

## FEATURES

- Low noise: 2.7nV/√Hz at f = 10 kHz
- Low offset voltage: 250 μV max over VCM
- Offset voltage drift: 0.4 μV/°C typ and 2.3 μV/°C max
- Bandwidth: 28 MHz
- Rail-to-rail input/output
- Unity gain stable
- 2.7 V to 5.5 V operation
- -40°C to +125°C operation
- Qualified for automotive applications

## APPLICATIONS

- ADC and DAC buffers
- Audi
- Industrial controls
- Precision filters
- Digital scales
- Automotive collision avoidance
- PLL filters

## GENERAL DESCRIPTION

The CBM8655/CBM8656 are the industry's lowest noise, precision CMOS amplifiers. They leverage the Analog Devices DigiTrim® technology to achieve high dc accuracy.

The CBM8655/CBM8656 provide low noise (2.7nV/√Hz at 10 kHz), low THD + N (0.0007%), and high precision performance (250 μV max over VCM) to low voltage applications. The ability to swing rail-to-rail at the input and output enables designers to buffer analog-to-digital converters (ADCs) and other wide dynamic range devices in single-supply systems.

The high precision performance of the CBM8655/CBM8656 improves the resolution and dynamic range in low voltage applications. Audio applications, such as microphone pre-amps and audio mixing consoles, benefit from the low noise, low distortion, and high output current capability of the CBM8655/CBM8656 to reduce system level noise performance and maintain audio fidelity. The high precision and rail-to-rail input and output of the CBM8655/ CBM8656 benefit data acquisition, process controls, and PLL filter applications.

The CBM8655/CBM8656 are fully specified over the -40°C to +125°C temperature range. The CBM8655/CBM8656 are available in Pb-free, 8-lead MSOP and SOIC packages. The CBM8655/CBM8656 are both available for automotive applications.

### ABSOLUTE MAXIMUM RATINGS

Table 2.

Parameter	Rating
Supply Voltage	6V
Input Voltage	VSS-0.3V to VDD+0.3V
Differential Input Voltage	±6 V
Output Short-Circuit Duration to GND	Indefinite
Electrostatic Discharge (HBM)	3.0kV
Storage Temperature Range R, RM Packages	-65°C to +150°C
Junction Temperature Range R, RM Packages	-65°C to +150°C
Lead Temperature (Soldering, 10 sec)	260°C

Table 4.

Package Type	$\theta_{JA}^1$	$\theta_{JC}$	Unit
8-Lead MSOP (RM)	210	45	°C/W
8-Lead SOIC (R)	158	43	°C/W

Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only; functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

### ESD SENSITIVITY CAUTION

ESD damage can range from subtle performance degradation to complete device failure. Precision integrated circuits may be more susceptible to damage because very small parametric changes could cause the device not to meet its published specifications.

## **THEORY OF OPERATION**

The CBM8655/CBM8656 amplifiers are voltage feedback, rail-to-rail input and output precision CMOS amplifiers, which operate from 2.7V to 5.0V of power supply voltage. These amplifiers use the Analog Devices DigiTrim technology to achieve a higher degree of precision than is available from most CMOS amplifiers. DigiTrim technology, used in a number of Analog Devices amplifiers, is a method of trimming the offset voltage of the amplifier after it is packaged. The advantage of post-package trimming is that it corrects any offset voltages caused by the mechanical stresses of assembly.

The CBM8655/CBM8656 are available in standard op amp pinouts, making DigiTrim completely transparent to the user. The input stage of the amplifiers is a true rail-to-rail architecture, allowing the input common-mode voltage range of the amplifiers to extend to both positive and negative supply rails. The open-loop gain of the CBM8655/CBM8656 with a load of 10k $\Omega$  is typically 110dB.

The CBM8655/CBM8656 can be used in any precision op amp application. The amplifier does not exhibit phase reversal for common-mode voltages within the power supply. The CBM8655/ CBM8656 are great choices for high resolution data acquisition systems with voltage noise of 2.7nV/ $\sqrt{\text{Hz}}$  and THD + Noise of  $-103$  dB for a 2V p-p signal at 10kHz. Their low noise, sub-pA input bias current, precision offset, and high speed make them superb preamps for fast filter applications. The speed and output drive capability of the CBM8655/CBM8656 also make them useful in video applications.

## **APPLICATIONS INFORMATION**

### **INPUT OVERVOLTAGE PROTECTION**

The internal protective circuitry of the CBM8655/CBM8656 allows voltages exceeding the supply to be applied at the input. It is recommended, however, not to apply voltages that exceed the supplies by more than 0.3V at either input of the amplifier. If a higher input voltage is applied, series resistors should be used to limit the current flowing into the inputs. The input current should be limited to less than 5mA.

The extremely low input bias current allows the use of larger resistors, which allows the user to apply higher voltages at the inputs. The use of these resistors adds thermal noise, which contributes to the overall output voltage noise of the amplifier. For example, a 10k $\Omega$  resistor has less than 12.6nV/ $\sqrt{\text{Hz}}$  of thermal noise and less than 10nV of error voltage at room temperature.

### **INPUT CAPACITANCE**

Along with bypassing and ground, high speed amplifiers can be sensitive to parasitic capacitance between the inputs and ground. For circuits with resistive feedback network, the total capacitance, whether it is the source capacitance, stray capacitance on the input pin, or the input capacitance of the amplifier, causes a breakpoint in the noise gain of the circuit. As a result, a capacitor must be added in parallel with the gain resistor to obtain stability. The noise gain is a function of frequency and peaks at the higher frequencies, assuming the feedback capacitor is selected to make the second-order system critically damped. A few picofarads of capacitance at the input reduce the input impedance at high frequencies, which increases the amplifier's gain, causing peaking in the frequency response or oscillations. With the CBM8655/CBM8656, additional input damping is required for stability with capacitive loads greater than 200 pF with direct input to output feedback. See the Driving Capacitive Loads section.

### **DRIVING CAPACITIVE LOADS**

Although the CBM8655/CBM8656 can drive capacitive loads up to 500 pF without oscillating, a large amount of ringing is present when operating the part with input frequencies above 100 kHz. This is especially true when the amplifiers are configured in positive unity gain (worst case). When such large capacitive loads are required, the use of external compensation is highly recommended. This reduces the overshoot and minimizes ringing, which, in turn, improves the stability of the CBM8655/ CBM8656 when driving large capacitive loads.

One simple technique for compensation is a snubber that consists of a simple RC network.

With this circuit in place, output swing is maintained, and the amplifier is stable at all gains. Figure 55 shows the implementation of a snubber, which reduces overshoot by more than 30% and eliminates ringing. Using a snubber does not recover the loss of bandwidth incurred from a heavy capacitive load.

## **LAYOUT, GROUNDING, AND BYPASSING CONSIDERATIONS**

### **POWER SUPPLY BYPASSING**

Power supply pins can act as inputs for noise, so care must be taken to apply a noise-free, stable dc voltage. The purpose of bypass capacitors is to create low impedances from the supply to ground at all frequencies, thereby shunting or filtering most of the noise. Bypassing schemes are designed to minimize the supply impedance at all frequencies with a parallel combination of capacitors with values of 0.1  $\mu\text{F}$  and 4.7  $\mu\text{F}$ . Chip capacitors of 0.1  $\mu\text{F}$  (X7R or NPO) are critical and should be as close as possible to the amplifier package. The 4.7  $\mu\text{F}$  tantalum capacitor is less critical for high frequency bypassing, and, in most cases, only one is needed per board at the supply inputs.

### **GROUNDING**

A ground plane layer is important for densely packed PC boards to minimize parasitic inductances. This minimizes voltage drops with changes in current. However, an understanding of where the current flows in a circuit is critical to implementing effective high speed circuit design. The length of the current path is directly proportional to the magnitude of parasitic inductances, and, therefore, the high frequency impedance of the path. Large changes in currents in an inductive ground return create unwanted voltage noise.

The length of the high frequency bypass capacitor leads is critical, and, therefore, surface-mount capacitors are recommended. A parasitic inductance in the bypass ground trace works against the low impedance created by the bypass capacitor. Because load currents flow from the supplies, the ground for the load impedance should be at the same physical location as the bypass capacitor grounds. For larger value capacitors intended to be effective at lower frequencies, the current return path distance is less critical.

### **LEAKAGE CURRENTS**

Poor PC board layout, contaminants, and the board insulator material can create leakage currents that are much larger than the input bias current of the CBM8655/CBM8656. Any voltage differential between the inputs and nearby traces creates leakage currents through the PC board insulator, for example,  $1 \text{ V}/100 \text{ G}\Omega = 10 \text{ pA}$ . Similarly, any contaminants on the board can create significant leakage (skin oils are a common problem).

To significantly reduce leakage, put a guard ring (shield) around the inputs and input leads that are driven to the same voltage potential as the inputs. This ensures there is no voltage potential between the inputs and the surrounding area to create any leakage currents. To be effective, the guard ring must be driven by a relatively low impedance source and should completely surround the input leads on all sides, above and below, by using a multilayer board.

The charge absorption of the insulator material itself can also cause leakage currents. Minimizing the amount of material between the input leads and the guard ring helps to reduce the absorption. Also, using low absorption materials, such as Teflon<sup>®</sup> or ceramic, may be necessary in some instances.

## AUTOMOTIVE PRODUCTS

The CBM8655 model and the CBM8656 model are available with controlled manufacturing to support the quality and reliability requirements of automotive applications. Note that these automotive models may have specifications that differ from the commercial models; therefore, designers should review the Specifications section of this data sheet carefully. Only the automotive grade products shown are available for use in automotive applications. Contact your local Analog Devices account representative for specific product ordering information and to obtain the specific Automotive Reliability reports for this model.
