Notes:

1. Vcc = 5, 12, 15 or 24 V according to the model (5 V standard - 12, 15 and 24 V on request).
2. A, B, C and D correspond respectively to 1, 2, 4 and 8 of BCD code.
3. In all C-MOS decoders, it is mandatory that all inputs be connected at ALL times either to the + or the ground (except RBI-RBO - see note 5). The use of bias resistors is therefore necessary (see diagram). Should an input not be used at all, it may be directly connected either to the + or the ground (depending on the function).
4. For TTL decoders, should an input not be connected to either the + or the ground, the decoder might not work properly (while not connected), but it would not be destroyed.
5. The non-significant zeros are cancelled when RBI (Ripple Blanking Input) is connected to the ground, if several modules are connected together the RBI of the module adjacent to the module of the units (eg: ten or tenth) must be connected to the RBO (Ripple Blanking Output) of the next unit (hundred or hundredth) etc. The first RBO's (ten and tenth) as well as the unit's are left unconnected. (the zero of the unit is never cancelled).

If the zero cancellation is not required, the RBI inputs must be connected to the + of the power supply and RBO must be left unconnected.

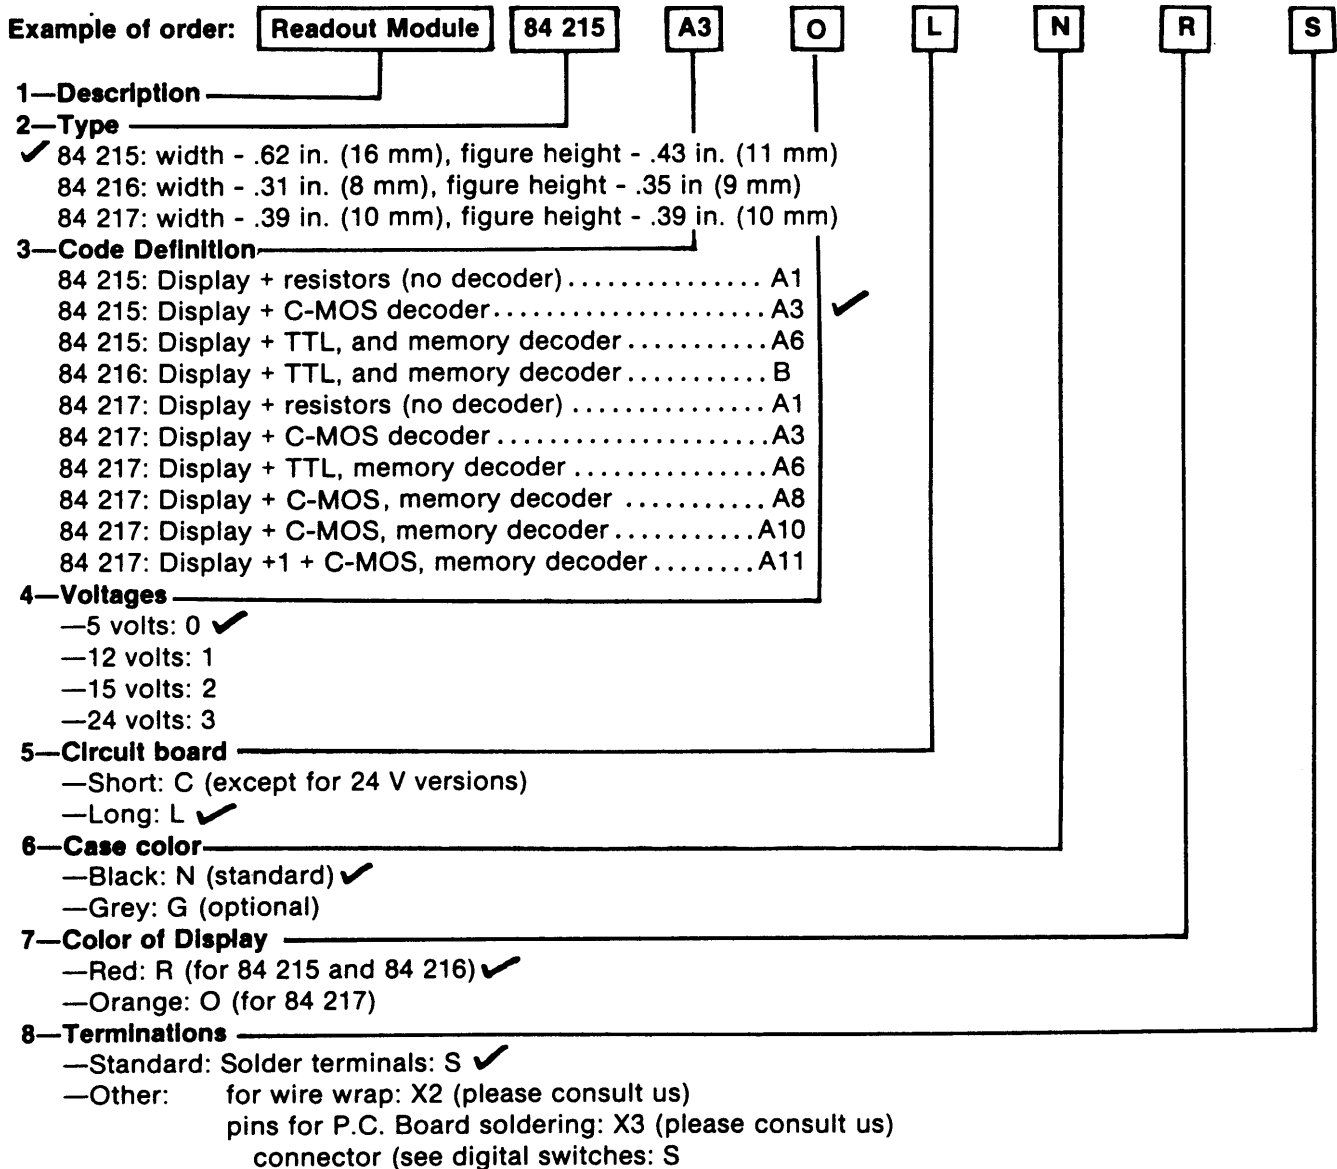

6. Connecting BI (Blanking Input) to the ground cancels the display (otherwise connect BI to + of supply)
7. Connecting LT (Lamp Test) input to ground makes possible to control all segments (otherwise connect to + of supply).
8. Connecting EL (Enable Latch) to + of supply keeps display in memory. Otherwise connect EL to ground.
9. TEN output is in state "0" when digits from 0 to 9 displayed and in state "1" when digits from A to F displayed.
10. VCR output is open for displays from 0 to E. When displayed the state is "0".
