Reset Table Memory Register (Page 03h: Address 03h)**

Bit	Name	R/W	Description	Default
7:6	RSVD	–	Reserved	0
5:0	RST_TBL_MEM	SC	<p>When the corresponding bit is set, the table memory is reset.</p> <ul style="list-style-type: none"> <li>• Bit 5: Resets the port-based egress rate control configuration memory</li> <li>• Bit 4: Resets the port-based ingress rate control configuration memory</li> <li>• Bit 3: Resets the Flow-based VLAN table</li> <li>• Bit 2: Resets the Protocol-based VLAN table</li> <li>• Bit 1: Resets the MAC-based VLAN table</li> <li>• Bit 0: Resets the VLAN-based VLAN table</li> </ul>	0

## Aging Time Control Register (Page 03h/Addr 04h–07h)

**Table 103: Aging Time Control Register (Page 03h: Address 04h–07h)**

Bit	Name	R/W	Description	Default
31:20	RSVD	RO	Reserved Write default. Ignore on read	0
19:0	AGE_TIME	R/W	<p>Specifies the aging time in seconds for dynamically learned address. Maximum age time is 1,048,575s.</p> <p><b>Note:</b> While 802.1D specifies a range of values of 10–1,000,000s, this register does not enforce this range. Setting the AGE_TIME to 0 disables the aging process.</p>	0x12C

## RMON MIB Steering Register (Page 03h/Addr 08h–0Fh)

*Table 104: RMON MIB Steering Register (Page 03h: Address 08h–0Fh)*

<b>Bit</b>	<b>Name</b>	<b>R/W</b>	<b>Description</b>	<b>Default</b>
63:53	RSVD	RO	Reserved Write default. Ignore on read	–
52:24	OR_RMON_RCV[52:24]	R/W	Override RMON Receive. Forces the RMON packet size “bucket” counters from the normal default of snooping on the receive side of the MAC, to the transmit side. This allows the RMON bucket counters to snoop either transmit or receive, allowing full-duplex MAC support. <ul style="list-style-type: none"> <li>• Bit 52 = Giga Port G3</li> <li>• Bit 51 = Giga Port G2</li> <li>• Bit 50 = GigaPort G1</li> <li>• Bit 49 = GigaPort G0</li> <li>• Bit 48 = IMP</li> <li>• Bits 47:24 = 10/100 ports [port 47-port 24]</li> </ul>	0
23:0	RSVD	–	Reserved	0

## Mirror Capture Control Register (Page 03h/Addr 10h–17h)

**Table 105: Mirror Capture Control Register (Page 03h: Address 10h–17h)**

<b>Bit</b>	<b>Name</b>	<b>R/W</b>	<b>Description</b>	<b>Default</b>
63	MIRROR_ENABLE	R/W	Global enable/disable for all mirroring on this chip. When reset, mirroring is disabled. When set, mirroring is enabled according to ingress and egress control rules, to the port designated as MIRROR_CAPTURE_PORT.	0
62	RSVD	–	Reserved	1
61:53	RSVD	RO	Reserved Write default. Ignore on read	0
52:24	MIRROR_CAPTURE_PORT	R/W	Mirror Capture Port. Bit mask which identifies the single unique port which is designated as the port to which all ingress and/or egress traffic is mirrored on this chip/system. <ul style="list-style-type: none"> <li>• Bit 52 = Giga Port G3</li> <li>• Bit 51 = Giga Port G2</li> <li>• Bit 50 = GigaPort G1</li> <li>• Bit 49 = GigaPort G0</li> <li>• Bit 48 = IMP</li> <li>• Bits 47:24 = 10/100 ports [port 47-port 24]</li> </ul>	0
23:0	RSVD	–	Reserved	0

## Ingress Mirror Control Register (Page 03h/Addr 18h–1Fh)

Table 106: Ingress Mirror Control Register (Page 03h: Address 18h–1Fh)

Bit	Name	R/W	Description	Default
63:62	IN_MIRROR_FILTER	R/W	Ingress Mirror Filter. Defines conditions under which frames received on a port that has been selected in the IN_MIRROR_MASK[52:24], is compared to in order to determine if they should be forwarded to the MIRROR_CAPTURE_PORT. <ul style="list-style-type: none"> <li>00 = Mirror all ingress frames</li> <li>01 = Mirror all received frames with DA = IN_MIRROR_MAC</li> <li>10 = Mirror all received frames with SA = IN_MIRROR_MAC</li> <li>11 = Reserved.</li> </ul>	0
61	IN_DIV_EN	R/W	Ingress Divider Enable. Mirror every n <sup>th</sup> received frame (n=IN_MIRROR_DIV, defined in Register Page 03h, Address 20h) that has passed through the IN_MIRROR_FILTER.	0
60:53	RSVD	RO	Reserved Write default. Ignore on read	0
52:24	IN_MIRROR_MASK[52:24]	R/W	Ingress Mirror Port Mask. A 29-bit mask which selectively allows any port with its corresponding bit set, to be mirrored to the port identified by the MIRROR_CAPTURE_PORT value. <b>Note:</b> While multiple bits in a device may be set, severe congestion and/or frame loss may occur if excessive bandwidth from the mirrored port(s) is directed to the MIRROR_CAPTURE_PORT. <ul style="list-style-type: none"> <li>Bit 52 = Giga Port G3</li> <li>Bit 51 = Giga Port G2</li> <li>Bit 50 = GigaPort G1</li> <li>Bit 49 = GigaPort G0</li> <li>Bit 48 = IMP</li> <li>Bits 47:24 = 10/100 ports [port 47-port 24]</li> </ul>	0
23:0	RSVD	–	Reserved	0

## Ingress Mirror Divider Register (Page 03h/Addr 20h–21h)

Table 107: Ingress Mirror Divider Register (Page 03h: Address 20h–21h)

Bit	Name	R/W	Description	Default
15:10	RSVD	RO	Reserved Write default. Ignore on read	0

**Table 107: Ingress Mirror Divider Register (Page 03h: Address 20h–21h)**

<b>Bit</b>	<b>Name</b>	<b>R/W</b>	<b>Description</b>	<b>Default</b>
9:0	IN_MIRROR_DIV	R/W	<p>Ingress Mirror Divider.</p> <p>Receive frames that have passed the IN_MIRROR_FILTER rule can further reduce the overall number of frames forwarded to the MIRROR_CAPTURE_PORT to avoid the congestion. When the IN_DIV_EN bit in the Ingress Mirror Control register is set, only one in n frames is mirrored.</p> <p><b>Note:</b> Where n = IN_MIRROR_DIV and n must not be set to 0.</p>	0

## Ingress Mirror MAC Address Register (Page 03h/Addr 22h–27h)

**Table 108: Ingress Mirror MAC Address Register (Page 03h: Address 22h–27h)**

<b>Bit</b>	<b>Name</b>	<b>R/W</b>	<b>Description</b>	<b>Default</b>
47:0	IN_MIRROR_MAC	R/W	<p>Ingress Mirror MAC Address.</p> <p>MAC address that is compared against ingress frames in accordance with the IN_MIRROR_FILTER rules in Register Page 03h, Address 18h.</p>	0

## Egress Mirror Control Register (Page 03h/Addr 28h–2Fh)

Table 109: Egress Mirror Control Register (Page 03h: Address 28h–2Fh)

Bit	Name	R/W	Description	Default
63:62	OUT_MIRROR_FILTER	R/W	Egress Mirror Filter. Defines the type of Egress frames to be mirrored. <ul style="list-style-type: none"> <li>00: Mirror all egress frames</li> <li>01: Mirror all transmitted frames with DA = OUT_MIRROR_MAC</li> <li>10: Mirror all transmitted frames with SA = OUT_MIRROR_MAC</li> <li>11: Reserved.</li> </ul>	0
61	OUT_DIV_EN	R/W	Egress Divider Enable. Mirror every nth transmitted frame (n=OUT_MIRROR_DIV) that has passed through the OUT_MIRROR_FILTER.	0
60:53	RSVD	RO	Reserved Write default. Ignore on read	0
52:24	OUT_MIRROR_MASK[52:24]	R/W	Egress Mirror Port Mask is to select the port(s) Egress traffic be forwarded to the MIRROR_CAPTURE_PORT. A 29-bit mask which selectively allows any port with its corresponding bit set, to be mirrored to the port identified by the MIRROR_CAPTURE_PORT value. <b>Note:</b> While multiple bits in a device may be set, severe congestion and/or frame loss may occur if excessive bandwidth from the mirrored port(s) is directed to the MIRROR_CAPTURE_PORT. <ul style="list-style-type: none"> <li>Bit 52 = Giga Port G3</li> <li>Bit 51 = Giga Port G2</li> <li>Bit 50 = GigaPort G1</li> <li>Bit 49 = GigaPort G0</li> <li>Bit 48 = IMP</li> <li>Bits 47:24 = 10/100 ports [port 47-port 24]</li> </ul>	0
23:0	RSVD	–	Reserved	–

## Egress Mirror Divider Register (Page 03h/Addr 30h–31h)

**Table 110: Egress Mirror Divider Register (Page 03h: Address 30h–31h)**

Bit	Name	R/W	Description	Default
15:10	RSVD	RO	Reserved Write default. Ignore on read	0
9:0	OUT_MIRROR_DIV	R/W	Egress Mirror Divider. Transmit frames that have passed the OUT_MIRROR_FILTER rule can further reduced the overall number of frames forwarded to the MIRROR_CAPTURE_PORT to avoid the congestion. When the OUT_DIV_EN bit in the Egress Mirror Control register is set, only one in n frames is mirrored. <b>Note:</b> Where n = OUT_MIRROR_DIV and n must not be set to 0.	0

## Egress Mirror MAC Address Register (Page 03h/Addr 32h–37h)

**Table 111: Egress Mirror MAC Address Register (Page 03h: Address 32h–37h)**

Bit	Name	R/W	Description	Default
47:0	OUT_MIRROR_MAC	R/W	Egress Mirror MAC Address. MAC address that is compared against egress frames in accordance with the OUT_MIRROR_FILTER rules.	0

## Special Management Control Register (Page 03h/Addr 40h)

**Table 112: Special Management Control Register (Page 03h: Address 40h)**

Bit	Name	R/W	Description	Default
7:6	RSVD	–	Reserved	10
5	EN_ARP_CONTROL	R/W	ARP Frame Control. <ul style="list-style-type: none"> <li>0 = ARP frames are flooded in the defined VLAN domain, but are not forwarded to IMP if the IMP does not belong to the same VLAN.</li> <li>1 = ARP frames are flooded in the defined VLAN domain and also copied to the IMP even if the IMP is not part of the same VLAN group.</li> </ul>	0
4	BYPASS_SPT_CHK	R/W	When this bit is set, incoming packet with DA= 01-80-c2-00-00-00 ~ 01-80-c2-00-00-10 bypasses spanning tree state checking.	0
3	En_ALL_Zero_DA_Drop	R/W	Drop All 0 MAC DA Frame Control. When set, any frame with MAC DA = 00:00:00:00:00:00 is dropped otherwise it is forwarded as is.	0
2	RSVD	R/W	Write as default. Ignore on read.	0
1	PASS_ARP_DHCP	R/W	Enable to Pass ARP and DHCP frames. When management mode is enabled, and if bit 2, RX_BCST_EN (Page 01h/Addr A0h) is disabled, set this bit to 1 to allow the receiving of ARP and DHCP packets.	0
0	PASS_BPDU/Rsvd-MCAST	R/W	Enable to Pass BPDU and Reserved Multicast Frames. Setting this bit allows any port in spanning tree Disable state to forward BPDU and reserved multicast frames within range 01:80:C2:00:00:02 through 01:80:C2:00:00:0F to the IMP port.	0

## MIB Snapshot Control Register (Page 03h/Addr 50h)

**Table 113: MIB Snapshot Control Register (Page 03h: Address 50h)**

Bit	Name	R/W	Description	Default
7	SNAPSHOT_START/DONE	R/W (SC)	Snapshot Start/Done Command. When enabled, this bit is self clear to indicate that the process is completed and the snapshot is ready at <a href="#">Table : "Page 85h: Snapshot Port MIB Registers,"</a> on page 338. <ul style="list-style-type: none"> <li>1 = Initiate MIB Snapshot function.</li> <li>0 = Snapshot function completed.</li> </ul>	0
6	SNAPSHOT_MIRROR	RO	1 = enable read address to port MIB from MIB snapshot memory 0 = enable to read from port MIB memory	0
5:0	SNAPSHOT_PORT	RO	MIB Snapshot Port Number. These bits specify the port number to snapshot. <ul style="list-style-type: none"> <li>52 = Giga Port G3</li> <li>51 = Giga Port G2</li> <li>50 = GigaPort G1</li> <li>49 = GigaPort G0</li> <li>48 = IMP</li> <li>24 ~ 47 = 10/100 ports [port 24-port 47]</li> <li>0 ~ 23 = Reserved</li> </ul>	0

## Ingress RMON Register (Page 03h/Addr 60h–67h)

**Table 114: Ingress RMON Register (Page 03h: Address 60h–67h)**

Bit	Name	R/W	Description	Default
63:60	INGRESS_CFG	R/W	Ingress RMON Setting. An exponential value indicating the percentage of traffic that is forwarded to CPU due to Ingress Extended RMON. Percentage = $1/(2^{\text{INGRESS\_CFG}})$	Fh
59:58	INGRESS_PRI	R/W	Ingress RMON Priority Define which priority queue to use for Ingress Extended RMON. <ul style="list-style-type: none"> <li>• 11 = Queue 3</li> <li>• 10 = Queue 2</li> <li>• 01 = Queue 1</li> <li>• 00 = Queue 0</li> </ul>	0
57:53	RSVD	RO	Reserved Write default. Ignore on read	0
52:24	EN_INGRESS_PORTMAP	R/W	Ingress RMON Enabled Port Map. A 29-bit mask which selectively allows any port with its corresponding bit set, to enable Ingress Extended RMON. <b>Note:</b> Bit 48 is reserved and must be set to 0. <ul style="list-style-type: none"> <li>• Bit 52 = Giga Port G3</li> <li>• Bit 51 = Giga Port G2</li> <li>• Bit 50 = GigaPort G1</li> <li>• Bit 49 = GigaPort G0</li> <li>• Bit 48 = Reserved. Must be 0.</li> <li>• Bits 47:24 = 10/100 ports [port 47-port 24]</li> </ul>	0
23:0	RSVD	–	Reserved	0

## Egress RMON Register (Page 03h/Addr 68h–69h)

Table 115: Egress RMON Register (Page 03h: Address 68h–69h)

Bit	Name	R/W	Description	Default
15:12	EGRESS_CFG	R/W	Egress RMON Setting. An exponential value indicating the percentage of traffic that is forwarded to CPU due to Ingress Extended RMON. Percentage = $1/(2^{\text{EGRESS\_CFG}})$	Fh
11:10	EGRESS_PRI	R/W	Egress RMON Priority Define which priority queue to use for Egress Extended RMON. <ul style="list-style-type: none"> <li>11 = Queue 3</li> <li>10 = Queue 2</li> <li>01 = Queue 1</li> <li>00 = Queue 0</li> </ul>	0
9:7	RSVD	RO	Reserved Write default. Ignore on read	0
6	EN_EGRESS_RMON	R/W	Enable Egress RMON <ul style="list-style-type: none"> <li>1 = Enable</li> <li>0 = Disable</li> </ul>	0
5:0	EGRESS_RMON_PORT	R/W	Egress RMON Port. Define which port is Egress RMON Port. <ul style="list-style-type: none"> <li>52 = GigaPort G3</li> <li>51 = GigaPort G2</li> <li>50 = GigaPort G1</li> <li>49 = GigaPort G0</li> <li>48 = IMP</li> <li>24 ~ 47 = 10/100 ports [port 24-port 47]</li> <li>0 ~ 23 = Reserved</li> </ul>	0

## Chip Reset Control Register (Page 03h/Addr 7Ch)

## Global ARL Configuration Register (Page 04h/Addr 00h)

**Table 118: Global ARL Configuration Register (Page 04h: Address 00h)**

Bit	Name	R/W	Description	Default
7:5	Reserved	RO	Reserved. Write default. Ignore on read.	0
4	MPORT_ADDR_EN	R/W	<p>Multiport Address Enable.</p> <ul style="list-style-type: none"> <li>When bit 4 is set to 1 by the host, a frame with matching DAs to the Multiport Address 1 and/or 2 registers is forwarded to the ports defined in their associated Multiport Vector 1 and/or 2 registers.</li> <li>When bit 4 is set to 0 (default): A frame with matching DAs to the Multiport Address 1 and/or 2 registers is forwarded to the IMP port. This allows for support of User defined BPDU packets.</li> </ul> <p><b>Note:</b> If only one multiport address is required, the host should write both Multiport Address/Vector entries to the same value.</p>	0

**Table 118: Global ARL Configuration Register (Page 04h: Address 00h)**

<b>Bit</b>	<b>Name</b>	<b>R/W</b>	<b>Description</b>	<b>Default</b>
3:0	RSVD	RO	Reserved. Write default. Ignore on read.	0

## BPDU Multicast Address Register (Page 04h/Addr 04h–09h)

**Table 119: BPDU Multicast Address Register (Page 04h: Address 04h–09h)**

<b>Bit</b>	<b>Name</b>	<b>R/W</b>	<b>Description</b>	<b>Default</b>
47:0	BPDU_MC_ADDR	R/W	BPDU Multicast Address 1. Defaults to the 802.1 defined reserved multicast address for the Bridge Group Address. Programming to an alternate value allows support of proprietary protocols in place of the normal Spanning Tree Protocol. Frames with a matching DA to this address are forwarded to the designated management port (IMP).	01-80-C2-00-00-00h

## Multiport Address 1 Register (Page 04h/Addr 10h–15h)

**Table 120: Multiport Address 1 Register (Page 04h: Address 10h–15h)**

<b>Bit</b>	<b>Name</b>	<b>R/W</b>	<b>Description</b>	<b>Default</b>
47:0	MPORT_ADDR_1	R/W	Multiport Address 1. Allows a frames with a matching DA to this address to be forwarded to any programmable group of ports on the chip, as defined in the bit map in the Multiport Vector 1 register. Must be enabled using the MPORT_ADDR_EN bit in the Global ARL Configuration register.	00-00-00-00-00-00h

## Multiport Vector 1 Register (Page 04h/Addr 18h–1Fh)

Table 121: Multiport Vector 1 Register (Page 04h: Address 18h–1Fh)

Bit	Name	R/W	Description	Default
63:53	RSVD	RO	Reserved. Write default. Ignore on read.	0
52:24	MPORT_VCTR_1 [52:24]	R/W	<p><b>Multiport Vector 1.</b> A 29-bit mask corresponding to the physical ports on the chip. A frame with a DA matching the content of the Multiport Address 1 register is forwarded to each port with a bit set in the Multiport Vector 1 bit map.</p> <ul style="list-style-type: none"> <li>• Bit 52 = GigaPort G3</li> <li>• Bit 51 = GigaPort G2</li> <li>• Bit 50 = GigaPort G1</li> <li>• Bit 49 = GigaPort G0</li> <li>• Bit 48 = IMP</li> <li>• Bits 47:24 = 10/100 ports [port 47-port 24]</li> </ul>	0
23:0	RSVD	–	Reserved	0

## Multiport Address 2 Register (Page 04h/Addr 20h–25h)

Table 122: Multiport Address 2 Register (Page 04h: Address 20h–25h)

Bit	Name	R/W	Description	Default
47:0	MPORT_ADDR_2	R/W	<p>Multiport Address 2.</p> <p>Allows a frames with a matching DA to this address to be forwarded to any programmable group of ports on the chip, as defined in the bit map in the Multiport Vector 2 register.</p> <p>Must be enabled using the MPORT_ADDR_EN bit in the Global ARL Configuration register.</p>	00-00-00-00-00-00h

## Multiport Vector 2 Register (Page 04h/Addr 28h–2Fh)

Table 123: Multiport Vector 2 Register (Page 04h: Address 28h–2Fh)

## ARL Read/Write Control Register (Page 05h/Addr 00h)

**Table 125: ARL Read/Write Control Register (Page 05h: Address 00h)**

Bit	Name	R/W	Description	Default
7	START/DONE	R/W (SC)	Start/Done Command. Write as 1 to initiate a read or write command after first loading the MAC_ADDR_INDX register with the MAC address for which the ARL entry is to be read or written. The BCM53262M resets the bit to indicate that a write or read operation has completed, and data from the bin entry is available in ARL Entry.	0
6:4	Reserved	RO	Reserved. Write default. Ignore on read.	0
3:1	TBL_INDEX	R/W	Index to Tables <ul style="list-style-type: none"> <li>• 111= Flow to VLAN Table</li> <li>• 110 = Protocol to VLAN Table</li> <li>• 101 = MAC to VLAN Table</li> <li>• 100 = VLAN to VLAN Table</li> <li>• 011 = Multiple Spanning Tree Table</li> <li>• 010 = Multicast Table</li> <li>• 001 = VLAN Table</li> <li>• 000 = ARL Table</li> </ul>	0
0	TBL_R/W	R/W	Table Read/Write. <ul style="list-style-type: none"> <li>• 1 = Read.</li> <li>• 0 = Write.</li> </ul>	0

## MAC Address Index Register (Page 05h/Addr 02h–07h)

**Table 126: MAC Address Index Register (Page 05h: Address 02h–07h)**

Bit	Name	R/W	Description	Default
47:0	MAC_ADDR_INDX	R/W	MAC Address Index. The MAC address for which status is to be read or written. By writing the 48 bit SA or DA address, and initiating a read command, the complete ARL bin location is returned in the ARL Entry location. The entry is 64 bits wide. Initiating a write command writes the contents of ARL Entry to the specified bin location and overwrites the current contents of the bin, regardless of the Valid bit status in each entry. <b>Note:</b> MAC_ADDR_INDX is also used as the index to the MAC to VLAN table.	00-00-00-00-00-00h

## VID Table Index Register (Page 05h/Addr 08h–09h)

*Table 127: VID Table Index Register (Page 05h: Address 08h–09h)*

Bit	Name	R/W	Description	Default
15:12	Reserved	RO	Reserved. Write default. Ignore on read.	0
11:0	VID_TBL_INDX	R/W	VLAN Table Index. When 802.1Q is enabled and VID_MAC Control, bits[6:5] of 802.1Q VLAN Control 0 register are asserted (Page 34h, Addr 00h), VID_TBL_INDX is used with the MAC_ADDR_INDX, defined in the MAC Address Index register, to form the hash index for which status is to be read or written.	000h

## ARL Entry 0 Register, for Unicast Address (Page 05h/Addr 10h–17h)

*Table 128: ARL Entry 0 Register, for Unicast Address Register (Page 05h: Address 10h–17h)*

Bit	Name	R/W	Description	Default
63	VALID	R/W	Valid. Set to indicate that a valid MAC address is stored in the MACADDR field, and that the entry has not aged out or been freed by the management processor. Reset when an entry is empty, the address has been aged out by the internal aging process, or the external management processor has invalidated the entry. Automatic learning takes place if an address location is not valid and has not been marked as static.	0
62	STATIC	R/W	Static. Set to indicate that the entry is controlled by the external management processor, and automatic learning and aging of the entry does not take place. When cleared, the internal learning and aging process controls the validity of the entry.	0
61:60	CON[1:0]	R/W	ARL mode control. These bits select the ARL mode, which determines the forwarding decision. <ul style="list-style-type: none"> <li>11 = Forward to destination port specified by ARL and also send to IMP. (Suggest to also set bit 62).</li> <li>10 = Drop if MAC_SA match. (Suggest to also set bit 62).</li> <li>01 = Drop if MAC_DA match. (Suggest to also set bit 62).</li> <li>00 = Normal ARL function. Forward to destination port specified by ARL.</li> </ul>	0

**Table 128: ARL Entry 0 Register, for Unicast Address Register (Page 05h: Address 10h–17h) (Cont.)**

Bit	Name	R/W	Description	Default
59	AGE0	R/W	Age Set to indicate that an address entry has been learned or accessed. Reset by the internal aging algorithm. If the internal aging process detects a Valid entry has remained unused for the period set by the AGE_TIME, and the entry has not been marked as Static, the entry has the Valid bit cleared. The Age bit is ignored if the entry has been marked as Static.	0
58:54	Reserved	R/W	Write as default. Ignore on read	0
53:48	PORTID[5:0]	R/W	Port Identification (for unicast address) The port number which identifies where the station with unique MACADDR is connected. <ul style="list-style-type: none"> <li>• 52 = Giga Port G3</li> <li>• 51 = Giga Port G2</li> <li>• 50 = GigaPort G1</li> <li>• 49 = GigaPort G0</li> <li>• 48 = IMP</li> <li>• 24 ~ 47 = 10/100 ports [port 24-port 47]</li> <li>• 0 ~ 23 = Reserved</li> </ul>	0
47:0	MACADDR	R/W	MAC Address	0

## ARL Entry 0 Register, for Multicast Address (Page 05h/Addr 10h–17h)

**Table 129: ARL Entry, for Multicast Address Register (Page 05h: Address 10h–17h)**

Bit	Name	R/W	Description	Default
63	VALID	R/W	Valid. Set to indicate that a valid MAC address is stored in the MACADDR field, and that the entry has not aged out or been freed by the management processor. Reset when an entry is empty, the address has been aged out by the internal aging process, or the external management processor has invalidated the entry. Automatic learning takes place if an address location is not valid and has not been marked as static.	0
62	STATIC	R/W	Static. Set to indicate that the entry is controlled by the external management processor, and automatic learning and aging of the entry does not take place. When cleared, the internal learning and aging process controls the validity of the entry.	0

**Table 129: ARL Entry, for Multicast Address Register (Page 05h: Address 10h–17h) (Cont.)**

<b>Bit</b>	<b>Name</b>	<b>R/W</b>	<b>Description</b>	<b>Default</b>

## Multitable Data 0 Register (Page 05h/Addr 38h–3Fh)

*Table 135: Multitable Data 0 Register (Page 05h: Address 38h–3Fh)*

<i>Bit</i>	<i>Name</i>	<i>R/W</i>	<i>Description</i>	<i>Default</i>
63:0	TBL_DATA_0	R/W	<p>When Flow to VLAN Table is accessed,</p> <ul style="list-style-type: none"> <li>TBL_DATA_0 [63:12] : reserved</li> <li>TBL_DATA_0 [11:0] : VID</li> </ul> <p>When Protocol to VLAN Table is accessed,</p> <ul style="list-style-type: none"> <li>TBL_DATA_0 [63:32]: reserved</li> <li>TBL_DATA_0 [31]: Valid</li> <li>TBL_DATA_0 [30:28]: Priority for Protocol base.</li> <li>TBL_DATA_0 [27:16]: VID</li> <li>TBL_DATA_0 [15:0]: Ether Type</li> </ul> <p>When MAC to VLAN Table is accessed,</p> <ul style="list-style-type: none"> <li>TBL_DATA_0 [63]: Valid_0</li> <li>TBL_DATA_0 [62:60]: PRI_0, Priority for MAC SA base</li> <li>TBL_DATA_0 [59:48]: VID_0</li> <li>TBL_DATA_0 [47:0]: MAC address</li> </ul> <p>When VLAN to VLAN Table is accessed,</p> <ul style="list-style-type: none"> <li>TBL_DATA_0 [63:13]: reserved</li> <li>TBL_DATA_0 [12]: <ul style="list-style-type: none"> <li>1: mapping mode</li> <li>0: transparent mode</li> </ul> </li> <li>TBL_DATA_0 [11:0]: New VID</li> </ul> <p>When Multiple Spanning Tree Table is accessed,</p> <ul style="list-style-type: none"> <li>TBL_DATA_0 [63:0]: reserved</li> </ul> <p>When Multicast Table is accessed,</p> <ul style="list-style-type: none"> <li>TBL_DATA_0 [63:53]: reserved</li> <li>TBL_DATA_0 [52:24]: Multicast Forwarding vector</li> <li>TBL_DATA_0 [23:0]: reserved</li> </ul> <p>When VLAN Table is accessed,</p> <ul style="list-style-type: none"> <li>TBL_DATA_0 [63:53]: reserved</li> <li>TBL_DATA_0 [52:24]: VLAN Table Forwarding vector</li> <li>TBL_DATA_0 [23:0]: reserved</li> </ul>	0

## Multitable Data 1 Register (Page 05h/Addr 40h–47h)

Broadcom Confidential

Broadcom Confidential

**Table 136: Multitable Data 1 Register (Page 05h: Address 40h–47h)**

Bit	Name	R/W	Description	Default
63:0	TBL_DATA_1	R/W	<p>When Flow to VLAN Table is accessed,</p> <ul style="list-style-type: none"> <li>TBL_DATA_1 [63:0]: reserved</li> </ul> <p>When Protocol to VLAN Table is accessed,</p> <ul style="list-style-type: none"> <li>TBL_DATA_1 [63:0]: reserved</li> </ul> <p>When MAC to VLAN Table is accessed,</p> <ul style="list-style-type: none"> <li>TBL_DATA_1 [63]: Valid_1</li> <li>TBL_DATA_1 [62:60]: PRI_1, Priority for MAC base (SA)</li> <li>TBL_DATA_1 [59:48]: VID_1</li> <li>TBL_DATA_1 [47:0]: MAC-1, MAC address</li> </ul> <p>When VLAN to VLAN Table is accessed,</p> <ul style="list-style-type: none"> <li>TBL_DATA_1 [63:0]: reserved</li> </ul> <p>When Multiple Spanning Tree Table is accessed,</p> <ul style="list-style-type: none"> <li>TBL_DATA_1 [63:60]: reserved</li> <li>TBL_DATA_1 [59:57]: Multiple Spanning tree state for port 39</li> <li>TBL_DATA_1 [56:54]: Multiple Spanning tree state for port 38</li> <li>TBL_DATA_1 [53:51]: Multiple Spanning tree state for port 37</li> <li>.....</li> <li>TBL_DATA_1 [17:15]: Multiple Spanning tree state for port 25</li> <li>TBL_DATA_1 [14:12]: Multiple Spanning tree state for port 24</li> </ul> <p><b>Note:</b> TBL_DATA [3bits]</p> <ul style="list-style-type: none"> <li>– 000 = no spanning tree</li> <li>– 001 = disable state</li> <li>– 010 = blocking state</li> <li>– 011 = listening state</li> <li>– 000 = learning state</li> <li>– 101 = forwarding state</li> <li>– 110,111 = reserved</li> </ul> <p>When Multicast Table is accessed,</p> <ul style="list-style-type: none"> <li>TBL_DATA_1 [63:0]: reserved</li> </ul> <p>When VLAN Table is accessed,</p> <ul style="list-style-type: none"> <li>TBL_DATA_1 [63:53]: reserved</li> <li>TBL_DATA_1 [52:24]: VLAN Table Untag vector</li> <li>TBL_DATA_1 [23:0]: reserved</li> </ul>	0

## Multitable Data 2 Register (Page 05h/Addr 48h–4Fh)

**Table 137: Multitable Data 2 Register (Page 05h: Address 48h–4Fh)**

Bit	Name	R/W	Description	Default
63:0	TBL_DATA_2	R/W	<p>When Flow to VLAN Table is accessed,</p> <ul style="list-style-type: none"> <li>TBL_DATA_2 [63:0]: reserved</li> </ul> <p>When Protocol to VLAN Table is accessed,</p> <ul style="list-style-type: none"> <li>TBL_DATA_2 [63:0]: reserved</li> </ul> <p>When MAC to VLAN Table is accessed,</p> <ul style="list-style-type: none"> <li>TBL_DATA_2 [63:0]: reserved</li> </ul> <p>When VLAN to VLAN Table is accessed,</p> <ul style="list-style-type: none"> <li>TBL_DATA_2 [63:0]: reserved</li> </ul> <p>When Multiple Spanning Tree Table is accessed,</p> <ul style="list-style-type: none"> <li>TBL_DATA_2 [63:39]: reserved</li> <li>TBL_DATA_2 [38:36]: Multiple Spanning tree state for port 52</li> <li>TBL_DATA_2 [35:33]: Multiple Spanning tree state for port 51</li> <li>.....</li> <li>TBL_DATA_2 [2:0]: Multiple Spanning tree state for port 40</li> </ul> <p><b>Note:</b> TBL_DATA[3bits]</p> <ul style="list-style-type: none"> <li>– 000 = no spanning tree</li> <li>– 001 = disable state</li> <li>– 010 = blocking state</li> <li>– 011 = listening state</li> <li>– 000 = learning state</li> <li>– 101 = forwarding state</li> <li>– 110,111 = reserved</li> </ul> <p>When Multicast Table is accessed:</p> <ul style="list-style-type: none"> <li>TBL_DATA_2 [63:0]: reserved</li> </ul> <p>When VLAN Table is accessed:</p> <ul style="list-style-type: none"> <li>TBL_DATA_2 [63:9]: reserved</li> <li>TBL_DATA_2 [8]: disable the learning process for packet that matches this VLAN</li> <li>TBL_DATA_2 [7:0]: VLAN Table Spanning ID is for mapping to the MSTP table</li> </ul>	0

## ARL Search Control Register (Page 05h/Addr 50h)

**Table 138: ARL Search Control Register (Page 05h: Address 50h)**

Bit	Name	R/W	Description	Default
7	START/DONE	R/W (SC)	Start/Done Command. Write as 1 to initiate a sequential search of the ARL entries, returning each entry that is currently occupied (Valid = 1 and AGE = 0) in the ARL Search Result register. Reading the ARL Search Result register causes the ARL search to continue. The BCM53262M clears this bit to indicate the entire ARL entry database has been searched.	0
6:1	RSVD	RO	Reserved. Write default. Ignore on read.	0
0	ARL_SR_VALID	RC	ARL Search Result Valid. Set by the BCM53262M to indicate that an ARL entry is available in the ARL Search Result register. Reset by a host read to the ARL Search Result register, which causes the ARL search process to continue through the ARL entries until the next entry is found with a Valid bit is set.	0

## ARL Search Address Register (Page 05h/Addr 52h–53h)

**Table 139: ARL Search Address Register (Page 05h: Address 52h–53h)**

Bit	Name	R/W	Description	Default
15	ARL_ADDR_VALID	R/W (SC)	ARL Address Valid. Indicates the lower 15 bits of this register contain a valid internal representation of the ARL entry currently being accessed.	0
14:13	RSVD	RO	Reserved. Write default. Ignore on read.	0
12:0	ARL_ADDR	R/W	ARL Address. 15-bit internal representation of the address of the ARL entry currently being accessed by the ARL search routine. This is not a direct address of the ARL location.	0

## ARL Search Result MAC Register (Page 05h/Addr 54h–5Bh)

**Table 140: ARL Search Result Register (Page 05h: Address 54h–5Bh)**

Bit	Name	R/W	Description	Default
63	VALID	RO	Valid. Set to indicate that a valid MAC address is stored in the MACADDR field, and that the entry has not aged out or been freed by the management processor. All entries returned by the ARL Search process has the VALID bit set.	0
62	STATIC	RO	Static. Set to indicate that the entry is controlled by the external management processor, and automatic learning and aging of the entry does not take place. When cleared, the internal learning and aging process controls the validity of the entry. All entries with STATIC bit set are returned by the ARL Search process.	0
61:60	CON[1:0]	RO	ARL mode control. These bits select the ARL mode, which determines the forwarding decision. <ul style="list-style-type: none"> <li>11 = Forward to destination port specified by ARL and also send to IMP. (Suggest to also set bit 62).</li> <li>10 = Drop if MAC_SA match. (Suggest to also set bit 62).</li> <li>01 = Drop if MAC_DA match. (Suggest to also set bit 62).</li> <li>00 = Normal ARL function. Forward to destination port specified by ARL.</li> </ul>	0
59	AGE	RO	Age. Set to indicate that an address entry has been learned or accessed. Reset by the internal aging algorithm. If the internal aging process detects a Valid entry has remained unused for the period set by the AGE_TIME, and the entry has not been marked as Static, the entry has the AGE bit cleared. The Age bit is ignored if the entry has been marked as Static.	0
58:54	RSVD	RO	Reserved. Write default. Ignore on read.	0
53:48	PORTID[5:0]	RO	Port Identification. The port number which identifies where the station with unique MACADDR is connected. <ul style="list-style-type: none"> <li>52 = Giga Port G3</li> <li>51 = Giga Port G2</li> <li>50 = GigaPort G1</li> <li>49 = GigaPort G0</li> <li>48 = IMP</li> <li>24 ~ 47 = 10/100 ports [port 24-port 47]</li> <li>0 ~ 23 = Reserved</li> </ul>	0

**Table 140: ARL Search Result Register (Page 05h: Address 54h–5Bh) (Cont.)**

<b>Bit</b>	<b>Name</b>	<b>R/W</b>	<b>Description</b>	<b>Default</b>
47:0	MACADDR	RO	MAC Address. The unique MAC address of the station occupying this ARL entry.	0

Broadcom Confidential

## ARL Search Result VID Register (Page 05h/Addr 5Ch–5Dh)

**Table 141: ARL Search Result VID Register (Page 05h: Address 5Ch–5Dh)**

<b>Bit</b>	<b>Name</b>	<b>R/W</b>	<b>Description</b>	<b>Default</b>
15	RSVD	RO	Reserved. Write default. Ignore on read.	0
14:12	USER_DEF	RO	User Defined Field These are user defined bits. These bits are also written into the ARL table along with ARL_VID_ENTRY.	0
11:0	VID	RO	VID search result.	0

**Note:** If 802.1Q is enabled, Broadcom recommends to read the ARL Search Result VID register first, then read the ARL Search Result MAC register.

## Page 0Ah: Priority Queue Control Registers

## Flow Control Diagnostic Register (Page 0Ah/Addr 00h–01h)

**Table 143: Flow Control Diagnostic Register (Page 0Ah: Address 00h–01h)**

Bit	Name	R/W	Description	Default
15:14	RSVD	RO	Reserved. Write default. Ignore on read.	0
13:12	DIAG_HIST_SEL	R/W	Select which histogram value to report.	0
11:8	DIAG_TXQ_SEL	R/W	Select which Tx Queue to be monitored.	0
7:6	FC_PRI-Q_SEL	R/W	<ul style="list-style-type: none"> <li>• 11 = Highest Queue</li> <li>• 10 = 2nd Queue</li> <li>• 01 = 1st Queue</li> <li>• 00 = Lowest Queue</li> </ul>	0
5:0	DIAG_FC_PORT	R/W	Diagnose Port Flow Control. These bits select which port to monitor. <ul style="list-style-type: none"> <li>• 52 = Port number for GigaPort G3</li> <li>• 51 = Port number for GigaPort G2</li> <li>• 50 = Port number for GigaPort G1</li> <li>• 49 = Port number for GigaPort G0</li> <li>• 48 = Port number for IMP</li> <li>• 24 ~ 47 = Port numbers for 10/100 ports [port 24-port 47]</li> </ul>	0x18

## Queue 0 100 TX Threshold Control 1 Register (Page 0Ah/Addr 06h–07h)

**Table 144: Queue 0 100 Tx Threshold Control 1 Register (Page 0Ah: Address 06h–07h)**

Bit	Name	R/W	Description	Default
15:8	Q0_BT100_HYST_THRS	RO	Q0 Unpause Threshold Regulates the transmission of the TXQ based flow control unpause frame. Under mixed-speed mode, when Q0 reaches the pause condition and the number of pointers queued up in the corresponding TXQ (Q0) drops below this threshold, an unpause frame is dispatched. The effective threshold is the default value multiplied by 8.	13h
7:0	Q0_BT100_PAUS_THRS	R/W	Q0 Pause Threshold Regulates the transmission of the TXQ based flow control pause frame. Under mixed-speed mode, when the number of pointers queued up in the corresponding TXQ (Q0) exceeds this threshold, a pause frame is dispatched. The effective threshold is the default value multiplied by 8.	1Ch

**Table 144: Queue 0 100 Tx Threshold Control 1 Register (Page 0Ah: Address 06h–07h)**

<i>Bit</i>	<i>Name</i>	<i>R/W</i>	<i>Description</i>	<i>Default</i>
<b>Note:</b> When QoS is disabled, this register is ignored.				

Broadcom Confidential

## Queue 0 100 TX Threshold Control 2 Register (Page 0Ah/Addr 08h–09h)

Table 145: Queue 0 100 Tx Threshold Control 2 Register (Page 0Ah: Address 08-09h)

Bit	Name	R/W	Description	Default	Recommended Value
15:8	Q0_BT100_DROP_THRS	RO	Q0 Unicast Drop Threshold Regulates incoming unicast frames. Under mixed-speed mode, when the number of pointers queued up in the corresponding TXQ (Q0) exceeds this threshold, all incoming unicast frames will be dropped. The effective threshold is the default value multiplied by 8.	9Fh	98
7:0	Q0_BT100_DROP_THRS	R/W	Q0 Multicast Drop Threshold Regulates incoming multicast frames. Under mixed-speed mode, when the number of pointers queued up in the corresponding TXQ (Q0) exceeds this threshold, all incoming multicast frames will be dropped. The effective threshold is the default value multiplied by 8.	9Fh	73

**Note:** When QoS is disabled, this register is ignored.

## Global Threshold Control 1 Register (Page 0Ah/Addr 0Eh–0Fh)

Table 146: Global Threshold Control 1 Register (Page 0Ah: Address 0E-0Fh)

Bit	Name	R/W	Description	Default	Recommended Value
15:8	FC_GLBL_HYST_THRS	RO	Flow Control Global Unpause Threshold Regulates the global transmission of the TXQ based flow control unpause frame. When the BCM53262M is in a pause condition, and the number of pointers queued up in all the corresponding TXQs drops below this threshold, an unpause frame is dispatched. The effective threshold is the default value multiplied by 8.	61h	44

**Table 146: Global Threshold Control 1 Register (Page 0Ah: Address 0E-0Fh)**

<b>Bit</b>	<b>Name</b>	<b>R/W</b>	<b>Description</b>	<b>Default</b>	<b>Recommended Value</b>
7:0	FC_GLBL_PAUSE_THRD	R/W	Flow Control Global Pause Threshold Regulates the global transmission of the TXQ-based flow control pause frame. When the number of pointers queued up in all the corresponding TXQs exceeds this threshold, a pause frame is dispatched. The effective threshold is the default value multiplied by 8.	85h	7E

## Global Threshold Control 2 Register (Page 0Ah/Addr 10h–11h)

**Table 147: Global Threshold Control 2 Register (Page 0Ah: Address 10-11h)**

<b>Bit</b>	<b>Name</b>	<b>R/W</b>	<b>Description</b>	<b>Default</b>	<b>Recommended Value</b>
15:8	FC_GLBL_DROP_THRS	RO	Flow Control Unicast Global Drop Threshold Regulates global incoming unicast frames. When the total number of pointers queued up in all the corresponding TXQs exceeds this threshold, all incoming unicast frames will be dropped. The effective threshold is the default value multiplied by 8.	B2h	9B
7:0	FC_GLBL_MC_DROP_THRD	R/W	Flow Control Multicast Global Drop Threshold Regulates global incoming multicast frames. When the total number of pointers queued up in all the corresponding TXQs exceeds this threshold, all incoming multicast frames will be dropped. The effective threshold is the default value multiplied by 8.	B2h	7E

## Global Option Control Register (Page 0Ah/Addr 30h–31h)

**Table 148: Global Option Control Register (Page 0Ah: Address 30h–31h)**

<b>Bit</b>	<b>Name</b>	<b>R/W</b>	<b>Description</b>	<b>Default</b>
15	RSVD	RO	Reserved Write default. Ignore on read.	0

**Table 148: Global Option Control Register (Page 0Ah: Address 30h–31h) (Cont.)**

Bit	Name	R/W	Description	Default
14	EN_DLF_BC_DROP_THRS	R/W	Enable DLF/BC Drop Threshold. Enable local port individual DLF and broadcast drop threshold.	0
13:11	RSVD	RO	Reserved	0x7
10	EN_MCAST_BLANCE	R/W	Enable multicast traffic balance <ul style="list-style-type: none"> <li>1 = use hund_pause and hund_unpause</li> <li>0 = use mcast_drop threshold</li> </ul>	1
9:8	RSVD	RO	Reserved. Write default. Ignore on read.	0
7	AGGRESSIVE_DROP	R/W	Aggressive Drop Mode. <ul style="list-style-type: none"> <li>1 = Enable.</li> <li>0 = Disable.</li> </ul>	0
6:5	RSVD	RO	Reserved. Write default. Ignore on read.	0
4	Enable Multicast Drop	R/W	Enable multicast drop feature due to RX base and TX base flow control scheme.	1
3	Enable Unicast Drop	R/W	Enable unicast drop feature due to TX base flow control scheme.	1(QOS on) / 0(QOS off)
2	Enable TXQ Pause	R/W	Enable unicast pause frame generation due to TX base flow control scheme.	1
1	Enable RX Drop	R/W	Enable unicast drop feature due to RX base flow control scheme.	0
0	Enable RX Pause	R/W	Enable unicast pause frame generation due to RX base flow control scheme.	0

## Queue 0 TxDsc Control Register (Page 0Ah/Addr 64h–65h)

**Table 149: Queue 0 TxDsc Control Register (Page 0Ah: Address 64h–65h)**

Bit	Name	R/W	Description	Default
15:6	RSVD	RO	Reserved. Write default. Ignore on read.	0
5:0	Q0_quota_size	R/W	The round robin weight for priority queue 0.	01h

**Note:** Maximum Q0\_quota\_size allowable is 37h.

## Queue 1 100BT Threshold Control 1 Register (Page 0Ah/Addr 6Ah–6Bh)

**Table 150: Queue 1 100BT Threshold Control 1 Register (Page 0Ah: Address 6Ah–6Bh)**

Bit	Name	R/W	Description	Default
15:8	Q1_BT100_HYST_THRS	R/W	Q1 Unpause Threshold Regulates the transmission of the TXQ-based flow control unpause frame. Under mixed-speed mode, when Q0 reaches a pause condition, and the number of pointers queued up in the corresponding TXQ (Q1) drops below this threshold, an unpause frame is dispatched. The effective threshold is the default value multiplied by 8.	13h
7:0	Q1_BT100_PAUS_THRS	R/W	Q1 Pause Threshold Regulates the transmission of the TXQ-based flow control pause frame. Under mixed-speed mode, when the number of pointers queued up in the corresponding TXQ (Q1) exceeds this threshold, a pause frame is dispatched. The effective threshold is the default value multiplied by 8.	1Ch

**Note:** When QoS is disabled, this register is ignored.

## Queue 1 100BT Threshold Control 2 Register (Page 0Ah/Addr 6Ch–6Dh)

**Table 151: Queue 1 100BT Threshold Control 2 Register (Page 0Ah: Address 6Ch–6Dh)**

Bit	Name	R/W	Description	Default	Recommended Value
15:8	Q1_BT100_DROP_THRS	R/W	Q1 Unicast Drop Threshold Regulates incoming unicast frames. Under mixed-speed mode, when the number of pointers queued up in the corresponding TXQ (Q1) exceeds this threshold, all incoming unicast frames will be dropped. The effective threshold is the default value multiplied by 8.	9Fh	98
7:0	Q1_BT100_MCDROP_THRS	R/W	Q1 Multicast Drop Threshold Regulates incoming multicast frames. Under mixed-speed mode, when the number of pointers queued up in the corresponding TXQ (Q1) exceeds this threshold, all incoming multicast frames will be dropped. The effective threshold is the default value multiplied by 8.	9Fh	73

**Table 151: Queue 1 100BT Threshold Control 2 Register (Page 0Ah: Address 6Ch–6Dh)**

Bit	Name	R/W	Description	Recommended Value
-----	------	-----	-------------	-------------------

**Note:** When QoS is disabled, this register is ignored.

## Queue 1 TxDsc Control Register (Page 0Ah/Addr 72h–73h)

**Table 152: Queue 1 TxDsc Control Register (Page 0Ah: Address 72h–73h)**

Bit	Name	R/W	Description	Default
15:6	RSVD	RO	Reserved. Write default. Ignore on read.	0
5:0	Q1_quota_size	R/W	The round robin weight for priority queue 0.	02h

**Note:** Maximum Q1\_quota\_size allowable is 37h.

## Queue 2 100TX Threshold Control 1 Register (Page 0Ah/Addr 78h–79h)

**Table 153: Queue 2 100TX Threshold Control 1 Register (Page 0Ah: Address 78h–79h)**

Bit	Name	R/W	Description	Default
15:8	Q2_BT100_HYST_THRS	R/W	Q2 Unpause Threshold Regulates the transmission of the TXQ-based flow control unpause frame. Under mixed-speed mode, when Q0 reaches a pause condition, and the number of pointers queued up in the corresponding TXQ (Q2) drops below this threshold, an unpause frame is dispatched. The effective threshold is the default value multiplied by 8.	13h
7:0	Q2_BT100_PAUS_THRS	R/W	Q2 Pause Threshold Regulates the transmission of the TXQ-based flow control pause frame. Under mixed-speed mode, when the number of pointers queued up in the corresponding TXQ (Q2) exceeds this threshold, a pause frame is dispatched. The effective threshold is the default value multiplied by 8.	1Ch

**Note:** When QoS is disabled, this register is ignored.

## Queue 2 100TX Threshold Control 2 Register (Page 0Ah/Addr 7Ah–7Bh)

**Table 154: Queue 2 100TX Threshold Control 2 Register (Page 0Ah: Address 7Ah–7Bh)**

Bit	Name	R/W	Description	Default	Recommended Value
15:8	Q2_BT100_DROP_THRS	R/W	Q2 Unicast Drop Threshold Regulates incoming unicast frames. Under mixed-speed mode, when the number of pointers queued up in the corresponding TXQ (Q2) exceeds this threshold, all incoming unicast frames will be dropped. The effective threshold is the default value multiplied by 8.	9Fh	98
7:0	Q2_BT100_MCDROP_THRS	R/W	Q2 Multicast Drop Threshold Regulates incoming multicast frames. Under mixed-speed mode, when the number of pointers queued up in the corresponding TXQ (Q2) exceeds this threshold, all incoming multicast frames will be dropped. The effective threshold is the default value multiplied by 8.	9Fh	73

**Note:** When QoS is disabled, this register is ignored.

## Queue 2 TxDsc Control Register (Page 0Ah/Addr 80h–81h)

**Table 155: Queue 2 TxDsc Control Register (Page 0Ah: Address 80h–81h)**

Bit	Name	R/W	Description	Default
15:6	RSVD	RO	Reserved. Write default. Ignore on read.	0
5:0	Q2_quota_size	R/W	The round robin weight for priority queue 0.	04h

**Note:** Maximum Q2\_quota\_size allowable is 37h.

## Queue 3 100TX Threshold Control 1 Register (Page 0Ah/Addr 86h–87h)

**Table 156: Queue 3 100TX Threshold Control 1 Register (Page 0Ah: Address 86h–87h)**

Bit	Name	R/W	Description	Default
15:8	Q3_BT100_HYST_THRS	R/W	Q3 Unpause Threshold Regulates the transmission of the TXQ-based flow control unpause frame. Under mixed-speed mode, when Q0 reaches a pause condition, and the number of pointers queued up in the corresponding TXQ (Q3) drops below this threshold, an unpause frame is dispatched. The effective threshold is the default value multiplied by 8.	13h
7:0	Q3_BT100_PAUS_THRS	R/W	Q3 Pause Threshold Regulates the transmission of the TXQ-based flow control pause frame. Under mixed-speed mode, when the number of pointers queued up in the corresponding TXQ (Q3) exceeds this threshold, a pause frame is dispatched. The effective threshold is the default value multiplied by 8.	1Ch

## Queue 3 100TX Threshold Control 2 Register (Page 0Ah/Addr 88h–89h)

**Table 157: Queue 3 100TX Threshold Control 2 Register (Page 0Ah: Address 88h–89h)**

Bit	Name	R/W	Description	Default	Recommended Value
15:8	Q3_BT100_DROP_THRS	R/W	Q3 Unicast Drop Threshold Regulates incoming unicast frames. Under mixed-speed mode, when the number of pointers queued up in the corresponding TXQ (Q3) exceeds this threshold, all incoming unicast frames will be dropped. The effective threshold is the default value multiplied by 8.	9Fh	98
7:0	Q3_BT100_MCDROP_THRS	R/W	Q3 Multicast Drop Threshold Regulates incoming multicast frames. Under mixed-speed mode, when the number of pointers queued up in the corresponding TXQ (Q3) exceeds this threshold, all incoming multicast frames will be dropped. The effective threshold is the default value multiplied by 8.	9Fh	73

## Queue 3 TxDsc Control Register (Page 0Ah/Addr 8Eh–8Fh)

Table 158: Queue 3 TxDsc Control Register (Page 0Ah: Address 8Eh–8Fh)

Bit	Name	R/W	Description	Default
15:6	RSVD	RO	Reserved Write default. Ignore on read.	0
5:0	Q3_quota_size	R/W	The round robin weight for priority queue 3.	08h

**Note:** Maximum Q3\_quota\_size allowable is 37h.

## DLF Threshold Drop Register (Page 0Ah/Addr 94h–95h)

Table 159: DLF Threshold Drop Register (Page 0Ah: Address 94h–95h)

Bit	Name	R/W	Description	Default	Recommended Value
15:8	TOTAL_INDV_DLFTH_DROP	R/W	Total individual DLF drop threshold. Regulates total incoming DLF frames. When EN_DLF_BC_DROP_THRS of <a href="#">“Global Option Control Register (Page 0Ah/Addr 30h–31h)”</a> on page 245 is asserted, the total incoming DLF frames exceed this threshold are dropped. The effective threshold is the default value multiplied by 8.	B2h	7E
7:0	INDV_DLFTH_DROP	R/W	Individual DLF drop threshold. Regulates individual port incoming DLF frames. When EN_DLF_BC_DROP_THRS of <a href="#">“Global Option Control Register (Page 0Ah/Addr 30h–31h)”</a> on page 245 is asserted, the incoming DLF frames at individual port exceed this threshold are dropped. The effective threshold is the default value multiplied by 8.	9Fh	–

## Broadcast Threshold Drop Register (Page 0Ah/Addr 96h–97h)

**Table 160: Broadcast Threshold Drop Register (Page 0Ah: Address 96h–97h)**

Bit	Name	R/W	Description	Default	Recommended Value
15:8	TOTAL_INDV_BCSTTH_DROP	R/W	Total individual broadcast drop threshold. Regulates total incoming Broadcast frames. When EN_DLF_BC_DROP_THRS of <a href="#">“Global Option Control Register (Page 0Ah/Addr 30h–31h)”</a> on page 245 is asserted, the total incoming Broadcast frames exceed this threshold are dropped. The effective threshold is the default value multiplied by 8.	B2h	7E
7:0	INDV_BCSTTH_DROP	R/W	Individual broadcast drop threshold. Regulates individual port incoming Broadcast frames. When EN_DLF_BC_DROP_THRS of <a href="#">“Global Option Control Register (Page 0Ah/Addr 30h–31h)”</a> on page 245 is asserted, the incoming Broadcast frames at individual port exceed this threshold are dropped. The effective threshold is the default value multiplied by 8.	9Fh	–

## LAN to IMP Unicast Control Register (Page 0Ah/Addr A0h–A1h)

**Table 161: LAN to IMP MC Control 1 Register (Page 0Ah: Address A0h–A1h)**

Bit	Name	R/W	Description	Default
15	IMP_CONGST_REMAP_EN	R/W	Remap IMP Port Congestion Status <ul style="list-style-type: none"> <li>1 = Remap from PAUSE to DROP</li> </ul>	0
14:0	RSVD	–	Reserved	1

## LAN to IMP Multicast Control 1 Register (Page 0Ah/Addr A2h–A3h)

**Table 162: LAN to IMP MC Control 1 Register (Page 0Ah: Address A2h–A3h)**

Bit	Name	R/W	Description	Default
15:1	RSVD	–	Reserved	0

**Table 162: LAN to IMP MC Control 1 Register (Page 0Ah: Address A2h–A3h)**

Bit	Name	R/W	Description	Default
0	MC_IMP_DROP_EN	R/W	When this bit is set, activates the MC_IMP_DROP_THRSHLD in “LAN to IMP Multicast Control 2 Register (Page 0Ah/Addr A4h–A5h)” on page 253.	0

**LAN to IMP Multicast Control 2 Register (Page 0Ah/Addr A4h–A5h)****Table 163: LAN to IMP MC Control 2 Register (Page 0Ah: Address A4h–A5h)**

Bit	Name	R/W	Description	Default
15:8	RSVD	RO	Reserved	0
7:0	MC_IMP_DROP_THRSHLD	R/W	Total use threshold for MC traffic from LAN to IMP.	6Ch

**IMP to LAN Control 1 Register (Page 0Ah/Addr B0h–B1h)****Table 164: IMP to LAN Control 1 Register (Page 0Ah: Address B0h–B1h)**

Bit	Name	R/W	Description	Default
15:1	RSVD	RO	Reserved	0
0	High_Rate_IMP_PAUSE_EN	R/W	<ul style="list-style-type: none"> <li>1 = Remap LAN-ports congestion status observed by IMP port from Drop/Pause to Pause/Hysteresis</li> </ul>	0

**IMP to LAN Control 2 Register (Page 0Ah/Addr B2h–B3h)****Table 165: LAN to IMP MC Control 2 Register (Page 0Ah: Address B2h–B3h)**

Bit	Name	R/W	Description	Default
15:8	DROP_IMP_THRSHLD	RO	If the total buffer use exceeds this threshold, the BCh drop congestion status observed by the IMP port does not remap to pause.	
7:0	PAUSE_IMP_THRSHLD	R/W	If the total buffer use exceeds this threshold, the AAh pause congestion status observed by the IMP port does not remap to hysteresis.	

## Queue 1 Total Threshold Control 1 Register (Page 0Ah/Addr C0h–C1h)

*Table 166: Queue 1 Total Threshold Control 1 Register (Page 0Ah: Address C0h–C1h)*

Bit	Name	R/W	Description	Default	Recommended Value
15:8	HYST_THRSHLD_Q1	RO	–	61h	46
7:0	PAUSE_THRSHLD_Q1	R/W	Total pause threshold for Q1	8Ch	80

## CFP UDF A0 Control Register (Page 22h/Addr 00h)

**Table 212: CFP UDF A0 Control Register (Page 22h: Address 00h)**

Bit	Name	R/W	Description	Default
7:6	UDF_REF_A0	R/W	Flag indicating the type of field for starting address <ul style="list-style-type: none"> <li>• 11 = reserved</li> <li>• 10 = end of IP header (including IPv4 option)</li> <li>• 01 = end of Ether Type</li> <li>• 00 = end of Tag</li> </ul>	0
5:0	UDF_OFFSET_A0	R/W	The offset used for UDF_A0 which is used in Slice 0. The number counts from the reference port of frame. Rx port extracts 16 bits of data from the corresponding location for CFP lookup. Unit: 16 bits (2-bytes)	0

## CFP UDF A1 Control Register (Page 22h/Addr 01h)

**Table 213: CFP UDF A1 Control Register (Page 22h: Address 01h)**

Bit	Name	R/W	Description	Default
7:6	UDF_REF_A1	R/W	Flag indicating the type of field for starting address <ul style="list-style-type: none"> <li>• 11 = reserved</li> <li>• 10 = end of IP header (including IPv4 option)</li> <li>• 01 = end of Ether Type</li> <li>• 00 = end of Tag</li> </ul>	0
5:0	UDF_OFFSET_A1	R/W	The offset used for UDF_A1 which is used in Slice 0. The number counts from the reference port of frame. Rx port extracts 16 bits of data from the corresponding location for CFP lookup. Unit: 16 bits (2-bytes)	0

## CFP UDF A2 Control Register (Page 22h/Addr 02h)

**Table 214: CFP UDF A2 Control Register (Page 22h: Address 02h)**

Bit	Name	R/W	Description	Default
7:6	UDF_REF_A2	R/W	Flag indicating the type of field for starting address <ul style="list-style-type: none"> <li>• 11 = reserved</li> <li>• 10 = end of IP header (including IPv4 option)</li> <li>• 01 = end of Ether Type</li> <li>• 00 = end of Tag</li> </ul>	0
5:0	UDF_OFFSET_A2	R/W	The offset used for UDF_A2 which is used in Slice 0. The number counts from the reference port of frame. Rx port extracts 16 bits data from the corresponding location for CFP lookup. Unit: 16 bits (2-bytes)	0

## CFP UDF B0 Control Register (Page 22h/Addr 10h)

*Table 215: CFP UDF B0 Control Register (Page 22h: Address 10h)*

<i>Bit</i>	<i>Name</i>	<i>R/W</i>	<i>Description</i>	<i>Default</i>
7:6	UDF_REF_B0	R/W	Flag indicating the type of field for starting address <ul style="list-style-type: none"> <li>• 11 = reserved</li> <li>• 10 = end of IP header (including IPv4 option)</li> <li>• 01 = end of Ether Type</li> <li>• 00 = end of Tag</li> </ul>	0
5:0	UDF_OFFSET_B0	R/W	The offset used for UDF_B0 which is used in Slice 1. The number counts from the reference port of frame. Rx port extracts 16 bits of data from the corresponding location for CFP lookup. Unit: 16 bits (2-bytes)	0

## CFP UDF B1 Control Register (Page 22h/Addr 11h)

*Table 216: CFP UDF B1 Control Register (Page 22h: Address 11h)*

<i>Bit</i>	<i>Name</i>	<i>R/W</i>	<i>Description</i>	<i>Default</i>
7:6	UDF_REF_B1	R/W	Flag indicating the type of field for starting address <ul style="list-style-type: none"> <li>• 11 = reserved</li> <li>• 10 = end of IP header (including IPv4 option)</li> <li>• 01 = end of Ether Type</li> <li>• 00 = end of Tag</li> </ul>	0
5:0	UDF_OFFSET_B1	R/W	The offset used for UDF_B1 which is used in Slice 1. The number counts from the reference port of frame. Rx port extracts 16 bits of data from the corresponding location for CFP lookup. Unit: 16 bits (2-bytes)	0

## CFP UDF B2 Control Register (Page 22h/Addr 12h)

*Table 217: CFP UDF B2 Control Register (Page 22h: Address 12h)*

<i>Bit</i>	<i>Name</i>	<i>R/W</i>	<i>Description</i>	<i>Default</i>
7:6	UDF_REF_B2	R/W	Flag indicating the type of field for starting address <ul style="list-style-type: none"> <li>• 11 = reserved</li> <li>• 10 = end of IP header (including IPv4 option)</li> <li>• 01 = end of Ether Type</li> <li>• 00 = end of Tag</li> </ul>	0

**Table 217: CFP UDF B2 Control Register (Page 22h: Address 12h)**

Bit	Name	R/W	Description	Default
5:0	UDF_OFFSET_B2	R/W	The offset used for UDF_B2 which is used in Slice 1. The number counts from the reference port of frame. Rx port extracts 16 bits of data from the corresponding location for CFP lookup. Unit: 16 bits (2-bytes)	0

## CFP UDF B3 Control Register (Page 22h/Addr 13h)

**Table 218: CFP UDF B3 Control Register (Page 22h: Address 13h)**

Bit	Name	R/W	Description	Default
7:6	UDF_REF_B3	R/W	Flag indicating the type of field for starting address <ul style="list-style-type: none"> <li>• 11 = reserved</li> <li>• 10 = end of IP header (including IPv4 option)</li> <li>• 01 = end of Ether Type</li> <li>• 00 = end of Tag</li> </ul>	0
5:0	UDF_OFFSET_B3	R/W	The offset used for UDF_B3 which is used in Slice 1. The number counts from the reference port of frame. Rx port extracts 16 bits of data from the corresponding location for CFP lookup. Unit: 16 bits (2-bytes)	0

## CFP UDF B4 Control Register (Page 22h/Addr 14h)

**Table 219: CFP UDF B4 Control Register (Page 22h: Address 14h)**

Bit	Name	R/W	Description	Default
7:6	UDF_REF_B4	R/W	Flag indicating the type of field for starting address <ul style="list-style-type: none"> <li>• 11 = reserved</li> <li>• 10 = end of IP header (including IPv4 option)</li> <li>• 01 = end of Ether Type</li> <li>• 00 = end of Tag</li> </ul>	0
5:0	UDF_OFFSET_B4	R/W	The offset used for UDF_B4 which is used in Slice 1. The number counts from the reference port of frame. Rx port extracts 16 bits of data from the corresponding location for CFP lookup. Unit: 16 bits (2-bytes)	0

## CFP UDF B5 Control Register (Page 22h/Addr 15h)

**Table 220: CFP UDF B5 Control Register (Page 22h: Address 15h)**

Bit	Name	R/W	Description	Default
7:6	UDF_REF_B5	R/W	Flag indicating the type of field for starting address <ul style="list-style-type: none"> <li>• 11 = reserved</li> <li>• 10 = end of IP header (including IPv4 option)</li> <li>• 01 = end of Ether Type</li> <li>• 00 = end of Tag</li> </ul>	0
5:0	UDF_OFFSET_B5	R/W	The offset used for UDF_B5 which is used in Slice 1. The number counts from the reference port of frame. Rx port extracts 16 bits of data from the corresponding location for CFP lookup. Unit: 16 bits (2-bytes)	0

## CFP UDF B6 Control Register (Page 22h/Addr 16h)

**Table 221: CFP UDF B6 Control Register (Page 22h: Address 16h)**

Bit	Name	R/W	Description	Default
7:6	UDF_REF_B6	R/W	Flag indicating the type of field for starting address <ul style="list-style-type: none"> <li>• 11 = reserved</li> <li>• 10 = end of IP header (including IPv4 option)</li> <li>• 01 = end of Ether Type</li> <li>• 00 = end of Tag</li> </ul>	0
5:0	UDF_OFFSET_B6	R/W	The offset used for UDF_B6 which is used in Slice 1. The number counts from the reference port of frame. Rx port extracts 16 bits of data from the corresponding location for CFP lookup. Unit: 16 bits (2-bytes)	0

## CFP UDF B7 Control Register (Page 22h/Addr 17h)

**Table 222: CFP UDF B7 Control Register (Page 22h: Address 17h)**

Bit	Name	R/W	Description	Default
7:6	UDF_REF_B7	R/W	Flag indicating the type of field for starting address <ul style="list-style-type: none"> <li>• 11 = reserved</li> <li>• 10 = end of IP header (including IPv4 option)</li> <li>• 01 = end of Ether Type</li> <li>• 00 = end of Tag</li> </ul>	0

**Table 222: CFP UDF B7 Control Register (Page 22h: Address 17h)**

<b>Bit</b>	<b>Name</b>	<b>R/W</b>	<b>Description</b>	<b>Default</b>
5:0	UDF_OFFSET_B7	R/W	The offset used for UDF_B7 which is used in Slice 1. The number counts from the reference port of frame. Rx port extracts 16 bits of data from the corresponding location for CFP lookup. Unit: 16 bits (2-bytes)	0

## CFP UDF B8 Control Register (Page 22h/Addr 18h)

**Table 223: CFP UDF B8 Control Register (Page 22h: Address 18h)**

<b>Bit</b>	<b>Name</b>	<b>R/W</b>	<b>Description</b>	<b>Default</b>
7:6	UDF_REF_B8	R/W	Flag indicating the type of field for starting address <ul style="list-style-type: none"> <li>• 11 = reserved</li> <li>• 10 = end of IP header (including IPv4 option)</li> <li>• 01 = end of Ether Type</li> <li>• 00 = end of Tag</li> </ul>	0
5:0	UDF_OFFSET_B8	R/W	The offset used for UDF_B8 which is used in Slice1. The number counts from the reference port of frame. Rx port extracts 16 bits of data from the corresponding location for CFP lookup. Unit: 16 bits (2-bytes)	0

## CFP UDF B9 Control Register (Page 22h/Addr 19h)

**Table 224: CFP UDF B9 Control Register (Page 22h: Address 19h)**

<b>Bit</b>	<b>Name</b>	<b>R/W</b>	<b>Description</b>	<b>Default</b>
7:6	UDF_REF_B9	R/W	Flag indicating the type of field for starting address <ul style="list-style-type: none"> <li>• 11 = reserved</li> <li>• 10 = end of IP header (including IPv4 option)</li> <li>• 01 = end of Ether Type</li> <li>• 00 = end of Tag</li> </ul>	0
5:0	UDF_OFFSET_B9	R/W	The offset used for UDF_B9 which is used in Slice 1. The number counts from the reference port of frame. Rx port extracts 16 bits of data from the corresponding location for CFP lookup. Unit: 16 bits (2-bytes)	0

## CFP UDF B10 Control Register (Page 22h/Addr 1Ah)

*Table 225: CFP UDF B10 Control Register (Page 22h: Address 1Ah)*

<i>Bit</i>	<i>Name</i>	<i>R/W</i>	<i>Description</i>	<i>Default</i>
7:6	UDF_REF_B10	R/W	Flag indicating the type of field for starting address <ul style="list-style-type: none"> <li>• 11 = reserved</li> <li>• 10 = end of IP header (including IPv4 option)</li> <li>• 01 = end of Ether Type</li> <li>• 00 = end of Tag</li> </ul>	0
5:0	UDF_OFFSET_B10	R/W	The offset used for UDF_B10 which is used in Slice 1. The number counts from the reference port of frame. Rx port extracts 16 bits of data from the corresponding location for CFP lookup. Unit: 16 bits (2-bytes)	0

## CFP UDF C0 Control Register (Page 22h/Addr 20h)

*Table 226: CFP UDF C0 Control Register (Page 22h: Address 20h)*

<i>Bit</i>	<i>Name</i>	<i>R/W</i>	<i>Description</i>	<i>Default</i>
7:6	UDF_REF_C0	R/W	Flag indicating the type of field for starting address <ul style="list-style-type: none"> <li>• 11 = start of packet (Revision B silicon)</li> <li>• 11 = reserved (Revision A silicon)</li> <li>• 10 = end of IP header (including IPv4 option)</li> <li>• 01 = end of Ether Type</li> <li>• 00 = end of Tag</li> </ul>	0
5:0	UDF_OFFSET_C0	R/W	The offset used for UDF_C0 which is used in Slice 2. The number counts from the reference port of frame. Rx port extracts 16 bits of data from the corresponding location for CFP lookup. Unit: 16 bits (2-bytes)	0

## CFP UDF C1 Control Register (Page 22h/Addr 21h)

*Table 227: CFP UDF C1 Control Register (Page 22h: Address 21h)*

<i>Bit</i>	<i>Name</i>	<i>R/W</i>	<i>Description</i>	<i>Default</i>
7:6	UDF_REF_C1	R/W	Flag indicating the type of field for starting address <ul style="list-style-type: none"> <li>• 11 = start of packet (Revision B silicon)</li> <li>• 11 = reserved (Revision A silicon)</li> <li>• 10 = end of IP header (including IPv4 option)</li> <li>• 01 = end of Ether Type</li> <li>• 00 = end of Tag</li> </ul>	0

**Table 227: CFP UDF C1 Control Register (Page 22h: Address 21h)**

<b>Bit</b>	<b>Name</b>	<b>R/W</b>	<b>Description</b>	<b>Default</b>
5:0	UDF_OFFSET_C1	R/W	The offset used for UDF_C1 which is used in Slice 2. The number counts from the reference port of frame. Rx port extracts 16 bits of data from the corresponding location for CFP lookup. Unit: 16 bits (2-bytes)	0

## CFP UDF C2 Control Register (Page 22h/Addr 22h)

**Table 228: CFP UDF C2 Control Register (Page 22h: Address 22h)**

<b>Bit</b>	<b>Name</b>	<b>R/W</b>	<b>Description</b>	<b>Default</b>
7:6	UDF_REF_C2	R/W	Flag indicating the type of field for starting address <ul style="list-style-type: none"> <li>• 11 = start of packet (Revision B silicon)</li> <li>• 11 = reserved (Revision A silicon)</li> <li>• 10 = end of IP header (including IPv4 option)</li> <li>• 01 = end of Ether Type</li> <li>• 00 = end of Tag</li> </ul>	0
5:0	UDF_OFFSET_C2	R/W	The offset used for UDF_C2 which is used in Slice 2. The number counts from the reference port of frame. Rx port extracts 16 bits of data from the corresponding location for CFP lookup. Unit: 16 bits (2-bytes)	0

## CFP UDF D0 Control Register (Page 22h/Addr 30h)

**Table 229: CFP UDF D0 Control Register (Page 22h: Address 30h)**

<b>Bit</b>	<b>Name</b>	<b>R/W</b>	<b>Description</b>	<b>Default</b>
7:6	UDF_REF_D0	R/W	Flag indicating the type of field for starting address <ul style="list-style-type: none"> <li>• 11 = reserved</li> <li>• 10 = end of IP header (including IPv4 option)</li> <li>• 01 = end of Ether Type</li> <li>• 00 = end of Tag</li> </ul>	0
5:0	UDF_OFFSET_D0	R/W	The offset used for UDF_D0 which is used in Slice 2. The number counts from the reference port of frame. Rx port extracts 16 bits of data from the corresponding location for CFP lookup. Unit: 32 bits (4-bytes)	0

## CFP UDF D1 Control Register (Page 22h/Addr 31h)

**Table 230: CFP UDF D1 Control Register (Page 22h: Address 31h)**

Bit	Name	R/W	Description	Default
7:6	UDF_REF_D1	R/W	Flag indicating the type of field for starting address <ul style="list-style-type: none"> <li>• 11 = reserved</li> <li>• 10 = end of IP header (including IPv4 option)</li> <li>• 01 = end of Ether Type</li> <li>• 00 = end of Tag</li> </ul>	0
5:0	UDF_OFFSET_D1	R/W	The offset used for UDF_D1 which is used in Slice 2. The number counts from the reference port of frame. Rx port extracts 16 bits of data from the corresponding location for CFP lookup. Unit: 32 bits (4-bytes)	0

## CFP UDF D2 Control Register (Page 22h/Addr 32h)

**Table 231: CFP UDF D2 Control Register (Page 22h: Address 32h)**

Bit	Name	R/W	Description	Default
7:6	UDF_REF_D2	R/W	Flag indicating the type of field for starting address <ul style="list-style-type: none"> <li>• 11 = reserved</li> <li>• 10 = end of IP header (including IPv4 option)</li> <li>• 01 = end of Ether Type</li> <li>• 00 = end of Tag</li> </ul>	0
5:0	UDF_OFFSET_D2	R/W	The offset used for UDF_D2 which is used in Slice 2. The number counts from the reference port of frame. Rx port extracts 16 bits of data from the corresponding location for CFP lookup. Unit: 32 bits (4-bytes)	0

## CFP UDF D3 Control Register (Page 22h/Addr 33h)

**Table 232: CFP UDF D3 Control Register (Page 22h: Address 33h)**

Bit	Name	R/W	Description	Default
7:6	UDF_REF_D3	R/W	Flag indicating the type of field for starting address <ul style="list-style-type: none"> <li>• 11 = reserved</li> <li>• 10 = end of IP header (including IPv4 option)</li> <li>• 01 = end of Ether Type</li> <li>• 00 = end of Tag</li> </ul>	0

**Table 232: CFP UDF D3 Control Register (Page 22h: Address 33h)**

Bit	Name	R/W	Description	Default
5:0	UDF_OFFSET_D3	R/W	The offset used for UDF_D3 which is used in Slice 2. The number counts from the reference port of frame. Rx port extracts 16 bits of data from the corresponding location for CFP lookup. Unit: 32 bits (4-bytes)	0

## CFP UDF D4 Control Register (Page 22h/Addr 34h)

**Table 233: CFP UDF D4 Control Register (Page 22h: Address 34h)**

Bit	Name	R/W	Description	Default
7:6	UDF_REF_D4	R/W	Flag indicating the type of field for starting address <ul style="list-style-type: none"> <li>• 11 = reserved</li> <li>• 10 = end of IP header (including IPv4 option)</li> <li>• 01 = end of Ether Type</li> <li>• 00 = end of Tag</li> </ul>	0
5:0	UDF_OFFSET_D4	R/W	The offset used for UDF_D4 which is used in Slice 2. The number counts from the reference port of frame. Rx port extracts 16 bits of data from the corresponding location for CFP lookup. Unit: 32 bits (4-bytes)	0

## CFP UDF D5 Control Register (Page 22h/Addr 35h)

**Table 234: CFP UDF D5 Control Register (Page 22h: Address 35h)**

Bit	Name	R/W	Description	Default
7:6	UDF_REF_D5	R/W	Flag indicating the type of field for starting address <ul style="list-style-type: none"> <li>• 11 = reserved</li> <li>• 10 = end of IP header (including IPv4 option)</li> <li>• 01 = end of Ether Type</li> <li>• 00 = end of Tag</li> </ul>	0
5:0	UDF_OFFSET_D5	R/W	The offset used for UDF_D5 which is used in Slice 2. The number counts from the reference port of frame. Rx port extracts 16 bits of data from the corresponding location for CFP lookup. Unit: 32 bits (4-bytes)	0

## CFP UDF D6 Control Register (Page 22h/Addr 36h)

*Table 235: CFP UDF D6 Control Register (Page 22h: Address 36h)*

<b>Bit</b>	<b>Name</b>	<b>R/W</b>	<b>Description</b>	<b>Default</b>
7:6	UDF_REF_D6	R/W	Flag indicating the type of field for starting address <ul style="list-style-type: none"> <li>• 11 = reserved</li> <li>• 10 = end of IP header (including IPv4 option)</li> <li>• 01 = end of Ether Type</li> <li>• 00 = end of Tag</li> </ul>	0
5:0	UDF_OFFSET_D6	R/W	The offset used for UDF_D6 which is used in Slice 2. The number counts from the reference port of frame. Rx port extracts 16 bits of data from the corresponding location for CFP lookup. Unit: 32 bits (4-bytes)	0

## CFP UDF D7 Control Register (Page 22h/Addr 37h)

*Table 236: CFP UDF D7 Control Register (Page 22h: Address 37h)*

<b>Bit</b>	<b>Name</b>	<b>R/W</b>	<b>Description</b>	<b>Default</b>
7:6	UDF_REF_D7	R/W	Flag indicating the type of field for starting address <ul style="list-style-type: none"> <li>• 11 = reserved</li> <li>• 10 = end of IP header (including IPv4 option)</li> <li>• 01 = end of Ether Type</li> <li>• 00 = end of Tag</li> </ul>	0
5:0	UDF_OFFSET_D7	R/W	The offset used for UDF_D7 which is used in Slice 2. The number counts from the reference port of frame. Rx port extracts 16 bits of data from the corresponding location for CFP lookup. Unit: 32 bits (4-bytes)	0

## Page 30h: QoS Registers

**Table 237: QoS Registers (Page 30h)**

<b>Address</b>	<b>Bits</b>	<b>Description</b>
00h–0Fh	Reserved	
10h–17h	64	“QoS Control Register (Page 30h/Addr 10h–17h)” on page 287
18h–1Fh	64	“QoS 802.1p Enable Register (Page 30h/Addr 18h–1Fh)” on page 288
20h–27h	64	“QoS DiffServ Enable Register (Page 30h/Addr 20h–27h)” on page 289
28h–2Fh	64	“QoS Pause Enable Register (Page 30h/Addr 28h–2Fh)” on page 290
30h–31h	16	“Priority Threshold Register (Page 30h/Addr 30h–31h)” on page 290
–	Reserved	
40h–47h	64	“DiffServ DSCP Priority Register (Page 30h/Addr 40h–4Fh)” on page 291
48h–4Fh	64	DiffServ DSCP Priority register 2
58h–5Fh	16	“QoS Reason Code Enable Register (Page 30h/Addr 58h–59h)” on page 292
60h	Reserved	
F0h–F7h	64	SPI Data I/O[0:7]
F8h–FDh	Reserved	
FEh	8	SPI Status
FFh	8	Page Register

## QoS Control Register (Page 30h/Addr 10h–17h)

**Table 238: QoS Control Register (Pages: 30h, Address 10h–17h)**

Bit	Name	R/W	Description	Default
63	CPU Control Enable	R/W	<ul style="list-style-type: none"> <li>1 = Register values control the port-based priority settings. This includes:               <ul style="list-style-type: none"> <li>– QOS_Enable setting (bit 59:58 of this register).</li> <li>– Flow control enable/disable is controlled on a per- port basis in the “<a href="#">QoS Pause Enable Register (Page 30h/Addr 28h–2Fh)</a>” on page 290.</li> </ul> </li> <li>0 = Reserved.</li> </ul>	1

## QoS 802.1p Enable Register (Page 30h/Addr 18h–1Fh)

**Table 239: QoS 802.1p Enable Register (Page 30h: Address 18h–1Fh)**

<b>Bit</b>	<b>Name</b>	<b>R/W</b>	<b>Description</b>	<b>Default</b>
63:53	RSVD	RO	Reserved Write default. Ignore on read.	0
52:24	QOS_1P_EN	R/W	802.1p QoS enable bit for per-port. A 29-bit mask which selectively allows any port with its corresponding bit set, to enable 802.1p QoS. <ul style="list-style-type: none"> <li>• Bit 52 = Giga Port G3</li> <li>• Bit 51 = Giga Port G2</li> <li>• Bit 50 = GigaPort G1</li> <li>• Bit 49 = GigaPort G0</li> <li>• Bit 48 = IMP</li> <li>• Bits 47:24 = 10/100 ports [port 47-port 24]</li> </ul>	1E-FFFF-FF
23:0	RSVD	–	Reserved	0

## QoS DiffServ Enable Register (Page 30h/Addr 20h–27h)

*Table 240: QoS DiffServ Enable Register (Page 30h: Address 20h–27h)*

<b>Bit</b>	<b>Name</b>	<b>R/W</b>	<b>Description</b>	<b>Default</b>
63:53	RSVD	RO	Reserved Write default. Ignore on read.	0
52:24	QoS_Diff_EN	R/W	DiffServ QoS enable bit for per-port. A 29-bit mask which selectively allows any port with its corresponding bit set, to enable DiffServ QoS. <ul style="list-style-type: none"> <li>• Bit 52 = GigaPort G3</li> <li>• Bit 51 = GigaPort G2</li> <li>• Bit 50 = GigaPort G1</li> <li>• Bit 49 = GigaPort G0</li> <li>• Bit 48 = IMP</li> <li>• Bits 47:24 = 10/100 ports [port 47-port 24]</li> </ul>	0
23:0	RSVD	–	Reserved	0

## QoS Pause Enable Register (Page 30h/Addr 28h–2Fh)

**Table 241: QoS Pause Enable Register (Page 30h: Address 28h–2Fh)**

Bit	Name	R/W	Description	Default
63:53	RSVD	RO	Reserved Write default. Ignore on read.	0
52:49	GE_PAUSE_EN	R/W	Per port QoS PAUSE Enable bit. <ul style="list-style-type: none"> <li>Bit 52 = GigaPort G3</li> <li>Bit 41 = GigaPort G2</li> <li>Bit 50 = GigaPort G1</li> <li>Bit 49 = GigaPort G0</li> </ul>	0
48	IMP_PAUSE_EN	R/W	Per port QoS PAUSE Enable bit. <ul style="list-style-type: none"> <li>Bit 48 = IMP or as a network port.</li> </ul>	0
47:24	FE_PAUSE_EN	R/W	Per port QoS PAUSE Enable bit. A 24-bit mask which selectively allows any port with its corresponding bit set, to enable PAUSE. <ul style="list-style-type: none"> <li>Bits 47:24 = 10/100 ports [port 47-port 24]</li> </ul>	0
23:0	RSVD	–	Reserved	0

Note: When software control of QoS is enabled by asserting the QOS\_Enable, bits[59:58] of the “QoS Control Register (Page 30h/Addr 10h–17h)” on page 287, the QoS PAUSE Enable of individual port is controlled by setting:

- 0 = Half-duplex back pressure and full-duplex flow control are disabled. Only dropping of frames is supported on the given port.
- 1 = Individual port supports half-duplex back pressure and full-duplex flow control.

However, the per port PAUSE\_EN state (if enabled) allows transmission of the Pause frame only from the switch when buffers are near capacity. When the link partner sends Pause frame, the switch does not pause transmission. Any change of state on PAUSE\_EN has neither effect on the “Pause Status Summary Register (Page 02h/Addr 30h–37h)” on page 203.

## Priority Threshold Register (Page 30h/Addr 30h–31h)

**Table 242: Priority Threshold Register (Page 30h: Address 30h–31h)**

Bit	Name	R/W	Description	Default
15:14	802.1p Priority Tag 111	R/W	These two bits are used to assign priority queue of tag 111.	3h
13:12	802.1p Priority Tag 110	R/W	These two bits are used to assign priority queue of tag 110.	3h
11:10	802.1p Priority Tag 101	R/W	These two bits are used to assign priority queue of tag 101.	2h
9:8	802.1p Priority Tag 100	R/W	These two bits are used to assign priority queue of tag 100.	2h
7:6	802.1p Priority Tag 011	R/W	These two bits are used to assign priority queue of tag 011.	1h

**Table 242: Priority Threshold Register (Page 30h: Address 30h–31h)**

Bit	Name	R/W	Description	Default
5:4	802.1p Priority Tag 010	R/W	These two bits are used to assign priority queue of tag 010.	1h
3:2	802.1p Priority Tag 001	R/W	These two bits are used to assign priority queue of tag 001.	0h
1:0	802.1p Priority Tag 000	R/W	These two bits are used to assign priority queue of tag 000.	0h

## DiffServ DSCP Priority Register (Page 30h/Addr 40h–4Fh)

Register 40h to register 4Fh are used to assign priority to different Differentiated Service. To provides 4 priority queues and 64 different traffic classes, a 64x2 table is needed. Each entry represents one traffic class. Two bits in an entry represents the priority of that traffic.

Table 243 and Table 244 define four entries: the remaining 60 traffic classes have the same format (they are not represented in this document).

**Table 243: DiffServ DSCP Priority Register 1 (Page 30h: Address 40h–47h)**

Bit	Name	R/W	Description	Default
63:62	Priority of DSCP=011111	R/W	See detail description above.	0
.....	.....	R/W		
7:6	Priority of DSCP=000011	R/W	See detail description above.	0
5:4	Priority of DSCP=000010	R/W	See detail description above.	0
3:2	Priority of DSCP=000001	R/W	See detail description above.	0
1:0	Priority of DSCP=000000	R/W	See detail description above.	0

**Table 244: DiffServ DSCP Priority Register 2 (Page 30h: Address 48h–4Fh)**

Bit	Name	R/W	Description	Default
63:62	Priority of DSCP=111111	R/W	See detail description above.	0
.....	.....	R/W		
7:6	Priority of DSCP=100011	R/W	See detail description above.	0
5:4	Priority of DSCP=100010	R/W	See detail description above.	0
3:2	Priority of DSCP=100001	R/W	See detail description above.	0
1:0	Priority of DSCP=100000	R/W	See detail description above.	0

## QoS Reason Code Enable Register (Page 30h/Addr 58h–59h)

**Table 245: QoS Reason Code Enable Register (Page 30h: Address 58h–59h)**

<i>Bit</i>	<i>Name</i>	<i>R/W</i>	<i>Description</i>	<i>Default</i>
15:12	RSVD	–	Reserved	0
11:10	PRI_EXCEPT	R/W	To assign priority queue of Reason Code = EXCEPTION / FLOODING packets	01
9:8	PRI_PROTOCOL_SNOOP	R/W	To assign priority queue of Reason Code = PROTOCOL SNOOPING packets	10
7:6	PRI_PROTOCOL_TERM	R/W	To assign priority queue of Reason Code = PROTOCOL TERMINATION packets	11
5:4	PRI_SWITCH	R/W	To assign priority queue of Reason Code = SWITCH packets	10
3:2	PRI_SA_LEARN	R/W	To assign priority queue of Reason Code = SA LEARNING packets	0

## 802.1Q Control 0 Register (Page 34h/Addr 00h)

Table 252: 802.1Q Control 0 Register (Pages: 34h, Address 00h)

Bit	Name	R/W	Description	Default
7	EN_1QVLAN	R/W	Enable 802.1Q VLAN. When set to 1, enable 802.1Q VLAN function.	0
6:5	VID_MAC Control	R/W	ARL Table Hashing Control. When 802.1Q VLAN is enabled, these bits determine the ARL Table hashing scheme. <ul style="list-style-type: none"> <li>11: Use both [VID, MAC].</li> <li>10: Reserved.</li> <li>01: Reserved.</li> <li>00: Use only [MAC].</li> </ul>	11
4	EN_DROP_VID_MISS	R/W	Enable Drop VID Miss Frames When asserted, any incoming frames with a matching DA, but not VLAN ID, are dropped.	0
3:0	RSVD	–	Reserved	0x2

## 802.1Q Control 1 Register (Page 34h/Addr 01h)

Table 253: 802.1Q Control 1 Register (Pages: 34h, Address 01h)

Bit	Name	R/W	Description	Default
7	Reserved	RO	Reserved	0
6	IPMC_UntagMap_Chk	R/W	Bypass IP MultiCast VLAN Untag_Map Check. <ul style="list-style-type: none"> <li>1: Enables checking IPMC frame against VLAN Untag_Map.</li> <li>0: When asserted disables checking IPMC frame against VLAN Untag_Map.</li> </ul>	0
5	IPMC_FwdMap_Chk	R/W	Bypass IP MultiCast VLAN Fwd_Map Check. <ul style="list-style-type: none"> <li>1: Enables checking IPMC frame against VLAN Fwd_Map.</li> <li>0: When asserted disables checking IPMC frame against VLAN Fwd_Map.</li> </ul>	0
4	RSVD	RO	Reserved Write default. Ignore on read.	0

**Table 253: 802.1Q Control 1 Register (Pages: 34h, Address 01h) (Cont.)**

<b>Bit</b>	<b>Name</b>	<b>R/W</b>	<b>Description</b>	<b>Default</b>
3	Rsvd MC_UntagMap_Chk	R/W	Reserved MultiCast (except GMRP and GVRP) VLAN Untag_Map Check. <ul style="list-style-type: none"> <li>• 1: When asserted enables checking reserved MC frame against VLAN Untag_Map. <ul style="list-style-type: none"> <li>– For untagged incoming packets, check against VLAN Untag_Map from the port default tag.</li> </ul> </li> <li>• 0: Disables checking reserved MC frame against VLAN Untag_Map. <ul style="list-style-type: none"> <li>– When incoming packet is untagged, port default tag is stripped on egress.</li> <li>– A tagged incoming packet is tagged on egress.</li> </ul> </li> </ul>	0
2	Rsvd MC_FwdMap_Chk	R/W	Reserved MultiCast (except GMRP and GVRP) VLAN Fwd_Map Check. <ul style="list-style-type: none"> <li>• 1: When asserted enables checking reserved MC frame against VLAN Fwd_Map. <ul style="list-style-type: none"> <li>– For untagged incoming packets, check against VLAN Fwd_Map from the port default tag.</li> </ul> </li> <li>• 0: Disables checking reserved MC frame against VLAN Fwd_Map. <ul style="list-style-type: none"> <li>– For untagged incoming packets, use VLAN Fwd_Map from the port default tag.</li> </ul> </li> </ul>	0
1	Special Entry MC_UntagMap_Chk	R/W	Special Entry MAC Untag Map Check. When an ingress MAC DA matches what is defined in either Multiport Address 1 or Multiport Address 2 register, the frame bypasses ARL checking. The forwarding vector for this frame is determined by either Multi Vector 1 or Multi Vector 2 register respectively. <ul style="list-style-type: none"> <li>• 1: When asserted enables checking reserved MC frame against VLAN Untag_Map. <ul style="list-style-type: none"> <li>– For untagged incoming packets, check against VLAN Untag_Map from the port default tag.</li> </ul> </li> <li>• 0: Disables checking reserved MC frame against VLAN Untag_Map. <ul style="list-style-type: none"> <li>– When incoming packet is untagged, port default tag is stripped on egress.</li> <li>– A tagged incoming packet is tagged on egress.</li> </ul> </li> </ul>	0

**Table 253: 802.1Q Control 1 Register (Pages: 34h, Address 01h) (Cont.)**

<b>Bit</b>	<b>Name</b>	<b>R/W</b>	<b>Description</b>	<b>Default</b>
0	Special Entry MC_FwdMap_Chk	R/W	<p>Special Entry MAC Forward Map Check.</p> <p>When an ingress MAC DA matches what is defined in either Multiport Address 1 or Multiport Address 2 register, the frame bypasses ARL checking. The forwarding vector for this frame is determined by either Multi Vector 1 or Multi Vector 2 register respectively.</p> <ul style="list-style-type: none"> <li>• 1: When asserted enables checking reserved MC frame against VLAN Fwd_Map. <ul style="list-style-type: none"> <li>– For untagged incoming packets, check against VLAN Fwd_Map from the port default tag.</li> </ul> </li> <li>• 0: Disables checking reserved MC frame against VLAN Fwd_Map. <ul style="list-style-type: none"> <li>– For untagged incoming packets, use VLAN Fwd_Map from the port default tag.</li> </ul> </li> </ul>	0

## 802.1Q Control 2 Register (Page 34h/Addr 02h)

Table 254: 802.1Q Control 2 Register (Pages: 34h, Address 02h)

Bit	Name	R/W	Description	Default
7	RSVD	R/W	Reserved Write as default. Ignore on read.	0
6	GMRP/GVRP UntagMap_Chk	R/W	GMRP or GVRP Untag_Map Check <ul style="list-style-type: none"> <li>• 1: When asserted enables checking GMRP and GVRP frame against Untag_Map.</li> <li>• 0: Disables checking GMRP and GVRP frame against Untag_Map.</li> </ul> <b>Note:</b> This feature does not apply to IMP configured as a management port.	0
5	GMRP/ GVRP_FwdMap_Chk	R/W	GMRP or GVRP VLAN Fwd_Map Check <ul style="list-style-type: none"> <li>• 1: When asserted enables checking GMRP or GVRP frame against VLAN Fwd_Map.</li> <li>• 0: Disables checking GMRP or GVRP frame against VLAN Fwd_Map.</li> </ul> <b>Note:</b> This feature does not apply to IMP configured as a management port.	0
4	RSVD	R/W	Reserved Write as default. Ignore on read.	0
3	RSVD	RO	Reserved. Write as default. Ignore on read.	0
2	IMP Mngt Frm_FwdMap_Chk	R/W	MII Management Frame VLAN Fwd_Map Check <ul style="list-style-type: none"> <li>• 1: When asserted disables checking frames received at IMP management port against VLAN Fwd_Map.</li> <li>• 0: Enables checking frame received at IMP management port against VLAN Fwd_Map.</li> </ul> <b>Note:</b> An untagged frame received by the IMP management port is never tagged.	0
1:0	RSVD	RO	Reserved. Write as default. Ignore on read.	0

## 802.1Q Control 3 Register (Page 34h/Addr 08h–0Fh)

**Note:** The offset address for this register is out of sequence.

**Table 255: 802.1Q Control 3 Register (Pages: 34h, Address 08h–0Fh)**

Bit	Name	R/W	Description	Default
63	VID_FFF	R/W	VID Special Handling Any frame with VID = FFF is treated 1 = As normal frame. 0 = As VID violation frame. (Default)	0
62:53	RSVD	RO	Reserved. Write default. Ignore on read.	0
52:24	Enable Drop Non 1Q Frame	R/W	Enable Drop Non 1Q Frames. A 29-bit mask corresponds to the physical ports on the chip. Setting any bit to 1 enables non_1Q (untagged or priority tagged) ingress frame to be dropped by the corresponding port. <ul style="list-style-type: none"> <li>• Bit 52 = GigaPort G3</li> <li>• Bit 51 = GigaPort G2</li> <li>• Bit 50 = GigaPort G1</li> <li>• Bit 49 = GigaPort G0</li> <li>• Bit 48 = IMP.</li> <li>• Bits 47:24 = 10/100 ports [port 47-port 24]</li> </ul>	0
23:0	RSVD	–	Reserved	0

## 802.1Q Control 4 Register (Page 34h/Addr 03h)

Table 256: 802.1Q Control 4 Register (Pages: 34h, Address 03h)

Bit	Name	R/W	Description	Default																		
7:6	Ingress_VID_check	R/W	<p>Perform ingress VLAN source port membership check. Ingress VID violation is detected when the source port is not found in the VLAN Fwd_Map that is referred to by the ingress VID.</p> <ul style="list-style-type: none"> <li>00: Forward ingress VID violation frame but do not learn SA into ARL table.</li> <li>01: Drop frame if ingress VID violation is detected.</li> <li>10: Bypass checking for ingress VID violation but SA is learned into ARL table.</li> </ul> <p><b>Note:</b> Ingress_VID_check does not apply to the IMP configured as management port.</p>	10																		
5	Mngt_Rcv_GVRP	R/W	<p>Forward GVRP frame to management port</p> <p>When set this bit to 1, forward GVRP frames to management port.</p>	0																		
4	Mngt_Rcv_GMRP	R/W	<p>Forward GMRP frame to management port</p> <p>When set this bit to 1, forward GMRP frames to management port.</p>	0																		
3:2	RSVD	RO	<p>Reserved.</p> <p>Write default. Ignore on read.</p>	0																		
1	VLAN_VLAN_OPT	R/W	<p>VLAN to VLAN Table Optional Control (Revision B Silicon only). This bit selects the index used to search the VLAN to VLAN table.</p> <p><b>Note:</b> PORTID is referred to as the physical port ID. The logical port ID starts from 0, 1, 2, ... The physical port ID starts from 24, 25, 26..... The logical to physical port ID mapping is as follows:</p> <table border="1" style="margin-left: 40px;"> <thead> <tr> <th>Logical Port ID</th> <th>PORTID</th> </tr> </thead> <tbody> <tr><td>0</td><td>24</td></tr> <tr><td>1</td><td>25</td></tr> <tr><td>2</td><td>26</td></tr> <tr><td>...</td><td>...</td></tr> <tr><td>23</td><td>47</td></tr> <tr><td>IMP</td><td>48</td></tr> <tr><td>GigaPort G0</td><td>49</td></tr> <tr><td>GigaPort G1</td><td>50</td></tr> </tbody> </table> <ul style="list-style-type: none"> <li>0 = Select VID[11:0] as the index</li> <li>1 = Select {(PORTID-24)[4:0], VID[6:0]} as the index</li> </ul>	Logical Port ID	PORTID	0	24	1	25	2	26	...	...	23	47	IMP	48	GigaPort G0	49	GigaPort G1	50	0
Logical Port ID	PORTID																					
0	24																					
1	25																					
2	26																					
...	...																					
23	47																					
IMP	48																					
GigaPort G0	49																					
GigaPort G1	50																					
0	RSVD	RO	<p>Reserved.</p> <p>Write default. Ignore on read.</p>	0																		

## 802.1Q Control 5 Register (Page 34h/Addr 04h)

**Table 257: 802.1Q Control 5 Register (Pages: 34h, Address 04h)**

Bit	Name	R/W	Description	Default
7	RSVD	–	Reserved	0
6	Preserve_non_1Q	R/W	Egress non_1Q frame control. <ul style="list-style-type: none"> <li>1 = Preserve ingress non_1Q frames.</li> <li>0 = Apply VLAN rules if enabled to ingress non_1Q frames.</li> </ul>	0
5	Dis_Egress_Dir_Bypass_Trunking	R/W	Disable Egress Direct Frame Trunking Rule Check. <ul style="list-style-type: none"> <li>1 = Egress direct frames from the host management system do not bypass trunking rule check.</li> <li>0 = Allow egress direct frames from the host management system to bypass.</li> </ul>	0
4	RSVD	RO	Reserved. Write as default. Ignore on read.	1
3	drop_Vtable_miss	R/W	Ingress VID is pointing to a nonvalid entry in the VLAN table. When set to: <ul style="list-style-type: none"> <li>1, a frame with VLAN table miss is dropped.</li> <li>0, a frame with VLAN table miss is trapped to IMP.</li> </ul>	0
2	RSVD	RO	Reserved. Write default. Ignore on read.	0
1	Bypass_Mngt_Rx_CRC_Chk	R/W	Bypass CRC Check at Management port. <ul style="list-style-type: none"> <li>1 = The management port with CPU on it ignores any CRC from BRCM tagged frame or Ethernet frame.</li> <li>0 = The management port checks both CRCs.</li> </ul> <p><b>Note:</b> With this option, CPU does not need to calculate CRC for BRCM tagged frame. However it is still required to include a place holder for the BRCM tag CRC.</p>	0
0	RSVD	R/W	Write default. Ignore on read.	0

**Note:** For normal operation, Broadcom recommends to set bits 3, 1, and 0 of this register to 1.

## 802.1Q Default Port Tag Register (Page 34h/Addr 40h–79h)

See [Table 259: “Default 802.1Q Tag,” on page 308.](#)

**Table 258: 802.1Q Default Port Tag Register (Page: 34h, Address 40h–79h)**

<b>Bit</b>	<b>Name</b>	<b>R/W</b>	<b>Description</b>	<b>Default</b>
Addr 40h–41h bit [15:0]	Default Tag Port 24	R/W	Default 802.1Q tag assigned to port 24.	0018h

## MII Control Register (Page A0h–B7h/Addr 00h–01h)

**Table 295: MII Control Register (Pages A0h–B7h, Address 00h–01h)**

Bit	Name	R/W	Description	Default
15	Reset	R/W (SC)	<ul style="list-style-type: none"> <li>1 = PHY reset.</li> <li>0 = Normal operation.</li> </ul>	0
14	Loopback	R/W	<ul style="list-style-type: none"> <li>1 = Loopback mode.</li> <li>0 = Normal operation.</li> </ul>	0
13	Forced Speed Selection	R/W	<ul style="list-style-type: none"> <li>1 = 100 Mbps.</li> <li>0 = 10 Mbps.</li> </ul>	1
12	Auto-negotiation Enable	R/W	<ul style="list-style-type: none"> <li>1 = Auto-negotiation enable.</li> <li>0 = Auto-negotiation disable.</li> </ul>	1
11	Power Down	RO	<ul style="list-style-type: none"> <li>0 = Normal operation.</li> <li>The BCM53262M does not implement a low-power mode.</li> </ul>	0
10	Isolate	R/W	<ul style="list-style-type: none"> <li>1 = Electrically isolate PHY from MII.</li> <li>0 = Normal operation.</li> </ul>	0
9	Restart Auto-negotiation	R/W (SC)	<ul style="list-style-type: none"> <li>1 = Restart auto-negotiation process.</li> <li>0 = Normal operation.</li> </ul>	0
8	Duplex Mode	R/W	<ul style="list-style-type: none"> <li>1 = Full-duplex.</li> <li>0 = Half-duplex.</li> </ul>	0
7:0	Reserved	RO	Ignore when read.	0

**Note:** R/W = Read/Write, RO = Read only, SC = Self Clear, LL = Latched Low, LH = Latched High, LL and LH Clear after read operation.

### Reset

To reset an individual part PHY, the BCM53262M by software control, a 1 must be written to bit 15 of the Control register using an MII write operation. The bit clears itself after the reset process is complete, and need not be cleared using a second MII write. Writes to other Control register bits have no effect until the reset process is completed, which requires approximately 1  $\mu$ s. Writing a 0 to this bit has no effect. Because this bit is self-clearing, after a few cycles from a write operation, it returns a 0 when read.

### Loopback

An individual part of the BCM53262M can be placed into loopback mode by writing a 1 to bit 14 of the Control register. The loopback mode can be cleared by writing a 0 to bit 14 of the control register, or by resetting the chip. When this bit is read, it returns a 1 when the chip is in software-controlled loopback modes; otherwise it returns a 0.

## Forced Speed Selection

If auto-negotiation is enabled, this bit has no effect on the speed selection. However, if auto-negotiation is disabled by software control, the operating speed of the BCM53262M port can be forced by writing the appropriate value to bit 13 of the Control register. Writing a 1 to this bit forces 100Base-X operation, while writing a 0 forces 10Base-T operation. When this bit is read, it returns the value of the software-controlled forced speed selection only. To read the overall state of forced speed selection, including both hardware and software control, use bit 8 of the Auxiliary Control register.

## Auto-Negotiation Enable

Auto-negotiation is enabled by default. If bit 12 of the Control register is written with a value of 0, auto-negotiation is disabled by software control. Writing a 1 to the same bit of the Control register or resetting the chip re-enables auto-negotiation. When read, this bit returns the value most recently written to this location, or 1 if it has not been written since the last chip reset.

## Power Down

The BCM53262M does not implement a low-power mode.

## Isolate

Each individual PHY can be isolated from its Media Independent Interface by writing a 1 to bit 10 of the Control register. All MII outputs are tri-stated and all MII inputs are ignored. Because the MII management interface is still active, the isolate mode can be cleared by writing a 0 to bit 10 of the control register, or by resetting the chip. When this bit is read, it returns a 1 when the chip is in isolate mode; otherwise it returns a 0.

## Restart Auto-Negotiation

Bit 9 of the Control register is a self-clearing bit that allows the auto-negotiation process to be restarted, regardless of the current status of the auto-negotiation state machine. For this bit to have an effect, auto-negotiation must be enabled. Writing a 1 to this bit restarts the auto-negotiation, while writing a 0 to this bit has no effect. Because the bit is self-clearing after only a few cycles, it always returns a 0 when read. The operation of this bit is identical to bit 9 of the Auxiliary Multiple PHY register.

## Duplex Mode

By default, at reset this bit indicates BCM53262M half-duplex mode. If the Auto-negotiation is enabled, this bit has no effect on the duplex selection. The chip can be forced into full-duplex mode by writing a 1 to bit 8 of the Control register while auto-negotiation is disabled. Half-duplex mode can be resumed by writing a 0 to bit 8 of the control register, or by resetting the chip.

## Reserved Bits

All reserved MII register bits must be written as 0 at all times. Ignore the BCM53262M output when these bits are read.

## MII Status Register (Page A0h–B7h/Addr 02h–03h)

**Table 296: MII Status Register (Pages A0h–B7h, Address 02h–03h)**

Bit	Name	R/W	Description	Default
15	100Base-T4 Capability	RO	0 = Not 100Base-T4 capable.	0
14	100Base-TX FDX Capability	RO	1 = 100Base-TX full-duplex capable.	1
13	100Base-TX Capability	RO	1 = 100Base-TX half-duplex capable.	1
12	10Base-T FDX Capability	RO	1 = 10Base-T full-duplex capable.	1
11	10Base-T Capability	RO	1 = 10Base-T half-duplex capable.	1
10:7	Reserved	RO	Ignore when read.	0
6	MF Preamble Suppression	R/W	<ul style="list-style-type: none"> <li>1 = Preamble may be suppressed.</li> <li>0 = Preamble always required.</li> </ul>	0
5	Auto-negotiation Complete	RO	<ul style="list-style-type: none"> <li>1 = Auto-negotiation process completed.</li> <li>0 = Auto-negotiation process not completed.</li> </ul>	0
4	Remote Fault	RO LH	<ul style="list-style-type: none"> <li>1 = Remote/far-end fault condition detected.</li> <li>0 = No remote/far-end fault condition detected.</li> </ul>	0
3	Auto-negotiation Capability	RO	<ul style="list-style-type: none"> <li>1 = Auto-negotiation capable.</li> <li>0 = Not auto-negotiation capable.</li> </ul>	1
2	Link Status	RO LL	<ul style="list-style-type: none"> <li>1 = Link is up (Link Pass state).</li> <li>0 = Link is down (Link Fail state).</li> </ul>	0
1	Jabber Detect	RO LH	<ul style="list-style-type: none"> <li>1 = Jabber condition detected.</li> <li>0 = No jabber condition detected.</li> </ul>	0
0	Extended Capability	RO	1 = Extended register capable.	1

**Note:** R/W = Read/Write, RO = Read only, SC = Self Clear, LL = Latched Low, LH = Latched High, LL & LH Clear after read operation.

### 100Base-T4 Capability

The BCM53262M is not capable of 100Base-T4 operation, and returns a 0 when bit 15 of the status register is read.

### 100Base-X Full-Duplex Capability

The BCM53262M is capable of 100Base-X full-duplex operation, and returns a 1 when bit 14 of the Status register is read.

### 100Base-X Half-Duplex Capability

The BCM53262M is capable of 100Base-X half-duplex operation, and returns a 1 when bit 13 of the Status register is read.

## 10Base-T Full-Duplex Capability

The BCM53262M is capable of 10Base-T full-duplex operation, and returns a 1 when bit 12 of the Status register is read.

## 10Base-T Half-Duplex Capability

The BCM53262M is capable of 10Base-T half-duplex operation, and returns a 1 when bit 11 of the Status register is read.

## Reserved Bit

Ignore the BCM53262M output when these bits are read.

## MF Preamble Suppression

This bit is the only writable bit in the Status register. Setting this bit to a 1 allows subsequent MII management frames to be accepted with or without the standard preamble pattern. When Preamble Suppression is enabled, only 2 preamble bits are required between successive Management Commands, instead of the normal 32.

## Auto-Negotiation Complete

Bit 5 of the Status register returns a 1 if the auto-negotiation process has been completed and the contents of registers 4, 5 and 6 are valid.

## Remote Fault

When set at the completion of auto-negotiation, indicates that a remote fault condition has been signaled by the link partner. When set in 100Base-FX mode, indicates that a far-end fault condition has been detected. This bit is latched high, and self-clears when read. Is immediately set once again in FX mode after clearing if the far-end fault condition remains true.

## Auto-Negotiation Capability

The BCM53262M can perform IEEE auto-negotiation, and returns a 1 when bit 4 of the Status register is read, regardless of whether the auto-negotiation function has been disabled.

## Link Status

The BCM53262M returns a 1 on bit 2 of the Status register when the link state machine is in Link Pass, indicating that a valid link has been established. Otherwise, it returns 0. When a link failure occurs after the Link Pass state has been entered, the Link Status bit is latched at 0 and remains so until the bit is read. After the bit is read, it becomes 1 if the Link Pass state has been entered again.

## Jabber Detect

10Base-T operation only. The BCM53262M returns a 1 on bit 1 of the Status register if a jabber condition has been detected. After the bit is read, or if the chip is reset, it reverts to 0.

## Extended Capability

The BCM53262M supports extended capability registers, and returns a 1 when bit 0 of the Status register is read. Several extended registers have been implemented in the BCM53262M, and their bit functions are defined later in this section.

## PHY Identifier Registers (Page A0h–B7h/Addr 04h–07h)

**Table 297: PHY Identifier Registers (Pages A0h–B7h, Addresses 04h–05h and 06h–07h)**

Bit	Name	R/W	Description	Default
15:0	MII Address 00010	RO	PHYID HIGH	0143h
15:0	MII Address 00011	RO	PHYID LOW	BF2Nh <sup>a</sup>

a. Refer to [Table 178 on page 257](#) for the value of N and the associated chip revision.

## Auto-Negotiation Advertisement Register (Page A0h–B7h/Addr 08h–09h)

**Table 298: Auto-Negotiation Advertisement Register (Pages A0h–B7h, Address 08h–09h)**

Bit	Name	R/W	Description	Default
15	Next Page	R/W	<ul style="list-style-type: none"> <li>1 = Next Page Operation supported.</li> <li>0 = Next Page Operation disabled.</li> </ul>	0
14	Reserved	RO	Ignore when Read.	–
13	Remote Fault	R/W	1 = Transmit Remote Fault.	0
12:11	Reserved Technologies	RO	Ignore when Read.	–
10	Advertise Pause Capability	R/W	1 = Pause Operation for full-duplex.	1
9	Advertise 100Base-T4	R/W	0 = Do Not Advertise T4 Capability.	0
8	Advertise 100Base-X FDX	R/W	<ul style="list-style-type: none"> <li>1 = Advertise 100Base-X full-duplex.</li> <li>0 = Do Not Advertise 100Base-X full-duplex.</li> </ul>	1
7	Advertise 100Base-X	R/W	1 = Advertise 100Base-X.	1
6	Advertise 10Base-T FDX	R/W	<ul style="list-style-type: none"> <li>1 = Advertise 10Base-T full-duplex.</li> <li>0 = Do Not Advertise 10Base-T full-duplex.</li> </ul>	1
5	Advertise 10Base-T	R/W	1 = Advertise 10Base-T.	1
4:0	Advertise Selector Field	R/W	Fixed value: indicates 802.3.	00001

## Next Page

The BCM53262M supports the Next Page function. To enable this operation, write a 1 to this bit.

## Remote Fault

Writing a 1 to bit 13 of the Advertisement register sends a Remote Fault indicator to the Link Partner during auto-negotiation. Writing a 0 to this bit or resetting the chip clears the Remote Fault transmission bit. This bit returns the value last written to it, or else 0 if no write has been completed since the last chip reset.

## Reserved Bits

Ignore output when read.

## Pause Operation for Full-Duplex Links

The use of this bit is independent of the negotiated data rate, medium, or link technology. The setting of this bit indicates the availability of additional DTE capability when full-duplex operation is in use. This bit is used by one MAC to communicate Pause Capability to its Link Partner and has no effect on PHY operation.

## Advertisement Bits

Use bits 9:5 of the Advertisement register to customize the ability information transmitted to the Link Partner. The default value for each bit reflects the abilities of the BCM53262M. By writing a 1 to any of the bits, the corresponding ability is transmitted to the Link Partner. Writing a 0 to any bit causes the corresponding ability to be suppressed from transmission. Resetting the chip restores the default bit values. Reading the register returns the values last written to the corresponding bits, or else the default values if no write has been completed since the last chip reset.

## Selector Field

Bits 4:0 of the Advertisement register contain the value 00001, indicating that the chip belongs to the 802.3 class of PHY transceivers

## Auto-Negotiation Link Partner Ability Register (Page A0h–B7h/Addr 0Ah–0Bh)

*Table 299: Auto-Negotiation Link Partner Ability Register (Pages A0h–B7h, Address 0Ah–0Bh)*

<b>Bit</b>	<b>Name</b>	<b>R/W</b>	<b>Description</b>	<b>Default</b>
15	LP Next Page	RO	Link Partner next page bit.	0
14	LP Acknowledge	RO	Link Partner acknowledge bit.	0
13	LP Remote Fault	RO	Link Partner remote fault indicator.	0
12:11	Reserved Technologies	RO	Ignore when read.	000

**Table 299: Auto-Negotiation Link Partner Ability Register (Pages A0h–B7h, Address 0Ah–0Bh)**

<b>Bit</b>	<b>Name</b>	<b>R/W</b>	<b>Description</b>	<b>Default</b>
10	LP Advertise Pause	RO	Link Partner has Pause Capability.	0
9	LP Advertise 100Base-T4	RO	Link Partner has 100Base-T4 capability.	0
8	LP Advertise 100Base-X FDX	RO	Link Partner has 100Base-X FDX capability.	0
7	LP Advertise 100Base-X	RO	Link Partner has 100Base-X capability.	0
6	LP Advertise 10Base-T FDX	RO	Link Partner has 10Base-T FDX capability.	0
5	LP Advertise 10Base-T	RO	Link Partner has 10Base-T capability.	0
4:0	Link Partner Selector Field	RO	Link Partner selector field.	00000

The values contained in the Auto-negotiation Link Partner Ability register are only guaranteed to be valid after auto-negotiation has successfully completed, as indicated by bit 5 of the MII Status register.

## Next Page

Bit 15 of the Link Partner Ability register returns a value of 1 when the Link Partner implements the Next Page function and has Next Page information to transmit.

## Acknowledge

Bit 14 of the Link Partner Ability register is used by auto-negotiation to indicate that a device has successfully received its Link Partner's Link Code Word.

## Remote Fault

Bit 13 of the Link Partner Ability register returns a value of 1 when the Link Partner signals that a remote fault has occurred. The BCM53262M simply copies the value to this register and does not act upon it.

## Reserved Bits

Ignore when read.

## Pause

Indicates that the Link Partner pause bit is set.

## Advertisement Bits

Bits 9:5 of the Link Partner Ability register reflect the abilities of the Link Partner. A 1 on any of these bits indicates that the Link Partner is capable of performing the corresponding mode of operation. Bits 9:5 are cleared any time auto-negotiation is restarted or the BCM53262M is reset.

## Selector Field

Bits 4:0 of the Link Partner Ability register reflect the value of the Link Partner's selector field. These bits are cleared any time auto-negotiation is restarted or the chip is reset.

## Auto-Negotiation Expansion Register (Page A0h–B7h/Addr 0Ch–0Dh)

**Table 300: Auto-Negotiation Expansion Register (Pages A0h–B7h, Address 0Ch–0Dh)**

Bit	Name	R/W	Description	Default
15:5	Reserved	RO	Ignore when read.	
4	Parallel Detection Fault	RO LH	<ul style="list-style-type: none"> <li>1 = Parallel Detection fault.</li> <li>0 = No Parallel Detection fault.</li> </ul>	0
3	Link Partner Next Page Able	RO	<ul style="list-style-type: none"> <li>1 = Link Partner has Next Page capability.</li> <li>0 = Link Partner does not have Next Page capability.</li> </ul>	0
2	Next Page Able	RO	<ul style="list-style-type: none"> <li>1 = Next Page is enabled.</li> <li>0 = Next Page capability.</li> </ul>	–
1	Page Received	RO	<ul style="list-style-type: none"> <li>1 = New page has been received.</li> <li>0 = New page has not been received.</li> </ul>	0
0	Link Partner Auto-negotiation Able	RO LH	<ul style="list-style-type: none"> <li>1 = Link Partner has auto-negotiation capability.</li> <li>0 = Link Partner does not have auto-negotiation capability.</li> </ul>	0

**Note:** R/W = Read/Write, RO = Read only, SC = Self Clear, LL = Latched Low, LH = Latched High, LL and LH clear after read operation.

### Parallel Detection Fault

Bit 4 of the Auto-negotiation Expansion register is a read-only bit that gets latched high when a parallel detection fault occurs in the auto-negotiation state machine. For further details, please consult the IEEE standard. The bit is reset to 0 after the register is read, or when the chip is reset.

### Link Partner Next Page Able

Bit 3 of the Auto-negotiation Expansion register returns a 1 when the Link Partner has Next Page capabilities. It has the same value as bit 15 of the Link Partner Ability register.

### Page Received

Bit 1 of the Auto-negotiation Expansion register is latched high when a new Link Code Word is received from the Link Partner, checked, and acknowledged. It remains high until the register is read, or until the chip is reset.

## Link Partner Auto-Negotiation Able

Bit 0 of the Auto-negotiation Expansion register returns a 1 when the Link Partner is known to have auto-negotiation capability. Before any auto-negotiation information is exchanged, or if the Link Partner does not comply with IEEE auto-negotiation, the bit returns a value of 0.

## Auto-Negotiation Next Page Register (Page A0h–B7h/Addr 0Eh–0Fh)

*Table 301: Next Page Transmit Register (Pages A0h–B7h, Address 0Eh–0Fh)*

<b>Bit</b>	<b>Name</b>	<b>R/W</b>	<b>Description</b>	<b>Default</b>
15	Next Page	R/W	<ul style="list-style-type: none"> <li>1 = Additional Next Page(s) follow.</li> <li>0 = Last page.</li> </ul>	0
14	Reserved	R/W	Ignore when Read.	0
13	Message Page	R/W	<ul style="list-style-type: none"> <li>1 = Message page.</li> <li>0 = Unformatted page.</li> </ul>	1
12	Acknowledge 2	R/W	<ul style="list-style-type: none"> <li>1 = Complies with the message.</li> <li>0 = Cannot comply with message.</li> </ul>	0
11	Toggle	RO	<ul style="list-style-type: none"> <li>1 = Previous value of the transmitted Link Code Word equalled logic 0.</li> <li>0 = Previous value of the transmitted Link Code Word equalled logic one.</li> </ul>	0
10:0	Message/Unformatted Code Field	R/W		1

### Next Page

Indicates whether this is the last Next Page to be transmitted.

### Message Page

Differentiates a Message Page from an Unformatted Page.

### Acknowledge 2

Indicates that a device has the ability to comply with the message.

### Toggle

Used by the Arbitration function to ensure synchronization with the Link Partner during Next Page exchange.

### Message Code Field

An 11-bit-wide field, encoding 2048 possible messages.

## Unformatted Code Field

An 11-bit-wide field, which may contain an arbitrary value.

## Link Partner Next Page Register (Page A0h–B7h/Addr 10h–11h)

*Table 302: Link Partner Next Page Register (Pages A0h–B7h, Address 10h–11h)*

Bit	Name	R/W	Description	Default
15	Next Page	RO	<ul style="list-style-type: none"> <li>1 = Additional Next Page(s) follow.</li> <li>0 = Last page.</li> </ul>	0
14	Reserved	RO	Ignore when Read.	0
13	Message Page	RO	<ul style="list-style-type: none"> <li>1 = Message page.</li> <li>0 = Unformatted page.</li> </ul>	0
12	Acknowledge 2	RO	<ul style="list-style-type: none"> <li>1 = Complies with the message.</li> <li>0 = Cannot comply with message.</li> </ul>	0
11	Toggle	RO	<ul style="list-style-type: none"> <li>1 = Previous value of the transmitted Link Code Word equalled logic 0.</li> <li>0 = Previous value of the transmitted Link Code Word equalled logic one.</li> </ul>	0
10:0	Message/Unformatted Code Field	RO	–	0

### Next Page

indicates whether this is the last Next Page.

### Message Page

Differentiates a Message Page from an Unformatted Page.

### Acknowledge 2

Indicates that Link Partner has the ability to comply with the message.

### Toggle

Used by the Arbitration function to ensure synchronization with the Link Partner during Next Page exchange.

### Message Code Field

An 11-bit-wide field, encoding 2048 possible messages.

## Unformatted Code Field

An 11-bit-wide field, which may contain an arbitrary value.

Broadcom Confidential

11:0	Reserved	RO	Reserved, write as 0, ignore read.	000

**SerDes/SGMII Control 1 (Page B9h–BCh: Address 20H ~ 21H, BLOCK 0)****Table 311: SerDes/SGMII Control1 (Page B9h–BCh: Address 20h–21h, Block 0)**

Bit	Name	R/W	Description	Default
15	Reserved	RO	Reserved, write as 0, ignore read.	0
14	DIS_SD_FILTER	R/W	Filtering the signal detect pin adds hysteresis to the signal to stabilize the readings near the threshold. The status of resulting signal detect, regardless of whether the filter is active, is recorded via “SerDes/SGMII Status 3 (Page B9h–BCh: Address 2Ch–2Dh)” bit[9]. 0 = filter signal detection from pin before using for synchronization. 1 = disable filter for signal detect.	0
13	Global Write	R/W	MDC/MDIO commands addressed to PHYADD 00 will affect all ports that have the Global Write enabled. 0 = Normal operation 1 = Global Write Enabled	0
12	Reserved SERDES_TX_AMP_OVR	RO R/ W	Reserved. 0 = normal operation (selected by SGMII or fiber mode). 1 = override SerDes transmit amplitude from register 1*10h bit 14.	0
11	Counter Select	R/W	Error Counter Register Definition Configures the type of events counted in BER/CRC Error Counter Register (Page 10h ~ 17h: Address 2Eh). 0 = Select CRC errors 1 = Select received packets	0
10	REMOTE_LPBK	R/W	Remote loopback operates in all available speeds. 0 = normal operation. 1 = enable remote loopback (operates in 10/100/1000 speed).	0
9	Reserved ZERO_CD_PHASE	RO R/ W	Reserved 0 = normal operation. 1 = force comma detector phase to zero.	0
8	CD_EN	R/W	0 = disable comma detection 1 = enable comma detection	1
7	CRC_DIS	R/W	0 = enable CRC checker. 1 = disable CRC checker by gating the clock to save power.	1

**Table 311: SerDes/SGMII Control1 (Page B9h-BCh: Address 20h-21h, Block 0) (Cont.)**

<b>Bit</b>	<b>Name</b>	<b>R/W</b>	<b>Description</b>	<b>Default</b>
6	Reserved DIS_PLL_PWRDN	R/W	Reserved 0 = PLL is powered down when Register 22 is set. 1 = PLL is never powered down. (Use this when the MAC/Switch uses the pll_clk125 output).	1
5	SGMII_MSTR	R/W	This bit configures the port to operate in Master mode (typical of PHY device) to allow testing link conditions between two Switch ports. 0 = normal operation. 1 = SGMII mode operates in master PHY mode. If auto-negotiation is enabled, then the local device sends out the following auto-negotiation code word: [15] = 1 [14] = ack [13] = 0 [12] = Register 0, bit 8 [11] = Register 0, bit 6 [10] = Register 0, bit 13 [9:0] = "000000001" To disable the link, set Register 22 = 1. To enable the link, set Register 22 = 0.	0
4	AUTODET_EN	R/W	0 = disable auto-detection (fiber or SGMII mode is set according to bit 0 of this register). 1 = enable auto-detection (fiber and SGMII mode switches each time a auto-negotiation page is received with the wrong selector field in bit 0.)	1
3	INVERT_SD	R/W	0 = use signal detect from pin. 1 = invert signal detect from pin.	0
2	SD_EN	R/W	0 = ignore signal detect from pin. 1 = signal detect from pin must be set in order to achieve synchronization. In SGMII the signal detect is always ignored regardless of the setting of this bit.	0
1	RSVD	R/W	Write as default. Ignore on read.	0
0	FIBER	R/W	0 = SGMII mode. 1 = Fiber SerDes mode.	0

## Analog Transmit Register (Page B9h–BCh: Address 20H–21H Block 1)

Refer to Page 10h ~ 1Fh: Address 3E on how to select this register.

**Table 312: Analog Transmit register (Page B8h–BCh: Address 20h–21h, Block 1)**

Bit	Name	R/W	Description	Default
15:12	Output_Voltage_Level	R/W	Controls the Output Voltage level from 0V ~ 750V in 16 equal steps (Before any loss or variations in resistance). NOTE: This is approximate. The actual voltage swing can be determine by measuring the device on the board.	4'b1100
11:9	Reserved	–	Reserved	3'b100
8:6	Pre_Emphasis_Coeff	R/W	Allows eight possible combinations ranging from 0 percent to 50 percent. 0x7 is 50 percent and 0x0 is 0 percent. The granularity is roughly linear across the eight settings.	0h
5:0	Reserved	R/W	Reserved	6'b10-0000

## SerDes/SGMII Control 2 (Page B9h–BCh: Address 22h–23h)

**Table 313: SerDes/SGMII Control 2 (Page B9h–BCh: Address 22h–23h)**

Bit	Name	R/W	Description	Default
15	Reserved	RO	Reserved, write as 0, ignore read.	0
14	CLEAR_BER_CNTR	R/W SC	1 = Clear bit-error-rate counter "BER/CRC Error Counter Register (Page 10h ~ 17h: Address 2E)" bit[15:8]. 0 = Normal operation.	0
13	TRANSMIT_IDLE_JAM_SEQ_TEST	R/W	This bit activates a transmit idle test sequence for testing purposes. The 16-stage, 10-bit transmit test sequence is forced regardless of link conditions. Setting Force Transmit 1/2 in addition to this bit can modify the idle test sequence. "Force Transmit 1 Register (Page 10h ~ 17h: Address 3Ch)" bit[9:0] will override D16.2 for stage 6 (289h) 1 = Enable transmit idle test sequence 0 = Normal operation	0
12:8	Reserved	RO	Reserved, write as 0, ignore read.	0
7	Reserved DIS_CARRIER_EXT	R/W	Reserved. 0 = Normal operation. 1 = Disable carrier extension in pcs receive.	0
6	Reserved	RO	Reserved, write as 0, ignore read.	0
5	FORCE_XMIT_DATA_ON_TXSIDE	R/W	1 = Allow packets to be transmitted regardless of the condition of the link or synchronization. 0 = Normal operation.	0
4	DIS_RF_SENSE	R/W	0 = Automatically detect remote faults and send remote fault status to link partner via auto-negotiation when fiber mode is selected. SGMII does not support remote faults. 1 = Disable automatic sensing of remote faults, such as auto-negotiation error.	0

**Table 313: SerDes/SGMII Control 2 (Page B9h-BCh: Address 22h-23h) (Cont.)**

Bit	Name	R/W	Description	Default
3	Reserved EN_AN_ ERR_TIMER	ROR/ W	Reserved.0 = Normal operation. 1 = Enable auto-negotiation error timer. Error occurs when timer expires in ability-detect, ack-detect, or idle-detect. When the error occurs, config words of all zeros are sent until an ability match occurs; then the auto-negotiation-enable state is entered.	0
2	Stable Link Filter	R/W	This bit forces the constant sync status for 10ms before establishing link. This prevents potential false-link events in SerDes applications not using Auto-negotiation or the Signal Detect pin. 0 = Normal operation. 1 = Sync-status must be set for a solid 10 ms before a valid link is established when auto-negotiation is disabled.	0
1	DIS_FALSE_LINK	R/W	0 = Normal operation. 1 = Do not allow link to be established when auto-negotiation is disabled and receiving auto-negotiation code words. The link is only established in this case after idles are received. (This bit does not need to be set, if bit 0 is set.)	0
0	EN_PAR_DET	R/W	0 = Disable. 1 = Enable parallel detection. (This turns auto negotiation on and off as needed to properly link up with the link partner. The idles and auto-negotiation code words received from the link partner are used to make this decision.)	1

## SerDes/SGMII Control 3 (Page B9h-BCh: Address 24h-25h)

**Table 314: SerDes/SGMII Control 3 (Page B9h-BCh: Address 24h-25h)**

Bit	Name	R/W	Description	Default
15	Reserved	RO	Reserved, write as 0, ignore read.	0
14	Reserved RXFIFO_GMII_RST	ROR/W	Reserved, write as 0, ignore read.0 = normal operation. 1 = reset receive FIFO and data_out_1000. FIFO remains in reset until this bit is cleared with a software write.	0
13	DIS_TX_CRS	R/W	0 = Normal operation. 1 = Disable generating CRS from transmitting in half-duplex mode. Only receiving generates CRS.	0
12:7	Reserved	RO	Reserved.	0
12	INV_EXT_PHY_CR	R/W	0 = Use receive CRS from PHY pin. 1 = Invert receive CRS from PHY pin.	0
11	EXT_PHY_CRS	R/W	0 = Normal operation. 1 = Use external pin for the PHY receive only CRS output. (Useful in SGMII 10/100 half-duplex applications in order to reduce the collision domain latency. Requires a PHY that generates a receive only CRS output to a pin.)	0

**Table 314: SerDes/SGMII Control 3 (Page B9h-BCh: Address 24h-25h) (Cont.)**

Bit	Name	R/W	Description	Default
10	JAM_FALSE_CRIS	R/W	0 = normal operation. 1 = change false carriers received into packets with preamble only. (Not necessary if MAC uses CRS to determine collision).	0
9	BLK_TXEN	R/W	0 = normal operation. 1 = block txen when necessary to guarantee an IPG of at least 6.5 bytes in 10/100 mode, 7 bytes in 1000 mode.	0
8	FORCE_TXFIFO_ON	R/W	0 = normal operation. 1 = force transmit FIFO to free-run in gigabit mode (Requires clk_in and pll_clk125 to be frequency locked.)	0
7	BYP_TXFIFO_1000	R/W	0 = normal operation. 1 = bypass transmit FIFO in gigabit mode. (Useful for fiber or gigabit only applications where the MAC is using the pll_clk125 as the clk_in port. User must meet timing to the pll_clk125 domain).	0
6	Reserved	RO	Reserved.	1
5:3	Reserved	RO	Reserved.	0
6	FREQ_LOCK_ELAS_TX	R/W	0 = normal operation. 1 = minimum FIFO latency to properly handle a clock which is frequency locked, but out of phase. (Overrides bits [2:1] of this register.) PLL_CLK125 and CLK_IN must be using the same crystal.	1
5	FREQ_LOCK_ELAS_RX	R/W	0 = normal operation 1 = minimum FIFO latency to properly handle a clock which is frequency locked, but out of phase. (Not necessary if MAC uses CRS to determine collision; overrides bits [2:1] of this register.) MAC and PHY must be using the same crystal for this mode to be enabled.	0
4	EARLY_PRE_TX	R/W	0 = normal operation. 1 = send extra bytes of preamble to avoid FIFO latency. (Not necessary if MAC uses CRS to determine collision.)	0
3	EARLY_PRE_RX	R/W	0 = normal operation. 1 = send extra bytes of preamble to avoid FIFO latency. (Used in half-duplex applications to reduce collision domain latency. MAC must send 5 bytes of preamble or less to avoid noncompliant behavior.)	0
2:1	FIFO_ELAS_TX_RX	R/W	00 = supports packets up to 5 KB. 01 = supports packets up to 10 KB. 1X = supports packets up to 13.5 KB.	01
0	Reserved TXFIFO_RST	RO R/W	Reserved. 0 = normal operation. 1 = reset transmit FIFO. FIFO remains in reset until this bit is cleared with a software write.	0

## SerDes/SGMII 1000Base-X Control 4 (Page B9h–BCh: Address 26h–27h)

Table 315: SerDes/SGMII 1000Base-X Control 4 (Page B9h–BCh: Address 26h–27h)

Bit	Name	R/W	Description	Default
15:11	Reserved	RO	Reserved, write as 0, ignore read.	0x00
10	ZERO_DATA_OUT_1000	R/W	0 = normal operation. 1 = zero data_out_1000 when speed is not 1000 Mbps.	0
9	CLEAR_LINKDN	R/W SC	0 = normal operation. 1 = clear latching of link down. Latch_linkdown status bit is register 0*16h bit[[10] enable_latch_linkdown control bit is bit[8] of this register.	0
8	EN_LATCH_LINKDN	R/W	0 = normal operation. 1 = enable latching of link when link is down. Transmit FIFO, receive FIFO and data_out_1000 to remain in reset state until bit[9] of this register is 1.	0
7	LINK_FORCE	R/W	0 = normal operation. 1 = force link on.	0
6	DIG_RESET	R/W	0 = normal operation. 1 = resets digital logic datapath, MII registers are not in reset state.	0
5	ANA_PLL_LOCK_OVR_VAL	R/W	PLL lock status bit override value.	0
4	EN_ANA_PLL_LOCK_OVR	R/W	0 = Override PLL lock status bit with bit [5] of this register. 1 = Use PLL lock status bit from analog directly in analog reset logic.	0
3	DIG_PLL_LOCK_OVR_VAL	R/W	PLL lock status bit override value.	0
2	EN_DIG_PLL_LOCK_OVR	R/W	0 = Override PLL lock status bit with bit [3] of this register. 1 = Use PLL lock status bit from analog directly in digital logic.	0
1	ANA_SD_OVR_VAL	R/W	Analog signal detect status bit override value.	0
0	EN_ANA_SD_OVR	R/W	0 = Override analog signal detect status with bit [1] of this register. 1 = Use analog signal detect.	0

## SerDes/SGMII Status 1 (Page B9h–BCh: Address 28h–29h)

Table 316: SerDes/SGMII Status 1 (Page B9h–BCh: Address 28h–29h)

Bit	Name	R/W	Description	Default
15	TXFIFO_ERR	RO	0 = No transmit FIFO error detected since last read. 1 = Transmit FIFO error detected since last read.	0
14	RXFIFO_ERR	RO	0 = No receive FIFO error detected since last read. 1 = Receive FIFO error detected since last read.	0

**Table 316: SerDes/SGMII Status 1 (Page B9h-BCh: Address 28h-29h) (Cont.)**

Bit	Name	R/W	Description	Default
13	FALSE_CRIS	RO	0 = No false carrier detected since last read. 1 = False carrier detected since last read.	0
12	CRC_ERR	RO	0 = No CRC error detected since last read or detection is disabled via "SerDes/SGMII Control 1 Register (Page 10h ~ 1Fh: Address 20h)" bit[7]. 1 = CRC error detected since last read.	0
11	TX_ERR	RO	0 = No transmit error code detected since last read. 1 = Transmit error code detected since last read (rx_data_error state in PCS receive FSM).	0
10	RX_ERR	RO	0 = No receive error since last read. 1 = Receive error since last read (early_end state in PCS receive FSM).	0
9	CRS_EXT	RO	0 = No carrier extend error since last read. 1 = Carrier extend error since last read (extend_err in PCS receive FSM).	0
8	EARLY_END_EXT	RO	0 = No early end extension since last read. 1 = Early end extension since last read (early_end_ext in PCS receive FSM).	0
7	LINK_CHG	RO	0 = Link status has not changed since last read. 1 = Link status has changed since last read.	0
6	PAUSE_RES_RX	RO	0 = Disable pause receive. 1 = Enable pause receive.	0
5	PAUSE_RES_TX	RO	0 = Disable pause transmit. 1 = Enable pause transmit.	0
4:3	SPEED_STAT	RO	00 = 10 Mbps. 01 = 100 Mbps. 1X = 1000 Mbps.	0x0
2	DUPLEX_STAT	RO	0 = Half-duplex. 1 = Full-duplex.	0
1	LINK_STAT	RO	0 = Link is down. 1 = Link is up.	0
0	SGMII_MODE	RO	0 = SerDes mode (1000Base-X). 1 = SGMII mode.	0

## SerDes/SGMII Status 2 (Page B9h–BCh: Address 2Ah–2Bh)

**Table 317: SerDes/SGMII Status 2 (Page B9h–BCh: Address 2Ah–2Bh)**

Bit	Name	R/W	Description	Default
15	SGMII_MODE_CHG	RO	0 = SGMII/SerDes mode has not changed since last read (fixed in SGMII or SerDes mode). 1 = SGMII/SerDes mode has changed since last read (SGMII mode enabled or disabled). This bit is useful when the auto-detection is enabled in "SerDes/SGMII Control 1 Register (Page 10h ~ 1Fh: Address 20h bit[4])".	0
14	CONS_MISMATCH	RO	A consistency mismatch results from incompatibilities represented in the link code word of the local and remote link partners. SerDes or SGMII mode. 0 = Consistency mismatch has not been detected since last read. 1 = Consistency mismatch detected since last read.	0
13	AN_RES_ERR	RO	0 = Auto-negotiation error has not been detected since last read. 1 = Auto-negotiation error detected since last read.	0
12	SGMII_SEL_MIS	RO	A SGMII selector mismatch occurs when the auto-negotiation page received from the link partner has bit[0] = 0 while local device is in SGMII mode. 0 = SGMII selector mismatch not detected since last read. 1 = SGMII selector mismatch detected since last read.	0
11	SYNC_STAT_FAIL	RO	0 = Sync_status has not failed since last read. 1 = Sync_status has failed since last read (synchronization has been lost).	0
10	SYNC_STAT_OK	RO	0 = Sync_status ok has not been detected since last read. 1 = Sync_status ok detected since last read (synchronization has been achieved).	0
9	RUDI_C	RO	0 = Rudi_c has not been detected since last read. 1 = Rudi_c detected since last read.	0
8	RUDI_I	RO	0 = Rudi_i has not been detected since last read. 1 = Rudi_i detected since last read.	0
7	RUDI_INVALID	RO	0 = Rudi_invalid has not been detected since last read. 1 = Rudi_invalid detected since last read.	0
6	LINK_DN_SYNC_LOSS	RO	0 = Failure condition has not been detected since last read. 1 = A valid link went down due to a loss of synchronization for over 10 ms.	0
5	IDLE_DETECT	RO	0 = Idle detect state not entered since last read. 1 = Idle detect state in auto-negotiation FSM entered since last read.	0

**Table 317: SerDes/SGMII Status 2 (Page B9h-BCh: Address 2Ah-2Bh) (Cont.)**

Bit	Name	R/W	Description	Default
4	CMPLT_ACK	RO	0 = Complete acknowledge state not entered since last read. 1 = Complete acknowledge state in auto-negotiation FSM entered since last read.	0
3	ACK_DETECT	RO	0 = Acknowledge detect state not entered since last read. 1 = Acknowledge detect state in auto-negotiation FSM entered since last read.	0
2	ABILITY_DETECT	RO	0 = Ability detect state not entered since last read. 1 = Ability detect state in auto-negotiation FSM entered since last read.	0
1	AN_DIS_LINK_OK	RO	0 = An_disable_link_ok not entered since last read. 1 = An_disable_link_ok state in auto-negotiation FSM entered since last read.	0
0	AN_EN_LINK_OK	RO	0 = An_enable state has not been entered since last read. 1 = An_enable state in auto-negotiation FSM entered since last read.	0

### SerDes/SGMII Status 3 (Page B9h-BCh: Address 2Ch-2Dh)

**Table 318: SerDes/SGMII Status 3 (Page B9h-BCh: Address 2Ch-2Dh)**

Bit	Name	R/W	Description	Default
15:1011	Reserved	RO	Reserved. Write as 0, ignore read.	0x0
10	LATCH_LINKDN	RO	Reserved.	0
9	Signal Detect Filter Output	RO	This bit represents the output of the Signal Detect filter, regardless of whether the filter is active or not. This status signal is still valid when "SerDes/SGMII Control 1 Register (Page 10h ~ 1Fh: Address 20h)" bit[14] = 1. Noise pulses less than 16 ns wide are still removed whenever the filter is disabled 0 = Output of signal detect is not set. 1 = Output of signal detect filter is set. This signal is used for the PCS synchronization. When the Signal Detect signal is disabled "SerDes/SGMII Control 1 Register (Page 10h ~ 17H: Address 20h)" bit[2] = 0, then the output of the filter is forced high.	0
8	Signal Detect Inversion Output	RO	This status signal is the signal detect result when "SerDes/SGMII Control 1 Register (Page 10h ~ 1Fh: Address 20h)" bit[3] = 0; Otherwise, it is the inversion of the signal detect. 0 = Output of signal detect is not set. 1 = Output of signal detect filter is set. This is the only valid Signal Detect status bit when the port is powered down from "MII Control Register (Page 10h ~ 1Fh: Address 00h)" bit[11].	0

**Table 318: SerDes/SGMII Status 3 (Page B9h-BCh: Address 2Ch-2Dh) (Cont.)**

<b>Bit</b>	<b>Name</b>	<b>R/W</b>	<b>Description</b>	<b>Default</b>
7	SD_FILTER_CHG	RO	0 = Signal detect has not changed since last read. 1 = Signal detect has changed since last read. The signal detect change is based on a change in bit [9] of this register.	0
6	SD	RO	Signal detect direct from pin.	0
5	ANA_SD	RO	Analog signal detect status bit. This status signal is the analog signal detect status if register 0*13h bit [0] is set; otherwise, it is the value based on register 0*13h bit [1].	0
4	Reserved ANA_SD_CHG	RO	Reserved. Write as 0, ignore read. 0 = Analog signal detect has not changed since last read. 1 = Analog signal detect has changed since last read. The analog signal detect change is based on a change in bit [5] of this register.	0
3:0	Reserved	RO	Reserved. Write as 0, ignore read.	0x0

## BER/CRC Error Counter Register (Page B9h–BCh: Address 2Eh–2Fh)

**Table 319: BER/CRC Error Counter Register (Page B9h–BCh: Address 2Eh–2Fh)**

Bit	Name	R/W	Description	Default
15:8	Bit Error Rate (BER) Counter	RO	Number if invalid code groups detect while sync_status = 1 Freezes at FFh Write "SerDes/SGMII Control 2 Register (Page 10h ~ 17h: Address 22h)" bit[14] = 1 in order to clear.	00h
7:0	CRC Error/Receive Packet Counter	R/W CR	Number of CRC errors detected since last read. Freezes at FFh. When "SerDes/SGMII Control 1 Register (Page 10h ~ 17h: Address 20h)" bit[11] is set, the counter detects the number of received packets instead of CRC errors.	00h

## PRBS Control Register (Page B9h–BCh: Address 30h–31h)

**Table 320: PRBS Control Register (Page B9h–BCh: Address 30h–31h)**

Bit	Name	R/W	Description	Default
15:4	Reserved	R/W	Write as 0, ignore on read.	00h
3:2	PRBS	R/W	11 = $x(n) = 1 + x(28) + x(31)$ 10 = $x(n) = 1 + x(18) + x(23)$ 01 = $x(n) = 1 + x(14) + x(15)$ 00 = $x(n) = 1 + x(6) + x(7)$	00
1	Invert PRBS Order	R/W	1 = Invert polynomial sequence 0 = Normal operation	0
0	PRBS Enable	R/W	1 = Enable PRBS 0 = Disable PRBS	0

## PRBS Control Register (Page B9h–BCh: Address 32h–33h)

**Table 321: PRBS Control Register (Page B9h–BCh: Address 32h–33h)**

Bit	Name	R/W	Description	Default
15:13	PRBS Error State	RO CR	Grey coded FSM: 100 = 1024 or more errors 101 = 512 ~ 1023 errors 111 = 256 ~ 511 errors 110 = 128 ~ 255 errors 010 = 64 ~ 127 errors 011 = 32 ~ 63 errors 001 = 1 ~ 31 errors 000 = No errors	000

**Table 321: PRBS Control Register (Page B9h–BCh: Address 32h–33h) (Cont.)**

Bit	Name	R/W	Description	Default
12	PRBS Lost Lock	RO LH	1 = PRBS has lost lock since last read 0 = PRBS has not lost lock since last read	0
11	PRBS Locked	RO	1 = PRBS monitor is locked 0 = PRBS monitor is not locked	0
10:0	PRBS Errors	RO CR	Number of PRBS errors detected while locked. Freezes at 7FFh. <b>Note:</b> Counter is not synchronized to read status clock. The might increment while reading, causing inaccurate results. The PRBS should be disabled before reading the 11-bit error counter.	000h

## Pattern Generator Control Register (Page B9h–BCh: Address 34h–35h)

**Table 322: Pattern Generator Control Register (Page B9h–BCh: Address 34h–35h)**

Bit	Name	R/W	Description	Default
15	Reserved	R/W	Write as 0, ignore on read.	0
14	TXER	R/W	1 = Set txer = 1 during CRC portion of packet 0 = Normal operation	0
13	Skip CRC	R/W	1 = Do not append 32-bit CRC to end of packet 0 = Normal operation	0
12	CRC Checker Enable	R/W	1 = Enable CRC Checker to detect CRC errors on packets of any size (1-byte or more) 0 = Normal operation (CRC checker only detects CRC errors on packets of at least 72-bytes)	0
11:9	IPG Select	R/W	000 = Invalid 001 = IPG of 6-bytes 010 = IPG of 10-bytes 011 = IPG of 14-bytes 100 = IPG of 18-bytes 101 = IPG of 22-bytes 110 = IPG of 26-bytes 111 = IPG of 30-bytes	100
8:3	Packet Size	R/W	000000 = Invalid 000001 = 256-bytes 000010 = 512-bytes 000011 = 768-bytes 000100 = 1024-bytes ... ... 111111 = 16,128-bytes	000100

**Table 322: Pattern Generator Control Register (Page B9h–BCh: Address 34h–35h) (Cont.)**

Bit	Name	R/W	Description	Default
2	Single Pass Mode	R/W	1 = Only send 1 packet and stop 0 = Send packets while bit 1 of this register is set	0
1	Run Pattern Generator	R/W	1 = A rising edge on this bit while the pattern generator is in 0 the idle state will start sending packets. If the single pass mode is set, then a single packet will be sent and the idle state will be entered. If the single pass mode is not set, then packets will be sent until this bit is cleared. At this point, the current packet will finish transmitting and then enter the idle state. <b>Note:</b> A valid link must be established prior to sending packets. 0 = Do not send packet	
0	Select Pattern Generator Data	R/W	1 = Send idles or pattern generator data into transmit FIFO 0 (Ignore MAC transmit data) 0 = Normal operation	

## Pattern Generator Control Register (Page B9h–BCh: Address 36h–37h)

**Table 323: Pattern Generator Control Register (Page B9h–BCh: Address 36h–37h)**

Bit	Name	R/W	Description	Default
15:4	Reserved	R/W	Write as 0, ignore on read.	000h
3	Pattern Generator Active	RO	1 = Pattern generator is still sending packets 0 = Pattern generator is idle	0
2:0	Pattern Generator FSM	RO	000 = Idle 001 = Transmit preamble 011 = Transmit SFD 010 = Transmit data 110 = Transmit CRC 100 = IPG 101 = IPG 2 (allows FSM to be grey-coded)	000

## Force Transmit 1 Register (Page B9h–BCh: Address 3Ah–3Bh)

**Table 324: Force Transmit 1 Register (Page B9h–BCh: Address 3Ah–3Bh)**

Bit	Name	R/W	Description	Default
15:11	Reserved	R/W	Write as 0, ignore on read.	00h

**Table 324: Force Transmit 1 Register (Page B9h–BCh: Address 3Ah–3Bh)**

Bit	Name	R/W	Description	Default
10	Force Transmit	R/W	This bit enables a test transmit mode of two alternating patterns. Additionally, can be used in conjunction with the Transmit Idle Test via "SerDes/SGMII Control 2 Register (Page 10h ~ 17h: Address 22h)" bit[13]. 1 = Provide alternating bit[9:0] from this register and "Force Transmit 2 Register (Page 10h ~ 17h: Address 3Ch)" bit[9:0] to SerDes analog register. 0 = Normal operation	0
9:0	Force Transmit Data 1	R/W	Value in this register will be provided to SerDes analog transmitter every other clock cycle when bit[10] is set.	17Ch

## Force Transmit 2 Register (Page B9h–BCh: Address 3Ch–3Dh)

**Table 325: Force Transmit 2 Register (Page B9h–BCh: Address 3Ch–3Dh)**

Bit	Name	R/W	Description	Default
15:10	Reserved	R/W	Write as 0, ignore on read.	00h
9:0	Force Transmit Data 2	R/W	Value in this register will be provided to SerDes analog transmitter every other clock cycle when "Force Transmit 1 Register (Page 10h ~ 17h: Address 3Ah)" bit[10] is set.	

## Block Address (Pages B9h–BCh: Address 3Eh–3Fh)

**Table 326: Block Address (Pages B9h–BCh: Address 3Eh–3Fh)**

Bit	Name	R/W	Description	Default
15:4	Reserved	RO	Reserved. Write 0, ignore read.	0x000
3:0	BLK_NO	R/W	Registers 00–0Fh and 1Fh do not use block addressing and are fixed. Block 0 and Block 1 selected via these bits. 0000 = valid (block 0). 0001 = valid (block 1). 0010–1111 = reserved for future implementation.	0x0

## Page D8h–DCh: External PHY Registers

Information on the External PHY registers should be obtained from the external PHY data sheet. Data is obtained by polling the registers of the external PHY via the “MDC/MDIO Interface” on page 118. The actual values or meanings of these bits are controlled by the external PHY. Table 327 maps the external PHY register address to the BCM53262M offset address.

**Table 327: External Port MII Registers Page Versus PHY**

<b>Page</b>	<b>Port #</b>	<b>Hardware PHY address</b>
D8h	48	11000
D9	49 (G0)	11001
DA	50 (G1)	11010
DBh	51 (G2)	11011
DCh	52 (G3)	11100

**Table 328: External PHY Registers (Page D8h–DCh)**

<b>External PHY</b>			
<b>Register Address</b>	<b>Switch Address</b>	<b>bits</b>	<b>Description</b>
00h	00h-01h	16	MII Control register
01h	02h-03h	16	MII Status register
02h	04h-07h	32	PHY Identifier registers
04h	08h–09h	16	Auto-negotiation Advertisement register
05h	0Ah–0Bh	16	Auto-negotiation Link Partner Ability register
06h	0Ch–0Dh	16	Auto-negotiation Expansion register
07h	0Eh–0Fh	16	Auto-negotiation Next Page register
08h	10h–11h	16	Link Partner Next Page register
09h–0Fh	12h–1Fh	Reserved

## Global Registers

**Table 329: Global Registers (Maps to All Pages)**

Address	Bits	Description
0xF0	8	0 "SPI Data I/O Register" on page 375
0xF1	8	1 "SPI Data I/O Register" on page 375
0xF2	8	2 "SPI Data I/O Register" on page 375
0xF3	8	3 "SPI Data I/O Register" on page 375
0xF4	8	4 "SPI Data I/O Register" on page 375
0xF5	8	5 "SPI Data I/O Register" on page 375
0xF6	8	6 "SPI Data I/O Register" on page 375
0xF7	8	7 "SPI Data I/O Register" on page 375
0xF8h–0xFD	Reserved	
0xFE	8	"SPI Status Register" on page 375
0xFF	8	"Page Register" on page 376

## SPI Data I/O Register

**Table 330: SPI Data I/O Register (Maps to All Registers, Address F0h–F7h)**

Bit	Name	R/W	Description	Default
7:0	SPI Data I/O	R/W	SPI data bytes[7:0]	–

## SPI Status Register

**Table 331: SPI Status Register (Maps to All Registers, Address FEh)**

Bit	Name	R/W	Description	Default
7	SPIF	RO	SPI Read/Write Complete Flag.	0
6	WCOL	RO	SPI Write Collision	0
5	RACK	RO (SC)	SPI Read Data Ready Acknowledgement (Self-Clearing).	0
4:3	Reserved	RO	Write as 000, ignore when read.	0
2	MDIO Start	RO	Start/Done MDC/MDIO operation	0
1	RXRDY	RO	Rx Ready Flag—Should check every 8 bytes.	0
0	TXRDY	RO	Tx Ready Flag—Should check every 8 bytes.	0

## Page Register

*Table 332: Page Register (Maps to All Registers, Address FFh)*

<i>Bit</i>	<i>Name</i>	<i>R/W</i>	<i>Description</i>	<i>Default</i>
7:0	PAGE_REG	R/W	Binary value determines the value of the accessed register page.	0

## Section 9: Electrical Characteristics

### Absolute Maximum Ratings

Table 333: Absolute Maximum Ratings

Symbol	Parameter	Minimum	Maximum	Units
V <sub>1.2</sub>	Supply Voltage	GND-0.3	1.32	V
V <sub>2.5</sub>	Supply Voltage	GND-0.3	2.75	V
V <sub>3.3</sub>	Supply Voltage	GND-0.3	3.63	V
I <sub>I</sub>	Input Current	–	±10	mA
T <sub>STG</sub>	Storage Temperature	–40	+125	°C
V <sub>ESD</sub>	Electrostatic Discharge	–	1000	V

**Note:** These specifications indicate conditions where permanent damage to the device may occur. Functional operation is not guaranteed under these conditions. Operation at absolute maximum conditions for extended periods may adversely affect the long-term reliability of the device.

### Recommended Operating Conditions

Table 334: Recommended Operating Conditions

Sym	Parameter	Pins	Mode	Minimum	Maximum	Units
VDD	Supply voltage (see Note)	AVDD2, AVDDL, SAVDD, DVDD, PLLAVDD, PLL2AVDD	–	1.14	1.26	V
		AVDD, BIASVDD, XTALVDD, OVDD, VREG_AVDD	–	2.375	2.625	V
		OVDD2	–	3.135	3.465	V
			–	2.375	2.625	V
V <sub>IH</sub>	High-level input voltage	All digital inputs	–	2.0	–	V
V <sub>IL</sub>	Low-level input voltage	All digital inputs	–	–	0.8	V
V <sub>IDIFF</sub>	Differential input voltage	RD± {24:47}	–	150	–	mV
CT	Magnetic center-tap	–	TX	2.375	2.625	V
V <sub>ICM</sub>	Common mode input voltage	RD±{24:47}	TX	2.375	2.625	V
			FX	1.14	2.625	V
R <sub>DAC</sub>	DAC current-setting resistance	RDAC	–	1.00	1.00	kΩ (1%)
T <sub>A</sub>	Ambient operating temperature	–	–	0	70	°C

**Table 334: Recommended Operating Conditions**

Sym	Parameter	Pins	Mode	Minimum	Maximum	Units
T <sub>A</sub>	Ambient operating temperature (Industrial Grade)	–	–	-40	85	°C
T <sub>J</sub>	Maximum Junction Temperature	–	–	–	125	°C

**Note:** OVDD2 can be set to 2.5V depending the device configuration. See [Table 48: “Hardware Signal Descriptions,”](#) on page 137.

**Note:** It is recommended to power up the 1.2V, 2.5V and 3.3V supplies as quickly as possible with a delay separation within 1 to 5 ms. The total ramp-up time should be maintained at less than 10 ms.

## Electrical Characteristics

**Table 335: Electrical Characteristics**

Sym	Parameter	Pins	Conditions	Minimum	Typical	Maximum	Units
I <sub>DD1.2</sub>	1.2V supply current	SAVDD	100Base-TX	–	–	279	mA
			10Base-T	–	–	279	
		DVDD	100Base-TX	–	–	1180	
			10Base-T	–	–	998	
		AVDDL, PLLAVDD, PLL2AVDD, AVDD2	100Base-TX	–	–	477	
			10Base-T	–	–	113	
I <sub>DD2.5</sub>	2.5V supply current	OVDD, AVDD	100Base-TX	–	–	132	mA
			10Base-T	–	–	123	
I <sub>DD1.8</sub>	1.8V supply current	Transformer center taps, termination resistors	100Base-TX	–	–	1079	mA
			10Base-T	–	–	1719	
I <sub>DD2.5/3.3</sub>	2.5 or 3.3V supply current	OVDD2	100Base-TX	–	–	20	mA
			10Base-T	–	–	20	
V <sub>OH</sub>	High-level output voltage	Digital output TD± {47:24}	I <sub>OH</sub> = -4/8/15 mA	2.0	–	–	V
			Driving loaded magnetics module	–	–	VDD + 1.5	V
V <sub>OL</sub>	Low-level output voltage	Digital output TD± {47:24}	I <sub>OL</sub> = 4/8/15 mA	–	–	0.4	V
			Driving loaded magnetics module	VDD – 1.5	–	–	V
V <sub>OP</sub>	Transmitter output peak-to-peak differential voltage	Serdes output pins	Programmable	150	500	1000	mV

**Table 335: Electrical Characteristics**

<b>Sym</b>	<b>Parameter</b>	<b>Pins</b>	<b>Conditions</b>	<b>Minimum</b>	<b>Typical</b>	<b>Maximum</b>	<b>Units</b>
$V_{ID}$	Peak-to-peak differential input voltage	Serdes Input Pins	AC coupled input signal, DC level biased in receiver	100	–	2000	mV
$R_{IN}$	Receiver input impedance	Serdes input pins	Differential, integrated on-chip	80	100	120	$\Omega$
$R_O$	Transmitter output impedance	Serdes output pins	Differential	80	100	120	$\Omega$
$I_I$	Input current	Digital inputs with pull-up resistors	$V_I = OVDD$	–	–	+100	$\mu A$
			$V_I = GND$	–	–	–200	$\mu A$
		Digital inputs with pull-down resistors	$V_I = OVDD$	–	–	+200	$\mu A$
			$V_I = GND$	–	–	–10	$\mu A$
		All other digital inputs	$GND \leq V_I \leq OVDD$	–	–	$\pm 100$	$\mu A$
$I_{OZ}$	High-impedance output current	All three-state outputs	$GND \leq V_O \leq OVDD$	–	–	$\pm 10$	$\mu A$
		All open-drain outputs	$V_O = OVDD$	–	–	+10	$\mu A$

\* = Per GMII interface.

# Section 10: BCM53262M Timing Characteristics

## Reset and Clock Timing

Figure 44: Reset and Clock Timing

Table 336: Reset and Clock Timing

Parameter	Description	Minimum	Typical	Maximum
t201	XTALI Period	39.998 ns	40 ns	40.002 ns
t202	XTALI High Time	18 ns	–	22 ns
t203	XTALI Low Time	18 ns	–	22 ns
t204	RESET Low Pulse Duration	400 ns	50 ms	–
t207	Configuration Valid Setup to RESET Rising	100 ns	–	–
t208	Configuration Valid Hold from RESET Rising	–	–	0 ns

## SGMII/SerDes Interface Timing

The SGMII/SerDes Interface timing specifications are outlined in the subsequent sections.

## SGMII/SerDes Interface Output Timing

Figure 45: SGMII/SerDes Interface Output Timing

Table 337: SGMII/SerDes Interface Output Timings

Description	Parameter	Minimum	Typical	Maximum	Unit
SD_TXD Signaling Speed	t101	—	1.25	—	GBd
SD_TXD Rise Time (20%-80%)	t102	100	—	200	ps
SD_TXD Fall Time (20%- 80%)	t103	100	—	200	ps
SD_TXD Output Differential Skew (SD_TXDP vs. SD_TXDN)	t104	—	—	20	ps
SD_TXD Total Jitter	t105	—	—	192	ps

## SGMII/SerDes Interface Input Timing

Figure 46: SGMII/SerDes Interface Input Timing

Table 338: SGMII/SerDes Interface Input Timing

Description	Parameter	Minimum	Typical	Maximum	Unit
SD_RXD Signaling Speed	t106	—	1.25	—	GBd
SD_RXD Input Differential Skew (SD_RXDP vs. SD_RXDN)	t107	—	—	40	ps
SD_RXD Jitter (pk-pk)	t108	—	—	480	ps
SD_RXD Differential Input (pk-pk)	t109	0.1	—	2.0	V

# LED Timing

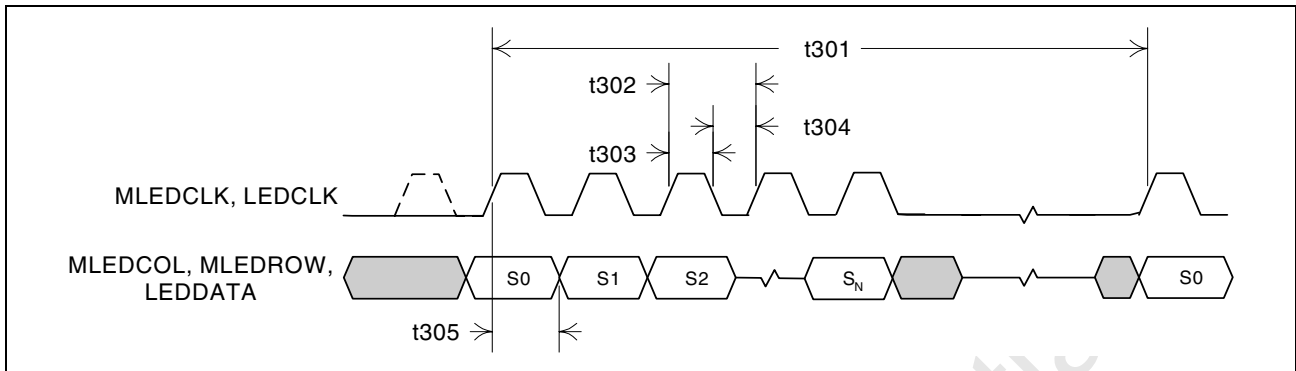

Figure 47: LED Timing

Table 339: LED Timing

Parameter	Description	Minimum	Typical	Maximum
t301	LED Update Cycle Period	–	40 ms	–
t302	MLEDCLK, LEDCLK Period	–	320 ns	–
t303	MLEDCLK, LEDCLK High Pulse Width	150 ns	–	170 ns
t304	MLEDCLK, LEDCLK Low Pulse Width	150 ns	–	170 ns
t305	LEDCLK to LEDDATA, MLEDCOL to MLEDROW Output time	140 ns	–	180 ns

## MII Input Timing

Figure 48: MII Input Timing

Table 340: MII Input Timing

Parameter	Description	Minimum	Typical	Maximum
t401	RXDV, RXD, RXER, to RXC Rising Setup Time	5 ns	–	–
t402	RXC Clock Period (10Base-T mode)	–	400 ns	–
	RXC Clock Period (100Base-T mode)	–	40 ns	–
t403	RXC High/Low Time (10Base-T mode)	160 ns	–	240 ns
	RXC High/Low Time (100Base-T mode)	14 ns	–	26 ns
t404	RXDV, RXD, RXER, to RXC Rising Hold Time	5 ns	–	–

## RvMII Input Timing

Figure 49: RvMII Input Timing

Table 341: RvMII Input Timing

Parameter	Description	Minimum	Typical	Maximum
t401R	RXDV, RXD, RXER, to RXC Rising Setup Time	10 ns	–	–
t402R	RXC Clock Period (100Base-T mode only)	–	40 ns	–
t403R	RXC High/Low Time (100Base-T mode only)	14 ns	–	26 ns
t404R	RXDV, RXD, RXER, to RXC Rising Hold Time	0 ns	–	–

## MII Output Timing

Figure 50: MII Output Timing

Table 342: MII Output Timing

Parameter	Description	Minimum	Typical	Maximum
t405	TXC High to TXEN, TXD, TXER Valid	–	–	22 ns
t406	TXC High to TXEN, TXD, TXER Invalid	3 ns	–	–

## RvMII Output Timing

Figure 51: RvMII Output Timing

Table 343: RvMII Output Timing

Parameter	Description	Minimum	Typical	Maximum
t405R	TXC High to TXEN, TXD, TXER Valid	–	–	29 ns
t406R	TXC High to TXEN, TXD, TXER Invalid	11 ns	–	–
t407R	TXC Clock Period	–	40 ns	–
t408R	TXC High/Low Time	14 ns	–	26 ns

# GMII Interface Timing

## GMII Interface Output Timing

Figure 52: GMII Output Timing

Table 344: GMII Output Timing

Description	Parameter	Minimum	Typical	Maximum	Unit
IMP_GTXCLK. clock period (1000M mode)	-	-	8	-	ns
IMP_GTXCLK. clock period (100M mode)	-	-	40	-	ns
IMP_GTXCLK. clock period (10M mode)	-	-	400	-	ns
Output delay from IMP_GTXCLK (rising)	$t_{502}$	0.5	-	5.5	ns

## GMII Interface Input Timing

Figure 53: GMII Input Timing

**Table 345: GMII Input Timing**

<b>Description</b>	<b>Parameter</b>	<b>Minimum</b>	<b>Typical</b>	<b>Maximum</b>	<b>Unit</b>
IMP_RXCLK clock period (1000M mode)	–	–	8	–	ns
IMP_RXCLK clock period (100M mode)	–	–	40	–	ns
IMP_RXCLK clock period (10M mode)	–	–	400	–	ns
Input setup time	t503	2.0	–	–	ns
Input hold time	t504	0.0	–	–	ns

Broadcom Confidential

## SPI Timing

Figure 54: SPI Timing,  $\overline{SS}$  Asserted During SCK High

Figure 55: SPI Timing,  $\overline{SS}$  Asserted During SCK Low

Table 346: SPI Timing

Parameter	Description	Minimum	Typical	Maximum
t601	SCK Clock Period	–	500 ns	–
t602	SCK High/Low Time	200 ns	–	300 ns
t603a, t603b	MOSI to SCK Setup Time	5 ns	–	–
t604a, t604b	MOSI to SCK Hold Time	12 ns	–	–
t605a, t605b	SCK to MISO Valid	–	–	25 ns
t606a, t606b	SCK to MISO Invalid	0 ns	–	–

**Note:** The BCM53262M behaves only as a slave device. The  $\overline{SS}$  is asynchronous. If  $\overline{SS}$  is asserted during SCK high then BCM53262M samples data on the rising edge of SCK and references the falling edge to output data. Otherwise BCM53262M samples data on the falling edge and outputs data on the rising edge of SCK.

Broadcom Confidential

## EEPROM Timing

Figure 56: EEPROM Timing

Table 347: EEPROM Timing

Parameter	Description	Minimum	Typical	Maximum
t701	CK Clock Frequency	–	100 KHz	–
t702	CK High/Low Time	–	5 us	–
t703	CK low to CS, DI Valid	–	–	500 ns
t704	CK low to CS, DI Invalid	500 ns	–	–
t705	DO to CK falling Setup Time	200 ns	–	–
t706	DO to CK falling Hold Time	200 ns	–	–

## EB Bus Timing

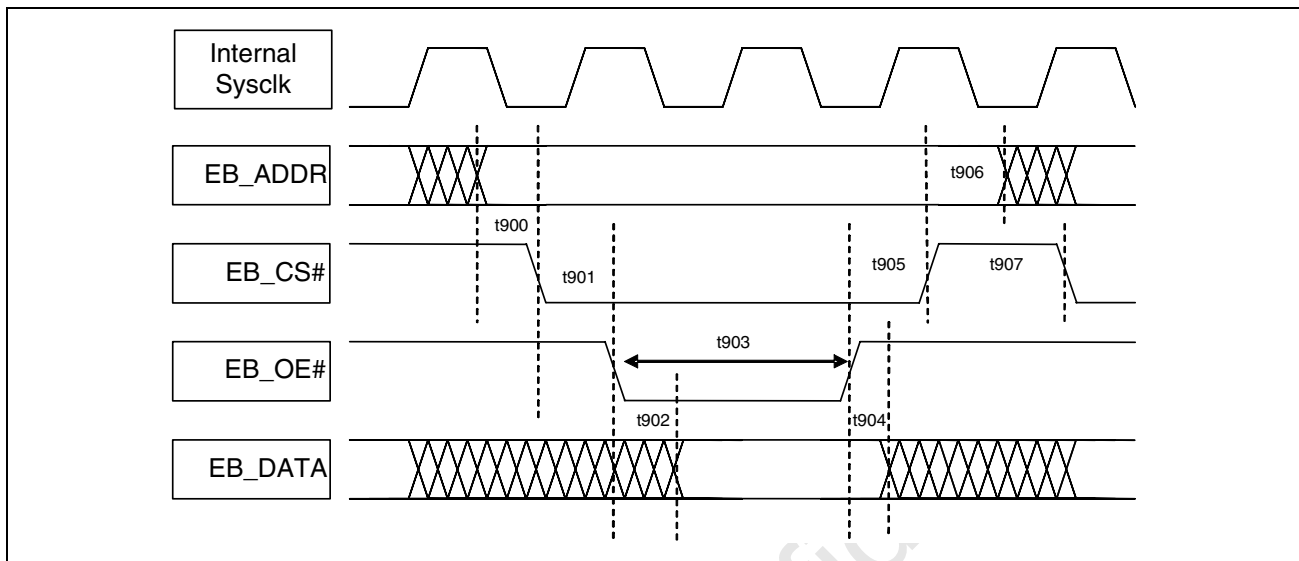

Figure 57: EB Bus Read Cycle

Table 348: EB Bus Read Cycle Timing

Parameter	Description	Minimum	Typical	Maximum
t900	Address setup time. (Address valid to CS# low)	0 ns	–	–
t901	CS# setup time. (CS# low to OE# low)	5 ns	–	–
t902	Data access time. (OE# low to Data valid)	–	20	–
t903	OE# active time (Based on 100 MHz system clock, minimum four cycles).	40 ns	–	–
t904	Data hold time. (OE# high to Data invalid)	0 ns	–	–
t905	CS# hold time. (OE# high to CS# high)	0 ns	–	–
t906	Address hold time. (CS# to Address invalid time)	5 ns	–	–
t907	CS# inactive time	5 ns	–	–

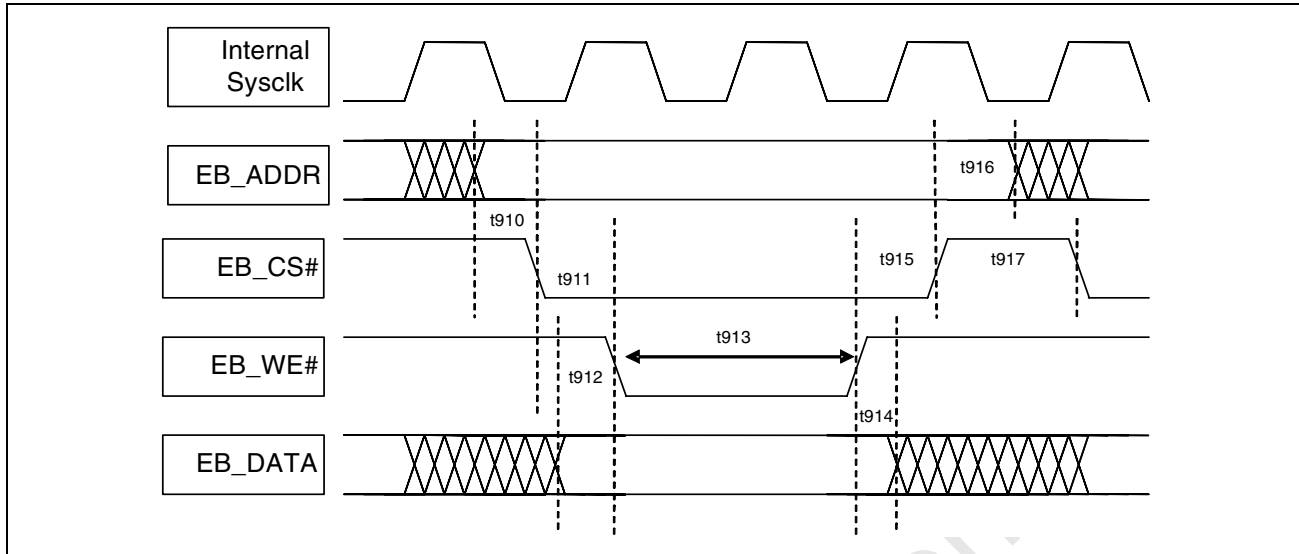

Figure 58: EB Bus Write Cycle

Table 349: EB Bus Write Cycle Timing

Parameter	Description	Minimum	Typical	Maximum
t910	Address setup time. (Address valid to CS# low)	0 ns	–	–
t911	CS# setup time. (CS# low to OE# low)	10 ns	–	–
t912	Data access time. (OE# low to Data valid)	10 ns	20	–
t913	WE# active time (Based on 100 MHz system clock, minimum four cycles).	40 ns	–	–
t914	Data hold time. (WE# high to Data invalid)	0 ns	–	–
t915	CS# hold time. (WE# high to CS# high)	0 ns	–	–
t916	Address hold time. (CS# to Address invalid time)	10 ns	–	–
t917	CS# inactive time	10 ns	–	–

## Management Data Interface

Figure 59: Management Data Interface

Table 350: Management Data Interface (Slave Mode)

Parameter	Description	Minimum	Typical	Maximum
t801	MDC Clock Period	–	80 ns	–
t802	MDC High/Low Time	30 ns	–	50 ns
t803	MDIO to MDC rising Setup Time	5 ns	–	–
t804	MDIO to MDC rising Hold Time	5 ns	–	–
t805	MDC rising to MDIO Valid	–	–	50 ns
t806	MDC rising to MDIO Invalid	10 ns	–	–

Table 351: Management Data Interface (Master Mode)

Parameter	Description	Minimum	Typical	Maximum
t801	MDC Clock Period	–	400 ns	–
t802	MDC High/Low Time	150 ns	–	250 ns
t803	MDIO to MDC rising Setup Time	10 ns	–	–
t804	MDIO to MDC rising Hold Time	10 ns	–	–
t805	MDC rising to MDIO Valid	–	–	100 ns
t806	MDC rising to MDIO Invalid	10 ns	–	–

## Section 11: Thermal Characteristics
