Functional Description

The CY7S1061G/CY7S1061GE is a high-performance CMOS fast static RAM organized as 1,048,576 words by 16 bits. This device features fast access times (10 ns) and a unique ultra-low power Deep Sleep mode. With Sleep mode currents as low as 22 µA, the CY7S1061G device combines the best features of fast and low-power SRAM in industry-standard package options. The device also features embedded ECC[2]. ECC logic can detect and correct single-bit error in the accessed location. The CY7S1061GE device includes an ERR pin that signals an error-detection and correction event during a read cycle.

To access devices with a single-chip enable input, assert the chip enable input ($\overline{CE}$) LOW. To access dual chip enable devices, assert both chip enable inputs – $\overline{CE_1}$ as LOW and CE_2 as HIGH.

To perform data writes, assert the Write Enable ($\overline{WE}$) input LOW, and provide the data and address on device data pins (I/O_0 through I/O_{15}) and address pins (A_0 through A_{19}) respectively. The Byte High Enable ($\overline{BHE}$) and Byte Low Enable ($\overline{BLE}$) inputs control byte writes, and write data on the corresponding I/O lines to the memory location specified. $\overline{BHE}$ controls I/O_8 through I/O_{15} and $\overline{BLE}$ controls I/O_0 through I/O_7.

To perform data reads, assert the Output Enable ($\overline{OE}$) input and provide the required address on the address lines. Read data is accessible on the I/O lines (I/O_0 through I/O_{15}). You can perform byte accesses by asserting the required byte enable signal ($\overline{BHE}$ or $\overline{BLE}$) to read either the upper byte or the lower byte of data from the specified address location.

All I/Os (I/O_0 through I/O_{15}) are placed in a high-impedance state when the device is deselected ($\overline{CE}$ HIGH for single chip enable devices and $\overline{CE_1}$ HIGH and CE_2 LOW for dual chip enable devices), or the control signals ($\overline{OE}$, $\overline{BLE}$, $\overline{BHE}$) are de-asserted.

The device is placed in a low power Deep Sleep mode when the Deep Sleep pin ($\overline{DS}$) is LOW. In this state, the device is disabled for normal operation and is placed in a data retention mode. The device can be activated by de-asserting the Deep Sleep pin ($\overline{DS}$ HIGH).

The CY7S1061G/CY7S1061G is available in 48-pin TSOP I, 54-pin TSOP II, and 48-ball VFBGA packages.

Notes

20. Test conditions assume signal transition time (rise/fall) of 3 ns or less, timing reference levels of 1.5 V (for $V_{CC} \geq 3$ V) and $V_{CC}/2$ (for $V_{CC} < 3$ V), and input pulse levels of 0 to 3 V (for $V_{CC} \geq 3$ V), and 0 to V_{CC} (for $V_{CC} < 3$V). Test conditions for the read cycle use the output loading shown in part (a) of Figure 6 on page 8, unless specified otherwise
21. DS must be HIGH for chip access. Refer to AN89371 for details.
22. t_{POWER} gives the minimum amount of time that the power supply is at stable V_{CC} until the first memory access is performed.
23. These parameters are guaranteed by design and are not tested.
24. t_{HZOE}, t_{HZCE}, t_{HZWE},and t_{HZBE} are specified with a load capacitance of 5 pF, as shown in part (b) of Figure 6 on page 8. Hi-Z, Lo-Z transition is measured ±200 mV from steady state voltage.
25. At any temperature and voltage condition, t_{HZCE} is less than t_{LZCE}, t_{HZBE} is less than t_{LZBE}, t_{HZOE} is less than t_{LZOE}, and t_{HZWE} is less than t_{LZWE} for any device.
26. Tested initially and after any design or process changes that may affect these parameters.
27. For all dual chip enable devices, $\overline{CE}$ is the logical combination of $\overline{CE}_1$ and CE_2. When $\overline{CE}_1$ is LOW and CE_2 is HIGH, $\overline{CE}$ is LOW; when $\overline{CE}_1$ is HIGH or CE_2 is LOW, $\overline{CE}$ is HIGH.
28. The internal write time of the memory is defined by the overlap of $\overline{WE} = V_{IL}$, $\overline{CE} = V_{IL}$, and $\overline{BHE}$ or $\overline{BLE} = V_{IL}$. These signals must be LOW to initiate a write, and the HIGH transition of any of these signals can terminate the operation. The input data setup and hold timing should be referenced to the edge of the signal that terminates the write.
29. The minimum write pulse width for Write Cycle No. 2 ($\overline{WE}$ controlled, $\overline{OE}$ LOW) should be the sum of t_{HZWE} and t_{SD}.

34. Address valid prior to or coincident with $\overline{CE}$ LOW transition.
35. The internal write time of the memory is defined by the overlap of $\overline{WE}$ = V_{IL}, $\overline{CE}$ = V_{IL} and $\overline{BHE}$ or $\overline{BLE}$ = V_{IL}. These signals must be LOW to initiate a write, and the HIGH transition of any of these signals can terminate the operation. The input data setup and hold timing should be referenced to the edge of the signal that terminates the write.
36. Data I/O is in high-impedance state if $\overline{CE}$ = V_{IH}, or $\overline{OE}$ = V_{IH} or $\overline{BHE}$, and/or $\overline{BLE}$ = V_{IH}.
37. During this period, the I/Os are in output state. Do not apply input signals.

39. The minimum write pulse width for Write Cycle No. 2 ($\overline{WE}$ controlled, $\overline{OE}$ LOW) should be sum of t_{HZWE} and t_{SD}.
40. The internal write time of the memory is defined by the overlap of $\overline{WE}$ = V_{IL}, $\overline{CE}$ = V_{IL} and $\overline{BHE}$ or $\overline{BLE}$ = V_{IL}. These signals must be LOW to initiate a write, and the HIGH transition of any of these signals can terminate the operation. The input data setup and hold timing should be referenced to the edge of the signal that terminates the write.

47. The input voltage levels on these pins should be either at V_{IH} or V_{IL}.
48. V_{IL} on $\overline{DS}$ must be $\leq$ 0.2 V.
49. This mode does not guarantee data retention. Power cycling needs to be performed for the device to return to normal operation.
50. ERR is an Output pin. If not used, this pin should be left floating.
