

# CMX885 Marine VHF Audio and Signalling Processor

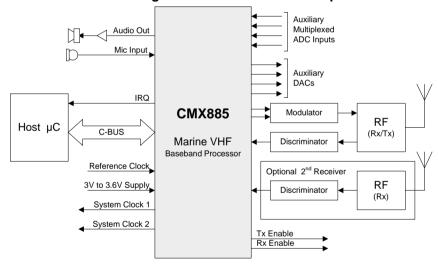

D/885/4 June 2017

# Audio and Signalling Processing, DTMF, DSC/ATIS and NOAA with Auxiliary Functions for use in Marine VHF Systems

#### **Features**

- Concurrent Audio/Signalling/Data Operations
- Complete Audio-band Processing:
  - Selectable Audio Processing Order
  - o Pre and De-emphasis
  - Selectable 2.55/3.0 kHz Filtering
  - Limiter
- DSC/ATIS Modem for Marine Applications
- Programmable Voice Scrambler
- Inband Signalling: DTMF, NOAA NWR
- C-BUS Serial Interface to Host µController
- DTMF and Audio Tone Encoder/Decoder
- Small VQFN and LQFP Packages

- Dual Auxiliary ADC, 4 Multiplexed Inputs
- 4 x Auxiliary DACs
- Dual Programmable System Clock Outputs
- Tx Outputs for Single, Two-Point Modulation
- 3 x Analogue Inputs (Mic or Discriminator)
- Digital Gain Adjustment
- Default 3.6864MHz Xtal/Clock
- Flexible Powersave Modes
- Low-power 3.0V to 3.6V Operation

#### 1 Brief Description

The CMX885 is a half-duplex, audio, signalling and data processing IC for use in Marine VHF radio systems.

Comprehensive audio processing facilities include complete audio processing, filtering, pre- or deemphasis and frequency inversion scrambling. Signal routing and filtering is included to assist host  $\mu$ C based signal encoding/decoding applications.

1200bps Digital Selcall (DSC) or Automatic Transmitter Identification System (ATIS) modem with protocol support and NWR decoding are supported.

A DTMF encoder/decoder, a full complement of auxiliary ADCs and DACs and dual synthesised clock outputs are included in this low power PMR processor. The device also has flexible powersaving modes and is available in 48-pin VQFN and LQFP packages.

# 3 Signal and Pin List

48-pin L4/Q3	Pin Name	Туре	Description
1	-	NC	reserved – leave unconnected
2	-	NC	reserved – leave unconnected
3	-	NC	reserved – leave unconnected
4	-	NC	reserved – leave unconnected
5	-	NC	reserved – leave unconnected
6	-	NC	reserved – leave unconnected
7	DVSS	PWR	Digital Ground
8	IRQN	OP	C-BUS: A 'wire-ORable' output for connection to the Interrupt Request input of the host. Pulled down to DV <sub>SS</sub> when active and is high impedance when inactive. An external pull-up resistor (R1) is required.
9	VDEC	PWR	Internally generated 2.5V digital supply voltage. Must be decoupled to DV <sub>SS</sub> by capacitors mounted close to the device pins. No other connections allowed.
10	RXENA	OP	Rx Enable – active low when in Rx mode (\$C1:b0 = 1)
11	-	NC	reserved – leave unconnected
12	-	NC	reserved – leave unconnected
13	SYSCLK1	OP	Synthesised Digital System Clock Output 1
14	DVSS	PWR	Digital Ground
15	TXENA	OP	Tx Enable – active low when in Tx mode (\$C1:b1 = 1)
16	DISCN	IP	Discriminator inverting input
17	DISCFB	OP	Discriminator input amplifier feedback
18	ALTN	IP	ALT inverting input
19	ALTFB	OP	ALT input amplifier feedback
20	MICFB	OP	MIC input amplifier feedback
21	MICN	IP	MIC inverting input
22	AVSS	PWR	Analogue Ground
23	MOD1	OP	Modulator 1 output
24	MOD2	OP	Modulator 2 output
25	VBIAS	OP	Internally generated bias voltage of about AV $_{DD}/2$ , except when the device is in 'Powersave' mode when $V_{BIAS}$ will discharge to AV $_{SS}$ . Must be decoupled to AV $_{SS}$ by a capacitor mounted close to the device pins. No other connections allowed.
26	AUDIO	OP	Audio output
27	ADC1	IP	Auxiliary ADC input (1)
28	ADC2	IP	Auxiliary ADC input (2)
29	ADC3	IP	Auxiliary ADC input (3)

48-pin L4/Q3	Pin Name	Туре	Description
30	ADC4	IP	Auxiliary ADC input (4)
31	AVDD	PWR	Positive 3.3V supply rail for the analogue on-chip circuits. Levels and thresholds within the device are proportional to this voltage. This pin should be decoupled to AV <sub>SS</sub> by capacitors mounted close to the device pins.
32	DAC1	OP	Auxiliary DAC output 1/RAMDAC
33	DAC2	OP	Auxiliary DAC output 2
34	AVSS	PWR	Analogue Ground
35	DAC3	OP	Auxiliary DAC output 3
36	DAC4	OP	Auxiliary DAC output 4
37	DVSS	PWR	Digital Ground
38	VDEC	PWR	Internally generated 2.5V supply voltage. Must be decoupled to $DV_SS$ by capacitors mounted close to the device pins. No other connections allowed.
39	XTAL/CLK	IP	Input to the oscillator inverter from the Xtal circuit or external clock source.
40	XTALN	OP	The output of the on-chip Xtal oscillator inverter
41	DVDD	PWR	The 3.3V positive supply rail for the digital on-chip circuits. This pin should be decoupled to DVss by capacitors mounted close to the device pins
42	CDATA	IP	C-BUS: Serial data input from the μC
43	RDATA	TS OP	C-BUS: A 3-state C-BUS serial data output to the $\mu$ C. This output is high impedance when not sending data to the $\mu$ C.
44	-	NC	Reserved – do not connect this pin
45	DVSS	PWR	Digital Ground
46	SCLK	IP	C-BUS: The C-BUS serial clock input from the μC
47	SYSCLK2	OP	Synthesised Digital System Clock Output 2
48	CSN	IP	C-BUS: The C-BUS chip select input from the $\mu C$ - there is no internal pullup on this input
EXPOSED METAL PAD	SUBSTRATE	~	On this device, the central metal pad (which is exposed on Q3 packages only) may be electrically unconnected or, alternatively, may be connected to Analogue Ground (AVss). No other electrical connections are permitted.

**Notes:** IP = Input (+ PU/PD = internal pullup/pulldown resistor)

OP = Output
BI = Bidirectional
TS OP = 3-state Output
PWR = Power Connection

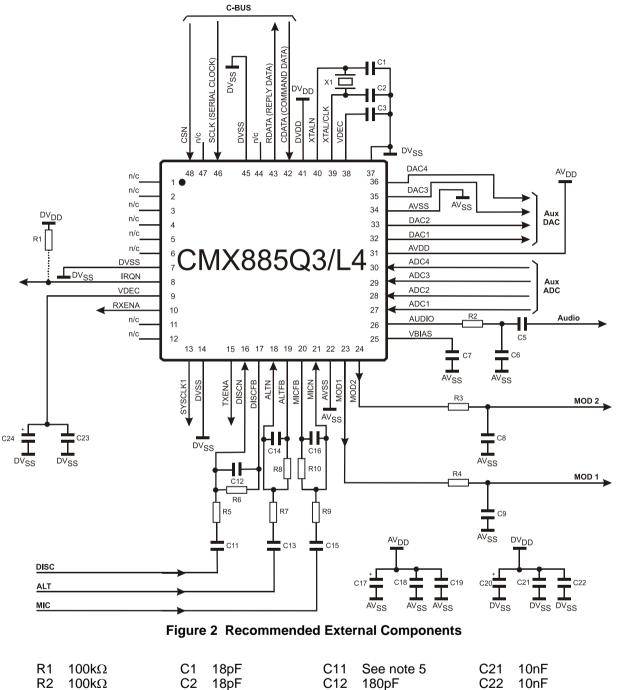

NC = No Connection - should NOT be connected to any signal

# 3.1 Signal Definitions

Table 1 Definition of Power Supply and Reference Voltages

Signal Name	Pins	Usage
$AV_{DD}$	AVDD	Power supply for analogue circuits
$DV_DD$	DVDD	Power supply for digital circuits
V <sub>DEC</sub>	VDEC	Power supply for core logic, derived from DV <sub>DD</sub> by on-chip regulator
$V_{BIAS}$	VBIAS	Internal analogue reference level, derived from AV <sub>DD</sub>
AV <sub>SS</sub>	AVSS	Ground for all analogue circuits
DV <sub>SS</sub>	DVSS	Ground for all digital circuits

Resistors  $\pm 5\%$ , capacitors and inductors  $\pm 20\%$  unless otherwise stated.

#### Notes:

- 1. X1 can be a crystal or an external clock generator; this will depend on the application. The tracks between the crystal and the device pins should be as short as possible to achieve maximum stability and best start up performance. By default, a 3.6864MHz clock is selected, other values could be used if the various internal clock dividers are set to appropriate values.
- 2. R5 should be selected to provide the desired dc gain (assuming C11 is not present) of the DISCN input, as follows:

$$|GAIN_{DISCN}| = 100k\Omega / R5$$

The gain should be such that the resultant output at the DISCFB pin is within the input signal range specified in 7.13.2.

3. R7 should be selected to provide the desired dc gain (assuming C13 is not present) of the ALTN input as follows:

$$|GAIN_{AITN}| = 100k\Omega / R7$$

The gain should be such that the resultant output at the ALTFB pin is within the input signal range specified in 7.13.

4. R9 should be selected to provide the desired dc gain (assuming C15 is not present) of the MICN input as follows:

$$|GAIN_{MICN}| = 100k\Omega / R9$$

The gain should be such that the resultant output at the MICFB pin is within the input signal range specified in 7.13.1. For optimum performance with low signal microphones, an additional external gain stage may be required.

C11, C13 and C15 should be selected to maintain the lower frequency roll-off of the MICN, ALTN and DISCN inputs as follows:

C11 
$$\geq$$
 100nF  $\times$  | GAIN<sub>DISCN</sub> |  
C13  $\geq$  100nF  $\times$  | GAIN<sub>ALTN</sub> |  
C15  $\geq$  30nF  $\times$  | GAIN<sub>MICN</sub> |

- 6. ALTN and ALTFB connections allow the user to have an additional signal input. Component connections and values are as for the respective DISCN and MICN networks. If this input is not required, the ALTN pin should be connected to AVss.
- C5 (AUDIO output) should be increased to 1.0μF if frequencies below 300Hz need to be used on this pin.
- 8. A single 10µF electrolytic capacitor (C24, fitted as shown) may be used for smoothing the power supply to both VDEC pins, providing they are connected together on the pcb with an adequate width power supply trace. Alternatively, separate smoothing capacitors should be connected to each VDEC pin. High frequency decoupling capacitors (C3 and C23) must always be fitted as close as possible to both VDEC pins.

# 5 PCB Layout Guidelines and Power Supply Decoupling

Figure 3 Power Supply and De-coupling

Component Values as per Figure 2.

#### Notes:

It is important to protect the analogue pins from extraneous inband noise and to minimise the impedance between the device and the supply and bias de-coupling capacitors. The de-coupling capacitors C3, C7, C18, C19, C21, C22, C24 and C25 should be as close as possible to the device. It is therefore recommended that the printed circuit board is laid out with separate ground planes for the  $AV_{SS}$  and  $DV_{SS}$  supplies in the area of the CMX885, with provision to make links between them, close to the device. Use of a multi-layer printed circuit board will facilitate the provision of ground planes on separate layers.

 $V_{BIAS}$  is used as an internal reference for detecting and generating the various analogue signals. It must be carefully decoupled, to ensure its integrity, so apart from the decoupling capacitor shown, no other loads should be connected. If  $V_{BIAS}$  needs to be used to set the discriminator mid-point reference, it must be buffered with a high input impedance buffer.

The single-ended microphone input and audio output must be ac coupled (as shown), so that their return paths can be connected to  $AV_{SS}$  without introducing dc offsets. Further buffering of the audio output is advised.

The crystal X1 may be replaced with an external clock source.

#### 6 General Description

The CMX885 is intended for use in half duplex analogue two-way mobile radio equipment and is particularly suited to the Marine VHF band. The CMX885 provides signal filtering, encoder and decoder functions for audio, inband tones, DTMF, NWR and DSC/ATIS, permitting simple to sophisticated levels of tone control and data transfer. A flexible power control facility allows the device to be placed in its optimum powersave mode when not actively processing signals.

The CMX885 includes a crystal clock generator, with a buffered output, to provide a common system clock if required. A block diagram of the CMX885 is shown in Figure 1.

The signal processing blocks can be individually assigned to either of two signal processing paths, which in turn, can be routed from any of the three audio/discriminator input pins. This allows for a very flexible routing architecture and allows the facility for different processing blocks to act on different analogue inputs.

For Marine use, it would be typical to route Rx Audio from the working channel receiver through from the DISCN input, while at the same time routing the DSC/ATIS FSK modem from the DSC channel 70 receiver from the ALTN input.

#### **Tx Functions:**

- Single/dual microphone inputs with input amplifier and programmable gain adjustment
- Filtering selectable for 12.5kHz and 25kHz channels
- o Selectable pre-emphasis
- Selectable frequency inversion voice scrambling
- Selectable audio processing order
- Two-point modulation outputs with programmable level adjustment
- Programmable audio tone generator (for custom audio tones)
- o Programmable DTMF generator
- o Tx Enable output
- 1200bps FSK modem for DSC/ATIS use (to ITU-R M.493-11)

#### **Rx Functions:**

- Single/dual demodulator inputs with input amplifier and programmable gain adjustment
- Audio-band and sub-audio rejection filtering
- Selectable de-emphasis
- Selectable frequency inversion voice de-scrambling
- Selectable audio processing order
- Software volume control
- o DTMF decoder
- o Rx Enable output
- 1200bps FSK modem for DSC/ATIS use (to ITU-R M.493-11)
- NWR SAME and WAT detector

#### **Auxiliary Functions:**

- 2 programmable system clock outputs
- 2 auxiliary ADCs with selectable input paths
- 4 auxiliary DACs, one with built-in programmable RAMDAC

#### Interface:

- C-BUS, 4 wire high speed synchronous serial command/data bus
- Open drain IRQ to host

#### 7 Detailed Descriptions

#### 7.1 Device Ident Code

Following a Power-on or Reset (see section 8.1.1), the device will report the Device Ident Code (\$8850) in the Tone Status register (\$CC) to indicate that it is operational.

#### 7.2 Xtal Frequency

The CMX885 is designed to work with a Xtal of 3.6864MHz. If this default configuration is not used, then Program Block 3 (see section 8.2.4) should be loaded with the correct values to ensure that the device will work to specification with the user specified clock frequency. A table of common values can be found in Table 2. Note the maximum Xtal frequency is 12.288MHz, although an external clock source of up to 24.576MHz can be used.

The register values in Table 1 are shown in hex (however only the lower 10 bits are relevant), the default settings are shown in bold, and the settings which do not give an exact setting (but are within acceptable limits) are in italics. The new P3.2-3 settings take effect following the write to P3.3 (the settings in P3.4-7 are implemented on a change to Rx or Tx mode).

	Prog	gram Block			Exte	rnal Frequen	cy Source (N	ИНz)			
			3.6864	6.144	9.216	12.0	12.8	16.368	16.8	19.2	
P3.2	Idle	GP Timer	\$01C	\$018	\$018	\$018	\$019	\$018			
P3.3	Þ	VCO output and AUX clk divide	\$084	\$088	\$08C	\$10F	\$110	\$095	\$115	\$099

Table 2 Xtal/clock Frequency Settings for Program Block 3

#### 7.3 Host Interface

A serial data interface (C-BUS) is used for command, status and data transfers between the CMX885 and the host  $\mu$ C; this interface is compatible with Microwire and SPI. Interrupt signals notify the host  $\mu$ C when a change in status has occurred and the  $\mu$ C should read the status register across the C-BUS and respond accordingly. Interrupts only occur if the appropriate mask bit has been set. See section 7.14.1.

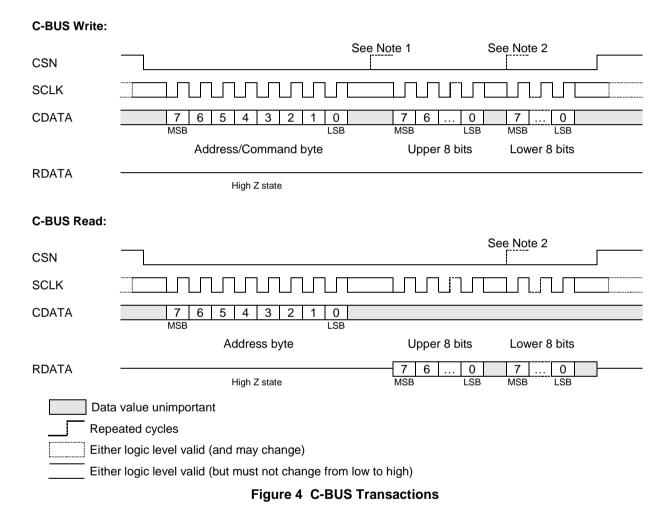

The CMX885 will monitor the state of the C-BUS registers that the host has written to every 250µs (the C-BUS latency period) hence it is not advisable for the host to make successive writes to the <u>same</u> C-BUS register within this period.

To minimise activity on the C-BUS interface, optimise response times and ensure reliable data transfers, it is advised that the IRQ facility be utilised (using the IRQ mask register, CE). It is permissible for the host to poll the IRQ pin if the host  $\mu$ C does not support a fully interrupt-driven architecture. This removes the need to continually poll the C-BUS status register (CE) for status changes.

The C-BUS block provides for the transfer of data and control or status information between the CMX885's internal registers and the host  $\mu$ C over the C-BUS serial interface. Each transaction consists of a single Address byte sent from the  $\mu$ C which may be followed by one or more Data byte(s) sent from the  $\mu$ C to be written into one of the CMX885's Write Only Registers, or one or more data byte(s) read out from one of the CMX885's Read Only Registers, as illustrated in Figure 4.

Data sent from the  $\mu$ C on the CDATA line is clocked into the CMX885 on the rising edge of the SCLK input. RDATA sent from the CMX885 to the  $\mu$ C is valid when SCLK is high. The CSN line must be held low during a data transfer and kept high between transfers. The C-BUS interface is compatible with most common  $\mu$ C serial interfaces and may also be easily implemented with general purpose  $\mu$ C I/O pins controlled by a simple software routine.

The number of data bytes following an Address byte is dependent on the value of the Address byte. The most significant bits of the address or data are sent first. For detailed timings see section 9.2. Note that, due to internal timing constraints, there may be a delay of up to 250µs between the end of a C-BUS write operation and the device reading the data from its internal register. Ensure that this C-BUS latency time (up to 250µs) is observed when writing multiple commands to the same C-BUS register.

#### Notes:

- 1. For Command byte transfers only the first 8 bits are transferred (\$01 = Reset).
- 2. For single byte data transfers only the first 8 bits of the data are transferred.
- 3. The CDATA and RDATA lines are never active at the same time. The Address byte determines the data direction for each C-BUS transfer.
- 4. The SCLK input can be high or low at the start and end of each C-BUS transaction.
- 5. The gaps shown between each byte on the CDATA and RDATA lines in the above diagram are optional, the host may insert gaps or concatenate the data as required.

#### 7.4 Device Control

The CMX885 can be set into many modes to suit the environment in which it is to be used. These modes are described in the following sections and are programmed over the C-BUS: either directly to operational registers or, for parameters that are not likely to change during operation, via the Programming register (\$C8).

For basic operation:

- 1. Enable the relevant hardware sections via the Power Down Control register
- 2. Set the appropriate mode registers to the desired state (Audio, Inband, Data, etc.)
- 3. Select the required Signal Routing and Gain
- 4. Use the Mode Control register to place the device into Rx or Tx mode

To conserve power when the device is not actively processing an analogue signal, place the device into Idle mode. Additional powersaving can be achieved by disabling the unused hardware blocks, however, care must be taken not to disturb any sections that are automatically controlled.

#### See:

- Powerdown Control \$C0 write
- Mode Control \$C1 write

#### 7.4.1 Signal Routing

The CMX885 offers a very flexible routing architecture, with three signal inputs, two separate signal processing paths and two modulator outputs (to suit 2-point modulation schemes) and a single audio output. Each of the signalling processing blocks can be independently routed from either of the Input blocks, which can be routed from any of the three input signal pins. The audio/voice processing blocks are always routed from Input 1. The outputs from signal processing blocks are determined by the settings of the AuxADC and Tx MOD mode register in Tx mode.

#### See:

- Input Gain and Output Signal Routing \$B1 write
- AuxADC and Tx MOD Mode \$A7 write
- Mode Control \$C1 write

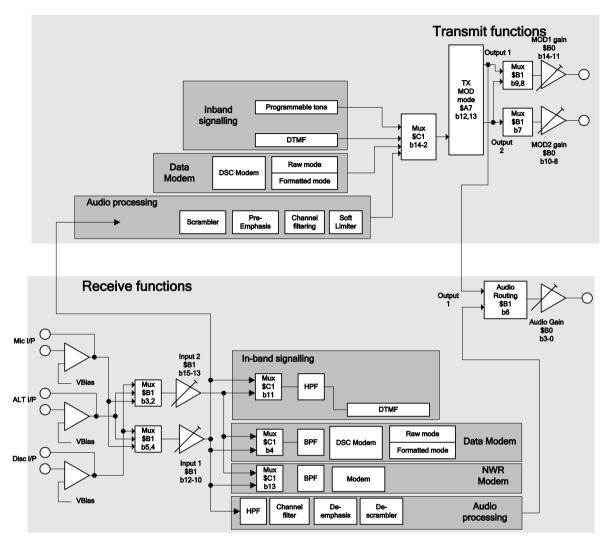

Figure 5 Signal Routing

The analogue gain/attenuation of each input and output can be set individually, with additional fine gain control available via the Programming register.

#### See:

- o Analogue Output Gain \$B0 write
- Input Gain and Output Signal Routing \$B1 write

#### 7.4.2 Mode Control

The CMX885 operates in one of three modes:

- o Idle
- o Rx
- о Тх

At power-on or following a Reset, the device will automatically enter Idle mode, which allows for the maximum powersaving whilst still retaining the capability of monitoring the four ADC inputs (if enabled). It is only possible to write to the Programming register whilst in Idle mode. See:

o Mode Control – \$C1 write

#### 7.5 Audio Functions

The audio signal can be processed in several ways, depending on the implementation required, by selecting the relevant bits in the Audio Control – \$C2 write register. In both Rx and Tx modes, a selectable channel filter to suit either the 12.5kHz or 25kHz TIA/ETSI channel mask can be selected. This filter also incorporates a soft limiter to reduce the effects of over-modulation. Other features include pre- and deemphasis, 300Hz HPF and frequency inversion scrambling, all of which may be individually enabled 1,2. The order in which these features are executed is selectable to ensure compatibility with existing implementations and provide optimal performance (see section 8.2.5).

#### 7.5.1 Audio Receive Mode

The CMX885 operates in half duplex, so whilst in receive mode the transmit path (microphone input and modulator output amplifiers) can be disabled and powered down if required. The AUDIO output signal level is equalised (to  $V_{BIAS}$ ) before switching between the audio port and the modulator ports, to minimise unwanted audible transients. The Off/Powersave level of the modulator outputs is the same as the VBIAS pin, so the audio output level must also be at this level before switching.

#### See:

Audio Control – \$C2 write

#### **Receiving Audio Band Signals**

When a voice-based signal is being received, it is up to the host  $\mu$ C, in response to signal status information provided by the CMX885, to control muting/enabling of the audio signal to the AUDIO output.

The discriminator path through the device has a programmable gain stage. Whilst in receive mode this should normally be set to 0dB (the default) gain.

#### **Receive Filtering**

The incoming signal is filtered, as shown in Figure 6 (with the 300Hz HPF also active), to remove subaudio components and to minimise high frequency noise. When appropriate, the audio signal can then be routed to the AUDIO output. Separate selectable filters are available for:

- 300Hz High Pass
- 2.55kHz Low Pass (for 12.5kHz channel operation)
- 3.0kHz Low Pass (for 25kHz channel operation)

Note that with  $\underline{no}$  filters selected, the low frequency response extends to below 5Hz at the low end but still rolls off above 3.3kHz at the top end. In Figure 6 and Figure 7, the template shows the +1 and -3dB limits.

\_

<sup>&</sup>lt;sup>1</sup> Use of an audio scrambler is not considered in the TIA/EIA standards and therefore this is regarded as an external process.

<sup>&</sup>lt;sup>2</sup> The typical responses shown in Figure 6, Figure 7, Figure 8, Figure 9 were recorded using the PE0201 Evkit, DISC to AUDIO and MOD1 out.

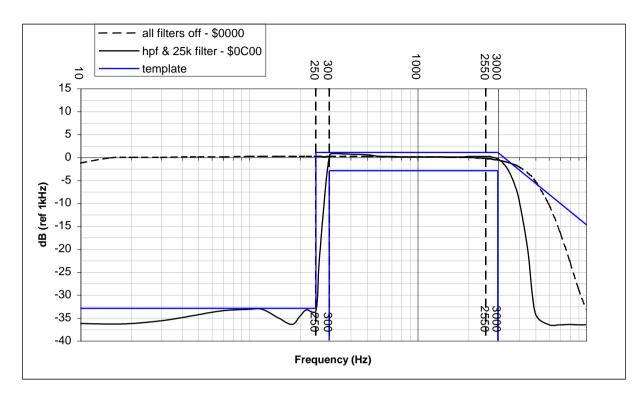

Figure 6 Rx 25kHz Channel Audio Filter Frequency Response

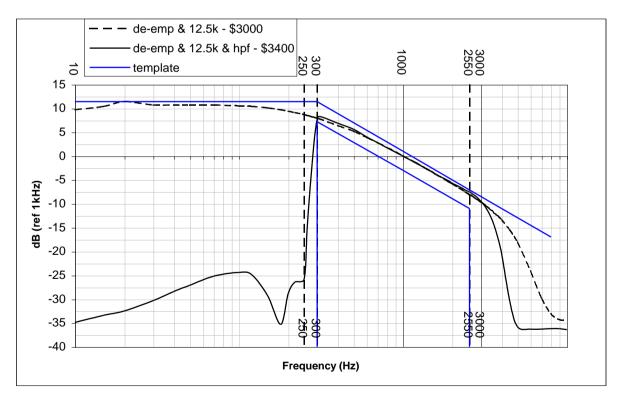

Figure 7 De-emphasis Curve for TIA/EIA-603 Compliance

#### **De-emphasis**

Optional de-emphasis at -6dB per octave from 300Hz to 3000Hz (shown in Figure 7) can be selected, to facilitate compliance with TIA/EIA-603, EN 300 086, EN 301 025.

#### **Audio De-scrambling**

The CMX885 incorporates an optional frequency inversion de-scrambler in receive mode. This descrambles received audio band signals that have been scrambled in the transmitter. The inversion frequency defaults to 3300Hz, but may be modified by writing to P4.8. See:

Audio Control – \$C2 write

#### 7.5.2 Audio Transmit Mode

The device operates in half duplex, so when in transmit mode the receive path (discriminator and audio output amplifiers) should be disabled, and can be powered down, by the host  $\mu$ C.

Two modulator outputs with independently programmable gains are provided to facilitate single or two-point modulation. If one of the modulator outputs is not used it can be disabled to conserve power.

To avoid spurious transmissions when changing from Rx to Tx, the MOD1 and MOD2 outputs are ramped to the quiescent modulator output level,  $V_{BIAS}$  before switching (if enabled by b7 of the Analogue Gain register, \$B0). Similarly, when starting a transmission, the transmitted signal is ramped up from the quiescent  $V_{BIAS}$  level and when ending a transmission the transmitted signal is ramped down to the quiescent  $V_{BIAS}$  level. The ramp rates are set in the Program Block P4.6. When the modulator outputs are disabled, their outputs will be set to  $V_{BIAS}$ . When the modulator output drivers are powered down, their outputs will be floating (high impedance), so the RF modulator will need to be turned off.

For all transmissions, the host  $\mu$ C must only enable signals after the appropriate data and settings for those signals are loaded into the C-BUS registers. As soon as any signalling is enabled the CMX885 will use the settings to control the way information is transmitted.

A programmable gain stage in the microphone input path facilitates a host controlled VOGAD capability, or an internal AGC function may be used.

#### See:

- Audio Control \$C2 write
- AuxADC and Tx MOD Mode \$A7 write
- Input Gain and Output Signal Routing \$B1 write

#### **Processing Audio Signals for Transmission over Analogue Channels**

The microphone input(s), with programmable gain, can be selected as the audio input source. Preemphasis is selectable with either of the two analogue Tx audio filters (for 12.5kHz and 25kHz channel spacing). These are designed for use in EN 300 086, TIA/EIA-603 or EN 301 025 compliant applications. When the 300Hz HPF is enabled, it will attenuate frequencies below 250Hz by more than 33dB with respect to the signal level at 1kHz. In Figure 8, Figure 9 and Figure 10, the template shows the +1 and -3dB limits.

These filters, together with a built in limiter, help ensure compliance with EN 300 086 and EN 301 025 (25kHz and 12.5kHz channel spacing) when levels and gain settings are set up correctly in the target system.

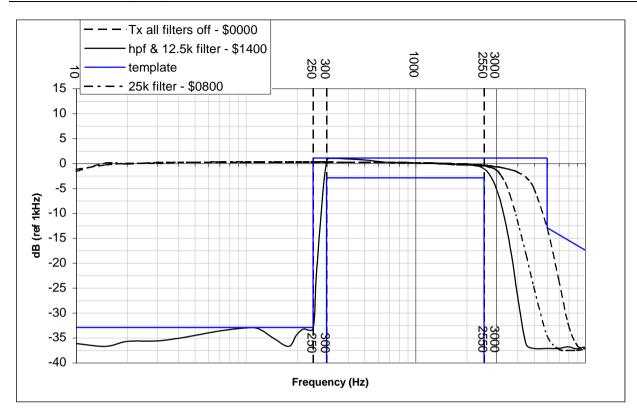

Figure 8 Tx Channel Audio Filter Response and Template (ETSI)

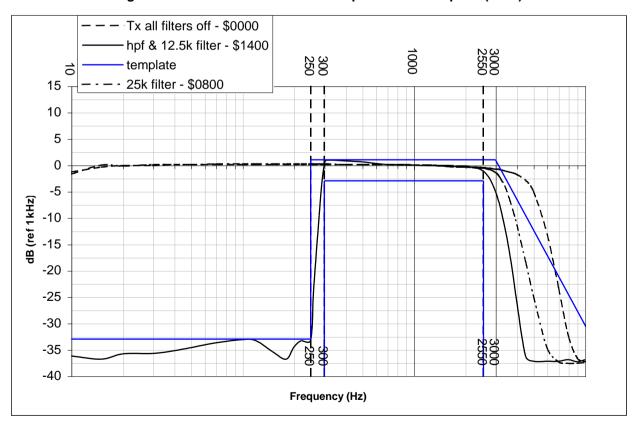

Figure 9 Tx Channel Audio Filter Response and Template (TIA)

The characteristics of the 12.5kHz channel filter fit the template shown in Figure 8 and Figure 9. This filter also facilitates implementation of systems compliant with TIA/EIA-603 'A', 'B' and 'C' bands .

The CMX885 provides selectable pre-emphasis filtering of +6dB per octave from 300Hz to 3000Hz, matching the template shown in Figure 10.

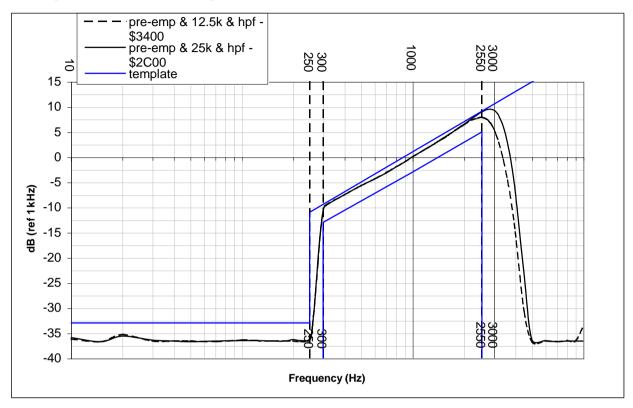

Figure 10 Audio Frequency Pre-emphasis

#### **Modulator Output Routing**

The Tx signal can be routed to both MOD1 and MOD2 outputs in accordance with the settings of:

- AuxADC and Tx MOD Mode \$A7 write
- o Input Gain and Output Signal Routing \$B1 write

#### Input AGC

An Automatic Gain Control system can be enabled by setting the relevant bits of the Program Block P4.9. The setting of the Input 1 Gain stage is recorded when the device enters Tx mode and if the signal exceeds the pre-set threshold, the Input 1 Gain is automatically reduced in 3.2dB steps until it falls within the operational levels or the range of the gain stage is exhausted. When the signal level drops, the gain will be automatically increased in 3.2dB steps at the rate set in P4.9 until the initial value has been reached. For maximum effect the system should be designed such that the +22.4dB setting of the Input 1 Gain stage achieves the nominal levels. To ensure consistent operation, it is recommended that the Input 1 Gain stage value be re-initialised before entering Tx mode. The signal that is used as an input to this process can be selected to be either the:

- Output of Input1 Gain Stage
- Output of the Pre-emphasis Filter

by selecting the relevant bit in P4.9. The pre-emphasis option should only be chosen if this block is actually in use.

- Input Gain and Output Signal Routing \$B1 write
- 0
- Program Block 4 Gain and Offset Setup

#### **Audio Scrambling**

The CMX885 incorporates an optional frequency inversion scrambler in transmit mode. This scrambles audio band signals, to be de-scrambled in the receiver. The inversion frequency defaults to 3300Hz, but maybe modified by writing to P4.8. See:

Audio Control – \$C2 write

#### 7.6 Inband Signalling

The CMX885 supports DSC, NWR (Rx only) and DTMF signalling and a user-programmable audio tone generator (288Hz to 3000Hz). Note that if tones below 400Hz are used, the 300Hz HPF should be disabled.

Selection of the Inband signalling mode is performed by bits 11-8 of the Mode register (\$C1). Detection of the selected Inband signalling mode can be performed in parallel with voice or data reception.

#### See:

- o Mode Control \$C1 write
- Tx Inband Tones \$C3 write
- o Tone Status \$CC read
- o Audio Tone \$CD write

#### 7.6.1 Receiving DTMF Tones

DTMF Tone detection may be enabled in the Mode register (\$C1) in parallel with other inband tone modes (however, this is not recommended due to the increased likelihood of false detects). When a DTMF tone has been detected, b10 of the Tone Status register (\$CC) and b12 of the IRQ Status register, \$C6, will be set. This value will overwrite any existing inband tone value that may be present. The DTMF detector returns the values shown below in Table 3.

#### 7.6.2 Transmitting DTMF Tones

The DTMF signals to be generated are defined in the TxTONE register (\$C3). Single tones and twist (lower frequency tone reduced by 2dB) can be enabled by setting the appropriate bit in the \$C3 register to 1. The DTMF level is set in Program Block P1.0. The DTMF tones must be transmitted on their own, the host  $\mu$ C must disable audio band signals prior to initiating transmission of the DTMF tones and (if required) restore the audio band signals after the DTMF transmission is complete. Table 3 shows the DTMF tone pairs, together with the values for programming the 'Tone Pair' field of the TxTONE register.

**Table 3 DTMF Tone Pairs** 

Tone Code (Hex)	Key Pad Position	Low Tone (Hz)	High Tone (Hz)
1	1	<u>697</u>	1209
2	2	<u>697</u>	1336
3	3	<u>697</u>	1477
4	4	<u>770</u>	1209
5	5	<u>770</u>	1336
6	6	<u>770</u>	1477
7	7	<u>852</u>	1209
8	8	852	<u>1336</u>
9	9	852	<u>1477</u>
Α	0	941	<u>1336</u>
В	*	941	<u>1209</u>
С	#	941	<u>1477</u>
D	Α	697	<u>1633</u>
E	В	770	<u>1633</u>
F	С	852	<u>1633</u>
0	D	<u>941</u>	1633

Note: Only the underlined tone is generated when the 'Single Tone' bit is enabled.

#### 7.7 DSC modem - (FSK 1200bps)

The device can implement a 1200 bps DSC (Digital Selective Call) modem conforming to the requirements of ITU-R M.493-11 for use in Marine VHF band radio equipment. This modem uses tones at 1300Hz and 2100Hz to represent binary 1's and 0's respectively, with 6dB/octave pre-emphasis in Tx.

#### See:

Figure 11 DSC format

To enable this mode, the En\_DSC bit of the Modem Configuration register \$C7:b11 must be set. The DSC modem itself can then be controlled by setting or clearing the Modem Enable bit \$C1:b2, after selecting the appropriate source with \$C1:b4. Note that, due to the C-BUS latency times, there should be a delay after clearing this bit, before re-enabling it again.

With DSC mode selected \$C7:b8 to b3 and \$C7:b1 to b0 are ignored.

Two modes of operation are provided:

- Raw Mode
- o Formatted Mode

Figure 12 DSC character format

#### 7.7.1 Receiving DSC Signals

The received signal is filtered and data is extracted with the aid of a PLL to recover the clock from the serial data stream. The recovered data is stored in a 2-byte buffer (grouped into 16-bit words) and an interrupt issued to indicate received data is ready. Data is transferred over the C-BUS under host  $\mu$ C control. If this data is not read before the next data is decoded it will be overwritten and it is up to the user to ensure that the data is transferred at an adequate rate following data ready being flagged. The DSC bit clock is not output externally.

The extracted data is compared with the 16-bit programmed Frame Sync pattern (preset to \$CB23 following a RESET command). An interrupt will be flagged when the programmed Frame Sync pattern is detected. The host  $\mu$ C may stop the frame sync search by disabling the DSC demodulator (\$C1:b2 cleared to 0). Once a valid Frame Sync pattern has been detected, the frame sync search algorithm is

disabled; it may be re-started by the host disabling the Modem Enable bit of the Mode Control register (\$C1:b2) and then re-enabling it (taking note of the C-BUS latency time).

In Rx Raw mode (En\_RAW=1) the modem will report back all data received as soon as it is enabled. (Note: If a valid DSC signal is <u>not</u> present when the modem is first enabled, it will still attempt to demodulate the input signal and output data. The host must determine if the data is valid or not. It is possible to use the SynC facility to reduce the amount of invalid data presented to the host, but this may also lead to DSC calls with errors in the SynC pattern being missed).

As soon as the Modem Enable bit has been asserted, the modem will attempt to demodulate the input signal. Data bits will then be delivered to the Rx Data 1 register, \$C5 as they are demodulated, indicated by the Data\_RDY bit. It is up to the host to align, decode and validate the data and to subsequently switch the modem off once an EOS (End of Sequence) has been detected (by clearing \$C1:b2 to 0). In this mode, the device does not perform byte alignment or phasing (synchronisation) detection<sup>3</sup>.

The host must read the RxData 1 register before the next 16 bits of data have been received, otherwise the data will be lost.

If the SynC facility is used in Raw mode, then the value of SynC must be programmed by the host to a suitable value via the Program Blocks, P0.0 and P0.1. The values \$5555 or \$AAAA are suggested for this setting, however, this will not completely remove false detections and the following received data must be analysed before assuming that a valid call is in progress (see ITU-R M.493-11 for details). The SynC enable bit \$C7:b15 must be asserted. Setting the Modem Enable bit \$C1:b2 will activate the DSC modem, which will then attempt to decode the signal at its input. Acquisition of the SynC data pattern will be reported to the host by the setting of the DSC bit \$C6:b3.

In Rx Formatted mode, (En\_Raw=0) the modem will check the incoming bit stream for a valid sequence of phasing characters (3x Rx, 2x Dx+ Rx or Dx + 2 x Rx) and then report any correctly decoded characters in the RxData1 (\$C5) register. The characters are packed into the 16-bit register as two 7-bit characters and an additional error indication bit (bits 15 and 7). In the case where an odd number of characters has been received, the unused field will be reported as 0000000. This mechanism significantly reduces the amount of data transferred to the host and the host processing requirements.

The decoded 7-bit characters will be delivered to the RxData1 register, \$C5, as indicated by the Data\_RDY bit. The modem will not report valid data until it has correctly received the initial phasing sequence. Once the Phasing sequence has been detected, the modem's internal DPLL bandwidth will be automatically reduced to improve the error performance. If one of the time-diversity received characters is in error, only the correct one will be reported. If both characters have errors, the last one received will be reported, with bit 7 (MSB) set. The characters reported back will correspond to the data sequence (see Figure 11)<sup>4</sup>:

A A B1 B2 B3 B4 B5 C D1 D2 D3 D4 D5 E1 E2 F1 F2 F3 G1 G2 G3 H I

Once the H and I fields have been received by the host, it should shut the DSC modem down by clearing the Modem Enable bit in the Mode Control register \$C1:b2.

#### 7.7.2 Transmitting DSC Signals

The DSC encoding operates in accordance with the bit settings in the Modem Configuration register (\$C7). When enabled the modulator will begin transmitting data using the settings and values in Program Block 0 (bit sync and frame sync patterns), the Modem Configuration register and the Tx Data registers. Therefore, these registers should be programmed to the required values before transmission is enabled.

The CMX885 generates its own internal data clock and converts the binary data into the appropriately phased frequencies. The binary data is taken from Tx DATA 1 register (\$CA), most significant bit first.

In Tx Raw mode (En\_RAW=1) the host must supply all data to be transmitted by the modem via the TxData register (\$CA) in the correct order and format to conform to the DSC standards.

<sup>&</sup>lt;sup>3</sup> This is similar to the FX604, CMX910 and CMX7032 operation.

<sup>&</sup>lt;sup>4</sup> This particular sequence corresponds to the example given in ITU-R M493-11. Different Telecommands will produce different sequences of varying lengths.

Setting the Modem Enable bit \$C1:b2, will enable the DSC modem, which will then transmit the data supplied by the host through the Tx Data 1 register, \$CA. The Modem Configuration register \$C7:b10 should also be set to enable/disable Raw data mode, as appropriate.

In Tx Formatted mode (En\_RAW=0), the modem will automatically transmit the dotting pattern followed by the phasing sequence and then encode the data presented at the Tx Data 1 register (\$CA) with the correct checksum bits and then transmit it in the correct position with automatic repetition to conform to the time diversity requirements of the standard. Data in the Tx Data 1 register is presented as two 7-bit characters, in the case where an odd number of characters needs to be sent, then the un-used character should be set to 0000000 and b7 set to 1. The final characters sent by the host should be a valid "End-of-Sequence" character followed by the "Error Check" character.

Valid DSC characters should be supplied by the host through the Tx Data 1 register, \$CA. Two characters can be loaded in the same C-BUS write operation. The modem will begin transmitting the dotting sequence followed by the phasing sequence as soon as the Modem Enable bit \$C1:b2 is set. The format of the data supplied by the host is similar to the Rx format:

```
A A B1 B2 B3 B4 B5 C D1 D2 D3 D4 D5 E1 E2 F1 F2 F3 G1 G2 G3 H I
```

There is no facility for automatically generating continuous dotting (preamble), Y data (all 1's), B data (all 0's) or phasing (synchronisation) sequences internally, however, the modem will continue to transmit the last data loaded into the TxData1 register, so only a single data load is required.

#### 7.8 NOAA/NWR SAME and WAT Decoding

A data decoder and tone detector suitable for use with the NOAA's NWR (NOAA Weather Radio) system is provided in the device. Full details of the system are publicly available from the NOAA website at <a href="http://www.nws.noaa.gov/nwr/">http://www.nws.noaa.gov/nwr/</a> and the CMX885 provides support for the WAT detection and SAME decoding. It is possible to route the signal input to either Input 1 or Input 2 so that NWR monitoring can be performed in parallel with existing radio operations (subject to suitable RF sections being provided externally).

#### See:

- o NWR Status and Data \$BB read
- Mode Control \$C1 write
- o Status \$C6 read
- Modem Configuration \$C7 write
- Interrupt Mask \$CE

The NWR SAME data message consists of six possible elements in the following sequence:

- 1 Preamble
- 2 Header Code
- 3 Warning Alarm Tone/Attention Signal
- 4 Voice Message
- 5 Preamble
- 6 End Of Message (EOM)

Elements 1, 2, 5 and 6 will always be transmitted in an NWR SAME message and repeated three times. Elements 3 and 4 may or may not be transmitted depending on the specific type of message or its application.

The coded message is transmitted, using Frequency Shift Keying (FSK), in the NWR audio channel. In this application and the implementation currently used by the FCC EAS, it is more accurate to refer to the code format as Audio Frequency Shift Keying (AFSK). It is transmitted at no less than 80% modulation (± 4.0kHz deviation minimum, ± 5.0kHz deviation maximum).

The coded message and voice message is transmitted over the NWR transmitter network using standard pre-emphasis for narrow band VHF Frequency Modulation (FM) of 6dB per octave increasing slope from 300Hz to 3,000Hz applied to the modulator.

**Preamble.** The preamble and header code are transmitted three times with a one second pause (± 5%) between each coded message burst prior to the broadcast of the actual voice message. Then the

preamble and End Of Message (EOM) code are transmitted three times with a one second pause (± 5%) between each EOM burst.

**Preamble Byte.** The first 16 bytes (prior to the header code and EOM) of the data transmission constitute a preamble with each byte having the value \$AB (8 bit byte [10101011]). For all bytes, the least significant bit (LSB) is sent first. The bytes following the preamble constitute the actual message data transmission.

NOTE: For NWR system maintenance, NWS will occasionally send a continuous string of preamble code, \$AB or a continuous tone through its communications links to the NWR transmitters, for several seconds up to around one minute.

**Bit Definition.** The following definitions of a bit are based on a bit period equaling 1920 microseconds (± one microsecond).

- The data rate is 520.83 bits per second
- Logic zero is 1562.5 Hz.
- o Logic one is 2083.3 Hz
- Mark and space bit periods are equal at 1.92 milliseconds.

**Header.** Bit and byte synchronization is attained by the preamble code at the beginning of each header code or EOM data transmission. The message data (header) code is transmitted using American Standard Code for Information Interchange (ASCII) characters as defined in ANSI INCITS 4 (rev 86, 2002), with the eighth bit always set to zero. Each separate header code data transmission should not exceed a total of 268 bytes if the maximum allowable geographic locations (31) are included.

**Warning Alarm Tone.** The Warning Alarm Tone (WAT), if transmitted, is sent within one to three seconds following the third header code burst. The frequency of the WAT is 1050Hz (±0.3%) for 8 to 10 seconds at no less than 80% modulation (±4.0 kHz deviation minimum, ±5.0 kHz deviation maximum).

**Voice Message**. If transmitted, the actual voiced message begins within three to five seconds following the last NWR SAME code burst or WAT, whichever is last. The voice audio ranges between 20% modulation (± 1 kHz deviation) and 90% modulation (± 4.5 kHz deviation) with occasional lulls near zero and peaks as high as, but not exceeding, 100% modulation (± 5.0 kHz deviation). Total length of the voice message should not exceed two minutes.

Preamble. A repeat of above.

End Of Message. EOM is identified by the use of "NNNN."

#### 7.8.1 Message Code Format

(Preamble) ZCZC-ORG-EEE-PSSCCC-PSSCCC+TTTT-JJJHHMM-LLLLLLLL (1 second pause)

(Preamble) ZCZC-ORG-EEE-PSSCCC-PSSCCC+TTTT-JJJHHMM-LLLLLLLL- (1 second pause)

(Preamble) ZCZC-ORG-EEE-PSSCCC-PSSCCC+TTTT-JJJHHMM-LLLLLLLL- (1 to 3 second pause)

1050 Hz Warning Alarm Tone for 8 to 10 seconds – (if transmitted) (3 to 5 second pause)

Voice /spoken oral text of message – (if transmitted) (1 to 3 second pause)

(Preamble) NNNN (1 second pause)

(Preamble) NNNN (1 second pause)

(Preamble) NNNN

#### 7.8.2 WAT Detection

The WAT detector is enabled by setting the NWR bit \$C1:b12 and indicated by setting b15 of the NWRData register (\$BB). If enabled, the NWR IRQ bit in the Status register \$C6:b14 will also be set. The detector will be reset after 500ms, so multiple detections may be indicated on long WAT tones.

#### 7.8.3 SAME Decoding

The SAME data is received at 520.83bps and decoded by the CMX885 whenever the NWR bit \$C1:b12 is set. Internally, the CMX885 monitors the selected input until it detects the preamble sequence and then passes the subsequently recovered data to the host uC via the NWR Data register (\$BB). The decoder will detect the data header and determine if it is "ZCZC" indicating that data follows or "NNNN" indicating the end of a transmission and report these states in bits 13 and 14 of the NWR Data register (\$BB) respectively). If enabled, the NWR IRQ bit in the Status register \$C6:b14 will also be set following the detection of the preamble and on every subsequently received byte.

When the En\_NWR\_data bit is set, the receiver outputs the received bitstream. The host is allowed to set this bit at any time to get "raw mode" data output with no preamble/header detection and no guarantee of byte alignment.

When the En\_NWR\_data bit is clear, the receiver searches for a valid SAME transmission but does not output data. If it sees a preamble followed by the data header ("ZCZC"), it raises an IRQ and \*automatically\* sets the En\_NWR\_data bit to put itself into data-output mode. It is then up to the host to decide when to clear the En\_NWR\_data bit to put the receiver back into sync-search mode (thus "rearming" it).

If the receiver sees a preamble followed by the end-of-message header ("NNNN") while doing sync-search, it informs the host [2] and then continues the search without putting itself into data-output mode.

It is the responsibility of the host to shut the decoder down at the end of a received burst by clearing the En NWR data bit \$C7:b12 to 0.

#### 7.9 Auxiliary ADC Operation

The input to the Auxiliary ADCs can be independently routed to any of the signal input pins under control of the AuxADC and Tx MOD mode register, \$A7. Conversions will be performed as long as a valid input source is selected; to stop the ADC, the input source should be set to "none". Register \$C0:b6, BIAS, must be enabled for Auxiliary ADC operation.

Averaging can be applied to the ADC readings by selecting the relevant bits in the AuxADC and Tx MOD mode register, \$A7, the length of the averaging is determined by the value in the Program Blocks P3.0 and P3.1, and defaults to a value of 0. This is a rolling average system such that a proportion of the current data will be added to the last value. The proportion is determined by the value of the average counter in P3.0 and P3.1. For an average value of 0; 50% of the current value will be applied, for a value of 1 = 25%, 2 = 12.5% etc. The maximum useful value of this field is 8. Averaging will begin with the current value of the AuxADC, therefore it is recommended that the AuxADC be enabled for at least one sample  $(250\mu s)$  before starting the average process to ensure that its initial value is as expected, otherwise the initial value will default to zero.

High and low thresholds may be independently applied to both ADC channels (the comparison is applied after averaging, if this is enabled) and an IRQ generated when either the high threshold is crossed by a rising edge signal or the low threshold is passed by a falling edge signal, which allows the user to implement a selectable degree of hysterisis. The thresholds are programmed via the AuxADC Threshold register, \$B5.

Auxiliary ADC data is read back in the AuxADC Data register (\$A9) and includes the threshold status as well as the actual conversion data (subject to averaging, if enabled).

#### See:

- AuxADC and Tx MOD Mode \$A7 write
- AuxADC1 Data \$A9 read
- o AuxADC2 Data \$AA read
- AuxADC Threshold Data \$B5 write

#### 7.10 Auxiliary DAC/RAMDAC Operation

The four Auxiliary DAC channels are programmed via the AuxDAC Control register, \$A8. AuxDAC channel 1 may also be programmed to operate as a RAMDAC which will automatically output a preprogrammed profile at a programmed rate. The AuxDAC Control register, \$A8, with b12 set, controls this mode of operation. The default profile is a raised cosine (see Table 8), but this may be over-written with a user defined profile by writing to Program Block P3.11. The RAMDAC operation is only available in Tx mode and, to avoid glitches in the ramp profile, it is important not to change to Idle or Rx mode whilst the RAMDAC is still ramping. The AuxDAC outputs (available on their respective DAC pins) hold the user-programmed level during a powersave operation if left enabled, otherwise they will return to zero. Note that access to all four AuxDACs is controlled by the AuxDAC Control register, \$A8, and therefore to update all AuxDACs requires four writes to this register. It is not possible to simultaneously update all four AuxDACs.

#### See:

AuxDAC Control/Data – \$A8 write

#### 7.11 Digital System Clock Generator

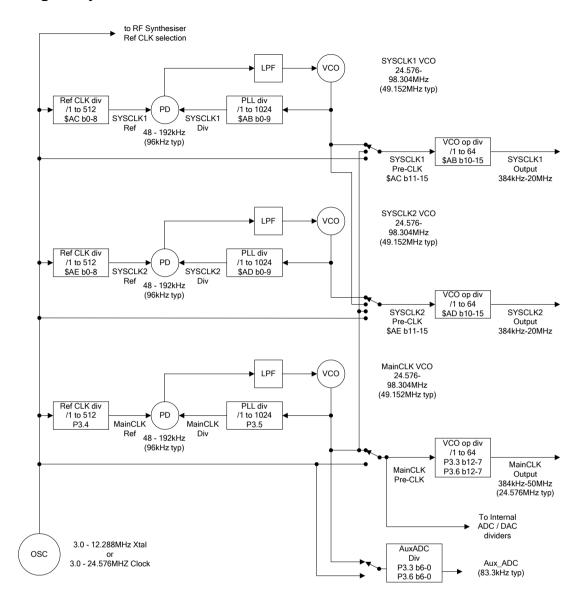

Figure 13 Digital Clock Generation Schemes

The CMX885 includes a 2-pin crystal oscillator circuit. This can either be configured as an oscillator, as shown in section 5, or the XTAL input can be driven by an externally generated clock. The crystal (Xtal) source frequency can go up to 12.288MHz (clock source frequency up to 24.576MHz), but by default, a 3.6864MHz Xtal is assumed for the functionality provided in the CMX885.

#### 7.11.1 Main Clock Operation

A PLL is used to create the main clock (MainCLK - nominally 24.576MHz) for the internal sections of the CMX885. At the same time, other internal clocks are generated by division of either the Xtal Reference Clock or the Main Clock. These internal clocks are used for determining the sample rates and conversion times of A-to-D and D-to-A converters, running a General Purpose Timer, the signal processing block. In particular, it should be noted that in Idle mode the setting of the GP Timer divider directly affects the C-BUS latency (with the default values this is nominally 250µs).

The CMX885 defaults to the settings appropriate for a 3.6864MHz Xtal, however if other frequencies are to be used (to facilitate commonality of Xtals between external RF synthesizers and the CMX885 for

instance) then the Program Block registers P3.2 to P3.7 will need to be programmed appropriately at power-on. A table of common values is provided in Table 2.

#### See:

o Program Block 3 – AuxDAC, RAMDAC and Clock Control

#### 7.11.2 System Clock Operation

Two System Clock outputs, SYSCLK1 and SYSCLK2, are available to drive additional circuits, as required. These are phase locked loop (PLL) clocks that can be programmed via the System Clock registers with suitable values chosen by the user. The System Clock PLL Configure registers (\$AB and \$AD) control the values of the VCO Output divider and Main Divide registers, while the System Clock Ref. Configure registers (\$AC and \$AE) control the values of the Reference Divider and signal routing configurations. The PLLs are designed for a reference frequency of 96kHz. If not required, these clocks can be independently powersaved. The clock generation scheme is shown in the block diagram of Figure 13. Note that at power-on, these outputs are disabled.

#### See:

- o SYSCLK1 and SYSCLK2 PLL Data \$AB, \$AD write
- SYSCLK1 and SYSCLK2 REF \$AC and \$AE write

#### 7.12 **GPIO**

Two pins are provided for control of external hardware. RXENA and TXENA are driven by the device to follow the state of the Rx and Tx Mode bits in the Mode register, \$C1:

\$C1 Mode:	b1	b0	TXENA	RXENA
Idle	0	0	1	1
Rx	0	1	1	0
Tx	1	0	0	1
reserved	1	1	1	1

#### 7.13 Signal Level Optimisation

The internal signal processing of the CMX885 will operate with wide dynamic range and low distortion only if the signal level at all stages in the signal processing chain is kept within the recommended limits. For a device working from a 3.3V  $\pm 10\%$  supply, the maximum signal level which can be accommodated without distortion is [(3.3 x 90%) – (2 x 0.3V)] Volts pk-pk = 838mVrms, assuming a sine wave signal. Compared to the reference level of 308mVrms, this is a signal of  $\pm 8.69$ dB. This level should not be exceeded at any stage.

#### 7.13.1 Transmit Path Levels

For the maximum signal out of the MOD1 and MOD2 attenuators, the signal level at the output of the Analogue Routing block should not exceed +8.69dB, assuming both fine and coarse output attenuators are set to a gain of 0dB. This means that the output from the soft limiter must not exceed 838mVrms. If pre-emphasis is used, an output signal at 3000Hz will have three times the amplitude of a signal at 1000Hz, so the signal level before pre-emphasis should not exceed 279mVrms. The Fine Input Gain adjustment has a maximum attenuation of 3.5dB and no gain, whereas the Coarse Input Gain adjustment has a variable gain of up to +22.4dB and no attenuation. If the highest gain setting were used, then the maximum allowable input signal level at the MICFB pin would be 54mV pk-pk. With the lowest gain setting (0dB), the maximum allowable input signal level at the MICFB pin would be 718mVrms.

#### 7.13.2 Receive Path Levels

For the maximum signal out of the AUDIO attenuator, the signal level at the output of the Analogue Routing block should not exceed +8.69dB, assuming both fine and coarse output attenuators are set to a gain of 0dB. That is a signal level of 838mVrms. If de-emphasis is used, an output signal at 300Hz will have three and one third times the amplitude of a signal at 1000Hz, so the signal level before deemphasis should not exceed 251mVrms. The Fine Input Gain adjustment has a maximum attenuation of 3.5dB and no gain, whereas the Coarse Input Gain adjustment has a variable gain of up to +22.4dB and no attenuation. If the highest gain setting were used, then the maximum allowable input signal level at the

DISCFB pin would be 12.0mVrms. With the lowest gain setting (0dB), the maximum allowable input signal level at the DISCFB pin would be 158mVrms. The signal level of +8.69dB (838mVrms) is an absolute maximum, which should not be exceeded anywhere in the signal processing chain if severe distortion is to be avoided.

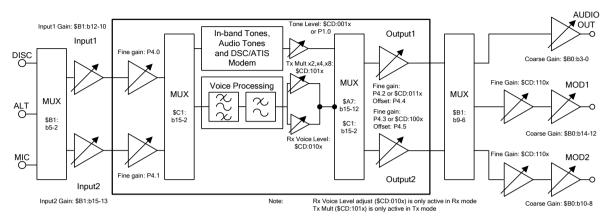

Figure 14 Level Adjustments

#### 7.14 C-BUS Interface

#### 7.14.1 Interrupt Operation

The CMX885 will issue an interrupt on the IRQN line when the IRQ bit (bit 15) of the Status register and the IRQ Mask bit (bit 15) are both set to 1. The IRQ bit is set when the state of the interrupt flag bits in the Status register change from a 0 to 1 and the corresponding mask bit(s) in the Interrupt Mask register is(are) set. Enabling an interrupt by setting a mask bit  $(0\rightarrow1)$  after the corresponding Status register bit has already been set to 1 will also cause the IRQ bit to be set.

All interrupt flag bits in the Status register, except the PRG flag (bit 0), are cleared and the interrupt request is cleared following the command/address phase of a C-BUS read of the Status register. The PRG flag bit is set to 1 only when it is permissible to write a new word to the Programming register. See:

- Status \$C6 read
- Interrupt Mask \$CE

#### 7.14.2 General Notes

In normal operation, the most significant registers are:

- Mode Control \$C1 write
- o Status \$C6 read
- o Analogue Output Gain \$B0 write
- Input Gain and Output Signal Routing \$B1 write
- Audio Control \$C2 write

Setting the Mode Control register to either Rx or Tx will automatically increase the internal clock speed to its operational rate, whilst setting the Mode Control register to Idle will automatically return the internal clock to a lower (powersaving) rate. To access the Program Blocks (through the Programming register, \$C8) the device MUST be in Idle mode.

Under normal circumstances, the CMX885 manages the main clock control automatically, using the default values loaded in Program Block 3.

The detailed descriptions of the C-BUS registers are presented in numerical order and should be read in conjunction with the relevant functional descriptions in the Datasheet.

All other C-BUS addresses (including those not listed above) are either reserved for future use or allocated for production testing and must not be accessed in normal operation.

## 8.1.1 Reset Operations

A reset is automatically performed when power is applied to the CMX885. A reset can be issued as a C-BUS command, either as a General Reset command (\$01), or by setting the appropriate bit (b5) in the Powerdown Control register (\$C0). In the latter case, an option exists to protect the values held in the Program Block (which is accessed via the Programming register, \$C8). The action of each reset type is shown in the table below:

**Protect Bit Program Reset Type** (\$C0 b4) State **Block State** 1 Power on cleared by h/w default General Reset cleared by h/w default (C-BUS \$01) Reset 3 0 default

(C-BUS \$C0 b5)

(C-BUS \$C0 b5)

Reset

4

**Table 4 Reset Operations** 

#### 8.1.2 General Reset - \$01 write

The General Reset command has no data attached to it. It sets all operational C-BUS registers to \$0000, (apart from the registers marked as *reserved*). Note that some transient data may appear in the following registers during the reset and power-up processes – this should be ignored:

b5	b4	Input 1 Signal Routing
b3	b2	Input 2 Signal Routing
0	0	bias (default)
0	1	DISCN
1	0	ALTN
1	1	MICN

Output 1 and Output 2 signal sources are also defined in section 8.1.3. Bits 1, 0 are reserved – clear to 0.

There are a number of applications where it may be desirable to split the processing across both inputs, such as monitoring two RF receivers, in which case, Input 1 could be routed from the DISCN input with voice and DSC or NWR processing set to Input 2 from the ALTN input.

Similarly, for the output routing, under normal operation, In Tx Mode, Output 1 would be routed to MOD1 and Output 2 to MOD2. The signals that appear on Output 1 and Output 2 are defined in the Tx MOD Mode register, \$A7:b14 to b12.

If the AUDIO output is selected in Tx mode (using b6) it will present the signal that has been routed to Output 1. This can be used for "sidetone" when transmitting Inband signalling in 1 or 2-point modulation modes. In Rx mode, the Audio Process is automatically routed to Output 1.

An audio output is only available when in Rx or Tx Mode.

Note: Output 1 and Output 2 may show a transient when switched from Idle to Rx or Tx mode as they power on. It is therefore recommended that the MOD1, MOD2 or AUDIO output routing be set to  $V_{BIAS}$  for a short period before implementing the operational routing and enabling the signalling. For Tx operation, the following sequence has been used successfully:

\$C1 - currently in Idle mode

Enable Tx mode:

\$B1 - Mod1/2 set to  $V_{BIAS}$  (b9-b7 = 000<sub>b</sub>)

\$C1 - Tx Mode Enabled

Delay of  $> 700 \mu s$ 

\$C1 - Tx Function Enabled (e.g., DSC)

\$B1 - Output1/2 routed to MOD1, MOD2

Program Block Protect b4 0 = normal1 = protected

> If cleared, the Program Blocks will be initialised on Power on or Reset. If set, then the Program Blocks will retain their previous contents.

XTAL Disable 0 = enabledb3 1 = disabled / powersave

Setting this bit effectively stops all signal processing within the device.

b2 Input 2 Enable 0 = off1 = enabled0 1 = DO NOT USE b1 reserved

b0 reserved 0 1 = DO NOT USE

Note: Care should be taken when writing to b5 and b3. These are automatically programmed to an operational state following a power-on (ie: all 0s). Writing a 1 to either b5 or b3 will effectively cause the device to cease all processing activity, including responding to other C-BUS commands (except General Reset, \$01).

When b5 is set, the device will be held in reset and all signal processing will cease (including AuxADC operation.

When b3 is set the Xtal is disabled. When b3 is subsequently cleared, it may take some time for the clock signal to become stable, hence care should be taken in using this feature.

8.1.18 Mode Control - \$C1 write

Changes to the settings of the bits in this register are implemented as soon as they are received over the C-BUS (note that the C-BUS has a potential latency of up to  $250\mu s$ ).

In Tx mode, it is only permissible to select ONE of the following at any time:

Audio Inband Signalling DSC Signalling

Note that if the Audio Processing bit (b14) is set at the same time as an Inband signalling bit in Tx mode, the Inband signal will be subjected to a 6dB gain.

It is essential that changes to the Programming register and the Audio Control register are completed before entering Rx or Tx mode.

The following other registers or bits can be changed as appropriate (Note: not all possible changes are appropriate), whilst the device is in Tx or Rx mode:

- Analogue Output Gain register (\$B0)
- AuxADC and Tx MOD Mode register (\$A7)
- Input Gain and Signal Routing register (\$B1)
- Power Down Control register (\$C0)
- Tx Inband Tones register (\$C3)
- Tx Data registers (\$CA & \$CB)
- Audio Tone register (\$CD)
- Interrupt Mask register (\$CE)

IR	Q NV	٧K	res	DTMF	res	res	ADC2	ADC1	End	RDY	res	res	DSC	res	res	PRG

#### b15 IRQ

Changes in the Status register will cause this bit to be set to 1 if the corresponding interrupt mask bit is enabled. An interrupt request is issued on the IRQN pin when this bit is 1 and the IRQ MASK bit (b15 of Interrupt Mask register, \$CE) is set to 1.

#### b14 NWR status change

The NOAA Weather Receiver has detected a change in the status of the WAT tone or SAME data. The NWR data/status register \$BB should be read to determine the exact cause.

b13 reserved

b12 DTMF event

A valid DTMF tone has been detected and can be read from the Tone Status register, \$CC.

b11 reserved

b10 reserved

b9 AuxADC2 Threshold change

AUX ADC2 signal has just gone above the high threshold or has just gone below the low threshold. The AuxADC2 data register \$AA should be read to determine the exact cause.

b8 AuxADC1 Threshold change

AUX ADC1 signal has just gone above the high threshold or has just gone below the low threshold The AuxADC1 data register \$A9 should be read to determine the exact cause.

b7 Data End

Rx mode: this bit is not used, so its value should be ignored. See section 7.7.1.

Tx mode: this will be set when the last bit of DSC data has been transmitted. After allowing a short time delay associated with the external components and radio circuitry, the host may power down the CMX885 and transmitter or set the CMX885 to transmit or receive new information as appropriate.

#### b6 Data Ready

Tx mode: indicates that new transmit data is required.

Rx mode: received data is ready to be read.

For continuous transmission or reception of information, a data transfer should be completed within the time appropriate for that data.

- b5 reserved
- b4 reserved
- b3 DSC

When set to 1, this bit indicates that a valid DSC data sequence has been received.

- b2 reserved
- b1 reserved
- b0 PRG

When set to 1, this bit indicates that the Programming register, \$C8 is available for the host to write to it. Cleared by writing to the Programming register, \$C8

Bits 2 to 15 of the Status register are cleared to 0 after the Status register is read.

The data in this register is not valid if bit 5 of the Power Down Control register, \$C0 is set to 1.

8.1.23 Modem Configuration - \$C7 write

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
			En NWR	En	En	Last Tx							User		
SynC	SynD	SynT	Data	DSC	RAW	Data	0	0	0	0	0	0	Bit	0	0

This register configures the way the CMX885 handles DSC data in Tx and Rx modes.

b15 SynC detect 0 = off 1 = enabledb14 SynD detect 0 = off 1 = enabledb13 SynT detect 0 = off 1 = enabled

note: SynC, SynD and SynT patterns are defined in Program Blocks P0.0-3

b12 En\_NWR\_data 0 = disabled 1 = enabled

The En\_NWR\_data bit is required to disable the NWR SAME data decoder at the end of a data frame. The decoder will detect and respond to the arrival of a sync signal (if \$C1:b12 is set to 1), and report any following data, however the host will need to decode the data from the CMX885, recognise the end of data and then disable the SAME decoder through this bit. Setting this bit to 1 will disable the sync search and output data immediately.

b11 En DSC data mode

0 = disabled 1 = enabled

Setting this bit selects DSC modem operation. The Modem Enable bit \$C1:b2 will start/stop the modem.

b10 En RAW:

0 = data packetising on 1 = raw data mode

This bit selects the raw or formatted (data packetising) mode for DSC data.

DSC Receive mode:

b10 = 1: device will look for the programmed Frame Sync. pattern, raise an interrupt (if enabled) and decode the following data 16 bits at a time, making them available in Rx Data 1 register (\$C5).

DSC Transmit mode:

b10 = 1: device will transmit data 16 bits at a time from Tx Data 1 register (\$CA). Bit and frame sync pattern generation and all formatting of the data have to be performed by the host in this case.

b9 Last Tx data:

This is only valid when transmitting data in DSC formatted mode and indicates to the CMX885 that it can cease modulation. The host must set this bit to 1 immediately after the interrupt for 'load more data' occurs \$C6:b6. In receive, or when transmitting other message formats, this bit must be cleared to 0.

b8-3 reserved, clear to 0

b2 User bit.

May be freely used by the host in DSC modes. This bit has no effect on the message format or encoding and will be reported in the Rx Data 1 register for the receiving host to use as appropriate. This bit could be used to indicate a special message, e.g. one containing handset or channel set-up information.

b1-0 reserved, clear to 0

8.1.24 Programming Register - \$C8 write

<del></del>	9	. •	<u></u>	9.000	<del>+</del>										
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Prog	gram Blo	ock Add	ress					Pro	ogram E	Block Da	ata				

See section 8.2 for a definition of program block operation.

#### 8.1.25 Tx Data 1 - \$CA write

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
\$CA	flag			DSC	Charac	cter 0			flag			DSC	Chara	cter 1		

This word holds the next 2 bytes (Byte 0 and 1) of DSC data to be transmitted. Outgoing data is continuous, if new data is not provided before the current data has been transmitted the current data will be re-transmitted, until new data is provided. Transmission of current data will be completed before transmission of newly loaded data begins. See section 7.7.2.

In DSC Formatted mode, if the flag bit (b15 or b7) is set, then the accompanying character is ignored.

### 8.1.26 Tone Status - \$CC read

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
						D	evice Id	ent Cod	de						
Х	DTI	MF Ton	e Detec	ted	DT	х	х	х	х	х	х	х	х	х	Х

After power-on or General Reset, this register will contain the Device Ident code related to this particular device. The host  $\mu$ C may use this to confirm that the device is in its correct operational mode before attempting to actively use the device.

In normal operation, this word holds the current status of the CMX885 DTMF detector. This word should be read by the host after an interrupt caused by a DTMF event. In Tx mode this register will be cleared to 0.

- b15 reserved ignore this bit.
- b10 set if b14-11 represent DTMF tone.
- b14-11 Detected inband frequency; identifies the frequency by its position in Table 3 DTMF Tone Pairs. A change in the state of bits 14 to 10 will cause the Status register \$C6:b12, to be set to 1.
- b9-0 reserved ignore these bits.

Bits 15-12 determine how the remaining bit fields will be interpreted:

#### $0000_2$ :

When the appropriate bit of the Mode Control register C1:b10 is set, an audio tone will be generated with the frequency set by bits (11-0) of the Audio Tone register in accordance with the formula below. If bits 11-0 are programmed with 0, no tone (i.e.  $V_{BIAS}$ ) will be generated when the Audio Tone is enabled.

The Audio Tone frequency should only be set to generate frequencies from 288Hz to 3000Hz.

The host should disable other audio band signalling and set the correct audio routing before generating an audio tone and re-enable signalling and audio routing on completion of the audio tone. The timing of intervals between these actions is controlled by the host  $\mu C$ .

This register may be written to whilst the audio tone is being generated, any change in frequency will take place after the end of the C-BUS write to this register. This allows complex sequences (e.g. ring or alert tunes) to be generated for the local speaker (Tx or Rx via the AUDIO pin) or transmitted signal (Tx via the MOD1/MOD2 pins).

#### 0010<sub>2</sub>:

The Audio Tone Level may be attenuated by the value written to b11-0. The default value of \$FFF is equivalent to x1. Note that this adjustment will affect ALL signals generated by the In-Band signalling block (DTMF, FSK, Audio Tone). This register operates in parallel with P1.0 so that the last register written (\$CD with value \$2xxx or \$C8 P1.0 with value \$Dxxx) will set the attenuation. Note that successive writes to \$CD register will only be actioned if the data values are different, even if another register is accessed in between.

#### Example:

The writes \$CD=\$2123, \$C8=\$D456, \$C3=2123 will result in the last write to \$CD being ignored, whereas the writes \$CD=\$2123, \$C8=\$D456, \$CD=2124 will result in the last write to \$CD being actioned.

## 01002:

In Rx mode, the voice level may be attenuated by the value written to b11-0. The default value of \$FFF is equivalent to x1. Note that this adjustment will only affect signals in the voice processing path as enabled by the Mode Control register \$C1:b14. This allows the voice level to be adjusted "on-the-fly" and in conjunction with the Audio Output attenuator \$B0:b3 to b0, offers a "fine gain" volume control. Approximate values for 0.2dB steps are shown in Table 5.

b11-0 Value (hex)	Attenuation (dB)	b11-0 Value (hex)	Attenuation (dB)
FFF	0	D50	1.6
F90	0.2	CF0	1.8
F40	0.4	CB0	2.0
EE0	0.6	C60	2.2
EA0	0.8	C20	2.4
E50	1.0	BF0	2.6
DE0	1.2	BA0	2.8
DA0	1.4	B60	3.0

**Table 5 Voice Level Attenuation** 

#### 0110<sub>2</sub>:

The Output 1 level may be attenuated by the value written to b11-0. The default value of \$FFF is equivalent to x1. This register operates in parallel with P4.2, but allows the level to be adjusted "on-the-fly" without needing to drop back into Idle mode. Approximate values are shown in Table 6.

#### $1000_2$ :

The Output 2 level may be attenuated by the value written to b11-0. The default value of \$FFF is equivalent to x1. This register operates in parallel with P4.4, but allows the level to be adjusted "on-the-fly" without needing to drop back into Idle mode. Approximate values are shown in Table 6.

b11-0 Value (hex)	Attenuation (dB)	b11-0 Value (hex)	Attenuation (dB)
FFF	0	CB5	2.0
FA2	0.2	C6B	2.2
F47	0.4	C22	2.4
EEE	0.6	BDC	2.6
E97	0.8	B97	2.8
E42	1.0	B53	3.0
DEF	1.2	B11	3.2
D9D	1.4	AD1	3.4
D4E	1.6	AB1	3.5
D01	1.8		

Table 6 Output 1 and 2 Level Attenuation

 $Gain = 20 \times log(OG / 4095)dB$ . OG is the unsigned integer value in the 'Fine Output Gain' field.

Please note that differences between the calculated values and measured levels is due to truncation of the programmed values.

### 1010<sub>2</sub>:

This sets the value of the Tx Voice Level Multiplier at the output of the Tx limiter stage. This can be useful in situations where it has been necessary to use a small limiting threshold and still maintain an acceptable level at the MOD outputs. The default state is x1.

b2	b1	b0	Tx Voice Level Multiplier
0	0	0	x1
0	0	1	x2
0	1	0	x4
0	1	1	x8
1	0	0	x16
1	0	1	x32

#### 1100<sub>2</sub>:

MOD1 and MOD2 fine attenuator controls. In conjunction with the coarse attenuator register (\$B0), these bits allow fine control over the MOD1 and MOD2 levels in 0.2dB steps. Additional gain and offset control of Output 1 and Output 2 is also provided in register \$CD:0111 and \$CD:1000 settings as well as Program Blocks P4.2 – 4.5. These bits may be changed whilst the device is in Tx or Rx modes.

b3	b2	b1	b0	MOD1 Fine Output Attenuation

	0	Disabled

## 8.1.29 Reserved - \$CF write

This C-BUS address is allocated for production testing and must not be accessed in normal operation.

## 8.2 Programming Register Operation

In order to support radio systems that may not comply with the default settings of the CMX885, a set of Program Blocks is available to customise the features of the device. It is envisaged that these blocks will usually only be written to following a power-on of the device and hence can only be accessed while the device is in Idle mode. Access to these blocks is via the Programming register (\$C8).

All other interrupt sources should be disabled and the AuxADCs switched off while loading the Program Blocks.

The Programming register should only be written to when the PRG flag in the Status register \$C8:b0 is set to 1 and the Rx and Tx modes are disabled (bits 0 and 1 of the Mode Control register both 0) and the AuxADC is disabled.

The PRG flag is cleared when the Programming register is written to by the host. When the corresponding programming action has been completed (normally within the C-BUS latency period, 250µs) the CMX885 will set the flag back to 1 to indicate that it is now safe to write the next programming value. The Programming register must not be written to while the PRG flag bit is 0. Programming is performed by writing a sequence of 16-bit words to the Programming register in the order shown in the following tables. Writing data to the Programming register MUST be performed in the order shown for each of the blocks, however the order in which the blocks are written is not critical. If later words in a block do not require updating the user may stop programming that block when the last change has been performed. e.g. If only 'Fine output Atten 1' needs to be changed the host will need to write to P4.0, P4.1 and P4.2 only.

The user must not exceed the defined word counts for each block.

The internal pointer for each Program block write is initialised by setting bit 15 to 1. Bits 14-12 are then used to select the particular Program block in use as shown in Table 7. Subsequent writes to the Program Register (with b15 cleared to 0) will increment the pointer until the end of the Program Block is reached. Program Block 3 has an additional feature to facilitate RAMDAC programming, where the first eleven entries of the block may be skipped by setting both b15 and b10 to 1 to initialise the pointer directly to the start of the RAMDAC table.

b14 b13 Bit Field (max) b15 b12 0 Select Block 4 14 Х Х Select Block 0 1 1 0 0 12 1 1 0 1 Select Block 1 12 1 0 1 1 Select Block 2 12 1 Select Block 3 12 1

**Table 7 Program Block Selection** 

Once the final write to the Programming register has been executed, a final check of the PRG flag should be performed before returning to normal operation.

8.2.1 Program Block 0 – Modem Configuration

Bit:	15	14	13	12	11 10 9 8				7	6	5	4	3	2	1	0

Default values: P1.0: \$800

## \$C8 (P1.0) Audio Band Tones Tx Level

Bits 11 (MSB) to 1 (LSB) set the transmitted DTMF, Audio Tone and FSK signal level (pk-pk) with a resolution of  $AV_{DD}/2048$  per LSB (1.611mV per LSB at  $AV_{DD}=3.3V$ ). Valid range for this value is 0 to 1536 – use with care as higher values may result in signal "clipping". Bit 0 reserved

#### 8.2.3 Program Block 2 - reserved

## 8.2.4 Program Block 3 – AuxDAC, RAMDAC and Clock Control

This block is divided into two sub-blocks to facilitate loading the RAMDAC buffer. Set bit 15 to restart a loading sequence. If bit 10 is set then loading the first ten locations will be skipped. If bit 10 is clear, the first ten locations must be loaded before continuing to the RAMDAC load.

The internal clock dividers only require modification if a non-standard XTAL frequency is used (see Table 2).

17F5	1.8		

Table 9 Output 1 and 2 Level Attenuation

Gain =  $20 \times \log([32768\text{-OG}]/32768)$ dB. OG is the unsigned integer value in the 'Fine Output Gain' field. Note that differences between the calculated values and measured levels is due to truncation of the programmed values.

Fine output gain adjustment should be kept within the range 0dB to -3.5dB. This adjustment occurs before the coarse output gain adjustment (register \$B0). Alteration of Fine Output Gain 1 will affect the gain of both MOD1 and AUDIO outputs.

\$C8 (P4.4-5) Output 1 Offset and Output 2 Offset

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
P4.4	0	0		2's complement Offset for MOD1, resolution = AV <sub>DD</sub> / 65536 per LSB													
P4.5	0	0		2's complement Offset for MOD2, resolution = AV <sub>DD</sub> / 65536 per LSB													

The programmed value is subtracted from the output signal. Can be used to compensate for inherent offsets in the output path via MOD1 (Output 1 Offset) and MOD2 (Output 2 Offset). It is recommended that the offset correction is kept within the range +/-50mV. This adjustment occurs before the coarse output gain adjustment (register \$B0), therefore an alteration to the latter register will require a compensation to be made to the output offsets.

\$C8 (P	4.6)	Rar	np Ra	te Co	ntrol											
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
P4.6	0	0		Ram	p Rate	Up Co	ntrol (F	RRU)			Ramp	Rate [	Down C	ontrol	(RRD)	

The ramp-up and ramp-down rates can be independently programmed. The ramp rates apply to all the analogue output ports. They only affect those ports being turned on (ramp-up) or turned off (ramp down). The ramp rates should be programmed before ramping any outputs.

Time to ramp-up to full gain = 
$$(1 + RRU) \times 1.333ms$$
  
Time to ramp down to zero gain =  $(1 + RRD) \times 1.333ms$ 

Ramp up starts from when the transmit mode starts (Mode Control Register \$C1:b1 set to 1). Ramp down starts from when transmit mode is turned off (Mode Control Register \$C1:b1 cleared to 0).

\$C8 (P	4.7)	Tra	nsmit	Limite	er Cor	ntrol										
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
P4.7	0	0		Limiter Setting												

This unsigned number sets the clipping point (maximum deviation from the centre value) for the MOD1 and MOD2 pins. The maximum setting (\$3FFF) is  $V_{BIAS} \pm (AV_{DD}/2)$  i.e. output limited from 0 to  $AV_{DD}$ .

For an AVDD of 3.3V, the resolution is approx. 0.3mV per LSB.

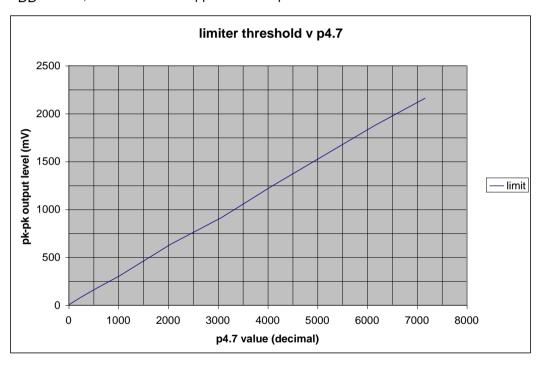

Figure 15 Limiter Values

The limiter is set to maximum following a C-BUS Reset or a Power-up Reset. The levels of internally generated signals may need to be adjusted by setting appropriate transmit levels to avoid unintentional limiting.

\$C8 (P	4.8)	Scr	amble	r Inve	rsion	Frequ	iency									
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
P4.8	0	0				S	cramble	er Inve	rsion F	requen	icy = f	/ 0.732	24			

This unsigned hex number sets the inversion frequency for the Voice Scrambler and de-Scrambler (Default is 3300Hz).

\$C8 (P	4.9)	Aud	dio Filte	r Seq	uence	!										
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
P4.9	0	0	Limit	src	Input AGC				Pre-	emp	0	1	Scra	mble	300	)Hz

b13 sets the position of the limiter in the Audio Processing chain. The default is a soft limiter function; setting this bit provides a hard limiter function (placing the limiter at the output of the channel filter).

b12 sets the source of the reference signal when InputAGC function is active.

0 = Audio Input

1 = Pre-emphasis output

b11-8 control the hardware InputAGC function and its release timer for Voice / Audio signals on Input 1 in 64ms steps:

0000	InputAGC off
0001	InputAGC on, release time = 64ms
0010	InputAGC on, release time = 128ms
0011	InputAGC on, release time = 196ms
0100	InputAGC on, release time = 256ms
0101	InputAGC on, release time = 320ms
1111	InputAGC on, release time = 960ms

b7-0 set the order of the Audio Filter processing. This feature can be used to optimise the signal to noise performance of particular radio hardware designs. Each filter/process block can be specified in any order. Each two-bit field specifies the order in which the process will be executed in Tx mode, therefore it is imperative that each set of bit fields be different. The reverse sequence is used in Rx mode. The Voice Filter and Soft Limiter will always be implemented as the final block in the Tx sequence.

The default settings (P4.9 = \$001B) are:

Pre-emph: 00
 Dummy: 01
 Scramble: 10
 300Hz HPF: 11

which will implement the line-up as shown below:

Figure 16 Default Tx Audio Filter Line-up

Figure 17 Default Rx Audio Filter Line-up

An alternative, preferred, line-up is shown below for the following settings (P4.9 = \$004B):

Dummy: 01
 Pre-emph: 00
 Scramble: 10
 300Hz HPF: 11

## Figure 18 Preferred Tx Audio Filter Line-up

Figure 19 Preferred Rx Audio Filter Line-up

## \$C8 (P4.10) Reserved - do not use

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
P4.10	0	0						reser	ved – s	set to \$	8090					

Reserved - set to \$0608

## \$C8 (P4.11) Input AGC Threshold Level

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
P4.11	0	0				Thresh	old Se	etting, r	esolutio	on = A\	V <sub>DD</sub> /16	384 pe	er LSB			

This unsigned number sets the threshold point (maximum deviation from the centre value) for the Input AGC function, where the input gain will be stepped to avoid exceeding the specification limits.

The threshold is set to half of full-scale ( $\$0FFF = V_{BIAS} \pm (AV_{DD}/4)$ ) following a C-BUS Reset or a Power-Up Reset.

## 8.2.6 Initialisation of the Program Blocks

Removal of the Signal Processing block from reset (Power Down register,  $C0:b5\ 1 \rightarrow 0$  transition), with b4 kept low (= 0), will cause all of the Program Blocks (P0 – P4) to be reset to their default values.

## 9 Performance Specification

## 9.1 Electrical Performance

## 9.1.1 Absolute Maximum Ratings

Exceeding these maximum ratings can result in damage to the device.

	Min.	Max.	Unit
Supply: DV <sub>DD</sub> - DV <sub>SS</sub>	-0.3	4.5	V
AV <sub>DD</sub> - AV <sub>SS</sub>	-0.3	4.5	V
Voltage on any pin to DV <sub>SS</sub>	-0.3	$DV_{DD} + 0.3$	V
Voltage on any pin to AV <sub>SS</sub>	-0.3	$AV_{DD} + 0.3$	V
Current into or out of any power supply pin (excluding VBIAS) (i.e. VDEC, AVDD, AVSS, DVDD, DVSS)	-30	+30	mA
Current into or out of any other pin	-20	+20	mA
Voltage differential between power supplies:			
DV <sub>DD</sub> and AV <sub>DD</sub>	0	0.3	V
DV <sub>SS</sub> and AV <sub>SS</sub>	0	50	mV

Q3 Package (48-pin VQFN)	Min.	Max.	Unit
Total Allowable Power Dissipation at Tamb = 25°C	_	1750	mW
Derating	_	17.5	mW/°C
Storage Temperature	-55	+125	°C
Operating Temperature	-40	+85	°C

L4 Package (48-pin LQFP)	Min.	Max.	Unit
Total Allowable Power Dissipation at Tamb = 25°C	_	1600	mW
Derating	_	16	mW/°C
Storage Temperature	-55	+125	°C
Operating Temperature	-40	+85	°C

## 9.1.2 Operating Limits

Correct operation of the device outside these limits is not implied.

	Notes	Min.	Max.	Unit
Supply Voltage:				
DVDD - DVss		3.0	3.6	V
AVDD - AVSS		3.0	3.6	V
VDEC - DVss	12	2.25	2.75	V
Operating Temperature		-40	+85	°C
XTAL/CLK Frequency (using a Xtal)	11	3.0	12.288	MHz
XTAL/CLK Frequency (using an external clock)	11	3.0	24.576	MHz

**Notes:** 11 Nominal XTAL/CLK frequency is 3.6864MHz.

The VDEC supply is automatically created from DVDD by the on-chip voltage regulator.

## 9.1.3 Operating Characteristics

For the following conditions unless otherwise specified:

External components as recommended in Figure 2.

Maximum load on digital outputs = 30pF.

Xtal Frequency = 3.6864MHz  $\pm 0.01\%$  (100ppm); Tamb = -40°C to +85°C.

 $AV_{DD} = DV_{DD} = 3.0V \text{ to } 3.6V.$ 

Reference Signal Level = 308mV rms at 1kHz with  $AV_{DD} = 3.3V$ .

Signal levels track with supply voltage, so scale accordingly.

Signal to Noise Ratio (SNR) in bit rate bandwidth.

Input stage gain = 0dB. Output stage attenuation = 0dB.

DC Parameters	Notes	Min.	Тур.	Max.	Unit

## Notes:

41

- Power-up refers to issuing a C-BUS command to turn on an output. These limits apply only if VBIAS is on and stable. At power supply switch-on, the default state is for all blocks, except the XTAL and C-BUS interface, to be placed in powersave mode.
- Small signal impedance, at  $AV_{DD} = 3.3V$  and Tamb = 25°C.
- With respect to the signal at the feedback pin of the selected input port.
- Centred about  $AV_{DD}/2$ ; with respect to the output driving a  $20k\Omega$  load to  $AV_{DD}/2$ .

#### Figure 20 C-BUS Timing

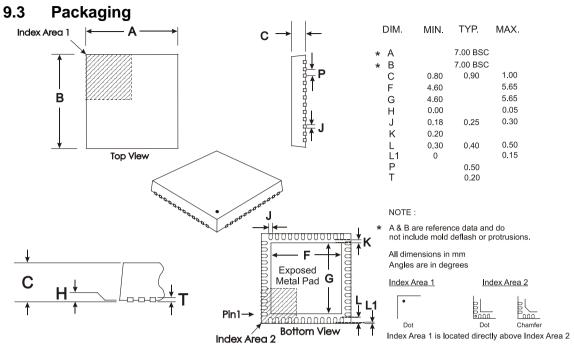

RDATA

Notes:

CDATA

- Depending on the command, 1 or 2 bytes of CDATA are transmitted to the peripheral MSB (Bit 7) first, LSB (Bit 0) last. RDATA is read from the peripheral MSB (Bit 7) first, LSB (Bit 0) last
- 2. Data is clocked into the peripheral on the rising SCLK edge.
- 3. Commands are acted upon at the end of each command (rising edge of CSN).
- 4. To allow for differing μC serial interface formats, C-BUS compatible ICs are able to work with SCLK pulses starting and ending at either polarity.
- 5. Maximum 30pF load on IRQN pin and each C-BUS interface line.

These timings are for the latest version of C-BUS and allow faster transfers than the original C-BUS timing specification. The CMX885 can be used in conjunction with devices that comply with the slower timings, subject to system throughput constraints.

Depending on the method of lead termination at the edge of the package, pull back (L1) may be present.

L minus L1 to be equal to, or greater than 0.3mm

The underside of the package has an exposed metal pad which should ideally be soldered to the pcb to enhance the thermal conductivity and mechanical strength of the package fixing. Where advised, an electrical connection to this metal pad may also be required
