Functional Description

The CY29947 is a low-voltage 200 MHz clock distribution buffer with the capability to select one of two LVCMOS/LVTTL compatible clock inputs. The two clock sources can be used to provide for a test clock as well as the primary system clock. All other control inputs are LVCMOS/LVTTL compatible. The 9 outputs are LVCMOS or LVTTL compatible and can drive 50 Ω series or parallel terminated transmission lines.For series terminated transmission lines, each output can drive one or two traces giving the device an effective fanout of 1:18. The outputs can also be three-stated via the three-state input TS#. Low output-to-output skews make the CY29947 an ideal clock distribution buffer for nested clock trees in the most demanding of synchronous systems.

The CY29947 also provides a synchronous output enable input for enabling or disabling the output clocks. Since this input is internally synchronized to the input clock, potential output glitching or runt pulse generation is eliminated.

Output Enable/Disable

The CY29947 features a control input to enable or disable the outputs. This data is latched on the falling edge of the input clock. When SYNC_OE is asserted LOW, the outputs are disabled in a LOW state. When SYNC_OE is set HIGH, the outputs are enabled as shown in Figure 2.

Maximum Ratings

Exceeding maximum ratings [2] may shorten the useful life of the device. User guidelines are not tested.

Maximum Input Voltage Relative to V_{SS}: .... V_{SS} – 0.3 V

Maximum Input Voltage Relative to V_{DD}: .... V_{DD} + 0.3 V

Storage Temperature: .... –65 °C to + 150 °C

Operating Temperature: .... –40 °C to +85 °C

Maximum ESD protection .... 2 kV

Maximum Power Supply: .... 5.5 V

Maximum Input Current: .... ±20 mA

This device contains circuitry to protect the inputs against damage due to high static voltages or electric field; however, precautions should be taken to avoid application of any voltage higher than the maximum rated voltages to this circuit. For proper operation, V_{in} and V_{out} should be constrained to the range:

$$V_{SS} < (V_{in} \text{ or } V_{out}) < V_{DD}$$

Unused inputs must always be tied to an appropriate logic voltage level (either V_{SS} or V_{DD}).
