

18-Mbit (512K × 36/1M × 18) Pipelined DCD Sync SRAM

Features

- Supports bus operation up to 200 MHz
- Available speed grades are 200, and 167 MHz
- Registered inputs and outputs for pipelined operation
- Optimal for performance (double-cycle deselect)
- Depth expansion without wait state
- 3.3 V core power supply (V_{DD})
- 2.5 V or 3.3 V I/O power supply (V_{DDQ})
- Fast clock-to-output times
 - 3 ns (for 200 MHz device)
- Provides high performance 3-1-1-1 access rate
- User selectable burst counter supporting Intel® Pentium® Interleaved or linear burst sequences
- Separate processor and controller address strobes
- Synchronous self-timed writes
- Asynchronous output enable
- CY7C1386D available in JEDEC-standard Pb-free 100-pin TQFP. CY7C1387D available in JEDEC-standard Pb-free 100-pin TQFP and non Pb-free 165-ball BGA package
- IEEE 1149.1 JTAG-compatible boundary scan
- ZZ sleep mode option

Functional Description

The CY7C1386D/CY7C1387D SRAM integrates 512K × 36/1M × 18 SRAM cells with advanced synchronous peripheral circuitry and a two-bit counter for internal burst operation. All synchronous inputs are gated by registers controlled by a positive edge triggered clock input (CLK). The synchronous inputs include all addresses, all data inputs, address-pipelining chip enable (\overline{CE}_1), depth expansion chip enables (\overline{CE}_2 and \overline{CE}_3), burst control inputs (\overline{ADSC} , \overline{ADSP} , and \overline{ADV}), write enables (\overline{BW}_X , and \overline{BWE}), and global write (\overline{GW}). Asynchronous inputs include the output enable (\overline{OE}) and the ZZ pin.

Addresses and chip enables are registered at rising edge of clock when either address strobe processor (\overline{ADSP}) or address strobe controller (\overline{ADSC}) are active. Subsequent burst addresses can be internally generated as controlled by the advance pin (\overline{ADV}).

Address, data inputs, and write controls are registered on-chip to initiate a self timed write cycle. This part supports byte write operations (see [Pin Configurations on page 5](#) and [Truth Table on page 11](#) for further details). Write cycles can be one to four bytes wide as controlled by the byte write control inputs. \overline{GW} active LOW causes all bytes to be written. This device incorporates an additional pipelined enable register which delays turning off the output buffers an additional cycle when a deselect is executed. This feature allows depth expansion without penalizing system performance.

The CY7C1386D/CY7C1387D operates from a +3.3 V core power supply while all outputs operate with a +3.3 V or +2.5 V supply. All inputs and outputs are JEDEC-standard and JESD8-5-compatible.

Pin Definitions

Name	I/O	Description
A ₀ , A ₁ , A	Input-Synchronous	Address inputs used to select one of the address locations. Sampled at the rising edge of the CLK if ADSP or ADSC is active LOW, and CE ₁ , CE ₂ , and CE ₃ are sampled active. A ₁ :A ₀ are fed to the two-bit counter.
\overline{BW}_A , \overline{BW}_B , \overline{BW}_C , \overline{BW}_D	Input-Synchronous	Byte write select inputs, active LOW. Qualified with \overline{BWE} to conduct byte writes to the SRAM. Sampled on the rising edge of CLK.
\overline{GW}	Input-Synchronous	Global write enable input, active LOW. When asserted LOW on the rising edge of CLK, a global write is conducted (all bytes are written, regardless of the values on \overline{BW}_X and BWE).
\overline{BWE}	Input-Synchronous	Byte write enable input, active LOW. Sampled on the rising edge of CLK. This signal must be asserted LOW to conduct a byte write.
CLK	Input-Clock	Clock input. Used to capture all synchronous inputs to the device. Also used to increment the burst counter when ADV is asserted LOW, during a burst operation.
\overline{CE}_1	Input-Synchronous	Chip enable 1 input, active LOW. Sampled on the rising edge of CLK. Used in conjunction with CE ₂ and CE ₃ to select or deselect the device. ADSP is ignored if CE ₁ is HIGH. CE ₁ is sampled only when a new external address is loaded.
CE ₂	Input-Synchronous	Chip enable 2 input, active HIGH. Sampled on the rising edge of CLK. Used in conjunction with \overline{CE}_1 and CE ₃ to select or deselect the device. CE ₂ is sampled only when a new external address is loaded.
\overline{CE}_3	Input-Synchronous	Chip enable 3 input, active LOW. Sampled on the rising edge of CLK. Used in conjunction with \overline{CE}_1 and CE ₂ to select or deselect the device. Not connected for BGA. Where referenced, CE ₃ is assumed active throughout this document for BGA. CE ₃ is sampled only when a new external address is loaded.
\overline{OE}	Input-Asynchronous	Output enable, asynchronous input, active LOW. Controls the direction of the I/O pins. When LOW, the I/O pins behave as outputs. When deasserted HIGH, DQ pins are tristated, and act as input data pins. OE is masked during the first clock of a read cycle when emerging from a deselected state.
\overline{ADV}	Input-Synchronous	Advance input signal, sampled on the rising edge of CLK, active LOW. When asserted, it automatically increments the address in a burst cycle.
\overline{ADSP}	Input-Synchronous	Address strobe from processor, sampled on the rising edge of CLK, active LOW. When asserted LOW, addresses presented to the device are captured in the address registers. A ₁ :A ₀ are also loaded into the burst counter. When ADSP and ADSC are both asserted, only ADSP is recognized. ADSP is ignored when CE ₁ is deasserted HIGH.
\overline{ADSC}	Input-Synchronous	Address strobe from controller, sampled on the rising edge of CLK, active LOW. When asserted LOW, addresses presented to the device are captured in the address registers. A ₁ :A ₀ are also loaded into the burst counter. When ADSP and ADSC are both asserted, only ADSP is recognized.
ZZ ^[4]	Input-Asynchronous	ZZ sleep input, active HIGH. When asserted HIGH places the device in a non-time critical sleep condition with data integrity preserved. For normal operation, this pin has to be LOW. ZZ pin has an internal pull down.
DQ _s , DQP _X	I/O-Synchronous	Bidirectional data I/O lines. As inputs, they feed into an on-chip data register that is triggered by the rising edge of CLK. As outputs, they deliver the data contained in the memory location specified by the addresses presented during the previous clock rise of the read cycle. The direction of the pins is controlled by OE. When OE is asserted LOW, the pins behave as outputs. When HIGH, DQ _s and DQP _X are placed in a tristate condition.
V _{DD}	Power Supply	Power supply inputs to the core of the device.
V _{SS}	Ground	Ground for the core of the device.
V _{SSQ}	I/O Ground	Ground for the I/O circuitry.
V _{DDQ}	I/O Power Supply	Power supply for the I/O circuitry.

Note

4. **Errata:** The ZZ pin needs to be externally connected to ground. For more information, see "Errata" on page 33.

Pin Definitions (continued)

Name	I/O	Description
MODE	Input-Static	Selects burst order. When tied to GND selects linear burst sequence. When tied to V_{DD} or left floating selects interleaved burst sequence. This is a strap pin and must remain static during device operation. Mode pin has an internal pull up.
TDO ^[5]	JTAG serial output Synchronous	Serial data-out to the JTAG circuit. Delivers data on the negative edge of TCK. If the JTAG feature is not used, this pin must be disconnected. This pin is not available on TQFP packages.
TDI ^[5]	JTAG serial input Synchronous	Serial data-in to the JTAG circuit. Sampled on the rising edge of TCK. If the JTAG feature is not used, this pin can be disconnected or connected to V_{DD} . This pin is not available on TQFP packages.
TMS ^[5]	JTAG serial input Synchronous	Serial data-in to the JTAG circuit. Sampled on the rising edge of TCK. If the JTAG feature is not used, this pin can be disconnected or connected to V_{DD} . This pin is not available on TQFP packages.
TCK ^[5]	JTAG-Clock	Clock input to the JTAG circuitry. If the JTAG feature is not used, this pin must be connected to V_{SS} . This pin is not available on TQFP packages.
NC	–	No Connects. Not internally connected to the die.
NC/(36M, 72M, 144M, 288M, 576M, 1G)	–	These pins are not connected. They are used for expansion up to 36M, 72M, 144M, 288M, 576M, and 1G densities.

Not Recommended for New Design

Note

5. **Errata:** The JTAG testing should be performed with these devices in BYPASS mode as the JTAG functionality is not guaranteed. For more information, see "Errata" on page 33.

Functional Overview

All synchronous inputs pass through input registers controlled by the rising edge of the clock. All data outputs pass through output registers controlled by the rising edge of the clock.

The CY7C1386D/CY7C1387D supports secondary cache in systems using either a linear or interleaved burst sequence. The interleaved burst order supports Pentium® and i486™ processors. The linear burst sequence is suited for processors that use a linear burst sequence. The burst order is user selectable, and is determined by sampling the MODE input. Accesses can be initiated with either the processor address strobe (ADSP) or the controller address strobe (ADSC). Address advancement through the burst sequence is controlled by the ADV input. A two-bit on-chip wraparound burst counter captures the first address in a burst sequence and automatically increments the address for the rest of the burst access.

Byte write operations are qualified with the byte write enable (BWE) and byte write select (BW_X) inputs. A global write enable (GW) overrides all byte write inputs and writes data to all four bytes. All writes are simplified with on-chip synchronous self timed write circuitry.

Synchronous chip selects \overline{CE}_1 , CE_2 , \overline{CE}_3 and an asynchronous output enable (\overline{OE}) provide for easy bank selection and output tristate control. ADSP is ignored if \overline{CE}_1 is HIGH.

Single Read Accesses

This access is initiated when the following conditions are satisfied at clock rise: (1) ADSP or ADSC is asserted LOW, (2) chip selects are all asserted active, and (3) the write signals (GW, BWE) are all deasserted HIGH. ADSP is ignored if CE_1 is HIGH. The address presented to the address inputs is stored into the address advancement logic and the address register while being presented to the memory core. The corresponding data is allowed to propagate to the input of the output registers. At the rising edge of the next clock the data is allowed to propagate through the output register and onto the data bus within t_{CO} if \overline{OE} is active LOW. The only exception occurs when the SRAM is emerging from a deselected state to a selected state, its outputs are always tristated during the first cycle of the access. After the first cycle of the access, the outputs are controlled by the \overline{OE} signal. Consecutive single read cycles are supported.

The CY7C1386D/CY7C1387D is a double cycle deselect part. After the SRAM is deselected at clock rise by the chip select and either ADSP or ADSC signals, its output tristates immediately after the next clock rise.

Single Write Accesses Initiated by ADSP

This access is initiated when both of the following conditions are satisfied at clock rise: (1) ADSP is asserted LOW and (2) chip select is asserted active. The address presented is loaded into the address register and the address advancement logic while being delivered to the memory core. The write signals (GW,

\overline{BWE} , and \overline{BW}_X) and \overline{ADV} inputs are ignored during this first cycle.

ADSP triggered write accesses require two clock cycles to complete. If GW is asserted LOW on the second clock rise, the data presented to the DQ_X inputs is written into the corresponding address location in the memory core. If GW is HIGH, the write operation is controlled by \overline{BWE} and \overline{BW}_X signals.

The CY7C1386D/CY7C1387D provides byte write capability that is described in the write cycle description table. Asserting the byte write enable input (BWE) with the selected byte write input, selectively writes to the desired bytes. Bytes not selected during a byte write operation remains unaltered. A synchronous self timed write mechanism has been provided to simplify the write operations.

The CY7C1386D/CY7C1387D is a common I/O device, the output enable (\overline{OE}) must be deasserted HIGH before presenting data to the DQ inputs. This tristates the output drivers. As a safety precaution, DQ are automatically tristated whenever a write cycle is detected, regardless of the state of \overline{OE} .

Single Write Accesses Initiated by ADSC

ADSC write accesses are initiated when the following conditions are satisfied: (1) ADSC is asserted LOW, (2) ADSP is deasserted HIGH, (3) chip select is asserted active, and (4) the appropriate combination of the write inputs (GW, \overline{BWE} , and \overline{BW}_X) are asserted active to conduct a write to the desired byte(s). ADSC triggered write accesses require a single clock cycle to complete. The address presented is loaded into the address register and the address advancement logic while being delivered to the memory core. The ADV input is ignored during this cycle. If a global write is conducted, the data presented to the DQ_X is written into the corresponding address location in the memory core. If a byte write is conducted, only the selected bytes are written. Bytes not selected during a byte write operation remains unaltered. A synchronous self timed write mechanism has been provided to simplify the write operations.

The CY7C1386D/CY7C1387D is a common I/O device, the output enable (\overline{OE}) must be deasserted HIGH before presenting data to the DQ_X inputs. This tristates the output drivers. As a safety precaution, DQ_X are automatically tristated whenever a write cycle is detected, regardless of the state of \overline{OE} .

Burst Sequences

The CY7C1386D/CY7C1387D provides a two-bit wraparound counter, fed by $A_{[1:0]}$, that implements either an interleaved or linear burst sequence. The interleaved burst sequence is designed specifically to support Intel Pentium applications. The linear burst sequence is designed to support processors that follow a linear burst sequence. The burst sequence is user selectable through the MODE input.

Asserting \overline{ADV} LOW at clock rise automatically increments the burst counter to the next address in the burst sequence. Both read and write burst operations are supported.

Sleep Mode

The ZZ input pin is an asynchronous input. Asserting ZZ places the SRAM in a power conservation sleep mode. Two clock cycles are required to enter into or exit from this sleep mode. While in this mode, data integrity is guaranteed. Accesses pending when entering the sleep mode are not considered valid nor is the completion of the operation guaranteed. The device must be deselected prior to entering the sleep mode. \overline{CEs} , ADSP, and ADSC must remain inactive for the duration of t_{ZZREC} after the ZZ input returns LOW.

Interleaved Burst Address Table

(MODE = Floating or V_{DD})

First Address A1:A0	Second Address A1:A0	Third Address A1:A0	Fourth Address A1:A0
00	01	10	11
01	00	11	10

Not Recommended for New Design

Notes

6. X = Do not care, H = Logic HIGH, L = Logic LOW.
7. $\overline{WRITE} = L$ when any one or more byte write enable signals, and $\overline{BWE} = L$ or $\overline{GW} = L$. $\overline{WRITE} = H$ when all byte write enable signals, \overline{BWE} , $\overline{GW} = H$.
8. The DQ pins are controlled by the current cycle and the \overline{OE} signal. \overline{OE} is asynchronous and is not sampled with the clock.
9. The \overline{SRAM} always initiates a read cycle when \overline{ADSP} is asserted, regardless of the state of \overline{GW} , \overline{BWE} , or \overline{BW}_x . Writes may occur only on subsequent clocks after the \overline{ADSP} or with the assertion of \overline{ADSC} . As a result, \overline{OE} must be driven HIGH prior to the start of the write cycle to allow the outputs to tristate. \overline{OE} is a don't care for the remainder of the write cycle.
10. \overline{OE} is asynchronous and is not sampled with the clock rise. It is masked internally during write cycles. During a read cycle all data bits are tristate when \overline{OE} is inactive or when the device is deselected, and all data bits behave as output when \overline{OE} is active (LOW).

Truth Table for Read/Write

The Truth Table for Read/Write for CY7C1386D follows. [11, 12]

Function (CY7C1386D)	\overline{GW}	\overline{BWE}	\overline{BW}_D	\overline{BW}_C	\overline{BW}_B	\overline{BW}_A
Read	H	H	X	X	X	X
Read	H	L	H	H	H	H

Write bytes D, C, B	H	L	L	L	L	H
Write all bytes	H	L	L	L	L	L
Write all bytes	L	X	X	X	X	X

Truth Table for Read/Write

The Truth Table for Read/Write for CY7C1387D follows. [11, 12]

Function (CY7C1387D)	\overline{GW}	\overline{BWE}	\overline{BW}_B	\overline{BW}_A
Read	H	H	X	X
Read	H	L	H	H
Write byte A – (DQ _A and DQP _A)	H	L	H	L
Write byte B – (DQ _B and DQP _B)	H	L	L	H
Write all bytes	H	L	L	L
Write all bytes	L	X	X	X

Notes

11. The DQ pins are controlled by the current cycle and the \overline{OE} signal. \overline{OE} is asynchronous and is not sampled with the clock.

12. Table only lists a partial listing of the byte write combinations. Any combination of \overline{BW}_X is valid appropriate write is done based on which byte write is active.

IEEE 1149.1 Serial Boundary Scan (JTAG ^[13])

The CY7C1387D incorporates a serial boundary scan test access port (TAP). This part is fully compliant with 1149.1. The TAP operates using JEDEC-standard 3.3 V or 2.5 V I/O logic levels.

The CY7C1387D contains a TAP controller, instruction register, boundary scan register, bypass register, and ID register.

Disabling the JTAG Feature

It is possible to operate the SRAM without using the JTAG feature. To disable the TAP controller, TCK must be tied LOW (V_{SS}) to prevent clocking of the device. TDI and TMS are internally pulled up and may be unconnected. They may alternately be connected to V_{DD} through a pull up resistor. TDO can be left unconnected. Upon power-up, the device comes up in a reset state which does not interfere with the operation of the device.

Test Access Port (TAP)

Test Clock (TCK)

The test clock is used only with the TAP controller. All inputs are captured on the rising edge of TCK. All outputs are driven from the falling edge of TCK.

Test Mode Select (TMS)

The TMS input is used to give commands to the TAP controller and is sampled on the rising edge of TCK. This pin may be left unconnected if the TAP is not used. The ball is pulled up internally, resulting in a logic HIGH level.

Test Data-In (TDI)

The TDI ball is used to serially input information into the registers and can be connected to the input of any of the registers. The register between TDI and TDO is chosen by the instruction that is loaded into the TAP instruction register. TDI is internally pulled up and can be unconnected if the TAP is unused in an application. TDI is connected to the most significant bit (MSB) of any register.

Test Data-Out (TDO)

The TDO output ball is used to serially clock data out from the registers. The output is active depending upon the current state of the TAP state machine. The output changes on the falling edge of TCK. TDO is connected to the least significant bit (LSB) of any register.

Performing a TAP Reset

A Reset is performed by forcing TMS HIGH (V_{DD}) for five rising edges of TCK. This Reset does not affect the operation of the SRAM and may be performed while the SRAM is operating.

At power-up, the TAP is reset internally to ensure that TDO comes up in a high Z state.

TAP Registers

Registers are connected between the TDI and TDO balls and allow data to be scanned into and out of the SRAM test circuitry. Only one register can be selected at a time through the instruction register. Data is serially loaded into the TDI ball on the rising edge of TCK. Data is output on the TDO ball on the falling edge of TCK.

Instruction Register

Three-bit instructions can be serially loaded into the instruction register. This register is loaded when it is placed between the TDI and TDO balls as shown in the [TAP Controller Block Diagram on page 16](#). Upon power-up, the instruction register is loaded with the IDCODE instruction. It is also loaded with the IDCODE instruction if the controller is placed in a reset state as described in the previous section.

When the TAP controller is in the Capture-IR state, the two least significant bits are loaded with a binary '01' pattern to allow for fault isolation of the board-level serial test data path.

Bypass Register

To save time when serially shifting data through registers, it is sometimes advantageous to skip certain chips. The bypass register is a single-bit register that can be placed between the TDI and TDO balls. This allows data to be shifted through the SRAM with minimal delay. The bypass register is set LOW (V_{SS}) when the BYPASS instruction is executed.

Boundary Scan Register

The boundary scan register is connected to all the input and bidirectional balls on the SRAM.

The boundary scan register is loaded with the contents of the RAM input and output ring when the TAP controller is in the Capture-DR state and is then placed between the TDI and TDO balls when the controller is moved to the Shift-DR state. The EXTEST, SAMPLE/PRELOAD, and SAMPLE Z instructions can be used to capture the contents of the input and output ring.

The boundary scan order tables show the order in which the bits are connected. Each bit corresponds to one of the bumps on the SRAM package. The MSB of the register is connected to TDI, and the LSB is connected to TDO.

Identification (ID) Register

The ID register is loaded with a vendor specific 32-bit code during the Capture-DR state when the IDCODE command is loaded in the instruction register. The IDCODE is hardwired into the SRAM and can be shifted out when the TAP controller is in the Shift-DR state. The ID register has a vendor code and other information described in the [Identification Register Definitions on page 19](#).

Note

13. **Errata:** The JTAG testing should be performed with these devices in BYPASS mode as the JTAG functionality is not guaranteed. For more information, see "Errata" on page 33.

TAP Instruction Set

Overview

Eight different instructions are possible with the three bit instruction register. All combinations are listed in [Identification Codes on page 19](#). Three of these instructions are listed as RESERVED and must not be used. The other five instructions are described in detail below.

Instructions are loaded into the TAP controller during the Shift-IR state when the instruction register is placed between TDI and TDO. During this state, instructions are shifted through the instruction register through the TDI and TDO balls. To execute the instruction after it is shifted in, the TAP controller needs to be moved into the Update-IR state.

EXTEST

The EXTEST instruction enables the preloaded data to be driven out through the system output pins. This instruction also selects the boundary scan register to be connected for serial access between the TDI and TDO in the Shift-DR controller state.

IDCODE

The IDCODE instruction causes a vendor specific 32-bit code to be loaded into the instruction register. It also places the instruction register between the TDI and TDO balls and allows the IDCODE to be shifted out of the device when the TAP controller enters the Shift-DR state.

The IDCODE instruction is loaded into the instruction register upon power-up or whenever the TAP controller is given a test logic reset state.

SAMPLE Z

The SAMPLE Z instruction causes the boundary scan register to be connected between the TDI and TDO balls when the TAP controller is in a Shift-DR state. The SAMPLE Z command places all SRAM outputs into a high Z state.

SAMPLE/PRELOAD

SAMPLE/PRELOAD is a 1149.1 mandatory instruction. When the SAMPLE/PRELOAD instructions are loaded into the instruction register and the TAP controller is in the Capture-DR state, a snapshot of data on the input and output pins is captured in the boundary scan register.

The user must be aware that the TAP controller clock can only operate at a frequency up to 20 MHz, while the SRAM clock operates more than an order of magnitude faster. As there is a large difference in the clock frequencies, it is possible that during the Capture-DR state, an input or output undergoes a transition. The TAP may then try to capture a signal while in transition (metastable state). This does not harm the device, but there is no guarantee as to the value that is captured. Repeatable results may not be possible.

To guarantee that the boundary scan register captures the correct value of a signal, the SRAM signal must be stabilized long enough to meet the TAP controller's capture setup plus hold times (t_{CS} and t_{CH}). The SRAM clock input might not be captured correctly if there is no way in a design to stop (or slow) the clock during a SAMPLE/PRELOAD instruction. If this is an issue, it is still possible to capture all other signals and simply ignore the value of the CK and CK captured in the boundary scan register.

After the data is captured, it is possible to shift out the data by putting the TAP into the Shift-DR state. This places the boundary scan register between the TDI and TDO pins.

PRELOAD allows an initial data pattern to be placed at the latched parallel outputs of the boundary scan register cells prior to the selection of another boundary scan test operation.

The shifting of data for the SAMPLE and PRELOAD phases can occur concurrently when required; that is, while data captured is shifted out, the preloaded data can be shifted in.

BYPASS

When the BYPASS instruction is loaded in the instruction register and the TAP is placed in a Shift-DR state, the bypass register is placed between the TDI and TDO balls. The advantage of the BYPASS instruction is that it shortens the boundary scan path when multiple devices are connected together on a board.

EXTEST Output Bus Tristate

IEEE Standard 1149.1 mandates that the TAP controller be able to put the output bus into a tristate mode.

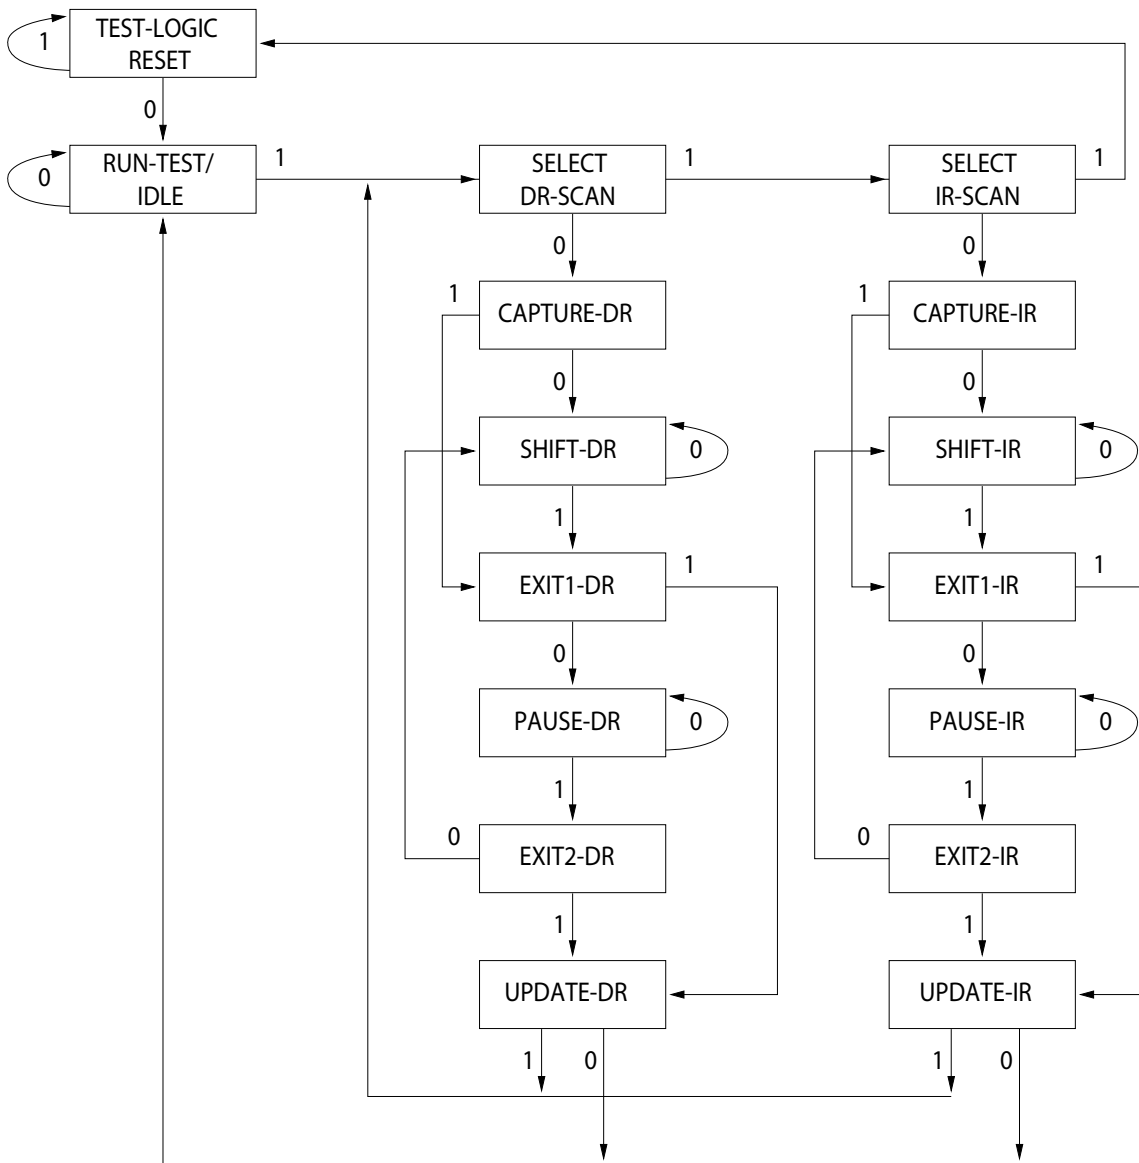

The boundary scan register has a special bit located at bit #85 (for 119-ball BGA package) or bit #89 (for 165-ball FBGA package). When this scan cell, called the "extest output bus tristate," is latched into the preload register during the Update-DR state in the TAP controller, it directly controls the state of the output (Q-bus) pins, when the EXTEST is entered as the current instruction. When HIGH, it enables the output buffers to drive the output bus. When LOW, this bit places the output bus into a high Z condition.

This bit can be set by entering the SAMPLE/PRELOAD or EXTEST command, and then shifting the desired bit into that cell, during the Shift-DR state. During Update-DR, the value loaded into that shift-register cell latches into the preload register. When the EXTEST instruction is entered, this bit directly controls the output Q-bus pins. Note that this bit is preset HIGH to enable the output when the device is powered-up, and also when the TAP controller is in the Test-Logic-Reset state.

Reserved

These instructions are not implemented but are reserved for future use. Do not use these instructions.

TAP Controller State Diagram

The 0 or 1 next to each state represents the value of TMS at the rising edge of TCK.

Not Recommended for New Design

Notes

23. Timing reference level is 1.5 V when V_{DDQ} = 3.3 V and is 1.25 V when V_{DDQ} = 2.5 V.

24. Test conditions shown in (a) of Figure 3 on page 23 unless otherwise noted.

25. This part has a voltage regulator internally; t_{POWER} is the time that the power needs to be supplied above V_{DD(minimum)} initially before a read or write operation can be initiated.

26. t_{CHZ}, t_{CLZ}, t_{OELZ}, and t_{OEHZ} are specified with AC test conditions shown in (b) of Figure 3 on page 23. Transition is measured ±200 mV from steady-state voltage.

27. At any voltage and temperature, t_{OEHZ} is less than t_{OELZ} and t_{CHZ} is less than t_{CLZ} to eliminate bus contention between SRAMs when sharing the same data bus. These specifications do not imply a bus contention condition, but reflect parameters guaranteed over worst case user conditions. Device is designed to achieve high Z prior to low Z under the same system conditions.

28. This parameter is sampled and not 100% tested.

Switching Waveforms

ns	nanosecond
Ω	ohm
%	percent
pF	picofarad
ps	picosecond
V	volt
W	watt

Errata

This section describes the Ram9 Sync ZZ pin and JTAG issues. Details include trigger conditions, the devices affected, proposed workaround and silicon revision applicability. Please contact your local Cypress sales representative if you have further questions.

Part Numbers Affected

Density & Revision	Package Type	Operating Range
18Mb-Ram9 Synchronous SRAMs: CY7C138*D	100-pin TQFP	Commercial
	165-ball FBGA	Industrial

Product Status

All of the devices in the Ram9 18Mb Sync family are qualified and available in production quantities.

Ram9 Sync ZZ Pin & JTAG Issues Errata Summary

The following table defines the errata applicable to available Ram9 18Mb Sync family devices.

Item	Issues	Description	Device	Fix Status
1.	ZZ Pin	When asserted HIGH, the ZZ pin places device in a "sleep" condition with data integrity preserved. The ZZ pin currently does not have an internal pull-down resistor and hence cannot be left floating externally by the user during normal mode of operation.	18M-Ram9 (90nm)	For the 18M Ram9 (90 nm) devices, there is no plan to fix this issue.
2.	JTAG Functionality	During JTAG test mode, the Boundary scan circuitry does not perform as described in the datasheet. However, it is possible to perform the JTAG test with these devices in "BYPASS mode".	18M-Ram9 (90nm)	This issue will be fixed in the new revision, which use the 65 nm technology. Please contact your local sales rep for availability.

1. ZZ Pin Issue

■ PROBLEM DEFINITION

The problem occurs only when the device is operated in the normal mode with ZZ pin left floating. The ZZ pin on the SRAM device does not have an internal pull-down resistor. Switching noise in the system may cause the SRAM to recognize a HIGH on the ZZ input, which may cause the SRAM to enter sleep mode. This could result in incorrect or undesirable operation of the SRAM.

■ TRIGGER CONDITIONS

Device operated with ZZ pin left floating.

■ SCOPE OF IMPACT

When the ZZ pin is left floating, the device delivers incorrect data.

■ WORKAROUND

Tie the ZZ pin externally to ground.

■ FIX STATUS

For the 18M Ram9 (90 nm) devices, there is no plan to fix this issue.

2. JTAG Functionality

■ PROBLEM DEFINITION

The problem occurs only when the device is operated in the JTAG test mode. During this mode, the JTAG circuitry can perform incorrectly by delivering the incorrect data or the incorrect scan chain length.

■ TRIGGER CONDITIONS

Several conditions can trigger this failure mode.

1. The device can deliver an incorrect length scan chain when operating in JTAG mode.
2. Some Byte Write inputs only recognize a logic HIGH level when in JTAG mode.
3. Incorrect JTAG data can be read from the device when the ZZ input is tied HIGH during JTAG operation.

■ SCOPE OF IMPACT

The device fails for JTAG test. This does not impact the normal functionality of the device.

■ WORKAROUND

1. Perform JTAG testing with these devices in "BYPASS mode".
2. Do not use JTAG test.

■ FIX STATUS

This issue will be fixed in the new revision, which use the 65 nm technology. Please contact your local sales rep for availability.

Document History Page

Document Title: CY7C1386D/CY7C1387D, 18-Mbit (512K × 36/1M × 18) Pipelined DCD Sync SRAM				
Document Number: 38-05545				
Revision	ECN	Orig. of Change	Submission Date	Description of Change
**	254550	RKF	See ECN	New data sheet.
*A	288531	SYT	See ECN	Updated Features (Removed 225 MHz speed bin information). Updated Selection Guide (Removed 225 MHz speed bin information). Updated IEEE 1149.1 Serial Boundary Scan (JTAG [13]) (Edited description for non-compliance with 1149.1). Updated Electrical Characteristics (Removed 225 MHz speed bin information). Updated Switching Characteristics (Removed 225 MHz speed bin information). Updated Ordering Information (Updated part numbers (Added Pb-free information for 100-pin TQFP, 119-ball BGA and 165-ball FBGA Packages) and added comment of 'Pb-free BG packages availability' below the Ordering Information).
*B	326078	PCI	See ECN	Updated Pin Configurations (Modified Address Expansion pins/balls in the pinouts for all packages as per JEDEC standards) Updated IEEE 1149.1 Serial Boundary Scan (JTAG [13]) (Updated TAP Instruction Set (Updated OVERVIEW , updated EXTEST , added EXTEST Output Bus Tristate)). Updated Identification Register Definitions (Splitted Device Width (23:18) into two rows, one row for 119-ball BGA and another row for 165-ball FBGA and updated the values). Updated Electrical Characteristics (Updated test conditions for V_{OH} and V_{OL} parameters). Updated Thermal Resistance (Changed values of Θ_{JA} and Θ_{JC} parameters for 100-pin TQFP Package from 31 and 6 °C/W to 28.66 and 4.08 °C/W respectively, changed values of Θ_{JA} and Θ_{JC} parameters for 119-ball BGA Package from 45 and 7 °C/W to 23.8 and 6.2 °C/W respectively, changed values of Θ_{JA} and Θ_{JC} parameters for 165-ball FBGA Package from 46 and 3 °C/W to 20.7 and 4.0 °C/W respectively). Updated Ordering Information (updated part numbers and removed comment of "Pb-free BG packages availability" below the Ordering Information).
*C	418125	NXR	See ECN	Changed status from Preliminary to Final. Changed address of Cypress Semiconductor Corporation on Page# 1 from "3901 North First Street" to "198 Champion Court". Updated Electrical Characteristics (Changed the description of I_X parameter from Input Load Current to Input Leakage Current, changed minimum and maximum values of I_X parameter for Input Current of MODE from -5 µA and 30 µA to -30 µA and 5 µA, changed minimum and maximum values of I_X parameter for Input Current of ZZ from -30 µA and 5 µA to -5 µA and 30 µA, updated Note 21 (changed $V_{IH} \leq V_{DD}$ to $V_{IH} < V_{DD}$)). Updated Ordering Information (updated part numbers and replaced Package Name column with Package Diagram in the Ordering Information table).
*D	475009	VKN	See ECN	Updated TAP AC Switching Characteristics (Changed minimum values of t_{TH} and t_{TL} parameters from 25 ns to 20 ns, changed maximum value of t_{TDOV} parameter from 5 ns to 10 ns). Updated Maximum Ratings (Added the Maximum Rating for Supply Voltage on V_{DDQ} Relative to GND). Updated Ordering Information (updated part numbers).
*E	793579	VKN	See ECN	Added Part numbers CY7C1386F and CY7C1387F Updated Features (Included all information related to CY7C1386F and CY7C1387F). Updated Functional Description (Included all information related to CY7C1386F and CY7C1387F).

Not Recommended for New Design

Document Title: CY7C1386D/CY7C1387D, 18-Mbit (512K × 36/1M × 18) Pipelined DCD Sync SRAM				
Document Number: 38-05545				
Revision	ECN	Orig. of Change	Submission Date	Description of Change
*E (Cont.)	793579	VKN	See ECN	Updated Logic Block Diagram and added a note regarding Chip Enable "CY7C1386F and CY7C1387F have only 1 Chip Enable (CE ₁)." Updated Pin Configurations (Included all information related to CY7C1386F and CY7C1387F). Updated Functional Overview (Included all information related to CY7C1386F and CY7C1387F). Updated Truth Table (Included all information related to CY7C1386F and CY7C1387F). Updated Truth Table for Read/Write (Included all information related to CY7C1386F and CY7C1387F). Updated Truth Table for Read/Write (Included all information related to CY7C1386F and CY7C1387F). Updated IEEE 1149.1 Serial Boundary Scan (JTAG [13]) (Included all information related to CY7C1386F and CY7C1387F). Updated Identification Register Definitions (Included all information related to CY7C1386F and CY7C1387F). Updated Ordering Information (updated part numbers).
*F	2756940	VKN	08/27/2009	Added Neutron Soft Error Immunity . Modified Ordering Information (by including parts that are available) and modified the disclaimer for the Ordering Information .
*G	3006369	NJY	08/12/10	Added Ordering Code Definitions . Added Acronyms . Updated to new template.
*H	3309506	OSN	07/12/2011	Updated Package Diagrams . Added Units of Measure . Updated to new template.
*I	3541411	PRIT	03/03/2012	Updated Features (Removed all information related to CY7C1386F and CY7C1387F). Updated Functional Description (Removed all information related to CY7C1386F and CY7C1387F, removed the notes "For best practices or recommendations, please refer to the Cypress application note AN1064, SRAM System Design Guidelines on www.cypress.com ." and "CE ₃ and CE ₂ are for 100-pin TQFP and 165-ball FBGA packages only. 119-ball BGA is offered only in Single Chip Enable."). Updated Selection Guide (Removed 250 MHz speed bin information). Updated Logic Block Diagram – CY7C1386D (Removed all information related to CY7C1386F and CY7C1387F). Updated Logic Block Diagram – CY7C1387D (Removed all information related to CY7C1386F and CY7C1387F). Updated Pin Configurations (Removed all information related to CY7C1386F and CY7C1387F). Updated Pin Definitions (Removed the note "CE ₃ and CE ₂ are for 100-pin TQFP and 165-ball FBGA packages only. 119-ball BGA is offered only in Single Chip Enable." and its references in the same section). Updated Functional Overview (Removed all information related to CY7C1386F and CY7C1387F, removed the note "CE ₃ and CE ₂ are for 100-pin TQFP and 165-ball FBGA packages only. 119-ball BGA is offered only in Single Chip Enable." and its references in the same section). Updated Truth Table (Removed all information related to CY7C1386F and CY7C1387F). Updated Truth Table for Read/Write (Removed all information related to CY7C1386F and CY7C1387F). Updated Truth Table for Read/Write (Removed all information related to CY7C1386F and CY7C1387F).
