PROGRAMMER'S REFERENCE MANUAL

(Includes **CPU32** Instructions)

M68000 FAMILY

Programmer's Reference Manual

(Includes CPU32 Instructions)

Introduction

1.1	Integer Unit User Programming Model
1.1.1	Data Registers (D7 – D0)
1.1.2	Address Registers (A7 – A0)
1.1.3	Program Counter
1.1.4	Condition Code Register
1.2	Floating-Point Unit User Programming Model
1.2.1	Floating-Point Data Registers (FP7 – FP0)
1.2.2	Floating-Point Control Register (FPCR)
1.2.2.1	Exception Enable Byte.
1.2.2.2	Mode Control Byte.
1.2.3	Floating-Point Status Register (FPSR)
1.2.3.1	Floating-Point Condition Code Byte.
1.2.3.2	Quotient Byte.
1.2.3.3	Exception Status Byte.
1.2.3.4	Accrued Exception Byte.
1.2.4	Floating-Point Instruction Address Register (FPIAR)
1.3	Supervisor Programming Model.
1.3.1	Address Register 7 (A7)
1.3.2	Status Register
1.3.3	Vector Base Register (VBR)
1.3.4	Alternate Function Code Registers (SFC and DFC)
1.3.5	Acu Status Register (MC68EC030 only)
1.3.6	Transparent Translation/access Control Registers
1.3.6.1	Transparent Translation/access Control Register Fields for the M68030.
1.3.6.2	Transparent Translation/access Control Register Fields for the M68040.
1.4	Integer Data Formats
1.5	Floating-Point Data Formats
1.5.1	Packed Decimal Real Format
1.5.2	Binary Floating-Point Formats
1.6	Floating-Point Data Types
1.6.1	Normalized Numbers.
1.6.2	Denormalized Numbers.
1.6.3	Zeros
1.6.4	Infinities
1.6.5	Not-A-Numbers
1.6.6	Data Format and Type Summary
1.7	Organization of Data in Registers
1.7.1	Organization of Integer Data Formats in Registers

Section 2

Addressing Capabilities

2.1	Instruction Format	
2.2	Effective Addressing Modes.	
2.2.1	Data Register Direct Mode	
2.2.2	Address Register Direct Mode.	
2.2.3	Address Register Indirect Mode	
2.2.4	Address Register Indirect with Postincrement Mode.	
2.2.5	Address Register Indirect with Predecrement Mode	
2.2.6	Address Register Indirect with Displacement Mode	
2.2.7	Address Register Indirect with Index (8-Bit Displacement) Mode	
2.2.8	Address Register Indirect with Index (Base Displacement) Mode.	
2.2.9	Memory Indirect Postindexed Mode	
2.2.10	Memory Indirect Preindexed Mode	
2.2.11	Program Counter Indirect with Displacement Mode	
2.2.12	Program Counter Indirect with Index (8-Bit Displacement) Mode	
2.2.13	Program Counter Indirect with Index (Base Displacement) Mode.	
2.2.14	Program Counter Memory Indirect Postindexed Mode	
2.2.15	Program Counter Memory Indirect Preindexed Mode.	
2.2.16	Absolute Short Addressing Mode	
2.2.17	Absolute Long Addressing Mode.	
2.2.18	Immediate Data	
2.3	Effective Addressing Mode Summary	
2.4	Brief Extension Word Format Compatibility	
2.5	Full Extension Addressing Modes	
2.5.1	No Memory Indirect Action Mode	
2.5.2	Memory Indirect Modes.	
2.5.2.1	Memory Indirect with Preindex.	
2.5.2.2	Memory Indirect with Postindex.	
2.5.2.3	Memory Indirect with Index Suppressed.	
2.6	Other Data Structures	
2.6.1	System Stack.	
2.6.2	Queues

SECTION 1 INTRODUCTION

This manual contains detailed information about software instructions used with microprocessors and coprocessors in the M68000 family, including:

MC68000	—	16-/32-Bit Microprocessor
MC68EC000	—	16-/32-Bit Embedded Controller
MC68HC000	—	Low Power 16-/32-Bit Microprocessor
MC68008	—	16-Bit Microprocessor with 8-Bit Data Bus
MC68010	—	16-/32-Bit Virtual Memory Microprocessor
MC68020	—	32-Bit Virtual Memory Microprocessor
MC68EC020	—	32-Bit Embedded Controller
MC68030	—	Second-Generation 32-Bit Enhanced Microprocessor
MC68EC030	—	32-Bit Embedded Controller
MC68040	—	Third-Generation 32-Bit Microprocessor
MC68LC040	—	Third-Generation 32-Bit Microprocessor
MC68EC040	—	32-Bit Embedded Controller
MC68330	—	Integrated CPU32 Processor
MC68340	—	Integrated Processor with DMA
MC68851	—	Paged Memory Management Unit
MC68881	—	Floating-Point Coprocessor
MC68882	—	Enhanced Floating-Point Coprocessor

NOTE

All references to the MC68000, MC68020, and MC68030 include the corresponding embedded controllers, MC68EC000, MC68EC020, and MC68EC030. All references to the MC68040 include the MC68LC040 and MC68EC040. This referencing method applies throughout the manual unless otherwise specified.

The M68000 family programming model consists of two register groups: user and supervisor. User programs executing in the user mode only use the registers in the user mode group. System software executing in the supervisor mode can access all registers in the user mode group and the control registers in the supervisor group to perform supervisor functions. The following paragraphs provide a brief description of the registers in the user and supervisor mode as well as the data organization in the registers.

- 32-Bit Program Counter (PC)
- 8-Bit Condition Code Register (CCR)

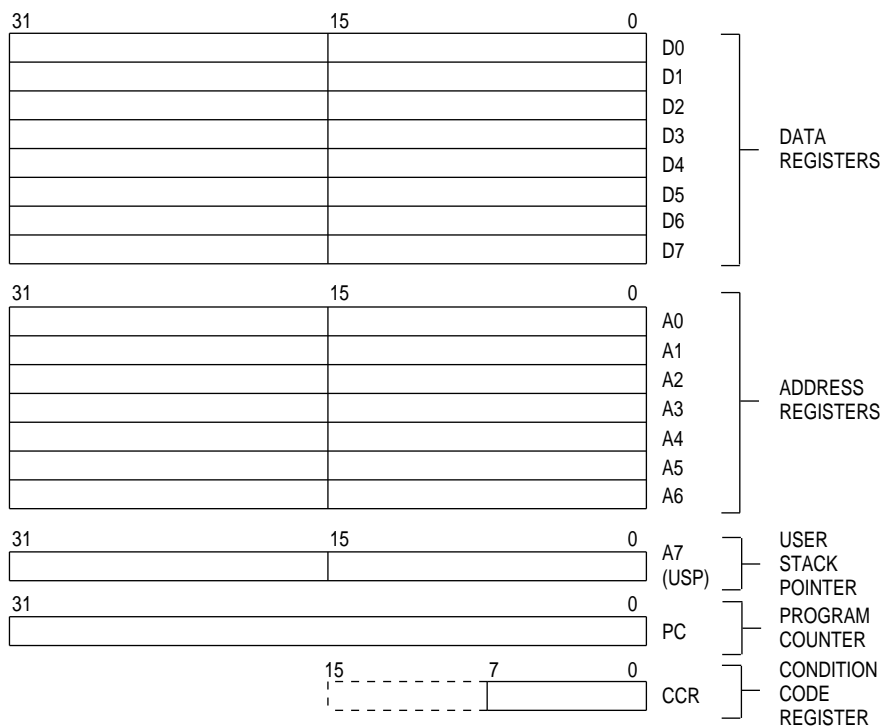

Figure 1-1. M68000 Family User Programming Model

1.1.1 Data Registers (D7 – D0)

These registers are for bit and bit field (1 – 32 bits), byte (8 bits), word (16 bits), long-word (32 bits), and quad-word (64 bits) operations. They also can be used as index registers.

1.1.2 Address Registers (A7 – A0)

These registers can be used as software stack pointers, index registers, or base registers. The base address registers can be used for word and long-word operations. Register A7 is used as a hardware stack pointer during stacking for subroutine calls and exception handling. In the user programming model, A7 refers to the user stack pointer (USP).

1.1.4 Condition Code Register

Consisting of five bits, the CCR, the status register's lower byte, is the only port status register (SR) available in the user mode. Many integer instructions affect indicating the instruction's result. Program and system control instructions also use combinations of these bits to control program and system flow. The condition codes are defined by two criteria: consistency across instructions, uses, and instances and meaningfulness with no change unless it provides useful information.

Consistency across instructions means that all instructions that are special cases of general instructions affect the condition codes in the same way. Consistency across instructions means that conditional instructions test the condition codes similarly and provide the same results whether a compare, test, or move instruction sets the condition codes. Consistency across instances means that all instances of an instruction affect the condition codes in the same way.

The first four bits represent a condition of the result generated by an operation. The extend bit (X-bit) is an operand for multiprecision computations. The carry bit (C) and the X-bit are separate in the M68000 family to simplify programming techniques (refer to Table 3-18 as an example). In the instruction set definitions, the condition codes are illustrated as follows:

X—Extend

Set to the value of the C-bit for arithmetic operations; otherwise not affected by the specified result.

N—Negative

Set if the most significant bit of the result is set; otherwise clear.

Z—Zero

Set if the result equals zero; otherwise clear.

V—Overflow

Set if an arithmetic overflow occurs implying that the result cannot be represented in the operand size; otherwise clear.

The following paragraphs describe the registers for the floating-point unit user programming model. Figure 1-2 illustrates the M68000 family user programming model's floating-point portion for the MC68040 and the MC68881/MC68882 floating-point coprocessor. This portion contains the following registers:

- 8 Floating-Point Data Registers (FP7 – FP0)
- 16-Bit Floating-Point Control Register (FPCR)
- 32-Bit Floating-Point Status Register (FPSR)
- 32-Bit Floating-Point Instruction Address Register (FPIAR)

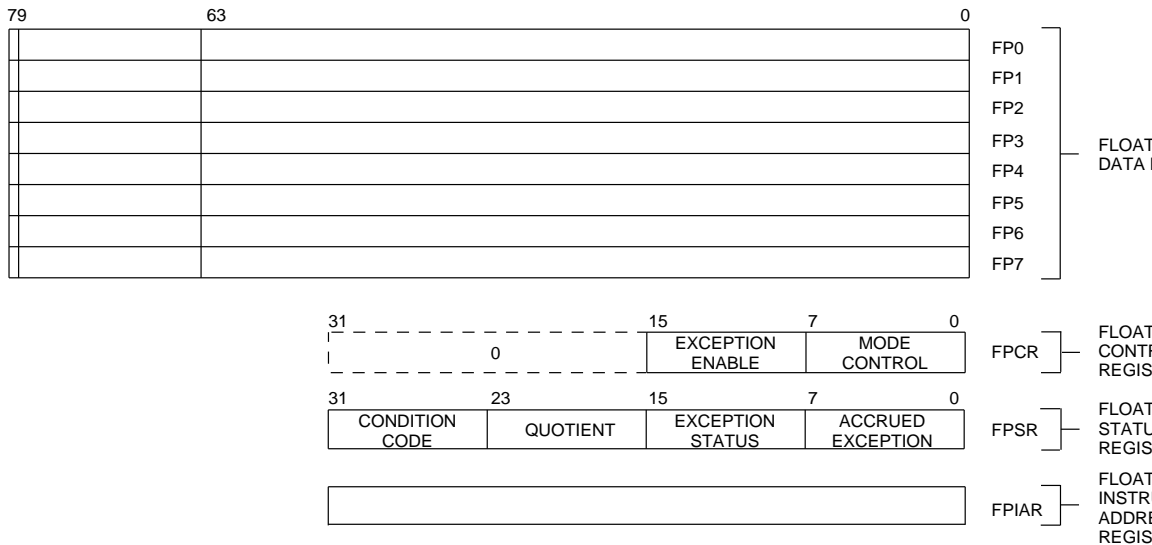

Figure 1-2. M68000 Family Floating-Point Unit User Programming Model

1.2.1 Floating-Point Data Registers (FP7 – FP0)

These floating-point data registers are analogous to the integer data registers in the M68000 family. They always contain extended-precision numbers. All external operations, despite the data format, are converted to extended-precision values before being used in any calculation or being stored in a floating-point data register. A reset or a null operation sets FP7 – FP0 positive, nonsignaling not-a-numbers (NaNs).

cleared, this register provides the IEEE 754 Standard for Binary Floating-Point A defaults.

1.2.2.1 EXCEPTION ENABLE BYTE. Each bit of the ENABLE byte (see Figure 1-3) corresponds to a floating-point exception class. The user can separately enable each class of floating-point exceptions.

1.2.2.2 MODE CONTROL BYTE. MODE (see Figure 1-3) controls the user- s rounding modes and precisions. Zeros in this byte select the IEEE 754 standard. The rounding mode (RND) field specifies how inexact results are rounded, and the precision (PREC) field selects the boundary for rounding the mantissa. Refer to Table 1-1 for encoding information. .

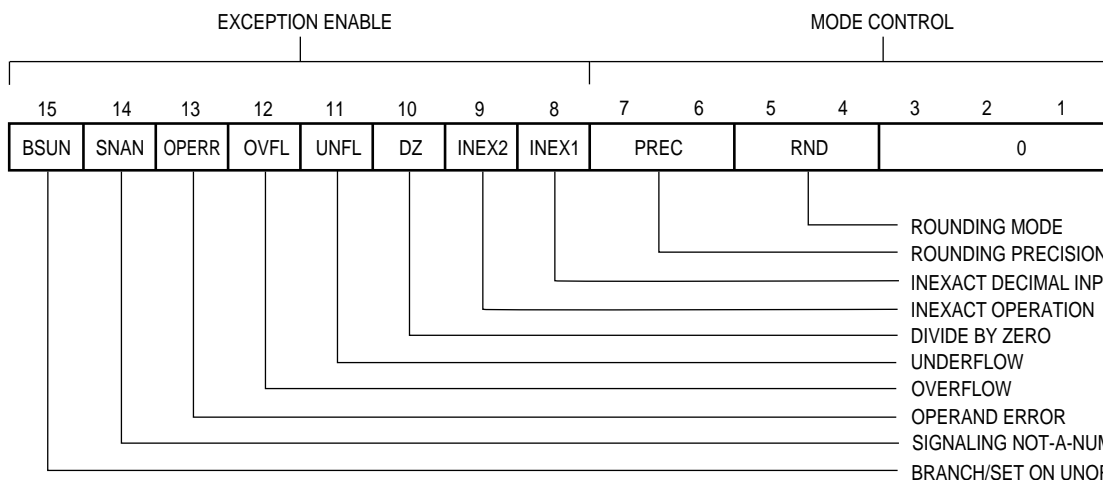

Figure 1-3. Floating-Point Control Register

1.2.3 Floating-Point Status Register (FPSR)

The FPSR (see Figure 1-2) contains a floating-point condition code (FPCC) byte, a floating-point exception status (EXC) byte, a quotient byte, and a floating-point accrued condition code (AEXC) byte. The user can read or write to all the bits in the FPSR. Execution of floating-point instructions modifies this register. The reset function or a restore operation on the null state clears the FPSR.

1.2.3.1 FLOATING-POINT CONDITION CODE BYTE. The FPCC byte, illustrated in Figure 1-4, contains four condition code bits that set after completion of all floating-point instructions involving the floating-point data registers. The move floating-point data

Figure 1-4. FPSR Condition Code Byte

1.2.3.2 QUOTIENT BYTE. The quotient byte contains the seven least significant bits of the unsigned quotient as well as the sign of the entire quotient (see Figure 1-5). The quotient bits can be used in argument reduction for transcendentals and other functions. For example, seven bits are more than enough to figure out the quadrant of a circle in which the operand resides. The quotient bits remain set until the user clears them. .

Figure 1-5. FPSR Quotient Code Byte

1.2.3.3 EXCEPTION STATUS BYTE. The EXC byte, illustrated in Figure 1- 6, contains one bit for each floating-point exception that might have occurred during the most recent arithmetic instruction or move operation. This byte is cleared at the start of all operations that generate floating-point exceptions. Operations that do not generate floating-point exceptions do not clear this byte. An exception handler can use this byte to determine which floating-point exception(s) caused a trap. .

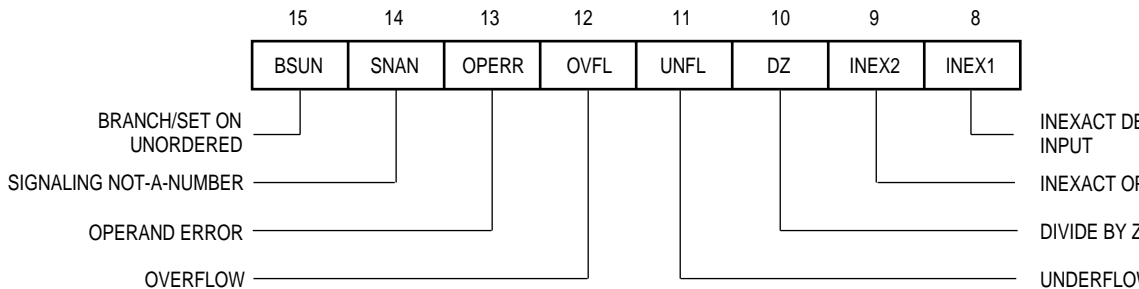

Figure 1-6. FPSR Exception Status Byte

Many users elect to disable traps for all or part of the floating-point exception class. The AEXC byte makes it unnecessary to poll the EXC byte after each floating-point instruction. At the end of most operations (FMOVEM and FMOVE excluded), the bits in the EXC byte are logically combined to form an AEXC value that is logically ORed into the existing AEXC byte. This operation creates "sticky" floating-point exception bits in the AEXC byte. A user needs to poll only once—i.e., at the end of a series of floating-point operations.

Figure 1-7. FPSR Accrued Exception Byte

Setting or clearing the AEXC bits neither causes nor prevents an exception. The following equations show the comparative relationship between the EXC byte and AEXC byte. Comparing the current value in the AEXC bit with a combination of bits in the EXC byte derives a new value in the corresponding AEXC bit. These equations apply to all AEXC bits at the end of each operation affecting the AEXC byte:

New AEXC Bit	= Old AEXC Bit	V	EXC Bits
IOP	= IOP	V	(SNAN V OPERR)
OVFL	= OVFL	V	(OVFL)
UNFL	= UNFL	V	(UNFL L INEX2)
DZ	= DZ	V	(DZ)
INEX	= INEX	V	(INEX1 V INEX2 V OVFL)

instruction.

For the subset of the FPU instructions that generate exception traps, the 32-bit FPIAR is loaded with the logical address of the instruction before the processor executes it. A floating-point exception handler can use this address to locate the floating-point instruction that caused an exception. Since the FPU FMOVE to/from the FPCR, FPSR, or FPMR instructions and FMOVEM instructions cannot generate floating-point exceptions, these instructions do not modify the FPIAR. A reset or a null-restore operation clears the FPIAR.

1.3 SUPERVISOR PROGRAMMING MODEL

System programmers use the supervisor programming model to implement system and operating system functions—e.g., I/O control and memory management unit control—through subsystems. The following paragraphs briefly describe the registers in the supervisor programming model. They can only be accessed via privileged instructions. Table 1-1 lists the supervisor registers and the processors not related to paged memory management. For information concerning page memory management programming, refer to the specific user's manual. Table 1-2 lists the supervisor registers and the processors related to paged memory management.

Registers	68HC000 68HC001 68EC000	68010	68020 68EC020	CPU32	68030	68EC030	68040	68EC040

URP	=	User Root Pointer
VAL	=	Valid Access Level Register

1.3.1 Address Register 7 (A7)

In the supervisor programming model register, A7 refers to the interrupt stack pointer, A7'(ISP) and the master stack pointer, A7" (MSP). The supervisor stack pointer is the stack pointer (ISP or MSP). For processors that do not support ISP or MSP, the system stack pointer is the system stack pointer (SSP). The ISP and MSP are general-purpose address registers for the supervisor mode. They can be used as software stack pointers, index registers, and base address registers. The ISP and MSP can be used for word and long-word operations.

1.3.2 Status Register

Figure 1-8 illustrates the SR, which stores the processor status and contains the condition codes that reflect the results of a previous operation. In the supervisor mode, software can access the full SR, including the interrupt priority mask and additional control bits. The SR indicates the following states for the processor: one of two trace modes (T1, T0), supervisor or user mode (S), and master or interrupt mode (M). For the MC68000, MC68008, MC68008, MC68010, MC68HC000, MC68HC001, and CPU32, only one trace mode is supported.

T1	T0	TRACE MODE
0	0	NO TRACE
1	0	TRACE ON ANY INSTRUCTION
0	1	TRACE ON CHANGE OF FLOW
1	1	UNDEFINED

S	M	ACTIVE STACK
0	x	USP
1	0	ISP
1	1	MSP

Figure 1-8. Status Register

1.3.3 Vector Base Register (VBR)

The VBR contains the base address of the exception vector table in memory. The displacement of an exception vector adds to the value in this register, which accesses the vector table.

1.3.4 Alternate Function Code Registers (SFC and DFC)

The alternate function code registers contain 3-bit function codes. Function codes are considered extensions of the 32-bit logical address that optionally provides as many as 8 4-Gbyte address spaces. The processor automatically generates function codes for data and programs at the user and supervisor modes. Instructions use SFC and DFC to specify the function codes for operations.

1.3.5 Access Status Register (MC68EC030 only)

The access control unit status register (ACUSR) is a 16-bit register containing the information returned by execution of the PTEST instruction. The PTEST instruction searches the access control (AC) registers to determine a match for a specified address. A match in either or both of the AC registers sets bit 6 in the ACUSR. All other bits in the ACUSR are undefined and must not be used.

blocks of logical addresses that are transparently translated to corresponding addresses. These registers are independent of the on-chip MMU. For embedded controllers, such as the MC68EC030 and MC68EC040, the access control registers are similar in function to the TT registers but just named differently. The AC registers function are to define blocks of address space that control address space properties such as cachability. The following paragraphs describe these registers.

NOTE

For the paged MMU related supervisor registers, please refer to the appropriate user's manual for specific programming detail.

1.3.6.1 TRANSPARENT TRANSLATION/ACCESS CONTROL REGISTER FIELD
THE M68030. Figure 1-9 illustrates the MC68030 transparent translation/MC68030 access control register format.

Figure 1-9. MC68030 Transparent Translation/MC68EC030 Access Control Register Format

Address Base

This 8-bit field is compared with address bits A31 – A24. Addresses that match the comparison (and are otherwise eligible) are transparently translated/access controlled.

Address Mask

This 8-bit field contains a mask for the address base field. Setting a bit in this field masks the corresponding bit of the address base field to be ignored. Blocks of memory larger than 16 Mbytes can be transparently translated/accessed controlled by setting some of the address mask bits to ones. The low-order bits of this field normally are set to zero for contiguous blocks larger than 16 Mbytes, although this is not required.

1 = Caching inhibited

R/W—Read/Write

0 = Only write accesses permitted

1 = Only read accesses permitted

R/WM—Read/Write Mask

0 = R/W field used

1 = R/W field ignored

FC BASE—Function Code Base

This 3-bit field defines the base function code for accesses to be transparently translated with this register. Addresses with function codes that match the FC BASE field (and are otherwise eligible) are transparently translated.

FC MASK—Function Code Mask

This 3-bit field contains a mask for the FC BASE field. Setting a bit in this field masks the corresponding bit of the FC BASE field to be ignored.

1.3.6.2 TRANSPARENT TRANSLATION/ACCESS CONTROL REGISTER FIELD

THE M68040. Figure 1-10 illustrates the MC68040 and MC68LC040 transparent translation/ MC68EC040 access control register format.

31							24		23				
ADDRESS BASE								ADDRESS MASK					
E	S FIELD		0	0	0	U1	U0	0	CM		0	0	W
15	14	13	12	11	10	9	8	7	6	5	4	3	2

Figure 1-10. MC68040 and MC68LC040 Transparent Translation/MC68EC040 Access Control Register Format

Address Base

This 8-bit field is compared with address bits A31 – A24. Addresses that match the comparison (and are otherwise eligible) are transparently translated/access controlled.

E—Enable

This bit enables and disables transparent translation/access control of the block by this register.

- 0 = Transparent translation/access control disabled
- 1 = Transparent translation/access control enabled

S—Supervisor/User Mode

This field specifies the use of the FC2 in matching an address.

- 00 = Match only if FC2 is 0 (user mode access)
- 01 = Match only if FC2 is 1 (supervisor mode access)
- 1X = Ignore FC2 when matching

U1, U2—User Page Attributes

The MC68040, MC68E040, MC68LC040 do not interpret these user-defined bits. On external bus transfer results from the access, U0 and U1 are echoed to the UPA0 and UPA1 signals, respectively.

CM—Cache Mode

This field selects the cache mode and access serialization for a page as follows:

- 00 = Cachable, Writethrough
- 01 = Cachable, Copyback
- 10 = Noncachable, Serialized
- 11 = Noncachable

W—Write Protect

This bit indicates if the block is write protected. If set, write and read-modify-write accesses are aborted as if the resident bit in a table descriptor were clear.

- 0 = Read and write accesses permitted
- 1 = Write accesses not permitted

1.4 INTEGER DATA FORMATS

The operand data formats supported by the integer unit, as listed in Table 1-3, include those supported by the MC68030 plus a new data format (16-byte block) for the MFC instruction. Integer unit operands can reside in registers, memory, or instructions themselves. The operand size for each instruction is either explicitly encoded in the instruction or implicitly defined by the instruction operation.

Binary-Coded Decimal (BCD)	8 Bits	Packed: 2 Digits/Byte; Unpacked: 1 Digit/Byte
Byte Integer	8 Bits	—
Word Integer	16 Bits	—
Long-Word Integer	32 Bits	—
Quad-Word Integer	64 Bits	Any Two Data Registers
16-Byte	128 Bits	Memory Only, Aligned to 16- Byte Boundary

1.5 FLOATING-POINT DATA FORMATS

The following paragraphs describe the FPU's operand data formats. The FPU supports seven data formats. There are three signed binary integer formats (byte, word, word) that are identical to those supported by the integer unit. The FPU supports the packed decimal real format. The MC68881 and MC68882 support this hardware and the processors starting with the MC68040 support it in software. The FPU also supports three binary floating-point formats (single, double, and extended precision) that fully comply with the IEEE 754 standard. All references in this manual to extended-precision format imply the double-extended-precision format defined by the IEEE 754 standard.

1.5.1 Packed Decimal Real Format

Figure 1-11 illustrates the packed decimal real format which is three long words long. It consists of a 3-digit base 10 exponent and a 17-digit base 10 mantissa. The first two long words (bits 63 – 0) are 64 bits and map directly to bit positions 63 – 0 of the extended-precision real format. There are two separate sign bits, one for the exponent, the other for the mantissa. An extra exponent (EXP3) is defined for overflows that can occur when converting from the extended-precision real format to the packed decimal real format.

NOTE

This section specifies ranges using traditional set notation with the format "bound...bound" specifying the boundaries of the range. The bracket types enclosing the range define whether the endpoint is inclusive or exclusive. A square bracket indicates inclusive, and a parenthesis indicates exclusive. For example, the range specification "[1.0...2.0]" defines the range of numbers greater than or equal to 1.0 and less than or equal to 2.0. The range specification "(0.0... + inf)" defines the range of numbers greater than 0.0 and less than positive infinity, but not equal to.

1.6 FLOATING-POINT DATA TYPES

Each floating-point data format supports five, unique, floating-point data types: 1) normalized numbers, 2) denormalized numbers, 3) zeros, 4) infinities, and 5) NaNs. Exponent values in each format represent these special data types. The normalized type never uses the maximum or minimum exponent value for a given format, except in the extended-precision format. The packed decimal real data format does not support denormalized numbers.

There is a subtle difference between the definition of an extended-precision number with an exponent equal to zero and a single- or double-precision number with an exponent equal to zero. The zero exponent of a single- or double-precision number denormalizes the number, and the implied integer bit is zero. An extended-precision number with an exponent of zero may have an explicit integer bit equal to one. This results in a normalized number, though the exponent is equal to the minimum value. For simplicity, the discussion treats all three floating-point formats in the same manner, where an exponent value of zero identifies a denormalized number. However, remember the extended-precision format can deviate from this rule.

exponent can be zero.

Figure 1-13. Normalized Number Format

1.6.2 Denormalized Numbers

Denormalized numbers represent real values near the underflow threshold. The occurrence of the underflow for a given data format and operation occurs when the result's exponent is less than or equal to the minimum exponent value. Denormalized numbers can be positive or negative. For denormalized numbers in single and double precision the implied integer bit is a zero. In extended precision, the mantissa's MSB, the explicit integer bit, can be a zero (see Figure 1-14).

Figure 1-14. Denormalized Number Format

Traditionally, the detection of underflow causes floating-point number systems to "flush-to-zero". This leaves a large gap in the number line between the smallest normalized number and zero. The IEEE 754 standard implements gradual underflow. When the result mantissa is shifted right (denormalized) while the result exponent is incremented, reaching the minimum value. If all the mantissa bits of the result are shifted off to the right during this denormalization, the result becomes zero. Usually a gradual underflow limits potential underflow damage to no more than a round-off error. This underflow denormalization description ignores the effects of rounding and the user-selectable rounding modes. Thus, the large gap in the number line created by "flush-to-zero" floating-point systems is filled with representable (denormalized) numbers in the IEEE "gradual underflow" floating-point number system.

Since the extended-precision data format has an explicit integer bit, a number formatted with a nonzero exponent, less than the maximum value, and a zero integer bit is an unnormalized number. The IEEE 754 standard does not define a zero integer bit. Such a number is an unnormalized number. Hardware does not directly support denormalized and unnormalized numbers, but implicitly supports them by trapping them as unimplemented data and allowing efficient conversion in software.

Figure 1-15. Zero Format

1.6.4 Infinities

Infinities can be positive or negative and represent real values that exceed the threshold. A result's exponent greater than or equal to the maximum exponent indicates the overflow for a given data format and operation. This overflow does not ignore the effects of rounding and the user-selectable rounding models. For single-precision infinities the fraction is a zero. For extended-precision infinities the mantissa's MSB, the explicit integer bit, can be either one or zero (see Figure 1-16).

Figure 1-16. Infinity Format

1.6.5 Not-A-Numbers

When created by the FPU, NaNs represent the results of operations having no mathematical interpretation, such as infinity divided by infinity. All operations involving a NaN operand as an input return a NaN result. When created by the user, NaNs can be used against uninitialized variables and arrays or represent user-defined data types. For single-precision NaNs, the mantissa's MSB, the explicit integer bit, can be either one or zero (see Figure 1-17).

Figure 1-17. Not-A-Number Format

The FPU implements two different types of NaNs identified by the value of the MSB of the mantissa for single- and double-precision, and the MSB of the mantissa minus one for extended-precision. If the bit is set, it is a nonsignaling NaN, otherwise, it is an signaling NaN.

mantissa, and storing the resulting nonsignaling NAN in the destination. Because IEEE formats for NANs, the result of setting an SNAN MSB is always a nonsignaling

When the FPU creates a NAN, the NAN always contains the same bit pattern in the mantissa. All bits of the mantissa are ones for any precision. When the user creates a NAN, any nonzero bit pattern can be stored in the mantissa.

1.6.6 Data Format and Type Summary

Tables 1-4 through 1-6 summarize the data type specifications for single-, double-, and extended-precision data formats. Packed decimal real formats support all data types and denormalized numbers. Table 1-7 summarizes the data types for the packed decimal format.

Field Size In Bits	
Sign (s)	1
Biased Exponent (e)	8
Fraction (f)	23
Total	32
Interpretation of Sign	
Positive Fraction	s = 0
Negative Fraction	s = 1
Normalized Numbers	
Bias of Biased Exponent	+127 (\$7F)
Range of Biased Exponent	$0 < e < 255$ (\$FF)
Range of Fraction	Zero or Nonzero
Fraction	1.f
Relation to Representation of Real Numbers	$(-1)^s \times 2^{e-127} \times 1.f$
Denormalized Numbers	
Biased Exponent Format Minimum	0 (\$00)
Bias of Biased Exponent	+126 (\$7E)
Range of Fraction	Nonzero
Fraction	0.f
Relation to Representation of Real Numbers	$(-1)^s \times 2^{-126} \times 0.f$
Signed Zeros	
Biased Exponent Format Minimum	0 (\$00)
Fraction	0.f = 0.0
Signed Infinities	
Biased Exponent Format Maximum	255 (\$FF)
Fraction	0.f = 0.0
NANs	
Sign	Don't Care
Biased Exponent Format Maximum	255 (\$FF)
Fraction	Nonzero
Representation of Fraction	
Nonsignaling	0.1xxxx...xxxx
Signaling	0.0xxxx...xxxx
Nonzero Bit Pattern Created by User	xxxxx...xxxx

–In-Range	1	0/1	X	X	\$000–\$999	\$XXX0–\$XXX9	\$00...01–\$99...99

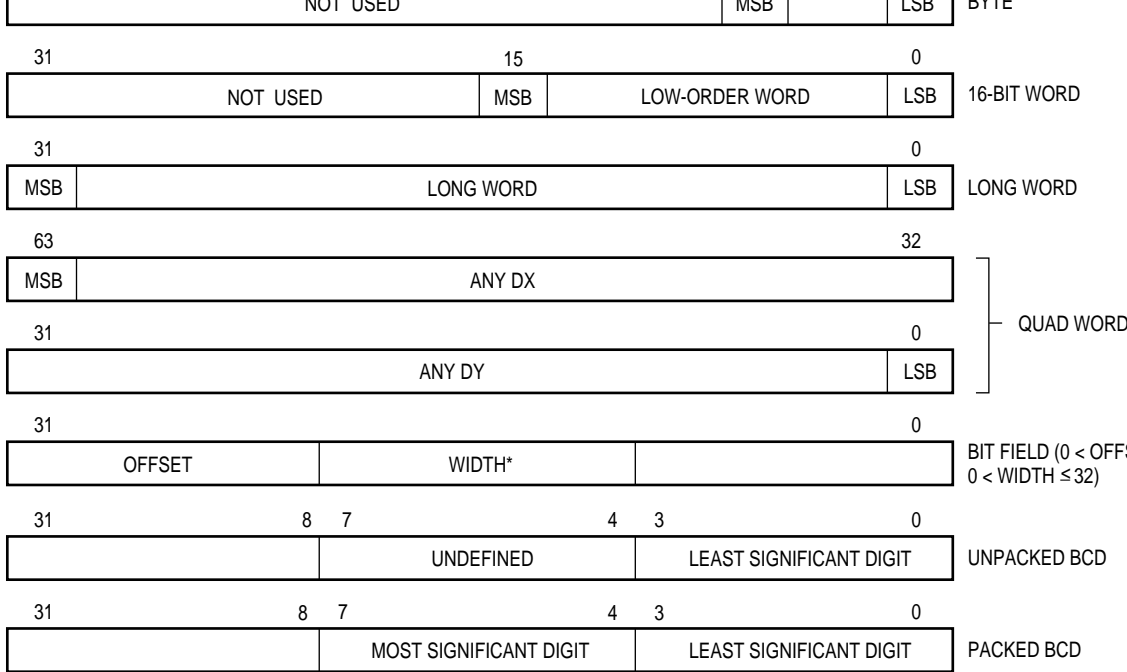

A packed decimal real data format with the SE and both Y bits set, an exponent of all ones, and a nonzero 16-bit decimal fraction is a NAN. When the FPU uses this format, the 16-bit decimal fraction of the NAN is moved bit- by-bit into the extended-precision mantissa of a floating-point register. The exponent of the register is set to signify a NAN, and no conversion occurs. If the MSB of the most significant digit in the decimal fraction (the MSB of digit 15) is a decimal digit, as in extended-precision NANs, and the MSB of minus one of digit 15 is the SNAN bit, then it is an SNAN.

If a non-decimal digit (\$A – \$F) appears in the exponent of a zero, the number is a truncated zero. The FPU does not detect non-decimal digits in the exponent, integer, or fraction digits of an in-range packed decimal real data format. These non-decimal digits are converted to decimal digits in the same manner as decimal digits; however, the result is probably useless although it is repeatable. Since an in-range number cannot overflow or underflow when converted to extended precision, conversion from the packed decimal real data format always produces normalized extended-precision numbers.

Each integer data register is 32 bits wide. Byte and word operands occupy the low 16-bit portions of integer data registers, respectively. Long- word operands occupy 32 bits of integer data registers. A data register that is either a source or destination only uses or changes the appropriate lower 8 or 16 bits (in byte or word operands, respectively). The remaining high-order portion does not change and goes unaltered. The address of the least significant bit (LSB) of a long-word integer is zero, and the MSB is 31. For bit fields, the address of the MSB is zero, and the LSB is the width of the register minus one (the offset). If the width of the register plus the offset is greater than 32, the address wraps around within the register. Figure 1-18 illustrates the organization of various data formats in the data registers.

An example of a quad word is the product of a 32-bit multiply or the quotient of a 32-bit divide operation (signed and unsigned). Quad words may be organized in any two integer registers without restrictions on order or pairing. There are no explicit instructions for the management of this data format, although the MOVEM instruction can be used to move a quad word into or out of registers.

Binary-coded decimal (BCD) data represents decimal numbers in binary form. Although there are many BCD codes, the BCD instructions of the M68000 family support two formats: packed and unpacked. In these formats, the LSBs consist of a binary number whose numeric value of the corresponding decimal number. In the unpacked BCD format, each byte defines one decimal number that has four LSBs containing the binary value of the least significant four bits and four undefined MSBs. Each byte of the packed BCD format contains two decimal numbers: the least significant four bits contain the least significant decimal number and the most significant four bits contain the most significant decimal number.

* IF WIDTH + OFFSET > 32, BIT FIELD WRAPS AROUND WITHIN THE REGISTER.

Figure 1-18. Organization of Integer Data Formats in Data Registers

Because address registers and stack pointers are 32 bits wide, address registers can be used for byte-size operands. When an address register is a source operand, either the low-order word or the entire long-word operand is used, depending upon the operation. When an address register is the destination operand, the entire register becomes a destination despite the operation size. If the source operand is a word size, it is sign-extended to 32 bits and then used in the operation to an address register destination. Address registers are primarily for addresses and address computation support. The instruction set includes instructions that add to, compare, and move the contents of address registers. Figure 1-19 illustrates the organization of addresses in address registers.

Figure 1-19. Organization of Integer Data Formats in Address Registers

alternate function code registers, supervisor function code (SFC) and data function code (DFC), are 32-bit registers with only bits 0P2 implemented. These bits contain the space values for the read or write operands of MOVES, PFLUSH, and PTEST instructions. Values transfer to and from the SFC and DFC by using the MOVEC instruction. The long-word transfers; the upper 29 bits are read as zeros and are ignored when writing.

1.7.2 Organization of Integer Data Formats in Memory

The byte-addressable organization of memory allows lower addresses to correspond to higher order bytes. The address N of a long-word data item corresponds to the address of the highest order word. The lower order word is located at address N + 2. The lowest order byte is the LSB at address N + 3 (see Figure 1-20). Organization of data formats in memory is consistent with the M68000 family data organization. The lowest address (\$00000000) is the location of the MSB, with each successive LSB located at address (N + 1, N + 2, etc.). The highest address (nearest \$FFFFFFF) is the location of the LSB.

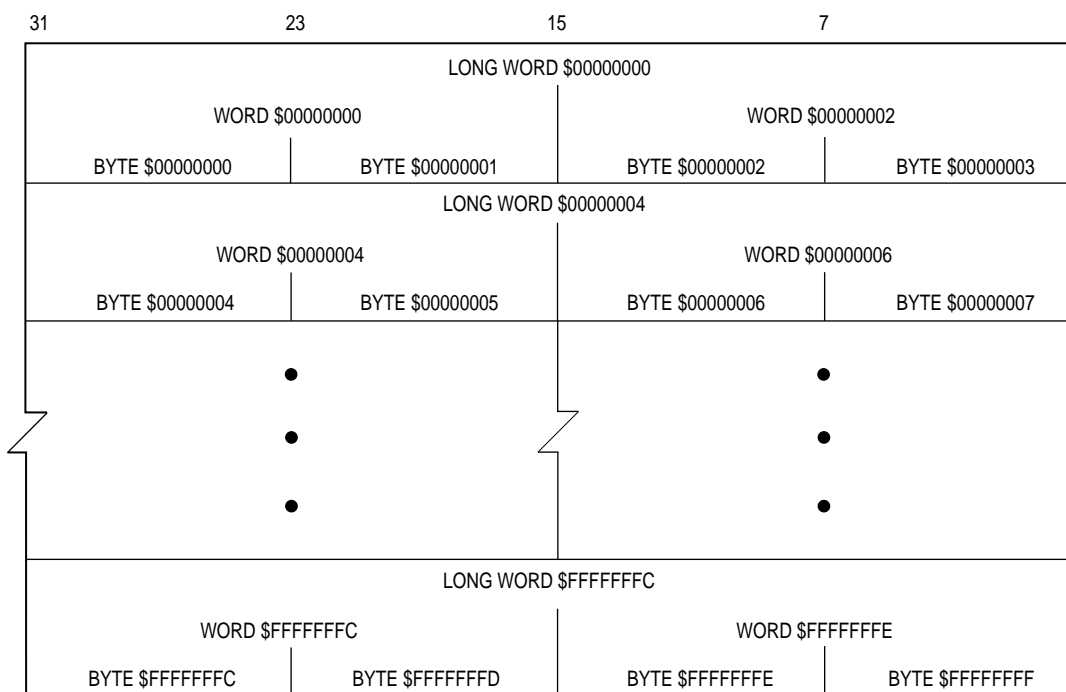

Figure 1-20. Memory Operand Addressing

1. A base address that selects one byte in memory.
2. A bit field offset that shows the leftmost (base) bit of the bit field in relation to the MSB of the base byte.
3. A bit field width that determines how many bits to the right of the base bit is the rightmost bit of the bit field.

The MSB of the base byte is bit field offset 0; the LSB of the base byte is bit field offset 7 and the LSB of the previous byte in memory is bit field offset – 1. Bit field offsets may have values between $2 - 31$ to $231 - 1$, and bit field widths may range from 1 to 32 bits.

A 16-byte block operand, supported by the MOVE16 instruction, has a block of 16 bytes aligned to a 16-byte boundary. An address that can point to any byte in the block selects this operand.

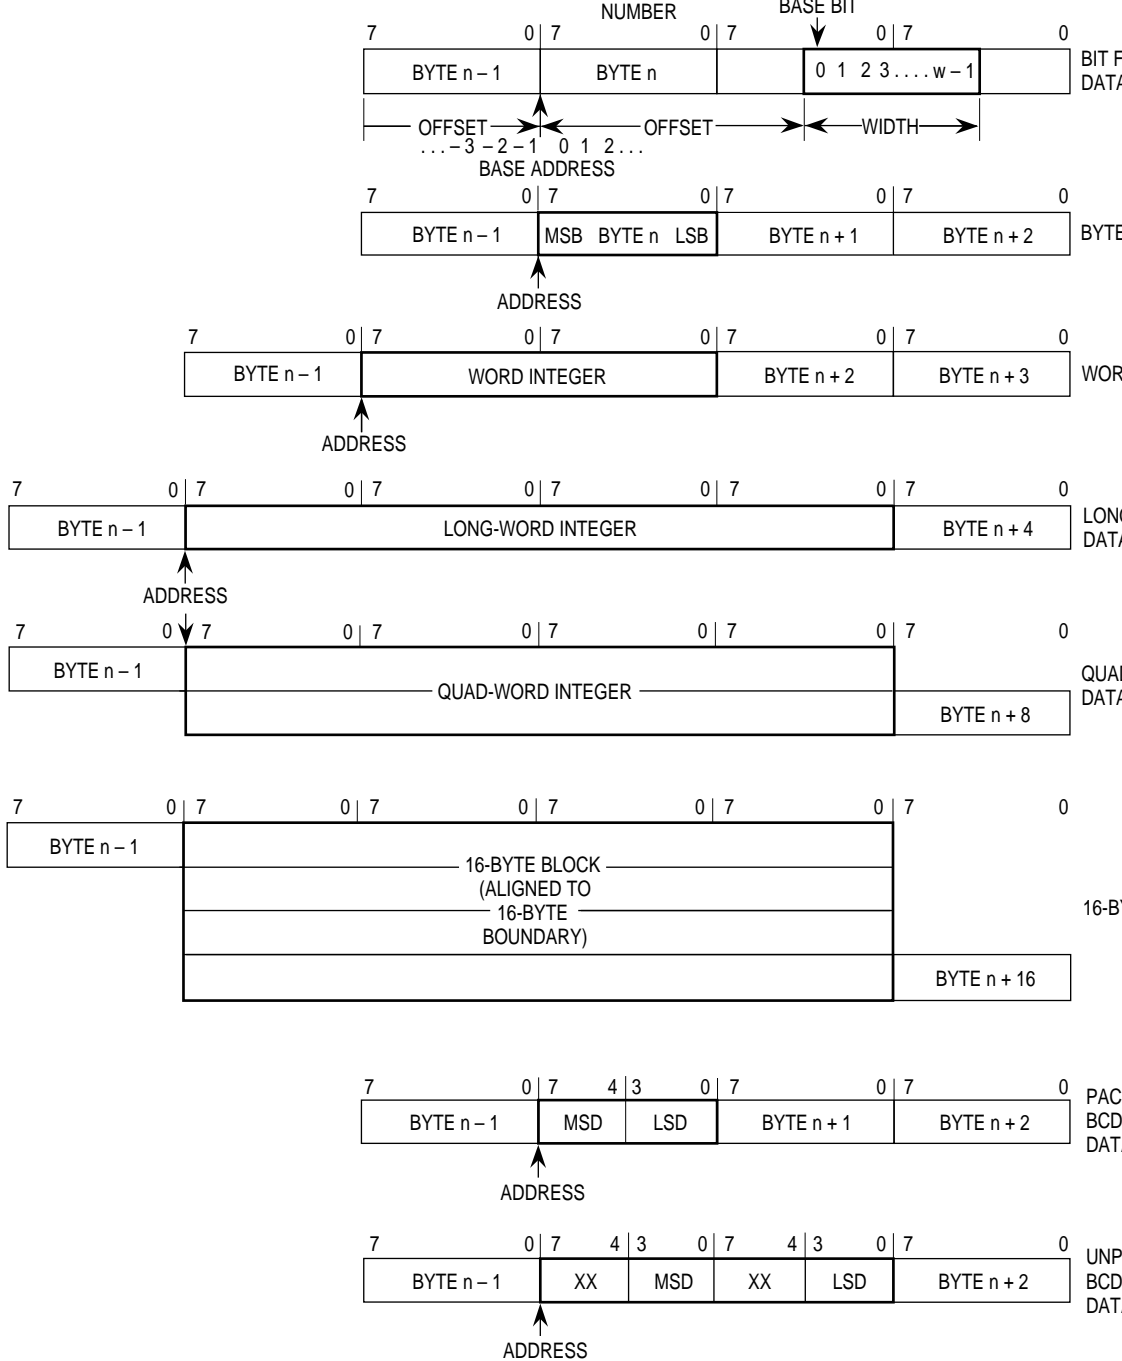

Figure 1-21. Memory Organization for Integer Operands

Table 1-8. MC68040 FPU Data Formats and Data Types

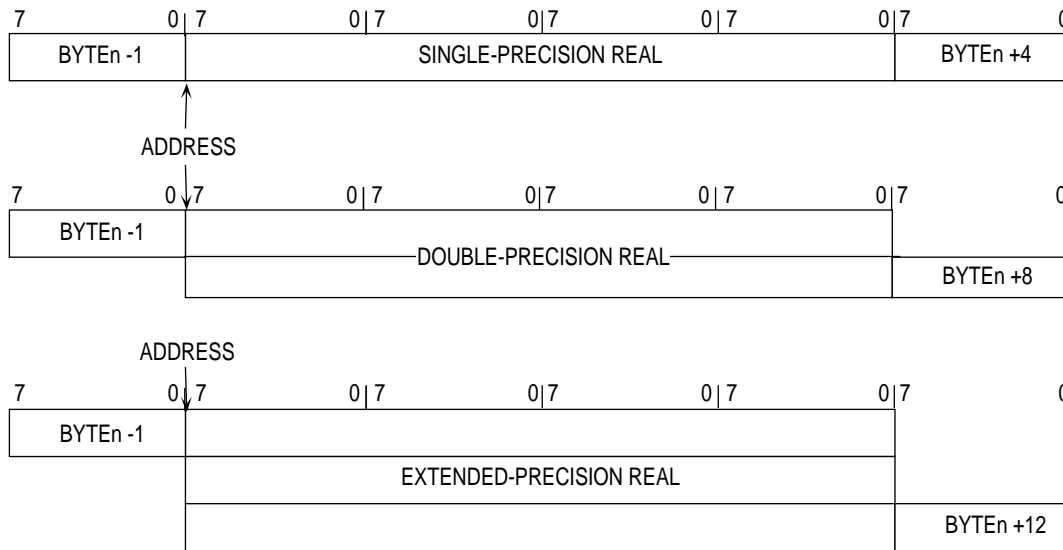

Figure 1-22. Organization of FPU Data Formats in Memory

SECTION 2 ADDRESSING CAPABILITIES

Most operations take a source operand and destination operand, compute them, and store the result in the destination location. Single-operand operations take a destination operand, compute it, and store the result in the destination location. External microprocessor references to memory are either program references that refer to program space or data references that refer to data space. They access either instruction words or operands (data items) for an instruction. Program space is the section of memory that contains the instructions and any immediate data operands residing in the instruction stream. Data space is the section of memory that contains the program data. Data items in the instruction stream can be accessed with the program counter relative addressing modes; these modes are classified as program references.

2.1 INSTRUCTION FORMAT

M68000 family instructions consist of at least one word; some have as many as six words. Figure 2-1 illustrates the general composition of an instruction. The first word of an instruction, called the simple effective address operation word, specifies the length of the instruction, the effective addressing mode, and the operation to be performed. The remaining words, called brief and full extension words, further specify the instruction operands. These words can be floating-point command words, conditional processor control words, immediate operands, extensions to the effective addressing mode specified in the simple effective address operation word, branch displacements, bit number or bit mask specifications, special register specifications, trap operands, pack/unpack control words, and argument counts.

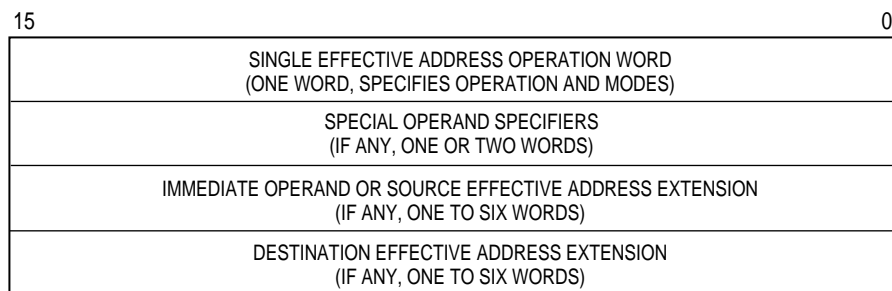

Figure 2-1. Instruction Word General Format

The single effective address operation word format is the basic instruction word (see Figure 2-2). The encoding of the mode field selects the addressing mode. The register field contains the general register number or a value that selects the addressing mode. The mode field contains opcode 111. Some indexed or indirect addressing modes consist of a combination of the simple effective address operation word followed by a brief extension word. Other indexed or indirect addressing modes consist of the simple effective address operation word and a full extension word. The longest instruction is a MOVE instruction that contains a full extension word for both the source and destination effective addresses and eight extension words. It also contains 32-bit base displacements and 32-bit outer displacements for both source and destination addresses. Figure 2-2 illustrates the three formats for an instruction word; Table 2-1 lists the field definitions for these three formats.

SINGLE EFFECTIVE ADDRESS OPERATION WORD FORMAT

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1

BASE DISPLACEMENT (0, 1, OR 2 WORDS)														
OUTER DISPLACEMENT (0, 1, OR 2 WORDS)														

Figure 2-2. Instruction Word Specification Formats

Register	General Register Number
Extensions	
D/A	Index Register Type 0 = Dn 1 = An
W/L	Word/Long-Word Index Size 0 = Sign-Extended Word 1 = Long Word
Scale	Scale Factor 00 = 1 01 = 2 10 = 4 11 = 8
BS	Base Register Suppress 0 = Base Register Added 1 = Base Register Suppressed
IS	Index Suppress 0 = Evaluate and Add Index Operand 1 = Suppress Index Operand
BD SIZE	Base Displacement Size 00 = Reserved 01 = Null Displacement 10 = Word Displacement 11 = Long Displacement
I/IS	Index/Indirect Selection Indirect and Indexing Operand Determined in Conjunction with Bit 6, Index Suppress

For effective addresses that use a full extension word format, the index suppress (I) and the index/indirect selection (I/IS) fields determine the type of indexing and indirect operations. Table 2-2 lists the index and indirect operations corresponding to all combinations of I/IS values.

0	010	Indirect Preindexed with Word Outer Displacement
0	011	Indirect Preindexed with Long Outer Displacement
0	100	Reserved
0	101	Indirect Postindexed with Null Outer Displacement
0	110	Indirect Postindexed with Word Outer Displacement
0	111	Indirect Postindexed with Long Outer Displacement
1	000	No Memory Indirect Action
1	001	Memory Indirect with Null Outer Displacement
1	010	Memory Indirect with Word Outer Displacement
1	011	Memory Indirect with Long Outer Displacement
1	100–111	Reserved

2.2 EFFECTIVE ADDRESSING MODES

Besides the operation code, which specifies the function to be performed, an instruction defines the location of every operand for the function. Instructions specify an operand location in one of three ways. A register field within an instruction can specify the register to be used; an instruction's effective address field can contain addressing mode information, or the instruction's definition can imply the use of a specific register. Other fields within an instruction specify whether the register selected is an address or data register and which register is to be used. **Section 1 Introduction** contains detailed register descriptions.

An instruction's addressing mode specifies the value of an operand, a register that contains the operand, or how to derive the effective address of an operand in memory. Each addressing mode has an assembler syntax. Some instructions imply the addressing mode for an operand. These instructions include the appropriate fields for operands that use only one addressing mode.

index operand. The value in the PC is the address of the extension word. This is a reference allowed only for reads. The user must include the displacement, the PC, index register when specifying this addressing mode.

GENERATION: $EA = (PC) + (Xn) + dg$
 ASSEMBLER SYNTAX: $(dg, PC, Xn.SIZE * SCALE)$
 EA MODE FIELD: 111
 EA REGISTER FIELD: 011
 NUMBER OF EXTENSION WORDS: 1

displacement, and the scaled contents of the sign-extended index register. The value of the PC is the address of the first extension word. This is a program reference allowed reads.

In this mode, the PC, the displacement, and the index register are optional. The user can supply the assembler notation ZPC (a zero value PC) to show that the PC is not used. This allows the user to access the program space without using the PC in calculating the effective address. The user can access the program space with a data register indirect addressing by placing ZPC in the instruction and specifying a data register as the index register.

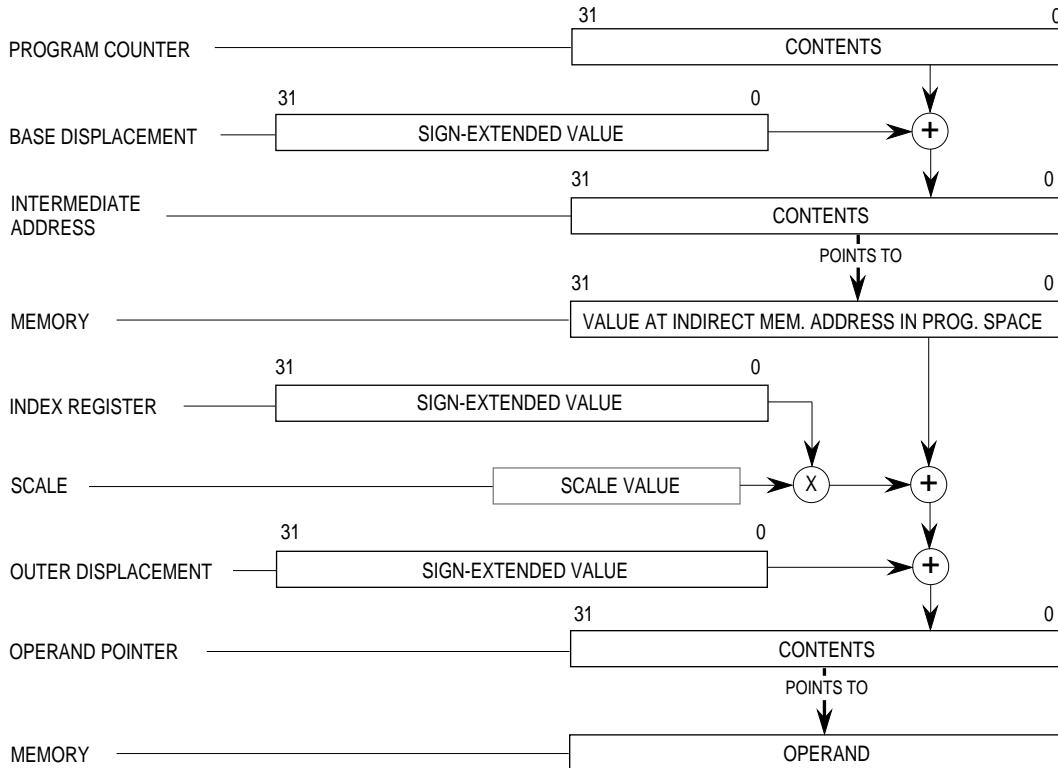

GENERATION: EA = (PC) + (Xn) + bd
 ASSEMBLER SYNTAX: (bd, PC, Xn, SIZE*SCALE)
 EA MODE FIELD: 111
 EA REGISTER FIELD: 011
 NUMBER OF EXTENSION WORDS: 1, 2, OR 3

adds the scaled contents of the index register and the optional outer displacement to the effective address. The value of the PC used in the calculation is the address of extension word. This is a program reference allowed only for reads.

In the syntax for this mode, brackets enclose the values used to calculate the intermediate memory address. All four user-specified values are optional. The user must supply assembler notation ZPC (a zero value PC) to show the PC is not used. This allows access to the program space without using the PC in calculating the effective address. The base and outer displacements may be null, word, or long word. When one displacement or suppressing an element, its value is zero in the effective address calculation.

NUMBER OF EXTENSION WORDS:	1,2,4, OR 6, EXCEPT FOR PACKED DECIMAL REAL OPERANDS

Table 2-3. Immediate Operand Location

Operation Length	Location
Byte	Low-order byte of the extension word.
Word	The entire extension word.
Long Word	High-order word of the operand is in the first extension word; the low-order word is in the second extension word.
Single-Precision	In two extension words.
Double-Precision	In four extension words.
Extended-Precision	In six extension words.
Packed-Decimal Real	In six extension words.

2.3 EFFECTIVE ADDRESSING MODE SUMMARY

Effective addressing modes are grouped according to the use of the mode. Data addressing modes refer to data operands. Memory addressing modes refer to memory operands. Alterable addressing modes refer to alterable (writable) operands. Control addressing modes refer to memory operands without an associated size.

These categories sometimes combine to form new categories that are more restrictive. The combined classifications are alterable memory (addressing modes that are both alterable and memory addresses) and data alterable (addressing modes that are both alterable and data). Table 2-4 lists a summary of effective addressing modes and their categories.

Address	An	001	reg. no.	—	—	—
Register Indirect						
Address	(An)	010	reg. no.	X	X	X
Address with Postincrement	(An)+	011	reg. no.	X	X	—
Address with Predecrement	-(An)	100	reg. no.	X	X	—
Address with Displacement	(d ₁₆ ,An)	101	reg. no.	X	X	X
Address Register Indirect with Index

that allows the CPU32, MC68020, MC68030, and MC68040 to distinguish the basic family architecture's new address extensions. Figure 2-3 illustrates these brief extension word formats. The encoding for SCALE used by the CPU32, MC68020, MC68030, and MC68040 is a compatible extension of the M68000 family architecture. A value of 0 for SCALE is the same encoding for both extension words. Software that uses this encoding is compatible with all processors in the M68000 family. Both brief extension word formats do not contain the other values of SCALE. Software can be easily migrated in any compatible direction, with downward support only for nonscaled addressing. If the processor were to execute an instruction that encoded a scaling factor, the scaling factor would be ignored and would not access the desired memory address. The earlier microprocessors do not recognize the brief extension word formats implemented by newer processors. If they can detect illegal instructions, they do not decode invalid encodings of the brief extension word formats as exceptions.

Figure 2-3. M68000 Family Brief Extension Word Formats

independently of each other. However, at least one element must be active suppressed. When an element is suppressed, it has an effective value of zero.

BR can be suppressed through the BS field of the full extension word format. The value of bits 0-5 in the single effective address word format (see Figure 2-2) selects BR as the PC when using program relative addressing modes, or An when using non-program relative addressing modes. The value of the PC is the address of the extension word when using the non-program relative addressing modes, BR is the contents of a selected An.

SIZE and SCALE can be used to modify Xn. The W/L field in the full extension word format selects the size of Xn as a word or long word. The SCALE field selects the scaling factor, a value of the Xn left multiplying the value by 1, 2, 4, or 8, respectively, without changing the value. Scaling can be used to calculate the address of arrayed structures. Figure 2-4 illustrates the scaling of an Xn.

The bd and od can be either word or long word. The size of od is selected through the encoding of the I/IS field in the full extension word format (refer to Table 2-2). There are four main modes of operation that use these four elements in different ways: no memory action and memory indirect. The od is provided only for using memory indirect addressing modes of which there are three types: with preindex, with postindex, and with no index suppressed.

Figure 2-8. Memory Indirect with Index Suppress

Address register seven (A7) is the system stack pointer. Either the user stack pointer, the interrupt stack pointer (ISP), or the master stack pointer (MSP) is active at any one time. Refer to **Section 1 Introduction** for details on these stack pointers. To keep data in the system stack aligned for maximum efficiency, the active stack pointer is automatically decremented or incremented by two for all byte-size operands moved to or from the stack. In long-word-organized memory, aligning the stack pointer on a long-word boundary significantly increases the efficiency of stacking exception frames, subroutine calls, returns, and other stacking operations.

The user can implement stacks with the address register indirect with postincrement or predecrement addressing modes. With an address register the user can implement stacks that fill either from high memory to low memory or from low memory to high memory. Important considerations are:

- Use the predecrement mode to decrement the register before using its contents as a pointer to the stack.
- Use the postincrement mode to increment the register after using its contents as a pointer to the stack.
- Maintain the stack pointer correctly when byte, word, and long-word items mix in the stacks.

To implement stack growth from high memory to low memory, use $-(A_n)$ to push data onto the stack and $(A_n) +$ to pull data from the stack. For this type of stack, after either a push or pull operation, the address register points to the top item on the stack.

2.6.2 Queues

The user can implement queues, groups of information waiting to be processed. Using a pair of address registers, the user implements a queue that fills either from high memory to low memory or from low memory to high memory. Two registers are used because queues get pushed from one end and pulled from the other. One address register is used as the put pointer; the other register the get pointer. To implement growth of the queue from low memory to high memory, use the put address register to put data into the queue and the get address register to get data from the queue.

After a put operation, the put address register points to the next available space in the queue; the unchanged get address register points to the next item to be removed from the queue. After a get operation, the get address register points to the next item to be removed from the queue; the unchanged put address register points to the next available space in the queue. .

To implement the queue as a circular buffer, the relevant address register should be incremented and adjusted. If necessary, do this before performing the put or get operation. Subtracting the buffer length (in bytes) from the register adjusts the address register. To implement growth of the queue from high memory to low memory, use the put address register to put data into the queue and get address register indirect to get data from the queue.

To implement the queue as a circular buffer, the get or put operation should be performed first. Then the relevant address register should be checked and adjusted, if necessary. Adding the buffer length (in bytes) to the address register contents adjusts the register.

SECTION 3 INSTRUCTION SET SUMMARY

This section briefly describes the M68000 family instruction set, using Motorola's language syntax and notation. It includes instruction set details such as notation and selected instruction examples, and an integer condition code discussion. The section concludes with a discussion of floating-point details such as computational and conditional test definitions, an explanation of the operation table, and a discussion of NaNs (NaNs) and postprocessing.

3.1 INSTRUCTION SUMMARY

Instructions form a set of tools that perform the following types of operations:

Data Movement	Program Control
Integer Arithmetic	System Control
Logical Operations	Cache Maintenance
Shift and Rotate Operations	Multiprocessor Communications
Bit Manipulation	Memory Management
Bit Field Manipulation	Floating-Point Arithmetic
Binary-Coded Decimal Arithmetic	

The following paragraphs describe in detail the instruction for each type of operation. Table 3-1 lists the notations used throughout this manual. In the operand syntax statements and instruction definitions, the operand on the right is the destination operand.

\times	Arithmetic multiplication.
\div	Arithmetic division or conjunction symbol.
\sim	Invert; operand is logically complemented.
\wedge	Logical AND
\vee	Logical OR
\oplus	Logical exclusive OR
\rightarrow	Source operand is moved to destination operand.
\leftrightarrow	Two operands are exchanged.
$\langle \text{op} \rangle$	Any double-operand operation.
$\langle \text{operand} \rangle \text{tested}$	Operand is compared to zero and the condition codes are set appropriately.
sign-extended	All bits of the upper portion are made equal to the high-order bit of the lower portion.
Other Operations	
TRAP	Equivalent to Format \pm Offset Word \rightarrow (SSP); SSP $- 2 \rightarrow$ SSP; PC \rightarrow (SSP); SSP $- 4 \rightarrow$ \rightarrow (SSP); SSP $- 2 \rightarrow$ SSP; (Vector) \rightarrow PC
STOP	Enter the stopped state, waiting for interrupts.
$\langle \text{operand} \rangle_{10}$	The operand is BCD; operations are performed in decimal.
If $\langle \text{condition} \rangle$ then $\langle \text{operations} \rangle$ else $\langle \text{operations} \rangle$	Test the condition. If true, the operations after "then" are performed. If the condition is false and optional "else" clause is present, the operations after "else" are performed. If the condition and else is omitted, the instruction performs no operation. Refer to the Bcc instruction data as an example.
Register Specifications	
An	Any Address Register n (example: A3 is address register 3)
Ax, Ay	Source and destination address registers, respectively.
Dc	Data register D7–D0, used during compare.
Dh, Dl	Data register's high- or low-order 32 bits of product.
Dn	Any Data Register n (example: D5 is data register 5)
Dr, Dq	Data register's remainder or quotient of divide.
Du	Data register D7–D0, used during update.
Dx, Dy	Source and destination data registers, respectively.
MRn	Any Memory Register n.
Rn	Any Address or Data Register
Rx, Ry	Any source and destination registers, respectively.
Xn	Index Register

B, W, L	Specifies a signed integer data type (twos complement) of byte, word, or long word.
D	Double-precision real data format (64 bits).
k	A twos complement signed integer (–64 to +17) specifying a number's format to be stored in packed decimal format.
P	Packed BCD real data format (96 bits, 12 bytes).
S	Single-precision real data format (32 bits).
X	Extended-precision real data format (96 bits, 16 bits unused).
– inf	Negative Infinity

Subfields and Qualifiers

#<xxx> or #<data>	Immediate data following the instruction word(s).
()	Identifies an indirect address in a register.
[]	Identifies an indirect address in memory.
bd	Base Displacement
ccc	Index into the MC68881/MC68882 Constant ROM
d _n	Displacement Value, n Bits Wide (example: d ₁₆ is a 16-bit displacement).
LSB	Least Significant Bit
LSW	Least Significant Word
MSB	Most Significant Bit
MSW	Most Significant Word
od	Outer Displacement
SCALE	A scale factor (1, 2, 4, or 8 for no-word, word, long-word, or quad-word scaling, respectively).
SIZE	The index register's size (W for word, L for long word).
{offset:width}	Bit field selection.

Register Names

CCR	Condition Code Register (lower byte of status register)
DFC	Destination Function Code Register
FPcr	Any Floating-Point System Control Register (FPCR, FPSR, or FPIAR)
FPm, FPn	Any Floating-Point Data Register specified as the source or destination, respectively.
IC, DC, IC/DC	Instruction, Data, or Both Caches
MMUSR	MMU Status Register
PC	Program Counter
Rc	Any Non Floating-Point Control Register
SFC	Source Function Code Register
SR	Status Register

CC	Condition Codes from CCR
FC	Function Code
N	Negative Bit in CCR
U	Undefined, Reserved for Motorola Use.
V	Overflow Bit in CCR
X	Extend Bit in CCR
Z	Zero Bit in CCR
—	Not Affected or Applicable.
Stack Pointers	
ISP	Supervisor/Interrupt Stack Pointer
MSP	Supervisor/Master Stack Pointer
SP	Active Stack Pointer
SSP	Supervisor (Master or Interrupt) Stack Pointer
USP	User Stack Pointer
Miscellaneous	
<ea>	Effective Address
<label>	Assemble Program Label
<list>	List of registers, for example D3–D0.
LB	Lower Bound
m	Bit m of an Operand
m–n	Bits m through n of Operand
UB	Upper Bound

and ensure that only valid address manipulations are executed. In addition to the MOVE instructions, there are several special data movement instructions: LMOVEM, MOVEM, MOVEP, MOVEQ, EXG, LEA, PEA, LINK, and UNLK. The MOVE16 instruction is an MC68040 extension to the M68000 instruction set.

The FMOVE instructions move operands into, out of, and between floating-point registers. FMOVE also moves operands to and from the floating-point control register (FPCR), floating-point status register (FPSR), and floating-point instruction address register (FPIAR). For operands moved into a floating-point data register, FSMOVE and FDMOVE explicitly select single- and double-precision rounding of the result, respectively. FMOVE moves any combination of either floating-point data registers or floating-point control registers. Table 3-2 lists the general format of these integer and floating-point movement instructions.

	F _{Pm} , <ea> <ea>, F _{Pcr} F _{Pcr} , <ea>	B, W, L, S, D, X, P 32 32	
FSMOVE, FDMOVE	F _{Pm} , F _{Pn} <ea>, F _{Pn}	X B, W, L, S, D, X	Source → Destination; round destination to single or double precision.
FMOVEM	<ea>, <list> ¹ <ea>, D _n <list> ¹ , <ea> D _n , <ea>	32, X X 32, X X	Listed Registers → Destination Source → Listed Registers
LEA	<ea>, A _n	32	<ea> → A _n
LINK	A _n , #<d>	16, 32	SP - 4 → SP; A _n → (SP); SP → A _n , SP + D → SP
MOVE MOVE16 MOVEA	<ea>, <ea> <ea>, <ea> <ea>, A _n	8, 16, 32 16 bytes 16, 32 → 32	Source → Destination Aligned 16-Byte Block → Destination
MOVEM	list, <ea> <ea>, list	16, 32 16, 32 → 32	Listed Registers → Destination Source → Listed Registers
MOVEP	D _n , (d ₁₆ , A _n) (d ₁₆ , A _n), D _n	16, 32	D _n 31–24 → (A _n + d _n); D _n 23–16 → (A _n + d _n + 4); D _n 15–8 → (A _n + d _n + 8); D _n 7–0 → (A _n + d _n + 12); (A _n + d _n) → D _n 31–24; (A _n + d _n + 2) → D _n 23–16; (A _n + d _n + 4) → D _n 15–8; (A _n + d _n + 6) → D _n 7–0
MOVEQ	#<data>, D _n	8 → 32	Immediate Data → Destination
PEA	<ea>	32	SP - 4 → SP; <ea> → (SP)
UNLK	A _n	32	A _n → SP; (SP) → A _n ; SP + 4 → SP

NOTE: A register list includes any combination of the eight floating-point data registers or any combination of the three control registers (FPCR, FPSR, and FPIAR). If a register list mask resides in a data register, or if a register list mask resides in a floating-point data register, floating-point data registers may be specified.

3.1.2 Integer Arithmetic Instructions

The integer arithmetic operations include four basic operations: ADD, SUB, MUL, and DIV. They also include CMP, CMPM, CMP2, CLR, and NEG. The instruction set includes ADD, SUB, MUL, and DIV instructions for both address and data operations with all operand sizes. CMP, and SUB instructions for both address and data operations with all operand sizes. Address operands consist of 16 or 32 bits. The CLR and NEG instructions apply to all sizes of data operands. Signed and unsigned MUL and DIV instructions include:

- Word multiply to produce a long-word product.
- Long-word multiply to produce a long-word or quad-word product.
- Long word divided by a word divisor (word quotient and word remainder).
- Long word or quad word divided by a long-word divisor (long-word quotient and long-word remainder).

Instruction	Operand Syntax	Operand Size	Operation
ADD ADDA	Dn,<ea> <ea>,Dn <ea>,An	8, 16, 32 8, 16, 32 16, 32	Source + Destination → Destination
ADDI ADDQ	#<data>,<ea> #<data>,<ea>	8, 16, 32 8, 16, 32	Immediate Data + Destination → Destination
ADDX	Dn,Dn -(An), -(An)	8, 16, 32 8, 16, 32	Source + Destination + X → Destination
CLR	<ea>	8, 16, 32	0 → Destination
CMP CMPA	<ea>,Dn <ea>,An	8, 16, 32 16, 32	Destination – Source
CMPI	#<data>,<ea>	8, 16, 32	Destination – Immediate Data
CMPM	(An)+,(An)+	8, 16, 32	Destination – Source
CMP2	<ea>,Rn	8, 16, 32	Lower Bound → Rn → Upper Bound
DIVS/DIVU DIVSL/DIVUL	<ea>,Dn <ea>,Dr-Dq <ea>,Dq <ea>,Dr-Dq	32 ÷ 16 → 16,16 64 ÷ 32 → 32,32 32 ÷ 32 → 32 32 ÷ 32 → 32,32	Destination ÷ Source → Destination (Signed or Unsigned Quotient, Remainder)
EXT EXTB	Dn Dn Dn	8 → 16 16 → 32 8 → 32	Sign-Extended Destination → Destination
MULS/MULU	<ea>,Dn <ea>,DI <ea>,Dh-DI	16 x 16 → 32 32 x 32 → 32 32 x 32 → 64	Source x Destination → Destination (Signed or Unsigned)

3.1.4 Shift and Rotate Instructions

The ASR, ASL, LSR, and LSL instructions provide shift operations in both directions. ROR, ROL, ROXR, and ROXL instructions perform rotate (circular shift) operations with and without the CCR extend bit (X-bit). All shift and rotate operations can be performed on either registers or memory.

Register shift and rotate operations shift all operand sizes. The shift count can be specified in the instruction operation word (to shift from 1 – 8 places) or in a register (modulo 32-bit count).

Memory shift and rotate operations shift word operands one bit position only. The ROR instruction exchanges the 16-bit halves of a register. Fast byte swapping is possible using the ROR and ROL instructions with a shift count of eight, enhancing the performance of the shift/rotate instructions. Table 3-5 is a summary of the shift and rotate operations. In Table 3-5, C and X refer to the C-bit and X-bit in the CCR.

ASL	Dn, Dn # (data), Dn ea	8, 16, 32 8, 16, 32 16	
ASR	Dn, Dn # (data), Dn ea	8, 16, 32 8, 16, 32 16	
LSL	Dn, Dn # (data), Dn ea	8, 16, 32 8, 16, 32 16	
LSR	Dn, Dn # (data), Dn ea	8, 16, 32 8, 16, 32 16	
ROL	Dn, Dn # (data), Dn ea	8, 16, 32 8, 16, 32 16	
ROR	Dn, Dn # (data), Dn ea	8, 16, 32 8, 16, 32 16	
ROXL	Dn, Dn # (data), Dn ea	8, 16, 32 8, 16, 32 16	
ROXR	Dn, Dn # (data), Dn ea	8, 16, 32 8, 16, 32 16	
SWAP	Dn	32	

NOTE: X indicates the extend bit and C the carry bit in the CCR.

operations; Z refers to the zero bit of the CCR.

Table 3-6. Bit Manipulation Operation Format

Instruction	Operand Syntax	Operand Size	Operation
BCHG	Dn,<ea> #<data>,<ea>	8, 32 8, 32	~ (<Bit Number> of Destination) → Z → Bit of Destination
BCLR	Dn,<ea> #<data>,<ea>	8, 32 8, 32	~ (<Bit Number> of Destination) → Z; 0 → Bit of Destination
BSET	Dn,<ea> #<data>,<ea>	8, 32 8, 32	~ (<Bit Number> of Destination) → Z; 1 → Bit of Destination
BTST	Dn,<ea> #<data>,<ea>	8, 32 8, 32	~ (<Bit Number> of Destination) → Z

3.1.6 Bit Field Instructions

The M68000 family architecture supports variable-length bit field operations on fields up to 32 bits. The BFINS instruction inserts a value into a bit field. BFEXTU and BFEXTS extract a value from the field. BFFFO finds the first set bit in a bit field. Also included are instructions analogous to the bit manipulation operations: BFTST, BFSET, BFCLR, and BFCHG. Table 3-7 summarizes bit field operations.

Table 3-7. Bit Field Operation Format

Instruction	Operand Syntax	Operand Size	Operation
BFCHG	<ea> {offset:width}	1–32	~ Field → Field
BFCLR	<ea> {offset:width}	1–32	0's → Field
BFEXTS	<ea> {offset:width}, Dn	1–32	Field → Dn; Sign-Extended
BFEXTU	<ea> {offset:width}, Dn	1–32	Field → Dn; Zero-Extended
BFFFO	<ea> {offset:width}, Dn	1–32	Scan for First Bit Set in Field; Offset → Dn
BFINS	Dn,<ea> {offset:width}	1–32	Dn → Field
BFSET	<ea> {offset:width}	1–32	1's → Field
BFTST	<ea> {offset:width}	1–32	Field MSB → N; ~ (OR of All Bits in Field)

NOTE: All bit field instructions set the CCR N and Z bits as shown for BFTST before performing the specified operation.

Table 3-8. Binary-Coded Decimal Operation Format

Instruction	Operand Syntax	Operand Size	Operation
ABCD	Dn,Dn -(An), -(An)	8 8	Source ₁₀ + Destination ₁₀ + X → Destination
NBCD	<ea>	8	0 – Destination ₁₀ – X → Destination
PACK	-(An), -(An) #<data> Dn,Dn,#<data>	16 → 8 16 → 8	Unpackaged Source + Immediate Data → Packed Destination
SBCD	Dn,Dn -(An), -(An)	8 8	Destination ₁₀ – Source ₁₀ – X → Destination
UNPK	-(An),-(An) #<data> Dn,Dn,#<data>	8 → 16 8 → 16	Packed Source → Unpacked Source Unpacked Source + Immediate Data → Unpacked Destination

3.1.8 Program Control Instructions

A set of subroutine call and return instructions and conditional and unconditional instructions perform program control operations. Also included are test operand instructions (TST and FTST), which set the integer or floating-point condition codes for use in program and system control instructions. NOP forces synchronization of the pipelines. Table 3-9 summarizes these instructions.

			If Dn → -1, Then PC + d _n → PC
Scc, FScc	<ea>	8	If Condition True, Then 1's → Destination; Else 0's → Destination
Unconditional			
BRA	<label>	8, 16, 32	PC + d _n → PC
BSR	<label>	8, 16, 32	SP - 4 → SP; PC → (SP); PC + d _n → PC
JMP	<ea>	none	Destination → PC
JSR	<ea>	none	SP - 4 → SP; PC → (SP); Destination → PC
NOP	none	none	PC + 2 → PC (Integer Pipeline Synchronized)
FNOP	none	none	PC + 4 → PC (FPU Pipeline Synchronized)
Returns			
RTD	#<data>	16	(SP) → PC; SP + 4 + d _n → SP
RTR	none	none	(SP) → CCR; SP + 2 → SP; (SP) → PC; SP + 4 → SP
RTS	none	none	(SP) → PC; SP + 4 → SP
Test Operand			
TST	<ea>	8, 16, 32	Set Integer Condition Codes
FTST	<ea> FPn	B, W, L, S, D, X, P X	Set Floating-Point Condition Codes

Letters cc in the integer instruction mnemonics Bcc, DBcc, and Scc specify testing one of the following conditions:

CC—Carry clear	GE—Greater than or equal
LS—Lower or same	PL—Plus
CS—Carry set	GT—Greater than
LT—Less than	T—Always true*
EQ—Equal	HI—Higher
MI—Minus	VC—Overflow clear
F—Never true*	LE—Less than or equal
NE—Not equal	VS—Overflow set

*Not applicable to the Bcc instructions.

3.1.9 System Control Instructions

Privileged and trapping instructions as well as instructions that use or modify the condition codes provide system control operations. FSAVE and FRESTORE save and restore the visible portion of the FPU during context switches in a virtual memory or multiprocessor system. The conditional trap instructions, which use the same conditional tests as the corresponding program control instructions, allow an optional 16- or 32-bit immediate operand to be included as part of the instruction for passing parameters to the operating system. These instructions cause the processor to flush the instruction pipe. Table 3-1 summarizes these instructions. See 3.2 Integer Unit Condition Code Computation for details on condition codes.

EORI to SR	#<data>,SR	16	Immediate Data \oplus SR \rightarrow SR
FRESTORE	<ea>	none	State Frame \rightarrow Internal Floating-Point Registers

3.1.11 Multiprocessor Instructions

The TAS, CAS, and CAS2 instructions coordinate the operations of processor multiprocessor systems. These instructions use read-modify-write bus cycles to ensure uninterrupted updating of memory. Coprocessor instructions control the coprocessor operations. Table 3- 12 summarizes these instructions.

Table 3-12. Multiprocessor Operations

Instruction	Operand Syntax	Operand Size	Operation
Read-Write-Modify			
CAS	Dc,Du,<ea>	8, 16, 32	Destination – Dc → CC If Z, Then Du → Destination Else Destination → Dc
CAS2	Dc1–Dc2, Du1–Du2, (Rn)–(Rn)	16, 32	Dual Operand CAS

3.1.13 Floating-Point Arithmetic Instructions

The following paragraphs describe the floating-point instructions, organized in categories of operation: dyadic (requiring two operands) and monadic (requiring one operand).

The dyadic floating-point instructions provide several arithmetic functions that require two input operands, such as add and subtract. For these operations, the first operand is located in memory, an integer data register, or a floating-point data register. The second operand is always located in a floating-point data register. The results of the operation are placed in the register specified as the second operand. All FPU operations support all data formats. Results are rounded to either extended-, single-, or double-precision format. Table 3-14 gives the general format of dyadic instructions, and Table 3-15 lists the available operations.

NOTE: < dop > is any one of the dyadic operation specifiers.

Table 3-15. Dyadic Floating-Point Operations

Instruction	Operation
FADD, FSADD, FDADD	Add
FCMP	Compare
FDIV, FSDIV, FDDIV	Divide
FMOD	Modulo Remainder
FMUL, FSMUL, FDMUL	Multiply
FREM	IEEE Remainder
FSCALE	Scale Exponent
FSUB, FSSUB, FDSUB	Subtract
FSGLDIV, FSGLMUL	Single-Precision Divide, Multiply

The monadic floating-point instructions provide several arithmetic functions requiring one input operand. Unlike the integer counterparts to these functions (e.g., NEG < source and a destination can be specified. The operation is performed on the operand and the result is stored in the destination, which is always a floating-point register. When the source is not a floating-point data register, all data formats are supported. The data format is always extended precision for register-to-register operations. Table 3-16 lists the general format of these instructions, and Table 3-17 lists the available operations.

Table 3-16. Monadic Floating-Point Operation Format

Instruction	Operand Syntax	Operand Format	Operation
F<mop>	<ea>,FPn FPm,FPn FPn	B, W, L, S, D, X, P X X	Source → Function → FPn FPn → Function → FPn

NOTE: < mop > is any one of the monadic operation specifiers.

FASIN	Arc Sine
FATAN	Hyperbolic Art Tangent
FCOS	Cosine
FCOSH	Hyperbolic Cosine
FETOX	e^x
FETOXM1	$e^x - 1$
FGETEXP	Extract Exponent
FGETMAN	Extract Mantissa
FINT	Extract Integer Part
FINTRZ	Extract Integer Part, Rounded-to-Zero

FLOG10	$\text{Log}_{10}(x)$
FLOG2	$\text{Log}_2(x)$
FNEG	Negate
FSIN	Sine
FSINH	Hyperbolic Sine
FSQRT	Square Root
FTAN	Tangent
FTANH	Hyperbolic Tangent
FTENTOX	10^x
FTWOTOX	2^x

3.2 INTEGER UNIT CONDITION CODE COMPUTATION

Many integer instructions affect the CCR to indicate the instruction's results. Processor system control instructions also use certain combinations of these bits to control processor operation and system flow. The condition codes meet consistency criteria across instructions and instances. They also meet the criteria of meaningful results, where no change occurs unless it provides useful information. Refer to **Section 1 Introduction** for details concerning the CCR.

Table 3-18 lists the integer condition code computations for instructions and Table 3-19 lists the condition names, encodings, and tests for the conditional branch and set instructions. The test associated with each condition is a logical formula using the current status of the condition codes. If this formula evaluates to one, the condition is true. If the formula evaluates to zero, the condition is false. For example, the T condition is always true. The EQ condition is true only if the Z-bit condition code is currently true.

*Not available for the Bcc instruction.

The CAS instruction compares the value in a memory location with the value in a register, and copies a second data register into the memory location if the compared values are equal. This provides a means of updating system counters, history information, and globally shared pointers. The instruction uses an indivisible read-modify-write cycle. When CAS reads the memory location, no other instruction can change that location before CAS has written the new value. This provides security in single-processor systems and multitasking environments, and in multiprocessor environments. In a single-processor system, the operation is protected from instructions of an interrupt routine. In a multiprocessor environment, no other task can interfere with writing the new value of a system variable. In a multiprocessor environment, the other processors must wait until the CAS instruction completes before accessing a global pointer.

3.3.2 Using the Moves Instruction

This instruction moves the byte, word, or long-word operand from the specified source register to a location within the address space specified by the destination function code (DFC) register. It also moves the byte, word, or long-word operand from a location within the address space specified by the source function code (SFC) register to the specified destination register.

3.3.3 Nested Subroutine Calls

The LINK instruction pushes an address onto the stack, saves the stack address where the address is stored, and reserves an area of the stack. Using this instruction in a subroutine calls results in a linked list of stack frames.

The UNLK instruction removes a stack frame from the end of the list by loading an address into the stack pointer and pulling the value at that address from the stack. When the address of the instruction is the address of the link address at the bottom of a stack frame, the instruction is to remove the stack frame from the stack and from the linked list.

3.3.4 Bit Field Instructions

One of the data types provided by the MC68030 is the bit field, consisting of as many consecutive bits. An offset from an effective address and a width value defines a bit field. The offset is a value in the range of -231 through $231 - 1$ from the most significant bit (7) at the effective address. The width is a positive number, 1 through 32. The most significant bit of a bit field is bit 0. The bits number in a direction opposite to the bits of an integer.

The instruction set includes eight instructions that have bit field operands. The insert (BFINS) instruction inserts a bit field stored in a register into a bit field. The extract signed (BFEXTS) instruction loads a bit field into the least significant bits of a register.

setting the condition codes accordingly. The test bit field (BFTST) instruction tests bits in the field, setting the condition codes appropriately without altering the bit field. The first one in bit field (BFFFO) instruction scans a bit field from bit 0 to the right until a bit set to one and loads the bit offset of the first set bit into the specified data register. If all bits in the field are set, the field offset and the field width is loaded into the register.

An important application of bit field instructions is the manipulation of the exponent of a floating-point number. In the IEEE standard format, the most significant bit is the sign bit, and the mantissa. The exponent value begins at the next most significant bit position. Because the exponent field does not begin on a byte boundary, the extract bit field (BFEXTU) instruction and the BFTST instruction are the most useful for this application, but other bit field instructions can also be used.

Programming of input and output operations to peripherals requires testing, setting, and inserting of bit fields in the control registers of the peripherals. This is another application of bit field instructions. However, control register locations are not memory locations; therefore, it is not always possible to insert or extract bit fields of a register without affecting other bits within the register.

Another widely used application for bit field instructions is bit-mapped graphics. In graphics, byte boundaries are ignored in these areas of memory, the field definitions used with bit field instructions are very helpful.

3.3.5 Pipeline Synchronization with the Nop Instruction

Although the no operation (NOP) instruction performs no visible operation, it serves an important purpose. It forces synchronization of the integer unit pipeline by waiting for all pending bus cycles to complete. All previous integer instructions and floating-point operand accesses complete execution before the NOP begins. The NOP instruction does not synchronize the FPU pipeline—floating-point instructions with floating-point operand destinations can be executing when the NOP begins. NOP is considered a control of flow instruction and traps for trace on change of flow. A single-cycle nonsynchronous operation can be affected with the TRAPF instruction.

3.4 FLOATING-POINT INSTRUCTION DETAILS

The following paragraphs describe the operation tables used in the instruction decoder and the conditional tests that can be used to change program flow based on floating-point conditions. Details on NaNs and floating-point condition codes are also discussed. The IEEE 754 standard specifies that each data format must support add, subtract, multiply, divide, remainder, square root, integer part, and compare. In addition to these a

operand type along the top, and the destination operand type along the side. numbers are normalized, denormalized, unnormalized real numbers, or integers converted to normalized or denormalized extended-precision numbers upon entering the FPU.

Table 3-20. Operation Table Example (FADD Instruction)

DESTINATION	SOURCE ¹			
		+ In Range	- + Zero -	+ Infinity -
In Range	+	ADD	ADD	+inf -inf
	-			
Zero	+	ADD	+ 0.0 0.0 ²	+inf -inf
	-		0.0 ² -0.0	
Infinity	+	+inf	+inf	+inf NAN ³
	-	-inf	-inf	NAN ³ -inf

NOTES:

- 1.If either operand is a NAN, refer to **1.6.5 NANs** for more information.
- 2.Returns +0.0 in rounding modes RN, RZ, and RP; returns -0.0 in RM.
- 3.Sets the OPERR bit in the FPSR exception byte.

For example, Table 3-20 illustrates that if both the source and destination operands are positive zero, the result is also a positive zero. If the source operand is a positive zero and the destination operand is an in-range number, then the ADD algorithm is executed and the result is the sum of the two operands. If a label such as ADD appears in the table, it indicates that the FPU performed the indicated operation and returns the correct result. If the source operand is a signaling NaN and the destination operand is a nonsignaling NaN, the result is undefined, a NaN is returned as the result, and the OPERR bit is set in the FPSR EXC byte.

In addition to the data types covered in the operation tables for each floating-point instruction, NaNs can also be used as inputs to an arithmetic operation. The operation tables do not contain a row and column for NaNs because NaNs are handled the same way for all operations. If either operand, but not both operands, of an operation is a nonsignaling NaN, then that NaN is returned as the result. If both operands are nonsignaling NaNs, the destination operand nonsignaling NaN is returned as the result.

If either operand to an operation is a signaling NaN (SNAN), then the SNAN bit is set in the FPSR EXC byte. If the SNAN exception enable bit is set in the FPCR ENABLE byte, the exception is taken and the destination is not modified. If the SNAN exception enable bit is not set, setting the SNAN bit in the operand to a one converts the SNAN to a nonsignaling NaN. The operation then continues as described in the preceding paragraph for nonsignaling NaNs.

that the result obtained by any conforming device can be predicted exactly for a precision and rounding mode. The error bound defined by the IEEE 754 standard is one unit in the last place of the destination data format in the RN mode, and one unit in the next-to-last place in the other rounding modes. The operation's data format must have the same input precision, rounding mode, and precision. The standard also specifies the maximum allowable error that can be introduced during a calculation and the manner in which rounding of the result is performed.

The single- and double-precision formats provide emulation for devices that only support those precisions. The execution speed of all instructions is the same whether using single- or double-precision rounding. When using these two data formats, the FPU produces the same results as any other device that conforms to the IEEE standard but does not support extended precision. The results are the same when performing the same operation in extended precision and storing the results in single- or double-precision format.

The FPU performs all floating-point internal operations in extended-precision. It performs mixed-mode arithmetic by converting single- and double-precision operands to extended-precision values before performing the specified operation. The FPU converts all input data formats to the extended-precision data format and stores the value in a floating-point register or uses it as the source operand for an arithmetic operation. The FPU also converts extended-precision data formats in a floating-point data register to any data format. The FPU either stores it in a memory destination or in an integer data register.

Additionally if the external operand is a denormalized number, the number is normalized before an operation is performed. However, an external denormalized number moving to a floating-point data register is stored as a denormalized number. The number is normalized and then denormalized before it is stored in the designated floating-point register. This method simplifies the handling of all other data formats and types.

If an external operand is an unnormalized number, the number is normalized before being used in an arithmetic operation. If the external operand is an unnormalized zero (i.e., a mantissa of all zeros), the number is converted to a normalized zero before the operation is performed. The regular use of unnormalized inputs not only defeats the intent of the IEEE 754 standard, but also can produce gross inaccuracies in the results.

Figure 3-1 illustrates the intermediate result format. The intermediate result's exponent and some dyadic operations (i.e., multiply and divide) can easily overflow or underflow the bit exponent of the designated floating-point register. To simplify the overflow and underflow detection, intermediate results in the FPU maintain a 16-bit (17 bits for the MC68000 and MC68882), two's complement, integer exponent. Detection of an overflow or underflow of an intermediate result always converts the 16-bit exponent into a 15-bit biased exponent before being stored in a floating-point data register. The FPU internally maintains the 16-bit exponent and the 63-bit mantissa for rounding purposes. The mantissa is always rounded to 64 bits (65 bits for the MC68000 and MC68882, depending on the selected rounding precision) before it is stored in a floating-point register.

Figure 3-1. Intermediate Result Format

If the destination is a floating-point data register, the result is in the extended-precision format and is rounded to the precision specified by the FPSR PREC bits before being stored. All mantissa bits beyond the selected precision are zero. If the single- or double-precision mode is selected, the exponent value is in the correct range even if it is stored in extended-precision format. If the destination is a memory location, the FPSR PREC bits are ignored. In this case, a number in the extended-precision format is taken from the source floating-point data register, rounded to the destination format precision, and then written to memory.

Depending on the selected rounding mode or destination data format in effect, the location of the least significant bit of the mantissa and the locations of the guard, round, and sticky bits in the 67-bit intermediate result mantissa varies. The guard and round bits are calculated exactly. The sticky bit is used to create the illusion of an infinitely precise intermediate result. As the arrow illustrates in Figure 3-1, the sticky bit is the logical OR of all the bits in the infinitely precise result to the right of the round bit. During the carry stage of an arithmetic operation, any non-zero bits generated that are to the right of the round bit set the sticky bit to one. Because of the sticky bit, the rounded intermediate result for all required IEEE arithmetic operations in the RN mode is in error by no more than half unit in the last place.

accomplished through the intermediate result. Single-precision results are rounded to a 24-bit boundary; double-precision results are rounded to a 53-bit boundary; and extended-precision results are rounded to a 64-bit boundary. Table 3-21 lists the encoding of the FPCR that denote the rounding and precision modes.

Table 3-21. FPCR Encodings

Rounding Mode (RND Field)	Encoding		Rounding Precision (PREC Field)
To Nearest (RN)	0	0	Extend (X)
To Zero (RZ)	0	1	Single (S)
To Minus Infinity (RM)	1	0	Double (D)
To Plus Infinity (RP)	1	1	Undefined

Rounding the intermediate result's mantissa to the specified precision and checking the bit intermediate exponent to ensure that it is within the representable range of the rounding precision accomplishes range control. Range control is a method used to ensure correct emulation of a device that only supports single- or double- precision arithmetic. If the intermediate result's exponent exceeds the range of the selected precision, the value appropriate for an underflow or overflow is stored as the result in the 16-bit exponent of the destination floating-point data register. For example, if the data format and rounding mode are single-precision RM and the result of an arithmetic operation overflows the magnitude of the destination floating-point data register, the largest normalized single-precision value is stored as an extended-precision number in the destination floating-point data register (i.e., an unbiased exponent of \$00FF and a mantissa of \$FFFFFF0000000000). If an infinity is the appropriate result for an underflow or overflow, the infinity value for the destination data format is stored as the result (i.e., an exponent with the maximum value and a mantissa of zero).

Figure 3-2 illustrates the algorithm that the FPU uses to round an intermediate result to the selected rounding precision and destination data format. If the destination is a floating-point register, either the selected rounding precision specified by the FPCR PREC status byte or by the instruction itself determines the rounding boundary. For example, FS and FDADD specify single- and double-precision rounding regardless of the precision specified in the FPCR PREC status byte. If the destination is external memory or an integer register, the destination data format determines the rounding boundary. If the rounding of an operation is not exact, then the INEX2 bit is set in the FPSR EXC status byte.

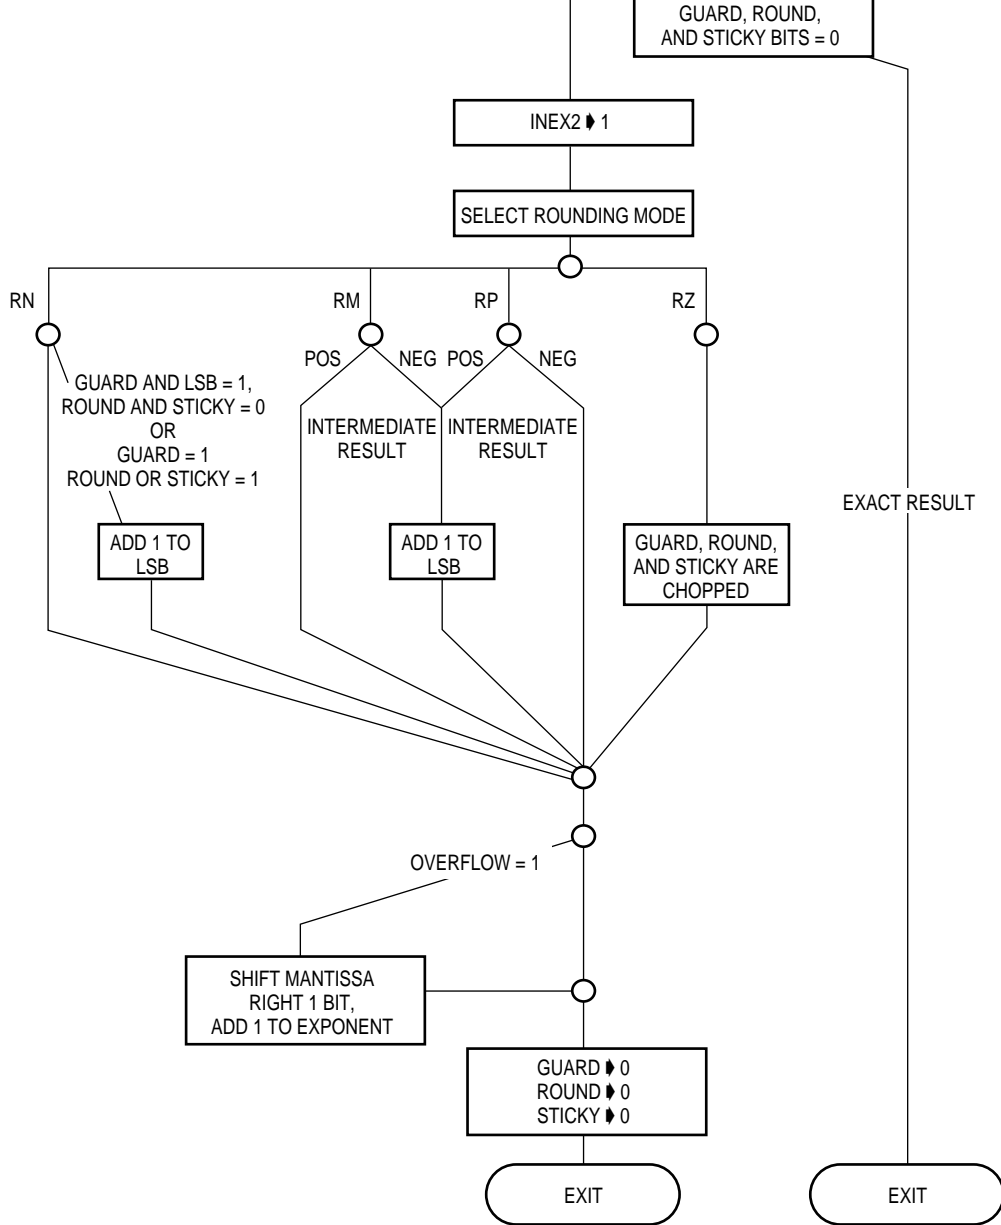

Figure 3-2. Rounding Algorithm Flowchart

The three additional bits beyond the extended-precision format, the difference between the intermediate result's 67-bit mantissa and the stored result's 64-bit mantissa, allow the processor to perform all calculations as though it were performing calculations using a float engine with infinite bit precision. The result is always correct for the specified destination's data format. The processor then performs rounding (unless an overflow or underflow error occurs). The specified rounding operation then produces a number that is as close as possible to the infinitely

Rounded-to-Nearest	x	xxx...x00	0	0	0
--------------------	---	-----------	---	---	---

The LSB of the rounded result does not increment though the guard bit is set in the intermediate result. The IEEE 754 standard specifies that tie cases should be handled in a round-to-nearest manner. If the destination data format is extended and there is a difference between the infinitely precise intermediate result and the round-to-nearest result, the relative error is 2^{-64} (the value of the guard bit). This error is equal to half of the least significant value and is the worst case error that can be introduced when using the RN mode. The term one-half unit in the last place correctly identifies the error bound for this operation. The error specification is the relative error present in the result; the absolute error bound is $2^{\text{exponent}} \times 2^{-64}$. The following example shows the error bound for the other modes:

Result	Integer	63-Bit Fraction	Guard	Round	Sticky
Intermediate	x	xxx...x00	1	1	1
Rounded-to-Nearest	x	xxx...x00	0	0	0

The difference between the infinitely precise result and the rounded result is $2^{-64} + 2^{-66}$, which is slightly less than 2^{-63} (the value of the LSB). Thus, the error in this operation is not more than one unit in the last place. For all arithmetic operations, the FPU meets these error bounds, providing accurate and repeatable results.

3.6 FLOATING-POINT POSTPROCESSING

Most operations end with a postprocessing step. The FPU provides two postprocessing steps. First, the condition code bits in the FPSR are set or cleared at the end of each arithmetic operation or move operation to a single floating-point data register. The condition code bits are consistently set based on the result of the operation. Second, the FPU supports 32 conditional tests that allow floating-point conditional instructions to test floating-point conditions in exactly the same way as the integer conditional instructions test the integer condition code. The combination of consistently set condition code bits and simple programming of conditional instructions gives the processor a very flexible and high-performance method of altering program flow based on floating-point results. While reviewing the summary for each instruction, it should be assumed that an instruction includes postprocessing unless the summary specifically states that the instruction does not include postprocessing. The following paragraphs describe postprocessing in detail.

precision. Also, the operation can generate a larger exponent or more bits of precision than can be represented in the chosen rounding precision. For these reasons, every floating-point instruction ends by rounding the result and checking for overflow and underflow.

At the completion of an arithmetic operation, the intermediate result is checked to see if it is too small to be represented as a normalized number in the selected precision. If so, the underflow (UNFL) bit is set in the FPSR EXC byte. It is also denormalized. Denormalization provides a zero value. Denormalizing a number causes a loss of accuracy, but a zero is not returned unless absolutely necessary. If a number is grossly underflowed, the FPU returns a zero or the smallest denormalized number with the correct sign, depending on the rounding mode in effect.

If no underflow occurs, the intermediate result is rounded according to the user-selected rounding precision and rounding mode. After rounding, the inexact bit (INEX2) is set appropriately. Lastly, the magnitude of the result is checked to see if it is too large to be represented in the current rounding precision. If so, the overflow (OVFL) bit is set. The result is correctly signed infinity or correctly signed largest normalized number is returned, depending on the rounding mode in effect.

3.6.2 Conditional Testing

Unlike the integer arithmetic condition codes, an instruction either always sets the floating-point condition codes in the same way or it does not change them at all. Therefore, instruction descriptions do not include floating-point condition code settings. The following paragraphs describe how floating-point condition codes are set for all instructions that modify condition codes.

The condition code bits differ slightly from the integer condition codes. Unlike the operation type dependent integer condition codes, examining the result at the end of the operation does not set or clear the floating-point condition codes accordingly. The M68000 family floating-point condition codes bits N and Z have this characteristic, but the V and C bits are set differently for different instructions. The data type of the operation's result determines how the floating-point condition code bits are set. Table 3-22 lists the condition code bit setting for each data type. Loading the FPCC with one of the other combinations and executing a conditional branch instruction can produce an unexpected branch condition.

- 0	1	1	0	0
+ Infinity	0	0	1	0
- Infinity	1	0	1	0
+ NAN	0	0	0	1
- NAN	1	0	0	1

The inclusion of the NAN data type in the IEEE floating-point number system requires a conditional test to include the NAN condition code bit in its Boolean equation. Because a comparison of a NAN with any other data type is unordered (i.e., it is impossible to determine if a NAN is bigger or smaller than an in-range number), the compare instruction sets the NAN condition code bit when an unordered compare is attempted. All arithmetic instructions also set the NAN bit if the result of an operation is a NAN. The conditional instructions interpret the NAN condition code bit equal to one as the unordered condition.

The IEEE 754 standard defines four conditions: equal to (EQ), greater than (GT), less than (LT), and unordered (UN). In addition, the standard only requires the generation of condition codes as a result of a floating-point compare operation. The FPU can test for these conditions at the end of any operation affecting the condition codes. For purposes of floating-point conditional branch, set byte on condition, decrement and branch on condition, and trap on condition instructions, the processor logically combines the four FPCC condition codes to form 32 conditional tests. There are three main categories of conditional tests: IEEE nonaware tests, IEEE aware tests, and miscellaneous. The set of IEEE aware tests is best used:

- when porting a program from a system that does not support the IEEE standard to a conforming system, or
- when generating high-level language code that does not support IEEE floating-point concepts (i.e., the unordered condition).

The 32 conditional tests are separated into two groups; 16 that cause an exception and 16 that do not. An unordered condition is present when the conditional test is attempted and 16 tests cause an exception. An unordered condition occurs when one or both of the operands are NAN. The inclusion of the unordered condition in floating-point branches destroys the familiar trichotomy relationship (greater than, equal, less than) that exists for integers. For example, the opposite of floating-point branch greater than (FBGT) is not floating-point branch less than or equal (FBLE). Rather, the opposite of FBGT is floating-point branch not greater than (FBNGT). If the result of the previous instruction is unordered, FBNGT is true; whereas, both FBGT and FBLE would be false since unordered fails both of these tests (and sets BSUN). Compiler programmers should be particularly careful of the lack of trichotomy in the floating-point branches since it is common for compilers to invert the sense of conditions.

conditions. Since the ordered or unordered attribute is explicitly included in the condition code, the BSUN bit is not set in the FPSR EXC byte when the unordered condition code is used. Table 3-23 summarizes the conditional mnemonics, definitions, equations, and predicates. The equation column lists the combination of FPCC bits for each test in the form of an equation. All condition codes with an overbar indicate cleared bits; all other bits are set.

NE	Not Equal	Z	001110	No
GT	Greater Than	$\overline{NAN} \overline{V} \overline{Z} \overline{V} \overline{N}$	010010	Yes

SNE	Signaling Not Equal	Z	011110	Yes

amalgamation of the various parts that make up an instruction description. Instruction descriptions for the integer unit differ slightly from those for the floating-point unit; instruction descriptions for the floating-point unit are no operation tables included for integer unit instruction descriptions.

The size attribute line specifies the size of the operands of an instruction. When an instruction uses operands of more than one size, the mnemonic of the instruction includes a suffix such as:

- .B—Byte Operands
- .W—Word Operands
- .L—Long-Word Operands
- .S—Single-Precision Real Operands
- .D—Double-Precision Real Operands
- .X—Extended-Precision Real Operands
- .P—Packed BCD Real Operands

The instruction format specifies the bit pattern and fields of the operation and constant words, and any other words that are always part of the instruction. The effective instruction extensions are not explicitly illustrated. The extension words, if any, follow immediately after the illustrated portions of the instructions.

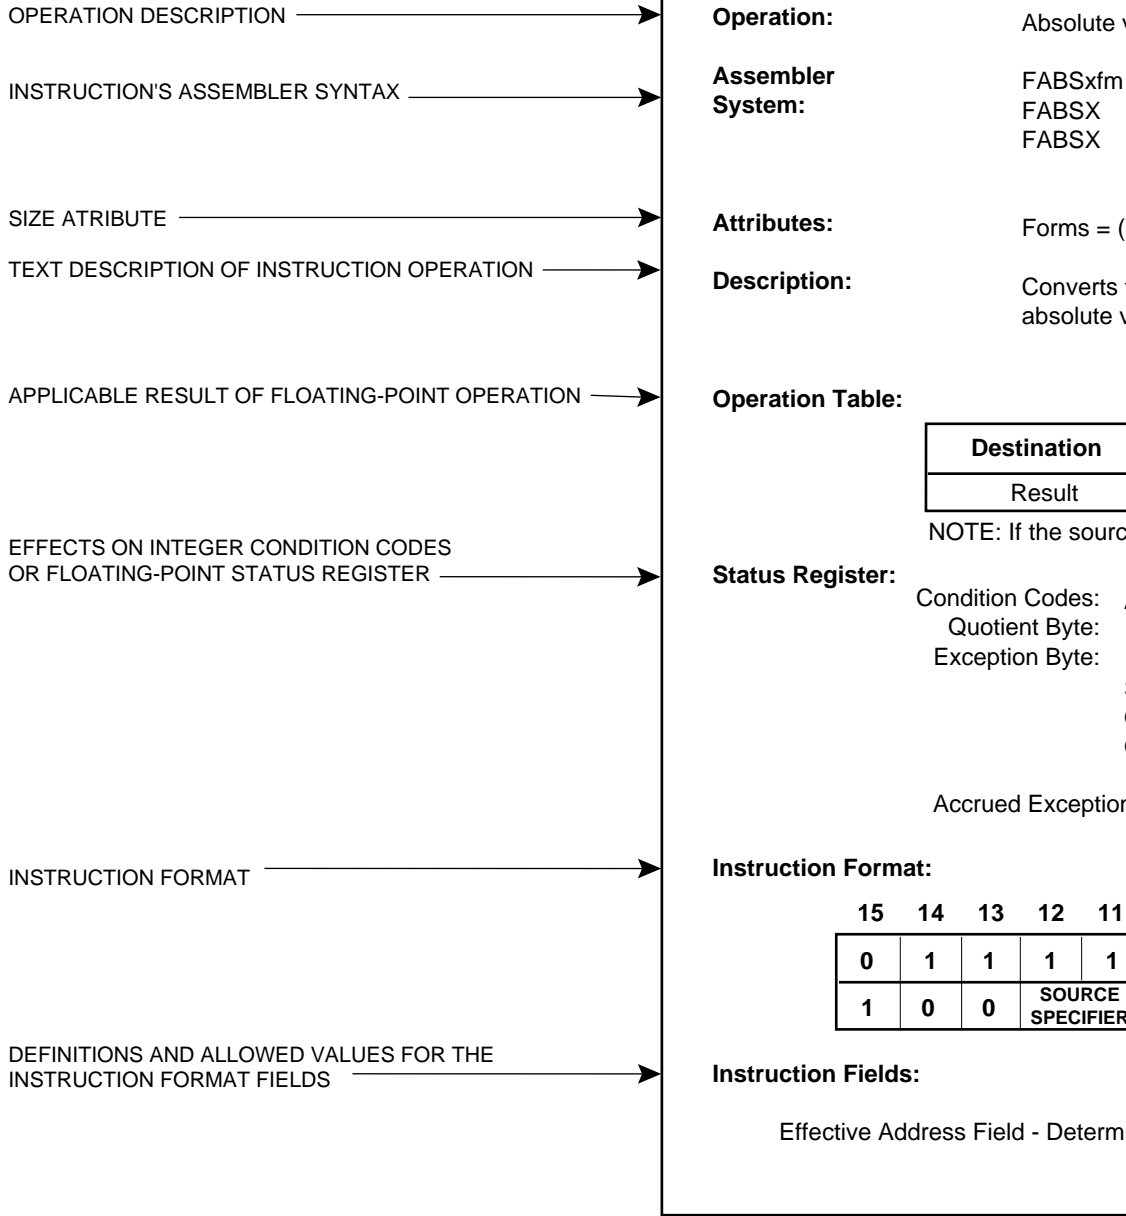

Figure 3-3. Instruction Description Format

SECTION 4 INTEGER INSTRUCTIONS

This section contains detailed information about the integer instructions for the family. A detailed discussion of each instruction description is arranged in alphabetical order by instruction mnemonic.

Each instruction description identifies the differences among the M68000 family members that apply to that instruction. Noted under the title of the instruction are all specific processors that use that instruction—for example:

Test Bit Field and Change (MC68030, MC68040)

The MC68HC000 is identical to the MC68000 except for power dissipation; therefore, all instructions that apply to the MC68000 also apply to the MC68HC000. All references to the MC68000, MC68020, and MC68030 include references to the corresponding embedded controllers, MC68EC000, MC68EC020, and MC68EC030. All references to the MC68040 include the MC68LC040 and MC68EC040. This referencing applies throughout the manual unless otherwise specified.

Identified within the paragraphs are the specific processors that use different instruction fields, instruction formats, etc.—for example:

MC68020, MC68030, and MC68040 only

(bd,An,Xn)	110	reg. number:An
------------	-----	----------------

(bd,PC,Xn)**	111
--------------	-----

**Can be used with CPU32 processor

Appendix A Processor Instruction Summary provides a listing of all processor instructions that apply to them for quick reference.

Syntax: ABCD – (Ay), – (Ax)

Attributes: Size = (Byte)

Description: Adds the source operand to the destination operand along with the extended carry and stores the result in the destination location. The addition is performed using packed decimal arithmetic. The operands, which are packed binary-coded decimal numbers, can be addressed in two different ways:

1. Data Register to Data Register: The operands are contained in the data registers specified in the instruction.
2. Memory to Memory: The operands are addressed with the predecremented addressing mode using the address registers specified in the instruction.

This operation is a byte operation only.

Condition Codes:

X	N	Z	V	C
*	U	*	U	*

X — Set the same as the carry bit.

N — Undefined.

Z — Cleared if the result is nonzero; unchanged otherwise.

V — Undefined.

C — Set if a decimal carry was generated; cleared otherwise.

NOTE

Normally, the Z condition code bit is set via programming before the start of an operation. This allows successful tests for zero results upon completion of multiple-precision operations.

1	1	0	0	REGISTER Rx	1	0	0	0	0	R/M	REGIS
---	---	---	---	-------------	---	---	---	---	---	-----	-------

Instruction Fields:

Register Rx field—Specifies the destination register.

If R/M = 0, specifies a data register.

If R/M = 1, specifies an address register for the predecrement addressing

R/M field—Specifies the operand addressing mode.

0 — The operation is data register to data register.

1 — The operation is memory to memory.

Register Ry field—Specifies the source register.

If R/M = 0, specifies a data register.

If R/M = 1, specifies an address register for the predecrement addressing

Syntax: ADD Dn, < ea >

Attributes: Size = (Byte, Word, Long)

Description: Adds the source operand to the destination operand using binary addition and stores the result in the destination location. The size of the operation may be byte, word, or long. The mode of the instruction indicates which operand is the source and which is the destination, as well as the operand size.

Condition Codes:

X	N	Z	V	C
*	*	*	*	*

X — Set the same as the carry bit.

N — Set if the result is negative; cleared otherwise.

Z — Set if the result is zero; cleared otherwise.

V — Set if an overflow is generated; cleared otherwise.

C — Set if a carry is generated; cleared otherwise.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1
1	1	0	1	REGISTER			OPMODE			EFFECTIVE ADDRESS				
											MODE			REGI

Opmode field

Byte	Word	Long	Operation
000	001	010	$\langle ea \rangle + Dn \rightarrow Dn$
100	101	110	$Dn + \langle ea \rangle \rightarrow \langle ea \rangle$

Effective Address field—Determines addressing mode.

- a. If the location specified is a source operand, all addressing modes can be used as listed in the following tables:

Addressing Mode	Mode	Register
Dn	000	reg. number:Dn
An*	001	reg. number:An
(An)	010	reg. number:An
(An) +	011	reg. number:An
– (An)	100	reg. number:An
(d ₁₆ ,An)	101	reg. number:An
(d ₈ ,An,Xn)	110	reg. number:An

Addressing Mode	Mode	Register

(bd,PC,Xn)*	—	.
([bd,PC,Xn],od)	—	.
([bd,PC],Xn,od)	—	.

*Can be used with CPU32

NOTE

The Dn mode is used when the destination is a data register; the destination < ea > mode is invalid for a data register.

ADDA is used when the destination is an address register. ADDI and ADDQ are used when the source is immediate data. Most assemblers automatically make this distinction.

Syntax: ADDA < ea > , An

Attributes: Size = (Word, Long)

Description: Adds the source operand to the destination address register and result in the address register. The size of the operation may be specified as word or long. The entire destination address register is used regardless of the operation size.

Condition Codes:

Not affected.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2
1	1	0	1	REGISTER			OPMODE			EFFECTIVE ADDRESS REGISTER			
										MODE			REG

Instruction Fields:

Register field—Specifies any of the eight address registers. This is the destination.

Opmode field—Specifies the size of the operation.

011— Word operation; the source operand is sign-extended to a long operation. The operation is performed on the address register using all 32 bits.

111— Long operation.

Addressing Mode	Mode	Register
Dn	000	reg. number:Dn
An	001	reg. number:An
(An)	010	reg. number:An
(An) +	011	reg. number:An
– (An)	100	reg. number:An

(d ₈ ,PC,Xn)	111	C

MC68020, MC68030, and MC68040 only

(bd,An,Xn)*	110	reg. number:An
([bd,An,Xn],od)	110	reg. number:An
([bd,An],Xn,od)	110	reg. number:An

(bd,PC,Xn)*	111	C
([bd,PC,Xn],od)	111	C
([bd,PC],Xn,od)	111	C

*Can be used with CPU32

Syntax: ADDI # < data > , < ea >

Attributes: Size = (Byte, Word, Long)

Description: Adds the immediate data to the destination operand and stores the result at the destination location. The size of the operation may be specified as byte, word, or long. The size of the immediate data matches the operation size.

Condition Codes:

X	N	Z	V	C
*	*	*	*	*

X — Set the same as the carry bit.

N — Set if the result is negative; cleared otherwise.

Z — Set if the result is zero; cleared otherwise.

V — Set if an overflow is generated; cleared otherwise.

C — Set if a carry is generated; cleared otherwise.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2
0	0	0	0	0	1	1	0	SIZE		EFFECTIVE ADDRESS			
										MODE		REG	
16-BIT WORD DATA										8-BIT BYTE DATA			
32-BIT LONG DATA													

- 00 — Byte operation
- 01 — Word operation
- 10 — Long operation

Effective Address field—Specifies the destination operand. Only data addressing modes can be used as listed in the following tables:

Addressing Mode	Mode	Register
Dn	000	reg. number:Dn
An	—	—
(An)	010	reg. number:An
(An) +	011	reg. number:An
– (An)	100	reg. number:An
(d ₁₆ ,An)	101	reg. number:An
(d ₈ ,An,Xn)	110	reg. number:An

*Can be used with CPU32

Immediate field—Data immediately following the instruction.

If size = 00, the data is the low-order byte of the immediate word.

If size = 01, the data is the entire immediate word.

If size = 10, the data is the next two immediate words.

Syntax: ADDQ # < data > , < ea >

Attributes: Size = (Byte, Word, Long)

Description: Adds an immediate value of one to eight to the operand at the destination location. The size of the operation may be specified as byte, word, or long. Word and long operations are also allowed on the address registers. When adding to address registers, the condition codes are not altered, and the entire destination register is used regardless of the operation size.

Condition Codes:

X	N	Z	V	C
*	*	*	*	*

X — Set the same as the carry bit.

N — Set if the result is negative; cleared otherwise.

Z — Set if the result is zero; cleared otherwise.

V — Set if an overflow occurs; cleared otherwise.

C — Set if a carry occurs; cleared otherwise.

The condition codes are not affected when the destination is an address register.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2
0	1	0	1	DATA			0	SIZE	EFFECTIVE ADDRESS MODE REG				

Immediate value zero representing a value of eight.

Size field—Specifies the size of the operation.

- 00— Byte operation
- 01— Word operation
- 10— Long operation

Effective Address field—Specifies the destination location. Only alterable addressing modes can be used as listed in the following tables:

Addressing Mode	Mode	Register
Dn	000	reg. number:Dn
An	001	reg. number:An
(An)	010	reg. number:An
(An) +	011	reg. number:An
– (An)	100	reg. number:An
(d ₁₆ ,An)	101	reg. number:An
(d ₈ ,An,Xn)	110	reg. number:An

Addressing Mode	Mode	Register
(xxx).W	111	C
(xxx).L	111	C
#<data>	—	—
(d ₁₆ ,PC)	—	—
(d ₈ ,PC,Xn)	—	—

MC68020, MC68030, and MC68040 only

(bd,An,Xn)**	110	reg. number:An
([bd,An,Xn],od)	110	reg. number:An
([bd,An],Xn,od)	110	reg. number:An

(bd,PC,Xn)†	—	—
([bd,PC,Xn],od)	—	—
([bd,PC],Xn,od)	—	—

*Word and long only.

**Can be used with CPU32.

Syntax: ADDX – (Ay), – (Ax)

Attributes: Size = (Byte, Word, Long)

Description: Adds the source operand and the extend bit to the destination operand and stores the result in the destination location. The operands can be addressed in two different ways:

1. Data register to data register—The data registers specified in the instruction contain the operands.
2. Memory to memory—The address registers specified in the instruction contain the operands using the predecrement addressing mode.

The size of the operation can be specified as byte, word, or long.

Condition Codes:

X	N	Z	V	C
*	*	*	*	*

X — Set the same as the carry bit.

N — Set if the result is negative; cleared otherwise.

Z — Cleared if the result is nonzero; unchanged otherwise.

V — Set if an overflow occurs; cleared otherwise.

C — Set if a carry is generated; cleared otherwise.

NOTE

Normally, the Z condition code bit is set via programming before the start of an operation. This allows successful tests for zero results upon completion of multiple-precision operations.

1	1	0	1	REGISTER Rx	1	SIZE	0	0	R/M	REGIST
---	---	---	---	-------------	---	------	---	---	-----	--------

Instruction Fields:

Register Rx field—Specifies the destination register.

If R/M = 0, specifies a data register.

If R/M = 1, specifies an address register for the predecrement addressing mode.

Size field—Specifies the size of the operation.

00 — Byte operation

01 — Word operation

10 — Long operation

R/M field—Specifies the operand address mode.

0 — The operation is data register to data register.

1 — The operation is memory to memory.

Register Ry field—Specifies the source register.

If R/M = 0, specifies a data register.

If R/M = 1, specifies an address register for the predecrement addressing mode.

Syntax: AND Dn, < ea >

Attributes: Size = (Byte, Word, Long)

Description: Performs an AND operation of the source operand with the destination operand and stores the result in the destination location. The size of the operation can be specified as byte, word, or long. The contents of an address register may be used as an operand.

Condition Codes:

X	N	Z	V	C
—	*	*	0	0

X — Not affected.

N — Set if the most significant bit of the result is set; cleared otherwise.

Z — Set if the result is zero; cleared otherwise.

V — Always cleared.

C — Always cleared.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2
1	1	0	0	REGISTER			OPMODE			EFFECTIVE ADDRESS MODE REG			

Instruction Fields:

Register field—Specifies any of the eight data registers.

Opmode field

Byte	Word	Long	Operation
000	001	010	< ea > \wedge Dn \rightarrow Dn
100	101	110	Dn \wedge < ea > \rightarrow < ea >

used as listed in the following tables:

Addressing Mode	Mode	Register
Dn	000	reg. number:Dn
An	—	—
(An)	010	reg. number:An
(An) +	011	reg. number:An

*Can be used with CPU32.

NOTE

The Dn mode is used when the destination is a data register; the destination < ea > mode is invalid for a data register.

Most assemblers use ANDI when the source is immediate data.

Syntax: ANDI # < data > , < ea >

Attributes: Size = (Byte, Word, Long)

Description: Performs an AND operation of the immediate data with the destination register operand and stores the result in the destination location. The size of the operation can be specified as byte, word, or long. The size of the immediate data matches the operation size.

Condition Codes:

X	N	Z	V	C
—	*	*	0	0

X — Not affected.

N — Set if the most significant bit of the result is set; cleared otherwise.

Z — Set if the result is zero; cleared otherwise.

V — Always cleared.

C — Always cleared.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1

(bd,PC,Xn)*	—	
([bd,PC,Xn],od)	—	
([bd,PC],Xn,od)	—	

*Can be used with CPU32

Immediate field—Data immediately following the instruction.

If size = 00, the data is the low-order byte of the immediate word.

If size = 01, the data is the entire immediate word.

If size = 10, the data is the next two immediate words.

Assembler**Syntax:** ANDI # < data > ,CCR**Attributes:** Size = (Byte)**Description:** Performs an AND operation of the immediate operand with the codes and stores the result in the low-order byte of the status register.**Condition Codes:**

X	N	Z	V	C
*	*	*	*	*

X — Cleared if bit 4 of immediate operand is zero; unchanged otherwise.

N — Cleared if bit 3 of immediate operand is zero; unchanged otherwise.

Z — Cleared if bit 2 of immediate operand is zero; unchanged otherwise.

V — Cleared if bit 1 of immediate operand is zero; unchanged otherwise.

C — Cleared if bit 0 of immediate operand is zero; unchanged otherwise.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	0	1	0	0	0	1	1	1	1	1	0
0	0	0	0	0	0	0	0	8-BIT BYTE DATA							

Syntax: ASd # < data > ,Dy
ASd < ea >
where d is direction, L or R

Attributes: Size = (Byte, Word, Long)

Description: Arithmetically shifts the bits of the operand in the direction (L or R). The carry bit receives the last bit shifted out of the operand. The shift count shifting of a register may be specified in two different ways:

1. Immediate—The shift count is specified in the instruction (shift range, 0 to 63).
2. Register—The shift count is the value in the data register specified in the instruction, modulo 64.

The size of the operation can be specified as byte, word, or long. An operand of size less than a word can be shifted one bit only, and the operand size is restricted to a word.

For ASL, the operand is shifted left; the number of positions shifted is the shift count. Bits shifted out of the high-order bit go to both the carry and the extend bits; bits shifted into the low-order bit. The overflow bit indicates if any sign changes occur during the shift.

Condition Codes:

X	N	Z	V	C
*	*	*	*	*

- X — Set according to the last bit shifted out of the operand; unaffected for a shift count of zero.
- N — Set if the most significant bit of the result is set; cleared otherwise.
- Z — Set if the result is zero; cleared otherwise.
- V — Set if the most significant bit is changed at any time during the shift operation; cleared otherwise.
- C — Set according to the last bit shifted out of the operand; cleared for a shift count of zero.

Instruction Format:

REGISTER SHIFTS

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1
1	1	1	0	COUNT? REGISTER			dr	SIZE		i/r	0	0	REGIS	

Instruction Fields:

- Count/Register field—Specifies shift count or register that contains the shift count.
- If $i/r = 0$, this field contains the shift count. The values 1 – 7 represent counts of 1 – 7; a value of zero represents a count of eight.
 - If $i/r = 1$, this field specifies the data register that contains the shift count (mode 0).

Size field—Specifies the size of the operation.

00 — Byte operation

01 — Word operation

10 — Long operation

i/r field

If i/r = 0, specifies immediate shift count.

If i/r = 1, specifies register shift count.

Register field—Specifies a data register to be shifted.

Instruction Format:

MEMORY SHIFTS

15	14	13	12	11	10	9	8	7	6	5	4	3	2
1	1	1	0	0	0	0	dr	1	1	EFFECTIVE ADDRESS		MODE	
										MODE		REG	

Instruction Fields:

dr field—Specifies the direction of the shift.

0 — Shift right

1 — Shift left

*Can be used with CPU32.

Assembler**Syntax:** Bcc < label >**Attributes:** Size = (Byte, Word, Long*)

*(MC68020, MC68030, and MC68040 only)

Description: If the specified condition is true, program execution continues at location + displacement. The program counter contains the address of the instruction immediately following the Bcc instruction plus two. The displacement is a twos-complement integer that represents the relative distance in bytes from the current program counter to the destination program counter. If the 8-bit displacement field in the instruction is zero, a 16-bit displacement (the word immediately following the instruction) is used. If the 8-bit displacement field in the instruction word is all ones (\$FF), the 32-bit displacement (long word immediately following the instruction) is used. Condition code specifies one of the following conditional tests (refer to Table 3-19 for more information on these conditional tests):

Mnemonic	Condition	Mnemonic	Condition
CC(HI)	Carry Clear	LS	Low or Same
CS(LO)	Carry Set	LT	Less Than
EQ	Equal	MI	Minus
GE	Greater or Equal	NE	Not Equal
GT	Greater Than	PL	Plus
HI	High	VC	Overflow Clear
LE	Less or Equal	VS	Overflow Set

Condition Codes:

Not affected.

0	1	1	0	CONDITION	8-BIT DISPLACEMENT
				16-BIT DISPLACEMENT IF 8-BIT DISPLACEMENT = \$00	
				32-BIT DISPLACEMENT IF 8-BIT DISPLACEMENT = \$FF	

Instruction Fields:

Condition field—The binary code for one of the conditions listed in the table.

8-Bit Displacement field—Twos complement integer specifying the number between the branch instruction and the next instruction to be executed if the condition is met.

16-Bit Displacement field—Used for the displacement when the 8-bit displacement field contains \$00.

32-Bit Displacement field—Used for the displacement when the 8-bit displacement field contains \$FF.

NOTE

A branch to the immediately following instruction automatically uses the 16-bit displacement format because the 8-bit displacement field contains \$00 (zero offset).

Assembler BCHG Dn, < ea >
Syntax: BCHG # < data > , < ea >

Attributes: Size = (Byte, Long)

Description: Tests a bit in the destination operand and sets the Z condition code appropriately, then inverts the specified bit in the destination. When the destination is a data register, any of the 32 bits can be specified by the modulo 32-bit number. When the destination is a memory location, the operation is a byte operation, and the bit number is modulo 8. In all cases, bit zero refers to the least significant bit. The bit number for this operation may be specified in either of two ways:

1. Immediate—The bit number is specified in a second word of the instruction.
2. Register—The specified data register contains the bit number.

Condition Codes:

X	N	Z	V	C
—	—	*	—	—

X — Not affected.

N — Not affected.

Z — Set if the bit tested is zero; cleared otherwise.

V — Not affected.

C — Not affected.

Bit Number field—Specifies the bit number.

Syntax: BFCHG < ea > {offset:width}

Attributes: Unsize

Description: Sets the condition codes according to the value in a bit field at the effective address, then complements the field.

A field offset and a field width select the field. The field offset specifies the start of the field. The field width determines the number of bits in the field.

Condition Codes:

X	N	Z	V	C
—	*	*	0	0

X — Not affected.

N — Set if the most significant bit of the field is set; cleared otherwise.

Z — Set if all bits of the field are zero; cleared otherwise.

V — Always cleared.

C — Always cleared.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2
1	1	1	0	1	0	1	0	1	1	EFFECTIVE ADDRESS			
										MODE		REG	
0	0	0	0	Do	OFFSET					Dw	WIDTH		

NOTE

For the MC68020, MC68030, and MC68040, all bit field instructions access only those bytes in memory that contain some portion of the bit field. The possible accesses are byte, word, 3-byte, long word, and long word with byte (for a 5-byte access).

direct or control alterable addressing modes can be used as listed in the table:

Addressing Mode	Mode	Register	Addressing Mode	Mode	Reg
Dn	000	reg. number:Dn	(xxx).W	111	C
An	—	—	(xxx).L	111	C
(An)	010	reg. number:An	#<data>	—	.
(An) +	—	—			
– (An)	—	—			
(d ₁₆ ,An)	101	reg. number:An	(d ₁₆ ,PC)	—	.
(d ₈ ,An,Xn)	110	reg. number:An	(d ₈ ,PC,Xn)	—	.
(bd,An,Xn)	110	reg. number:An	(bd,PC,Xn)	—	.
([bd,An,Xn],od)	110	reg. number:An	([bd,PC,Xn],od)	—	.
([bd,An],Xn,od)	110	reg. number:An	([bd,PC],Xn,od)	—	.

Do field—Determines how the field offset is specified.

0 — The offset field contains the bit field offset.

1 — Bits 8 – 6 of the extension word specify a data register that contains the offset. Bits 10 – 9 are zero.

Offset field—Specifies the field offset, depending on Do.

If Do = 0, the offset field is an immediate operand; the operand value is in the range of 0 – 31.

If Do = 1, the offset field specifies a data register that contains the offset. The offset value is in the range of -2^{31} to $2^{31} - 1$.

Dw field—Determines how the field width is specified.

0 — The width field contains the bit field width.

1 — Bits 2 – 0 of the extension word specify a data register that contains the width. Bits 3 – 4 are zero.

Width field—Specifies the field width, depending on Dw.

If Dw = 0, the width field is an immediate operand; an operand value in the range of 1 – 31 specifies a field width of 1 – 31, and a value of zero specifies a width of 32.

If Dw = 1, the width field specifies a data register that contains the width. The width value is modulo 32; values of 1 – 31 specify field widths of 1 – 31, and a value of 32 specifies a width of 32.

Syntax: BFCLR < ea > {offset:width}

Attributes: Unsize

Description: Sets condition codes according to the value in a bit field at the effective address and clears the field.

The field offset and field width select the field. The field offset specifies the start of the field. The field width determines the number of bits in the field.

Condition Codes:

X	N	Z	V	C
—	*	*	0	0

X — Not affected.

N — Set if the most significant bit of the field is set; cleared otherwise.

Z — Set if all bits of the field are zero; cleared otherwise.

V — Always cleared.

C — Always cleared.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2
1	1	1	0	1	1	0	0	1	1	EFFECTIVE ADDRESS			
										MODE		REG	
0	0	0	0	Do	OFFSET					Dw	WIDTH		

direct or control alterable addressing modes can be used as listed in the table:

Addressing Mode	Mode	Register	Addressing Mode	Mode	Reg
Dn	000	reg. number:Dn	(xxx).W	111	C
An	—	—	(xxx).L	111	C
(An)	010	reg. number:An	#<data>	—	.
(An) +	—	—			
– (An)	—	—			
(d ₁₆ ,An)	101	reg. number:An	(d ₁₆ ,PC)	—	.
(d ₈ ,An,Xn)	110	reg. number:An	(d ₈ ,PC,Xn)	—	.
(bd,An,Xn)	110	reg. number:An	(bd,PC,Xn)	—	.
([bd,An,Xn],od)	110	reg. number:An	([bd,PC,Xn],od)	—	.
([bd,An],Xn,od)	110	reg. number:An	([bd,PC],Xn,od)	—	.

Do field—Determines how the field offset is specified.

0 — The offset field contains the bit field offset.

1 — Bits 8 – 6 of the extension word specify a data register that contains the offset. Bits 10 – 9 are zero.

Offset field—Specifies the field offset, depending on Do.

If Do = 0, the offset field is an immediate operand; the operand value is in the range of 0 – 31.

If Do = 1, the offset field specifies a data register that contains the offset. The offset is in the range of -2^{31} to $2^{31} - 1$.

Dw field—Determines how the field width is specified.

0 — The width field contains the bit field width.

1 — Bits 2 – 0 of the extension word specify a data register that contains the width. Bits 3 – 4 are zero.

Width field—Specifies the field width, depending on Dw.

If Dw = 0, the width field is an immediate operand; operand values in the range of 1 – 31 specify a field width of 1 – 31, and a value of zero specifies a width of 32.

If Dw = 1, the width field specifies a data register that contains the width. The width is modulo 32; values of 1 – 31 specify field widths of 1 – 31, and a value of 32 specifies a width of 32.

Syntax: BFEXTS < ea > {offset:width},Dn

Attributes: Unsized

Description: Extracts a bit field from the specified effective address location, sign-extends the result to 32 bits, and loads the result into the destination data register. The field offset selects the bit field. The field width selects the bit field. The field offset specifies the starting bit of the field. The field width determines the number of bits in the field.

Condition Codes:

X	N	Z	V	C
—	*	*	0	0

X — Not affected.

N — Set if the most significant bit of the field is set; cleared otherwise.

Z — Set if all bits of the field are zero; cleared otherwise.

V — Always cleared.

C — Always cleared.

Instruction Format:

Register field—Specifies the destination register.

Do field—Determines how the field offset is specified.

0 — The offset field contains the bit field offset.

1 — Bits 8 – 6 of the extension word specify a data register that contains the offset. Bits 10 – 9 are zero.

Offset field—Specifies the field offset, depending on Do.

If Do = 0, the offset field is an immediate operand; the operand value is in the range of 0 – 31.

If Do = 1, the offset field specifies a data register that contains the offset. The offset value is in the range of -2^{31} to $2^{31} - 1$.

Dw field—Determines how the field width is specified.

0 — The width field contains the bit field width.

1 — Bits 2 – 0 of the extension word specify a data register that contains the width. Bits 4 – 3 are zero.

If $Dw = 1$, the width field specifies a data register that contains the width. T is modulo 32; values of 1 – 31 specify field widths of 1 – 31, and a value of 32 specifies a width of 32.

Syntax: BFEXTU < ea > {offset:width},Dn

Attributes: Unsized

Description: Extracts a bit field from the specified effective address location, zero to 32 bits, and loads the results into the destination data register. The field of field width select the field. The field offset specifies the starting bit of the field. width determines the number of bits in the field.

Condition Codes:

X	N	Z	V	C
—	*	*	0	0

X — Not affected.

N — Set if the most significant bit of the source field is set; cleared otherwise.

Z — Set if all bits of the field are zero; cleared otherwise.

V — Always cleared.

C — Always cleared.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	
1	1	1	0	1	0	0	1	1	1	EFFECTIVE ADDRESS MODE					REGIS
0	REGISTER			Do	OFFSET					Dw	WIDTH				

direct or control addressing modes can be used as listed in the following

Addressing Mode	Mode	Register	Addressing Mode	Mode	Re
Dn	000	reg. number:Dn	(xxx).W	111	
An	—	—	(xxx).L	111	
(An)	010	reg. number:An	#<data>	—	
(An) +	—	—

([bd,An],Xn,od)	110	reg. number:An	([bd,PC],Xn,od)	111	

Register field—Specifies the destination data register.

Do field—Determines how the field offset is specified.

0 — The offset field contains the bit field offset.

1 — Bits 8 – 6 of the extension word specify a data register that contains the offset. bits 10 – 9 are zero.

Offset field—Specifies the field offset, depending on Do.

If Do = 0, the offset field is an immediate operand; the operand value is in the range of 0 – 31.

If Do = 1, the offset field specifies a data register that contains the offset. The offset is in the range of -2^{31} to $2^{31} - 1$.

Dw field—Determines how the field width is specified.

0 — The width field contains the bit field width.

1 — Bits 2 – 0 of the extension word specify a data register that contains the width. bits 4 – 3 are zero.

If $Dw = 1$, the width field specifies a data register that contains the width. The width is modulo 32; values of 1 – 31 specify field widths of 1 – 31, and a value of 32 specifies a width of 32.

Syntax: BFFFO < ea > {offset:width},Dn

Attributes: Unsized

Description: Searches the source operand for the most significant bit that is set to one. The bit offset of that bit (the bit offset in the instruction plus the offset of the source operand plus one bit) is placed in Dn. If no bit in the bit field is set to one, the value in Dn is the bit offset plus the field width. The instruction sets the condition codes according to the field value. The field offset and field width select the field. The field offset specifies the starting bit of the field. The field width determines the number of bits in the field.

Condition Codes:

X	N	Z	V	C
—	*	*	0	0

X — Not affected.

N — Set if the most significant bit of the field is set; cleared otherwise.

Z — Set if all bits of the field are zero; cleared otherwise.

V — Always cleared.

C — Always cleared.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2

Register field—Specifies the destination data register operand.

Do field—Determines how the field offset is specified.

0 — The offset field contains the bit field offset.

1 — Bits 8 – 6 of the extension word specify a data register that contains the offset. Bits 10 – 9 are zero.

Offset field—Specifies the field offset, depending on Do.

If Do = 0, the offset field is an immediate operand; the operand value is in the range of 0 – 31.

If Do = 1, the offset field specifies a data register that contains the offset. The offset value is in the range of -2^{31} to $2^{31} - 1$.

Dw field—Determines how the field width is specified.

0 — The width field contains the bit field width.

1 — Bits 2 – 0 of the extension word specify a data register that contains the width. Bits 4 – 3 are zero.

If $Dw = 1$, the width field specifies a data register that contains the width. T is modulo 32; values of 1 – 31 specify field widths of 1 – 31, and a value of 32 specifies a width of 32.

Syntax: BFINS Dn, < ea > {offset:width}

Attributes: Unsize

Description: Inserts a bit field taken from the low-order bits of the specified data into a bit field at the effective address location. The instruction sets the condition codes according to the inserted value. The field offset and field width select the field. The field offset specifies the starting bit of the field. The field width determines the number of bits in the field.

Condition Codes:

X	N	Z	V	C
—	*	*	0	0

X — Not affected.

N — Set if the most significant bit of the field is set; cleared otherwise.

Z — Set if all bits of the field are zero; cleared otherwise.

V — Always cleared.

C — Always cleared.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1

Register field—Specifies the source data register operand.

Do field—Determines how the field offset is specified.

0 — The offset field contains the bit field offset.

1 — Bits 8 – 6 of the extension word specify a data register that contains the offset. Bits 10 – 9 are zero.

Offset field—Specifies the field offset, depending on Do.

If Do = 0, the offset field is an immediate operand; the operand value is in the range of 0 – 31.

If Do = 1, the offset field specifies a data register that contains the offset. The offset value is in the range of -2^{31} to $2^{31} - 1$.

Dw field—Determines how the field width is specified.

0 — The width field contains the bit field width.

1 — Bits 2 – 0 of the extension word specify a data register that contains the width. Bits 4 – 3 are zero.

If $Dw = 1$, the width field specifies a data register that contains the width. The width is modulo 32; values of 1 – 31 specify field widths of 1 – 31, and a value of 32 specifies a width of 32.

Syntax: BFSET < ea > {offset:width}

Attributes: Unsized

Description: Sets the condition codes according to the value in a bit field at the effective address, then sets each bit in the field.

The field offset and the field width select the field. The field offset specifies the bit of the field. The field width determines the number of bits in the field.

Condition Codes:

X	N	Z	V	C
—	*	*	0	0

X — Not affected.

N — Set if the most significant bit of the field is set; cleared otherwise.

Z — Set if all bits of the field are zero; cleared otherwise.

V — Always cleared.

C — Always cleared.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2
1	1	1	0	1	1	1	0	1	1	EFFECTIVE ADDRESS			
										MODE		REG	
0	0	0	0	Do	OFFSET					Dw	WIDTH		

direct or control alterable addressing modes can be used as listed in the table:

Addressing Mode	Mode	Register	Addressing Mode	Mode	Reg
Dn	000	reg. number:Dn	(xxx).W	111	C
An	—	—	(xxx).L	111	C
(An)	010	reg. number:An	#<data>	—	.
(An) +	—	—

([bd,An],Xn,od)	110	reg. number:An	([bd,PC],Xn,od)	—	.

Do field—Determines how the field offset is specified.

0 — The offset field contains the bit field offset.

1 — Bits 8 – 6 of the extension word specify a data register that contains the offset. Bits 10 – 9 are zero.

Offset field—Specifies the field offset, depending on Do.

If Do = 0, the offset field is an immediate operand; the operand value is in the range of 0 – 31.

If Do = 1, the offset field specifies a data register that contains the offset. The offset is in the range of -2^{31} to $2^{31} - 1$.

Dw field—Determines how the field width is specified.

0 — The width field contains the bit field width.

1 — Bits 2 – 0 of the extension word specify a data register that contains the width. Bits 4 – 3 are zero.

Width field—Specifies the field width, depending on Dw.

If Dw = 0, the width field is an immediate operand; operand values in the range of 1 – 31 specify a field width of 1 – 31, and a value of zero specifies a width of 32.

If Dw = 1, the width field specifies a data register that contains the width. The width is modulo 32; values of 1 – 31 specify field widths of 1 – 31, and a value of 32 specifies a width of 32.

Syntax: BFTST < ea > {offset:width}

Attributes: Unsized

Description: Sets the condition codes according to the value in a bit field at the effective address location. The field offset and field width select the field. The field offset specifies the starting bit of the field. The field width determines the number of bits in the field.

Condition Codes:

X	N	Z	V	C
—	*	*	0	0

X — Not affected.

N — Set if the most significant bit of the field is set; cleared otherwise.

Z — Set if all bits of the field are zero; cleared otherwise.

V — Always cleared.

C — Always cleared.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2
1	1	1	0	1	0	0	0	1	1	EFFECTIVE ADDRESS			
										MODE		REG	
0	0	0	0	Do	OFFSET					Dw	WIDTH		

direct or control addressing modes can be used as listed in the following

Addressing Mode	Mode	Register	Addressing Mode	Mode	Reg
Dn	000	reg. number:Dn	(xxx).W	111	C
An	—	—	(xxx).L	111	C
(An)	010	reg. number:An	#<data>	—	.
(An) +	—	—			
– (An)	—	—			
(d ₁₆ ,An)	101	reg. number:An	(d ₁₆ ,PC)	111	C
(d ₈ ,An,Xn)	110	reg. number:An	(d ₈ ,PC,Xn)	111	C
(bd,An,Xn)	110	reg. number:An	(bd,PC,Xn)	111	C
([bd,An,Xn],od)	110	reg. number:An	([bd,PC,Xn],od)	111	C
([bd,An],Xn,od)	110	reg. number:An	([bd,PC],Xn,od)	111	C

Do field—Determines how the field offset is specified.

0 — The offset field contains the bit field offset.

1 — Bits 8 – 6 of the extension word specify a data register that contains the offset. Bits 10 – 9 are zero.

Offset field—Specifies the field offset, depending on Do.

If Do = 0, the offset field is an immediate operand; the operand value is in the range of 0 – 31.

If Do = 1, the offset field specifies a data register that contains the offset. The register number is in the range of -2^{31} to $2^{31} - 1$.

Dw field—Determines how the field width is specified.

0 — The width field contains the bit field width.

1 — Bits 2 – 0 of the extension word specify a data register that contains the width. Bits 4 – 3 are zero.

Width field—Specifies the field width, depending on Dw.

If Dw = 0, the width field is an immediate operand, operand values in the range of 1 – 31 specify a field width of 1 – 31, and a value of zero specifies a width of 32.

If Dw = 1, the width field specifies a data register that contains the width. The register number is modulo 32; values of 1 – 31 specify field widths of 1 – 31, and a value of 32 specifies a width of 32.

Syntax: BKPT # < data >

Attributes: Unsized

Description: For the MC68010, a breakpoint acknowledge bus cycle is run with codes driven high and zeros on all address lines. Whether the breakpoint acknowledge bus cycle is terminated with \overline{DTACK} , \overline{BERR} , or \overline{VPA} , the processor always takes an illegal instruction exception. During exception processing, a debug monitor can distinguish different software breakpoints by decoding the field in the BKPT instruction. For the MC68000 and MC68008, the breakpoint cycle is not run, but an illegal instruction exception is taken.

For the MC68020, MC68030, and CPU32, a breakpoint acknowledge bus cycle is run and is terminated with the immediate data (value 0 – 7) on bits 2 – 4 of the address bus and \overline{DTACK} on bits 0 and 1 of the address bus. The breakpoint acknowledge bus cycle is run in the CPU space, addressing type 0, and provides the breakpoint number specified in the instruction on address lines A2 – A4. If the external hardware terminates the bus cycle with \overline{DSACKx} or \overline{STERM} , the data on the bus (an instruction word) is inserted into the instruction pipe and is executed after the breakpoint instruction. The breakpoint acknowledge bus cycle requires a word to be transferred so, if the first bus cycle accesses an 8-bit instruction, a second bus cycle is required. If the external logic terminates the breakpoint acknowledge bus cycle with \overline{BERR} (i.e., no instruction word available), the processor takes an illegal instruction exception.

For the MC68040, this instruction executes a breakpoint acknowledge bus cycle. Regardless of the cycle termination, the MC68040 takes an illegal instruction exception.

For more information on the breakpoint instruction refer to the appropriate user manual on bus operation.

This instruction supports breakpoints for debug monitors and real-time hardware monitors.

Not affected.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	0	0	1	0	0	0	0	1	0	0	1			VECT

Instruction Field:

Vector field—Contains the immediate data, a value in the range of 0 – 7. The breakpoint number.

Syntax: BRA < label >

Attributes: Size = (Byte, Word, Long*)
*(MC68020, MC68030, MC68040 only)

Description: Program execution continues at location (PC) + displacement. The counter contains the address of the instruction word of the BRA instruction. The displacement is a two's complement integer that represents the relative number of bytes from the current program counter to the destination program counter. If the displacement field in the instruction word is zero, a 16-bit displacement (immediately following the instruction) is used. If the 8-bit displacement field in the instruction word is all ones (\$FF), the 32-bit displacement (long word immediately following the instruction) is used.

Condition Codes:

Not affected.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2			
0	1	1	0	0	0	0	0	8-BIT DISPLACEMENT								
16-BIT DISPLACEMENT IF 8-BIT DISPLACEMENT = \$00																
32-BIT DISPLACEMENT IF 8-BIT DISPLACEMENT = \$FF																

Instruction Fields:

8-Bit Displacement field—Two's complement integer specifying the number of bytes between the branch instruction and the next instruction to be executed.

16-Bit Displacement field—Used for a larger displacement when the 8-bit displacement is equal to \$00.

32-Bit Displacement field—Used for a larger displacement when the 8-bit displacement is equal to \$FF.

NOTE

A branch to the immediately following instruction automatically uses the 16-bit displacement format because the 8-bit displacement field contains \$00 (zero offset).

Assembler BSET Dn, < ea >
Syntax: BSET # < data > , < ea >

Attributes: Size = (Byte, Long)

Description: Tests a bit in the destination operand and sets the Z condition code appropriately, then sets the specified bit in the destination operand. When a register is the destination, any of the 32 bits can be specified by a modulo 32 number. When a memory location is the destination, the operation is a byte operation and the bit number is modulo 8. In all cases, bit zero refers to the least significant bit. The bit number for this operation can be specified in either of two ways:

1. Immediate—The bit number is specified in the second word of the instruction.
2. Register—The specified data register contains the bit number.

Condition Codes:

X	N	Z	V	C
—	—	*	—	—

X — Not affected.

N — Not affected.

Z — Set if the bit tested is zero; cleared otherwise.

V — Not affected.

C — Not affected.

([bd,An],Xn,od)	110	reg. number:An

(bd,PC,Xn)†	—	—
([bd,PC,Xn],od)	—	—
([bd,PC],Xn,od)	—	—

*Long only; all others are byte only.

**Can be used with CPU32.

Bit Number field—Specifies the bit number.

Syntax: BSR < label >

Attributes: Size = (Byte, Word, Long*)
*(MC68020, MC68030, MC68040 only)

Description: Pushes the long-word address of the instruction immediately following the BSR instruction onto the system stack. The program counter contains the address of the instruction word plus two. Program execution then continues at location indicated by the displacement. The displacement is a twos complement integer that represents the relative distance in bytes from the current program counter to the destination program counter. If the 8-bit displacement field in the instruction word is zero, the 16-bit displacement (the word immediately following the instruction) is used. If the 8-bit displacement field in the instruction word is all ones (\$FF), the 32-bit displacement (long word immediately following the instruction) is used.

Condition Codes:

Not affected.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2
0	1	1	0	0	0	0	1	8-BIT DISPLACEMENT					
16-BIT DISPLACEMENT IF 8-BIT DISPLACEMENT = \$00													
32-BIT DISPLACEMENT IF 8-BIT DISPLACEMENT = \$FF													

between the branch instruction and the next instruction to be executed.

16-Bit Displacement field—Used for a larger displacement when the 8-bit displacement is equal to \$00.

32-Bit Displacement field—Used for a larger displacement when the 8-bit displacement is equal to \$FF.

NOTE

A branch to the immediately following instruction automatically uses the 16-bit displacement format because the 8-bit displacement field contains \$00 (zero offset).

Syntax: BTST # < data > , < ea >

Attributes: Size = (Byte, Long)

Description: Tests a bit in the destination operand and sets the Z condition code appropriately. When a data register is the destination, any of the 32 bits is specified by a modulo 32-bit number. When a memory location is the destination, the operation is a byte operation, and the bit number is modulo 8. In all cases, the bit number refers to the least significant bit. The bit number for this operation can be specified either of two ways:

1. Immediate—The bit number is specified in a second word of the instruction.
2. Register—The specified data register contains the bit number.

Condition Codes:

X	N	Z	V	C
—	—	*	—	—

X — Not affected.

N — Not affected.

Z — Set if the bit tested is zero; cleared otherwise.

V — Not affected.

C — Not affected.

Bit Number field—Specifies the bit number.

Assembler**Syntax:** CALLM # < data > , < ea >**Attributes:** Unsized

Description: The effective address of the instruction is the location of an external descriptor. A module frame is created on the top of the stack, and the current state is saved in the frame. The immediate operand specifies the number of arguments to be passed to the called module. A new module state is loaded descriptor addressed by the effective address.

Condition Codes:

Not affected.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1
0	0	0	0	0	1	1	0	1	1	EFFECTIVE ADDRESS				
										MODE		REGI		
0	0	0	0	0	0	0	0	ARGUMENT COUNT						

addressing modes can be used as listed in the following table:

Addressing Mode	Mode	Register
Dn	—	—
An	—	—
(An)	010	reg. number:An
(An) +	—	—
– (An)	—	—
(d ₁₆ ,An)	101	reg. number:An

(d ₈ ,PC,Xn)	111	
(bd,PC,Xn)	111	
([bd,PC,Xn],od)	111	
([bd,PC],Xn,od)	111	

Argument Count field—Specifies the number of bytes of arguments to be passed to the called module. The 8-bit field can specify from 0 to 255 bytes of arguments. The same number of bytes is removed from the stack by the RTM instruction.

If Z, Update Operand → Destination
 Else Destination → Compare Operand
 CAS2 Destination 1 – Compare 1 → cc;
 If Z, Destination 2 – Compare 2 → cc
 If Z, Update 1 → Destination 1; Update 2 → Destination 2
 Else Destination 1 → Compare 1; Destination 2 → Compa

Assembler CAS Dc,Du, < ea >
Syntax: CAS2 Dc1:Dc2,Du1:Du2,(Rn1):(Rn2)

Attributes: Size = (Byte*, Word, Long)

Description: CAS compares the effective address operand to the compare operand. If the operands are equal, the instruction writes the update operand (Du) to the address operand; otherwise, the instruction writes the effective address operand to the compare operand (Dc).

CAS2 compares memory operand 1 (Rn1) to compare operand 1 (Dc1). If the operands are equal, the instruction compares memory operand 2 (Rn2) to compare operand 2 (Dc2). If these operands are also equal, the instruction writes the update operands (Du1 and Du2) to the memory operands (Rn1 and Rn2). If either comparison fails, the instruction writes the memory operands (Rn1 and Rn2) to the compare operands (Dc1 and Dc2).

Both operations access memory using locked or read-modify-write transfer semantics, providing a means of synchronizing several processors.

Condition Codes:

X	N	Z	V	C
—	*	*	*	*

- X — Not affected.
- N — Set if the result is negative; cleared otherwise.
- Z — Set if the result is zero; cleared otherwise.
- V — Set if an overflow is generated; cleared otherwise.
- C — Set if a borrow is generated; cleared otherwise.

*. CAS2 cannot use byte operands.

15	14	13	12	11	10	9	8	7	6	5	4	3	2
0	0	0	0	1	SIZE		0	1	1	EFFECTIVE ADDRESS			REG
0	0	0	0	0	0	0	Du		0	0	0		

Instruction Fields:

Size field—Specifies the size of the operation.

- 01 — Byte operation
- 10 — Word operation
- 11 — Long operation

Effective Address field—Specifies the location of the memory operand. Only alterable addressing modes can be used as listed in the following table.

Addressing Mode	Mode	Register	Addressing Mode	Mode	Register
Dn	—	—	(xxx).W	111	
An	—	—	(xxx).L	111	
(An)	010	reg. number:An	#<data>	—	
(An) +	011	reg. number:An			
– (An)	100	reg. number:An			
(d ₁₆ ,An)	101	reg. number:An	(d ₁₆ ,PC)	—	
(d ₈ ,An,Xn)	110	reg. number:An	(d ₈ ,PC,Xn)	—	
(bd,An,Xn)	110	reg. number:An	(bd,PC,Xn)	—	
([bd,An,Xn],od)	110	reg. number:An	([bd,PC,Xn],od)	—	
([bd,An],Xn,od)	110	reg. number:An	([bd,PC],Xn,od)	—	

Du field—Specifies the data register that contains the update value to be written to the memory operand location if the comparison is successful.

Dc field—Specifies the data register that contains the value to be compared with the memory operand.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	1	SIZE		0	1	1	1	1	1	1	1	0
D/A1	Rn1			0	0	0	Du1			0	0	0	Dc1		
D/A2	Rn2			0	0	0	Du2			0	0	0	Dc2		

Instruction Fields:

Size field—Specifies the size of the operation.

10 — Word operation

11 — Long operation

D/A1, D/A2 fields—Specify whether Rn1 and Rn2 reference data or address registers, respectively.

0 — The corresponding register is a data register.

1 — The corresponding register is an address register.

Rn1, Rn2 fields—Specify the numbers of the registers that contain the addresses of the first and second memory operands, respectively. If the operands overflow the memory, the results of any memory update are undefined.

Du1, Du2 fields—Specify the data registers that contain the update values to be stored to the first and second memory operand locations if the comparison is successful.

Dc1, Dc2 fields—Specify the data registers that contain the test values to be compared to the first and second memory operands, respectively. If Dc1 and Dc2 specify the same data register and the comparison fails, memory operand 1 is stored to the data register.

NOTE

The CAS and CAS2 instructions can be used to perform secure update operations on system control data structures in a multiprocessing environment.

In the MC68040 if the operands are not equal, the destination or destination 1 operand is written back to memory to complete the locked access for CAS or CAS2, respectively.

Assembler**Syntax:** CHK < ea > ,Dn**Attributes:** Size = (Word, Long*)

*(MC68020, MC68030, MC68040 only)

Description: Compares the value in the data register specified in the instruction to the upper bound (effective address operand). The upper bound is a signed complement integer. If the register value is less than zero or greater than the upper bound, a CHK instruction exception (vector number 6) occurs.

Condition Codes:

X	N	Z	V	C
—	*	U	U	U

X — Not affected.

N — Set if Dn < 0; cleared if Dn > effective address operand; undefined otherwise.

Z — Undefined.

V — Undefined.

C — Undefined.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2
0	1	0	0	REGISTER			SIZE		0	EFFECTIVE ADDRESS			
										MODE		REG	

Size field—Specifies the size of the operation.

11— Word operation

10— Long operation

Effective Address field—Specifies the upper bound operand. Only data address modes can be used as listed in the following tables:

Addressing Mode	Mode	Register
Dn	000	reg. number:Dn
An	—	—
(An)	010	reg. number:An
(An) +	011	reg. number:An

([bd,PC],Xn,od)	111	C

*Can be used with CPU32.

Assembler**Syntax:** CHK2 < ea > ,Rn**Attributes:** Size = (Byte, Word, Long)

Description: Compares the value in Rn to each bound. The effective address contains a pair of bounds: the upper bound following the lower bound. For signed comparisons, the arithmetically smaller value should be used as the lower bound. For unsigned comparisons, the logically smaller value should be the lower bound.

The size of the data and the bounds can be specified as byte, word, or long. If the data register and the operation size is byte or word, only the appropriate low-order bits of Rn is checked. If Rn is an address register and the operation size is byte or word, the bounds operands are sign-extended to 32 bits, and the resultant operation is compared to the full 32 bits of An.

If the upper bound equals the lower bound, the valid range is a single value. If the register value is less than the lower bound or greater than the upper bound, a CHK2 exception (vector number 6) occurs.

Condition Codes:

X	N	Z	V	C
—	U	*	U	*

X — Not affected.

N — Undefined.

Z — Set if Rn is equal to either bound; cleared otherwise.

V — Undefined.

C — Set if Rn is out of bounds; cleared otherwise.

0	0	0	0	0	SIZE	0	1	1	EFFECTIVE ADDRESS			REGIS
D/A	REGISTER			1	0	0	0	0	0	0	0	0

Instruction Fields:

Size field—Specifies the size of the operation.

- 00 — Byte operation
- 01 — Word operation
- 10 — Long operation

Effective Address field—Specifies the location of the bounds operands. Only addressing modes can be used as listed in the following tables:

Addressing Mode	Mode	Register
Dn	—	—
An	—	—
(An)	010	reg. number:An

*Word and Long only.

**Can be used with CPU32.

NOTE

CMPA is used when the destination is an address register. CMPI is used when the source is immediate data. CMPM is used for memory-to-memory compares. Most assemblers automatically make the distinction.

Syntax: CMPA < ea > , An

Attributes: Size = (Word, Long)

Description: Subtracts the source operand from the destination address register; the condition codes according to the result; the address register is not changed; the size of the operation can be specified as word or long. Word length source operands are sign-extended to 32 bits for comparison.

Condition Codes:

X	N	Z	V	C
—	*	*	*	*

X — Not affected.

N — Set if the result is negative; cleared otherwise.

Z — Set if the result is zero; cleared otherwise.

V — Set if an overflow is generated; cleared otherwise.

(bd,PC,Xn)†	111	C
([bd,PC,Xn],od)	111	C
([bd,PC],Xn,od)	111	C

*PC relative addressing modes do not apply to MC68000, MC68008, or MC6801.
 **Can be used with CPU32.

Immediate field—Data immediately following the instruction.

If size = 00, the data is the low-order byte of the immediate word.

If size = 01, the data is the entire immediate word.

If size = 10, the data is the next two immediate words.

Syntax: CMPM (Ay) + ,(Ax) +

Attributes: Size = (Byte, Word, Long)

Description: Subtracts the source operand from the destination operand and condition codes according to the results; the destination location is not changed. Operands are always addressed with the postincrement addressing mode, address registers specified in the instruction. The size of the operation is specified as byte, word, or long.

Condition Codes:

X	N	Z	V	C
—	*	*	*	*

X — Not affected.

N — Set if the result is negative; cleared otherwise.

Z — Set if the result is zero; cleared otherwise.

V — Set if an overflow is generated; cleared otherwise.

C — Set if a borrow is generated; cleared otherwise.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2
1	0	1	1	REGISTER Ax			1	SIZE		0	0	1	REGI

Instruction Fields:

Register Ax field—(always the destination) Specifies an address register and the postincrement addressing mode.

Size field—Specifies the size of the operation.

00 — Byte operation

01 — Word operation

10 — Long operation

Register Ay field—(always the source) Specifies an address register and the postincrement addressing mode.

Syntax: CMP2 < ea > ,Rn

Attributes: Size = (Byte, Word, Long)

Description: Compares the value in Rn to each bound. The effective address contains a pair of bounds: upper bound following the lower bound. For signed comparisons, the arithmetically smaller value should be used as the lower bound. For unsigned comparisons, the logically smaller value should be the lower bound.

The size of the data and the bounds can be specified as byte, word, or long. If the operation size is byte or word, only the appropriate low-order bits of Rn is checked. If Rn is an address register and the operation size is byte or word, the bounds operands are sign-extended to 32 bits, and the resultant operation is compared to the full 32 bits of An.

If the upper bound equals the lower bound, the valid range is a single value.

NOTE

This instruction is identical to CHK2 except that it sets condition codes rather than taking an exception when the value in Rn is out of bounds.

Condition Codes:

X	N	Z	V	C
—	U	*	U	*

X — Not affected.

N — Undefined.

Z — Set if Rn is equal to either bound; cleared otherwise.

V — Undefined.

C — Set if Rn is out of bounds; cleared otherwise.

0	0	0	0	0	SIZE	0	1	1	EFFECTIVE ADDRESS			REG
D/A	REGISTER			0	0	0	0	0	0	0	0	0

Instruction Fields:

Size field—Specifies the size of the operation.

- 00 — Byte operation
- 01 — Word operation
- 10 — Long operation

Effective Address field—Specifies the location of the bounds pair. Only the following addressing modes can be used as listed in the following tables:

Addressing Mode	Mode	Register
Dn	—	—
An	—	—
(An)	010	reg. number:An
(An) +	—	—
– (An)	—	—
(d ₁₆ ,An)	101	reg. number:An
(d ₈ ,An,Xn)	110	reg. number:An
(bd,An,Xn)	110	reg. number:An

Addressing Mode	Mode	Register
(xxx).W	111	
(xxx).L	111	
#<data>	—	
(d ₁₆ ,PC)	111	
(d ₈ ,PC,Xn)	111	
(bd,PC,Xn)	111	

MC68020, MC68030, and MC68040 only

([bd,An,Xn],od)	110	reg. number:An
([bd,An],Xn,od)	110	reg. number:An

([bd,PC,Xn],od)	111	
([bd,PC],Xn,od)	111	

D/A field—Specifies whether an address register or data register is compared.

- 0 — Data register
- 1 — Address register

Register field—Specifies the address or data register that contains the value to be checked.

Assembler

Syntax: cpBcc < label >

Attributes: Size = (Word, Long)

Description: If the specified coprocessor condition is true, program execution continues at the location scan PC + displacement. The value of the scan PC is the address of the instruction containing the displacement word. The displacement is a two's complement integer that represents the relative distance in bytes from the scan PC to the destination program counter. The displacement can be either 16 or 32 bits. The coprocessor determines the condition from the condition field in the operation word.

Condition Codes:

Not affected.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1
1	1	1	1	COPROCESSOR ID		0	1	SIZE	COPROCESSOR CONDITION					
OPTIONAL COPROCESSOR-DEFINED EXTENSION WORDS														
WORD OR														
LONG-WORD DISPLACEMENT														

Instruction Fields:

Coprocessor ID field—Identifies the coprocessor for this operation. Coprocessor ID 000 results in an F-line exception for the MC68030.

Size field—Specifies the size of the displacement.

0 — The displacement is 16 bits.

1 — The displacement is 32 bits.

Coprocessor Condition field—Specifies the coprocessor condition to be tested. The condition field is passed to the coprocessor, which provides directives to the coprocessor for processing this instruction.

16-Bit Displacement field—The displacement value occupies 16 bits.

32-Bit Displacement field—The displacement value occupies 32 bits.

Assembler

Syntax: cpDBcc Dn, < label >

Attributes: Size = (Word)

Description: If the specified coprocessor condition is true, execution continues with the next instruction. Otherwise, the low-order word in the specified data register is decremented by one. If the result is equal to -1 , execution continues with the next instruction. If the result is not equal to -1 , execution continues at the location specified by the value of the scan PC plus the sign-extended 16-bit displacement. The scan PC is the address of the displacement word. The displacement is a sign-extended complement integer that represents the relative distance in bytes from the scan PC to the destination program counter. The coprocessor determines the specific condition to test from the condition word that follows the operation word.

Condition Codes:

Not affected.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	
1	1	1	1	COPROCESSOR ID			0	0	1	0	0	1		REG
0	0	0	0	0	0	0	0	0	0	COPROCESSOR CONDIT				
OPTIONAL COPROCESSOR-DEFINED EXTENSION WORDS														
16-BIT DISPLACEMENT														

Instruction Fields:

Coprocessor ID field—Identifies the coprocessor for this operation; coprocessor ID 000 results in an F-line exception for the MC68030.

Register field—Specifies the data register used as the counter.

Coprocessor Condition field—Specifies the coprocessor condition to be tested. This field is passed to the coprocessor, which provides directives to the coprocessor for processing this instruction.

Displacement field—Specifies the distance of the branch (in bytes).

Syntax: cpGEN < parameters as defined by coprocessor >

Attributes: Unsized

Description: Transfers the command word that follows the operation word to the coprocessor. The coprocessor determines the specific operation from the command word. Usually a coprocessor defines specific instances of this instruction to provide an instruction set.

Condition Codes:

May be modified by coprocessor; unchanged otherwise.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1
1	1	1	1	COPROCESSOR ID			0	0	0	EFFECTIVE ADDRESS MODE				
COPROCESSOR-DEPENDENT COMMAND WORD														
OPTIONAL EFFECTIVE ADDRESS OR COPROCESSOR-DEFINED EXTENSIONWORDS														

Instruction Fields:

Coprocessor ID field—Identifies the coprocessor for this operation; no coprocessor ID of 000 is reserved for MMU instructions for the MC68030.

Effective Address field—Specifies the location of any operand not resident in the coprocessor. The allowable addressing modes are determined by the operation to be performed.

Coprocessor Command field—Specifies the coprocessor operation to be performed. This word is passed to the coprocessor, which in turn provides directives to the main processor for processing this instruction.

Assembler**Syntax:** cpScc < ea >**Attributes:** Size = (Byte)

Description: Tests the specified coprocessor condition code. If the condition is true, the byte specified by the effective address is set to TRUE (all ones); otherwise, the byte is set to FALSE (all zeros). The coprocessor determines the specific condition code based on the condition word that follows the operation word.

Condition Codes:

Not affected.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2
1	1	1	1	COPROCESSOR ID			0	0	1	EFFECTIVE ADDRESS			
0	0	0	0	0	0	0	0	0	0	MODE		REG	
COPROCESSOR CONDIT													
OPTIONAL EFFECTIVE ADDRESS OR COPROCESSOR-DEFINED EXTENSIONWORDS													

Effective Address field—Specifies the destination location. Only data addressing modes can be used as listed in the following table:

Addressing Mode	Mode	Register	Addressing Mode	Mode	Register
Dn	000	reg. number:Dn	(xxx).W	111	000
An	—	—	(xxx).L	111	001
(An)	010	reg. number:An	#<data>	—	—
(An) +	011	reg. number:An			
– (An)	100	reg. number:An			
(d ₁₆ ,An)	101	reg. number:An	(d ₁₆ ,PC)	—	—
(d ₈ ,An,Xn)	110	reg. number:An	(d ₈ ,PC,Xn)	—	—
(bd,An,Xn)	110	reg. number:An	(bd,PC,Xn)	—	—
([bd,An,Xn],od)	110	reg. number:An	([bd,PC,Xn],od)	—	—
([bd,An],Xn,od)	110	reg. number:An	([bd,PC],Xn,od)	—	—

Coprocessor Condition field—Specifies the coprocessor condition to be tested. This field is passed to the coprocessor, which in turn provides directives to the processor for processing this instruction.

Assembler cpTRAPcc
Syntax: cpTRAPcc # < data >

Attributes: Unsized or Size = (Word, Long)

Description: Tests the specified coprocessor condition code; if the selected coprocessor condition is true, the processor initiates a cpTRAPcc exception, vector number 1. The program counter value placed on the stack is the address of the next instruction. If the selected condition is not true, no operation is performed, and execution continues with the next instruction. The coprocessor determines the specific condition code. The condition word that follows the operation word. Following the condition word is the defined data operand specified as immediate data to be used by the trap handler.

Condition Codes:

Not affected.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2
1	1	1	1	COPROCESSOR ID			0	0	1	1	1	1	OP
0	0	0	0	0	0	0	0	0	COPROCESSOR CONDIT				
OPTIONAL COPROCESSOR-DEFINED EXTENSION WORDS													
OPTIONAL WORD													
OR LONG-WORD OPERAND													

Instruction Fields:

Coprocessor ID field—Identifies the coprocessor for this operation; coprocessor ID 000 results in an F-line exception for the MC68030.

Opmode field—Selects the instruction form.

010—Instruction is followed by one operand word.

011—Instruction is followed by two operand words.

100—Instruction has no following operand words.

Coprocessor Condition field—Specifies the coprocessor condition to be tested. The condition field is passed to the coprocessor, which provides directives to the processor for processing this instruction.

Assembler**Syntax:** DBcc Dn, < label >**Attributes:** Size = (Word)

Description: Controls a loop of instructions. The parameters are a condition code register (counter), and a displacement value. The instruction first tests the condition for termination; if it is true, no operation is performed. If the termination condition is false, the low-order 16 bits of the counter data register decrement by one. If the result is -1 , execution continues with the next instruction. If the result is not equal to -1 , execution continues at the location indicated by the current value of the counter plus the sign-extended 16-bit displacement. The value in the program counter is the address of the instruction word of the DBcc instruction plus two times the displacement is a two's complement integer that represents the relative displacement in bytes from the current program counter to the destination program counter. The condition code cc specifies one of the following conditional tests (refer to Table 3-19 for more information on these conditional tests):

Mnemonic	Condition	Mnemonic	Condition
CC(HI)	Carry Clear	LS	Low or Same
CS(LO)	Carry Set	LT	Less Than
EQ	Equal	MI	Minus
F	False	NE	Not Equal
GE	Greater or Equal	PL	Plus
GT	Greater Than	T	True
HI	High	VC	Overflow Clear
LE	Less or Equal	VS	Overflow Set

Condition Codes:

Not affected.

0	1	0	1	CONDITION	1	1	0	0	1	REG
16-BIT DISPLACEMENT										

Instruction Fields:

Condition field—The binary code for one of the conditions listed in the table.

Register field—Specifies the data register used as the counter.

Displacement field—Specifies the number of bytes to branch.

NOTE

The terminating condition is similar to the UNTIL loop clauses of high-level languages. For example: DBMI can be stated as "decrement and branch until minus".

Most assemblers accept DBRA for DBF for use when only a count terminates the loop (no condition is tested).

A program can enter a loop at the beginning or by branching to the trailing DBcc instruction. Entering the loop at the beginning is useful for indexed addressing modes and dynamically specified bit operations. In this case, the control index count must be one less than the desired number of loop executions. However, when entering a loop by branching directly to the trailing DBcc instruction, the control count should equal the loop execution count. In this case, if a zero count occurs, the DBcc instruction does not branch, and the main loop is not executed.

Syntax:

*DIVS.L < ea > ,Dq 32/32 → 32q
 *DIVS.L < ea > ,Dr:Dq 64/32 → 32r – 32q
 *DIVSL.L < ea > ,Dr:Dq 32/32 → 32r – 32q

*Applies to MC68020, MC68030, MC68040, CPU32 only

Attributes: Size = (Word, Long)

Description: Divides the signed destination operand by the signed source operand and stores the signed result in the destination. The instruction uses one of four forms. The word form of the instruction divides a long word by a word. The result is a quotient in the lower word (least significant 16 bits) and a remainder in the upper word (most significant 16 bits). The sign of the remainder is the same as the sign of the dividend.

The first long form divides a long word by a long word. The result is a long quotient and a long remainder is discarded.

The second long form divides a quad word (in any two data registers) by a long word. The result is a long-word quotient and a long-word remainder.

The third long form divides a long word by a long word. The result is a long-word quotient and a long-word remainder.

Two special conditions may arise during the operation:

1. Division by zero causes a trap.
2. Overflow may be detected and set before the instruction completes. If the instruction detects an overflow, it sets the overflow condition code, and the destination registers are unaffected.

Condition Codes:

X	N	Z	V	C
—	*	*	*	0

X—Not affected.

N — Set if the quotient is negative; cleared otherwise; undefined if overflow or divide by zero occurs.

Z — Set if the quotient is zero; cleared otherwise; undefined if overflow or divide by zero occurs.

V — Set if division overflow occurs; undefined if divide by zero occurs; cleared otherwise.

C — Always cleared.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	
1	0	0	0	REGISTER			1	1	1	EFFECTIVE ADDRESS MODE				REG

Instruction Fields:

Register field—Specifies any of the eight data registers. This field always specifies the destination operand.

Effective Address field—Specifies the source operand. Only data alterable addressing modes can be used as listed in the following tables:

Addressing Mode	Mode	Register
Dn	000	reg. number:Dn
An	—	—
(An)	010	reg. number:An
(An) +	011	reg. number:An
– (An)	100	reg. number:An
(d ₁₆ ,An)	101	reg. number:An
(d ₈ ,An,Xn)	110	reg. number:An

Addressing Mode	Mode	Register
(xxx).W	111	
(xxx).L	111	
#<data>	111

([bd,PC,Xn],od)	111	0
([bd,PC],Xn,od)	111	0

Register Dq field—Specifies a data register for the destination operand. The low 32 bits of the dividend comes from this register, and the 32-bit quotient is stored into this register.

Size field—Selects a 32- or 64-bit division operation.

- 0 — 32-bit dividend is in register Dq.
- 1 — 64-bit dividend is in Dr – Dq.

dividend.

NOTE

Overflow occurs if the quotient is larger than a 32-bit signed integer.

Syntax: *DIVU.L < ea > ,Dq 32/32 → 32q
 *DIVU.L < ea > ,Dr:Dq 64/32 → 32r – 32q
 *DIVUL.L < ea > ,Dr:Dq 32/32 → 32r – 32q
 *Applies to MC68020, MC68030, MC68040, CPU32 only.

Attributes: Size = (Word, Long)

Description: Divides the unsigned destination operand by the unsigned operand and stores the unsigned result in the destination. The instruction uses four forms. The word form of the instruction divides a long word by a word. The result is a quotient in the lower word (least significant 16 bits) and a remainder in the upper word (most significant 16 bits).

The first long form divides a long word by a long word. The result is a long quotient and a long remainder is discarded.

The second long form divides a quad word (in any two data registers) by a long word. The result is a long-word quotient and a long-word remainder.

The third long form divides a long word by a long word. The result is a long-word quotient and a long-word remainder.

Two special conditions may arise during the operation:

1. Division by zero causes a trap.
2. Overflow may be detected and set before the instruction completes. If the instruction detects an overflow, it sets the overflow condition code, and the destination registers are unaffected.

Condition Codes:

X	N	Z	V	C
—	*	*	*	0

- X — Not affected.
- N — Set if the quotient is negative; cleared otherwise; undefined if overflow or division by zero occurs.
- Z — Set if the quotient is zero; cleared otherwise; undefined if overflow or division by zero occurs.
- V — Set if division overflow occurs; cleared otherwise; undefined if division overflow occurs.
- C — Always cleared.

([bd,PC,Xn],od)	111	0
([bd,PC],Xn,od)	111	0

Register Dq field—Specifies a data register for the destination operand. The low 32 bits of the dividend comes from this register, and the 32-bit quotient is stored into this register.

Size field—Selects a 32- or 64-bit division operation.

- 0 — 32-bit dividend is in register Dq.
- 1 — 64-bit dividend is in Dr – Dq.

dividend.

NOTE

Overflow occurs if the quotient is larger than a 32-bit unsigned integer.

Syntax: EOR Dn, < ea >

Attributes: Size = (Byte, Word, Long)

Description: Performs an exclusive-OR operation on the destination operand and source operand and stores the result in the destination location. The size of the operation may be specified to be byte, word, or long. The source operand may be a register or a data register. The destination operand is specified in the effective address field.

Condition Codes:

X	N	Z	V	C
—	*	*	0	0

X — Not affected.

N — Set if the most significant bit of the result is set; cleared otherwise.

Z — Set if the result is zero; cleared otherwise.

V — Always cleared.

C — Always cleared.

Instruction Format:

Instruction Fields:

Register field—Specifies any of the eight data registers.

Opmode field

*Can be used with CPU32.

NOTE

Memory-to-data-register operations are not allowed. Most assemblers use EORI when the source is immediate data.

Syntax: EORI # < data > , < ea >

Attributes: Size = (Byte, Word, Long)

Description: Performs an exclusive-OR operation on the destination operand and immediate data and the destination operand and stores the result in the destination location. The size of the operation may be specified as byte, word, or long. The operation is performed only if the immediate data matches the operation size.

Condition Codes:

X	N	Z	V	C
—	*	*	0	0

X — Not affected.

N — Set if the most significant bit of the result is set; cleared otherwise.

Z — Set if the result is zero; cleared otherwise.

V — Always cleared.

C — Always cleared.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1
0	0	0	0	1	0	1	0	SIZE		EFFECTIVE ADDRESS				
										MODE			REGIS	
16-BIT WORD DATA								8-BIT BYTE DATA						
32-BIT LONG DATA														

00— Byte operation
 01— Word operation
 10— Long operation

Effective Address field—Specifies the destination operand. Only data addressing modes can be used as listed in the following tables:

Addressing Mode	Mode	Register
Dn	000	reg. number:Dn
An	—	—
(An)	010	reg. number:An
(An) +	011	reg. number:An
– (An)	100	reg. number:An
(d ₁₆ ,An)	101	reg. number:An

(bd,PC,Xn)*	—	
([bd,PC,Xn],od)	—	
([bd,PC],Xn,od)	—	

*Can be used with CPU32.

Immediate field—Data immediately following the instruction.

If size = 00, the data is the low-order byte of the immediate word.

If size = 01, the data is the entire immediate word.

If size = 10, the data is next two immediate words.

Operation: Source \oplus CCR \rightarrow CCR

Assembler

Syntax: EORI # < data > ,CCR

Attributes: Size = (Byte)

Description: Performs an exclusive-OR operation on the condition code register and the immediate operand and stores the result in the condition code register (low-order 8 bits of the status register). All implemented bits of the condition code register are affected.

Condition Codes:

X	N	Z	V	C
*	*	*	*	*

X — Changed if bit 4 of immediate operand is one; unchanged otherwise.

N — Changed if bit 3 of immediate operand is one; unchanged otherwise.

Z — Changed if bit 2 of immediate operand is one; unchanged otherwise.

V — Changed if bit 1 of immediate operand is one; unchanged otherwise.

C — Changed if bit 0 of immediate operand is one; unchanged otherwise.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	1	0	1	0	0	0	1	1	1	1	1	0
										8-BIT BYTE DATA					

Syntax: EXG Ax,Ay EXG Dx,Ay

Attributes: Size = (Long)

Description: Exchanges the contents of two 32-bit registers. The instruction performs three types of exchanges.

1. Exchange data registers.
2. Exchange address registers.
3. Exchange a data register and an address register.

Condition Codes:

Not affected.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2
1	1	0	0	REGISTER Rx			1	OPMODE				REGIS	

Instruction Fields:

Register Rx field—Specifies either a data register or an address register depending on the mode. If the exchange is between data and address registers, this field specifies the data register.

Opmode field—Specifies the type of exchange.

01000—Data registers

01001—Address registers

10001—Data register and address register

Register Ry field—Specifies either a data register or an address register depending on the mode. If the exchange is between data and address registers, this field specifies the address register.

Syntax: EXT.L Dnextend word to long word
 EXT.B L Dnextend byte to long word (MC68020, MC68030
 MC68040, CPU32)

Attributes: Size = (Word, Long)

Description: Extends a byte in a data register to a word or a long word, or a word in a data register to a long word, by replicating the sign bit to the left. If the operation extends a byte to a word, bit 7 of the designated data register is copied to bits 15 – 8 of the data register. If the operation extends a word to a long word, bit 15 of the designated data register is copied to bits 31 – 16 of the data register. The EXT.B form copies bit 7 of the designated register to bits 31 – 8 of the data register.

Condition Codes:

X	N	Z	V	C
—	*	*	0	0

- X — Not affected.
- N — Set if the result is negative; cleared otherwise.
- Z — Set if the result is zero; cleared otherwise.
- V — Always cleared.
- C — Always cleared.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1
0	1	0	0	1	0	0	OPMODE			0	0	0	REGIS	

Instruction Fields:

- Opmode field—Specifies the size of the sign-extension operation.
 - 010— Sign-extend low-order byte of data register to word.
 - 011— Sign-extend low-order word of data register to long.
 - 111— Sign-extend low-order byte of data register to long.

Register field—Specifies the data register is to be sign-extended.

Illegal Instruction Vector Address → PC

*The MC68000 and MC68008 cannot write the vector offset and format code to the system stack.

Assembler

Syntax: ILLEGAL

Attributes: Unsized

Description: Forces an illegal instruction exception, vector number 4. All other instruction bit patterns are reserved for future extension of the instruction set and should not be used to force an exception.

Condition Codes:

Not affected.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2
0	1	0	0	1	0	1	0	1	1	1	1	1	1

Syntax: JMP < ea >

Attributes: Unsized

Description: Program execution continues at the effective address specified in the instruction. The addressing mode for the effective address must be a valid addressing mode.

Condition Codes:

Not affected.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1
0	1	0	0	1	1	1	0	1	1	EFFECTIVE ADDRESS MODE				REGIS

Instruction Field:

Effective Address field—Specifies the address of the next instruction. Only valid addressing modes can be used as listed in the following tables:

Addressing Mode	Mode	Register
Dn	—	—
An	—	—
(An)	010	reg. number:An
(An) +	—	—
– (An)	—	—
(d ₁₆ ,An)	101	reg. number:An
(d ₈ ,An,Xn)	110	reg. number:An

Addressing Mode	Mode	Reg
(xxx).W	111	0
(xxx).L	111	0
#<data>	—	—
(d ₁₆ ,PC)	111	0
(d ₈ ,PC,Xn)	111	0

MC68020, MC68030, and MC68040 only

(bd,An,Xn)*	110	reg. number:An
([bd,An,Xn],od)	110	reg. number:An
([bd,An],Xn,od)	110	reg. number:An

(bd,PC,Xn)*	111	0
([bd,PC,Xn],od)	111	0
([bd,PC],Xn,od)	111	0

*Can be used with CPU32.

Syntax: JSR < ea >

Attributes: Unsize

Description: Pushes the long-word address of the instruction immediately following the JSR instruction onto the system stack. Program execution then continues at the address specified in the instruction.

Condition Codes:

Not affected.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	EFFECTIVE ADDRESS	
0	1	0	0	1	1	1	0	1	0	MODE			REG		

Instruction Field:

Effective Address field—Specifies the address of the next instruction. Only the following addressing modes can be used as listed in the following tables:

Addressing Mode	Mode	Register
Dn	—	—
An	—	—
(An)	010	reg. number:An
(An) +	—	—
– (An)	—	—
(d ₁₆ ,An)	101	reg. number:An
(d ₈ ,An,Xn)	110	reg. number:An

Addressing Mode	Mode	Register
(xxx).W	111	
(xxx).L	111	
#<data>	—	
(d ₁₆ ,PC)	111	
(d ₈ ,PC,Xn)	111	

MC68020, MC68030, and MC68040 only

(bd,An,Xn)*	110	reg. number:An
([bd,An,Xn],od)	110	reg. number:An
([bd,An],Xn,od)	110	reg. number:An

(bd,PC,Xn)*	111	
([bd,PC,Xn],od)	111	
([bd,PC],Xn,od)	111	

*Can be used with CPU32.

Syntax: LEA < ea > ,An

Attributes: Size = (Long)

Description: Loads the effective address into the specified address register. All 32 address registers are affected by this instruction.

Condition Codes:

Not affected.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	
0	1	0	0	REGISTER			1	1	1	EFFECTIVE ADDRESS MODE					REGIS

Instruction Fields:

Register field—Specifies the address register to be updated with the effective address.

Effective Address field—Specifies the address to be loaded into the address register.
Only control addressing modes can be used as listed in the following table.

Addressing Mode	Mode	Register
Dn	—	—
An	—	—
(An)	010	reg. number:An
(An) +	—	—
– (An)	—	—
(d ₁₆ ,An)	101	reg. number:An
(d ₈ ,An,Xn)	110	reg. number:An

Addressing Mode	Mode	Register
(xxx).W	111	C
(xxx).L	111	C
#<data>	—	—
(d ₁₆ ,PC)	111	C
(d ₈ ,PC,Xn)	111	C

MC68020, MC68030, and MC68040 only

(bd,An,Xn)	110	reg. number:An
([bd,An,Xn],od)	110	reg. number:An
([bd,An],Xn,od)	110	reg. number:An

(bd,PC,Xn)*	111	C
([bd,PC,Xn],od)	111	C
([bd,PC],Xn,od)	111	C

*Can be used with CPU32.

Syntax: LINK An, # < displacement >

Attributes: Size = (Word, Long*)

*MC68020, MC68030, MC68040 and CPU32 only.

Description: Pushes the contents of the specified address register onto the stack. The stack pointer is incremented by the displacement value. Finally, the updated stack pointer is loaded into the address register. Finally, the displacement value is added to the stack pointer. For word-size operation, the displacement is the sign-extended word following the operation word. For long size operation, the displacement is the long word following the operation word. The address register occupies one long word on the stack. The user should specify a negative displacement in order to allocate stack area.

Condition Codes:

Not affected.

Instruction Format:

WORD

15	14	13	12	11	10	9	8	7	6	5	4	3	2	REG
0	1	0	0	1	1	1	0	0	1	0	1	0		
WORD DISPLACEMENT														

Instruction Format:

LONG

15	14	13	12	11	10	9	8	7	6	5	4	3	2	REG
0	1	0	0	1	0	0	0	0	0	0	0	1		
HIGH-ORDER DISPLACEMENT														
LOW-ORDER DISPLACEMENT														

Displacement field—Specifies the two's complement integer to be added to the pointer.

NOTE

LINK and UNLK can be used to maintain a linked list of local data and parameter areas on the stack for nested subroutine calls.

Syntax: LSh # < data > ,Dy
LSh < ea >
where d is direction, L or R

Attributes: Size = (Byte, Word, Long)

Description: Shifts the bits of the operand in the direction specified (L or R). The register receives the last bit shifted out of the operand. The shift count for the shift register is specified in two different ways:

1. Immediate—The shift count (1 – 8) is specified in the instruction.
2. Register—The shift count is the value in the data register specified in the instruction modulo 64.

The size of the operation for register destinations may be specified as byte, word, or long. The contents of memory, < ea > , can be shifted one bit only, and the size is restricted to a word.

The LSL instruction shifts the operand to the left the number of positions specified by the shift count. Bits shifted out of the high-order bit go to both the carry and the X register; zeros are shifted into the low-order bit.

The LSR instruction shifts the operand to the right the number of positions specified by the shift count. Bits shifted out of the low-order bit go to both the carry and the X register; zeros are shifted into the high-order bit.

*	*	*	0	*
---	---	---	---	---

- X — Set according to the last bit shifted out of the operand; unaffected for a shift count of zero.
- N — Set if the result is negative; cleared otherwise.
- Z — Set if the result is zero; cleared otherwise.
- V — Always cleared.
- C — Set according to the last bit shifted out of the operand; cleared for a shift count of zero.

Instruction Format:

REGISTER SHIFTS

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	0	COUNT/ REGISTER			dr	SIZE		i/r	0	1	REGIS		

Instruction Fields:

Count/Register field

If $i/r = 0$, this field contains the shift count. The values 1 – 7 represent shifts of 1 through 7; a value of zero specifies a shift count of eight.

If $i/r = 1$, the data register specified in this field contains the shift count (mod 8).

dr field—Specifies the direction of the shift.

- 0 — Shift right
- 1 — Shift left

Size field—Specifies the size of the operation.

- 00 — Byte operation
 - 01 — Word operation
 - 10 — Long operation i/r field
- If $i/r = 0$, specifies immediate shift count.
 If $i/r = 1$, specifies register shift count.

Register field—Specifies a data register to be shifted.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	EFFECTIVE ADDRESS	
1	1	1	0	0	0	1	dr	1	1	MODE			REG		

Instruction Fields:

dr field—Specifies the direction of the shift.

0 — Shift right

1 — Shift left

Effective Address field—Specifies the operand to be shifted. Only memory addressing modes can be used as listed in the following tables:

Addressing Mode	Mode	Register

([bd,PC],Xn,od)	—	

*Can be used with CPU32.

Syntax: MOVE < ea > , < ea >

Attributes: Size = (Byte, Word, Long)

Description: Moves the data at the source to the destination location and sets the condition codes according to the data. The size of the operation may be specified as byte, word, or long. Condition Codes:

X	N	Z	V	C
—	*	*	0	0

X — Not affected.

N — Set if the result is negative; cleared otherwise.

Z — Set if the result is zero; cleared otherwise.

V — Always cleared.

C — Always cleared.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1
0	0	SIZE			DESTINATION				SOURCE				REGIS	
				REGISTER			MODE			MODE				

Instruction Fields:

Size field—Specifies the size of the operand to be moved.

01 — Byte operation

11 — Word operation

10 — Long operation

Addressing Mode	Mode	Register

*For byte size operation, address register direct is not allowed.

**Can be used with CPU32.

NOTE

Most assemblers use MOVEA when the destination is an address register.

MOVEQ can be used to move an immediate 8-bit value to a data register.

Syntax: MOVEA < ea > ,An

Attributes: Size = (Word, Long)

Description: Moves the contents of the source to the destination address register of the operation is specified as word or long. Word-size source operands extended to 32-bit quantities.

Condition Codes:

Not affected.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2
0	0	SIZE	DESTINATION REGISTER	0	0	1	MODE		SOURCE		REG		

Instruction Fields:

Size field—Specifies the size of the operand to be moved.

11 — Word operation; the source operand is sign-extended to a long operation; all 32 bits are loaded into the address register.

10 — Long operation.

Destination Register field—Specifies the destination address register.

Addressing Mode	Mode	Register

*Can be used with CPU32.

Operation: CCR → Destination

Assembler

Syntax: MOVE CCR, < ea >

Attributes: Size = (Word)

Description: Moves the condition code bits (zero-extended to word size) to the destination location. The operand size is a word. Unimplemented bits are read as zeros.

Condition Codes:

Not affected.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2
0	1	0	0	0	0	1	0	1	1	EFFECTIVE ADDRESS			
										MODE		REG	

Instruction Field:

Effective Address field—Specifies the destination location. Only data addressing modes can be used as listed in the following tables:

Addressing Mode	Mode	Register
Dn	000	reg. number:Dn
An	—	—
(An)	010	reg. number:An
(An) +	011	reg. number:An
– (An)	100	reg. number:An

([bd,PC,Xn],od)	—	-
([bd,PC],Xn,od)	—	-

*Can be used with CPU32.

NOTE

MOVE from CCR is a word operation. ANDI, ORI, and EORI to CCR are byte operations.

Assembler**Syntax:** MOVE < ea > ,CCR**Attributes:** Size = (Word)

Description: Moves the low-order byte of the source operand to the condition code register. The upper byte of the source operand is ignored; the upper byte of the status register is not altered.

Condition Codes:

X	N	Z	V	C
*	*	*	*	*

X — Set to the value of bit 4 of the source operand.

N — Set to the value of bit 3 of the source operand.

Z — Set to the value of bit 2 of the source operand.

V — Set to the value of bit 1 of the source operand.

C — Set to the value of bit 0 of the source operand.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2
0	1	0	0	0	1	0	0	1	1	EFFECTIVE ADDRESS			
										MODE		REG	

Effective Address field—Specifies the location of the source operand. Other addressing modes can be used as listed in the following tables:

Addressing Mode	Mode	Register
Dn	000	reg. number:Dn
An	—	—
(An)	010	reg. number:An
(An) +	011	reg. number:An
– (An)	100	reg. number:An
(d ₁₆ ,An)	101	reg. number:An
(d ₈ ,An,Xn)	110	reg. number:An

Addressing Mode	Mode	Reg
(xxx).W	111	0
(xxx).L	111	0
#<data>	111	1
(d ₁₆ ,PC)	111	0
(d ₈ ,PC,Xn)	111	0

MC68020, MC68030, and MC68040 only

(bd,An,Xn)*	110	reg. number:An
([bd,An,Xn],od)	110	reg. number:An
([bd,An],Xn,od)	110	reg. number:An

(bd,PC,Xn)*	111	0
([bd,PC,Xn],od)	111	0
([bd,PC],Xn,od)	111	0

*Can be used with CPU32.

NOTE

MOVE to CCR is a word operation. ANDI, ORI, and EORI to CCR are byte operations.

Assembler**Syntax:** MOVE SR, < ea >**Attributes:** Size = (Word)**Description:** Moves the data in the status register to the destination location. The destination is word length. Unimplemented bits are read as zeros.**Condition Codes:**

Not affected.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2
0	1	0	0	0	0	0	0	1	1	EFFECTIVE ADDRESS MODE			REG

Instruction Fields:

Effective Address field—Specifies the destination location. Only data addressing modes can be used as listed in the following table:

Addressing Mode	Mode	Register	Addressing Mode	Mode	Register
Dn	000	reg. number:Dn	(xxx).W	111	
An	—	—	(xxx).L	111	
(An)	010	reg. number:An	#<data>	—	
(An) +	011	reg. number:An			
– (An)	100	reg. number:An			
(d ₁₆ ,An)	101	reg. number:An	(d ₁₆ ,PC)	—	
(d ₈ ,An,Xn)	110	reg. number:An	(d ₈ ,PC,Xn)	—	

NOTE

Use the MOVE from CCR instruction to access only the condition codes. Memory destination is read before it is written to.

Syntax: MOVE16 (xxx).L,(An)
 MOVE16 (xxx).L,(An) +
 MOVE16 (An),(xxx).L
 MOVE16 (An) + ,(xxx).L

Attributes: Size = (Line)

Description: Moves the source line to the destination line. The lines are aligned to boundaries. Applications for this instruction include coprocessor communication, memory initialization, and fast block copy operations.

MOVE16 has two formats. The postincrement format uses the postincrement addressing mode for both source and destination; whereas, the absolute format specifies an absolute long address for either the source or destination.

Line transfers are performed using burst reads and writes, which begin with a long word pointed to by the effective address of the source and destination, respectively. The address register used in the postincrement addressing mode is incremented after the transfer.

Example: MOVE16 (A0) + \$FE802 A0 = \$1400F

The line at address \$14000 is read into a temporary holding register by a burst transfer starting with long-word \$14000. Address values in A0 of \$14000 – \$1401F cause the same line to be read, starting at different long words. The line is then transferred to the line at address \$FE800 beginning with long-word \$FE800 after the instruction contains \$1401F.

Source line at \$14000:

\$14000	\$14004	\$14008	\$1400C
LONG WORD 0	LONG WORD 1	LONG WORD 2	LONG WORD 3

Destination line at \$FE8000:

\$FE800	\$FE804	\$FE808	\$FE80C
LONG WORD 0	LONG WORD 1	LONG WORD 2	LONG WORD 3

Instruction Format:

POSTINCREMENT SOURCE AND DESTINATION

15	14	13	12	11	10	9	8	7	6	5	4	3	2
1	1	1	1	0	1	1	0	0	0	1	0	0	REGI
1	REGISTER Ay			0	0	0	0	0	0	0	0	0	0

Instruction Fields:

Register Ax—Specifies a source address register for the postincrement addressing mode.

Register Ay—Specifies a destination address register for the postincrement addressing mode.

Instruction Format:

Absolute Long Address Source or Destination

15	14	13	12	11	10	9	8	7	6	5	4	3	2
1	1	1	1	0	1	1	0	0	0	0	OPMODE		REGI
HIGH-ORDER ADDRESS													
LOW-ORDER ADDRESS													

Instruction Fields:

Opmode field—Specifies the addressing modes used for source and destination.

Opmode	Source	Destination	Assembler Syntax
0 0	(Ay) +	(xxx).L	MOVE16 (Ay) + ,(xxx).L
0 1	(xxx).L	(Ay) +	MOVE16 (xxx).L,(Ay) +
1 0	(Ay)	(xxx).L	MOVE16 (Ay),(xxx).L
1 1	(xxx).L	(Ay)	MOVE16 (xxx).L,(Ay)

Register Ay—Specifies an address register for the indirect and postincrement addressing mode used as a source or destination.

32-Bit Address field—Specifies the absolute address used as a source or destination.

Syntax: MOVEM < ea > , < list >

Attributes: Size = (Word, Long)

Description: Moves the contents of selected registers to or from consecutive locations starting at the location specified by the effective address. A register is selected if the bit in the mask field corresponding to that register is set. The operand size determines whether 16 or 32 bits of each register are transferred. In the control word transfer to either address or data registers, each word is sign-extended to a long word and the resulting long word is loaded into the associated register.

Selecting the addressing mode also selects the mode of operation of the instruction, and only the control modes, the predecrement mode, and the postincrement mode are valid. If the effective address is specified by one of the control modes, the registers are transferred starting at the specified address, and the address is incremented by the operand length (2 or 4) following each transfer. The order of transfers is from D0 to D7, then from A0 to A7.

If the effective address is specified by the predecrement mode, only a register-to-memory operation is allowed. The registers are stored starting at the specified address minus the operand length (2 or 4), and the address is decremented by the operand length following each transfer. The order of storing is from A7 to A0, then from D0 to D7. When the instruction has completed, the decremented address register contains the address of the last operand stored. For the MC68020, MC68030, MC68040, MC68050, MC68060, MC68070, MC68080, MC68090, and MC68010, if the addressing register is also moved to memory, the value written is the initial register value decremented by the size of the operation. The MC68010 and MC68011 write the initial register value (not decremented).

If the effective address is specified by the postincrement mode, only a memory-to-register operation is allowed. The registers are loaded starting at the specified address, and the address is incremented by the operand length (2 or 4) following each transfer. The order of loading is the same as that of control mode addressing. When the instruction has completed, the incremented address register contains the address of the last operand loaded plus the operand length. If the addressing register is also loaded to memory, the memory value is ignored and the register is written with the incremented effective address.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2
0	1	0	0	1	dr	0	0	1	SIZE	EFFECTIVE ADDRESS			
										MODE	REG		
REGISTER LIST MASK													

Instruction Fields:

dr field—Specifies the direction of the transfer.

0 — Register to memory.

1 — Memory to register.

Size field—Specifies the size of the registers being transferred.

0 — Word transfer

1 — Long transfer

Effective Address field—Specifies the memory address for the operation. For to-memory transfers, only control alterable addressing modes. The postincrement addressing mode can be used as listed in the following table.

Addressing Mode	Mode	Register
Dn	—	—
An	—	—
(An)	010	reg. number:An
(An) +	—	—
– (An)	100	reg. number:An
(d ₁₆ ,An)	101	reg. number:An
(d ₈ ,An,Xn)	110	reg. number:An

Addressing Mode	Mode	Register
(xxx).W	111	
(xxx).L	111	
#<data>	—	
(d ₁₆ ,PC)	—	
(d ₈ ,PC,Xn)	—	

MC68020, MC68030, and MC68040 only

(bd,An,Xn)*	110	reg. number:An
([bd,An,Xn],od)	110	reg. number:An
([bd,An],Xn,od)	110	reg. number:An

(bd,PC,Xn)*	—	
([bd,PC,Xn],od)	—	
([bd,PC],Xn,od)	—	

*Can be used with CPU32.

Addressing Mode	Mode	Register
Dn	—	—
An	—	—
(An)	010	reg. number:An
(An) +	011	reg. number:An
– (An)	—	—
(d ₁₆ ,An)	101	reg. number:An

([bd,PC,Xn],od)	111	C
([bd,PC],Xn,od)	111	C

*Can be used with CPU32.

Register List Mask field—Specifies the registers to be transferred. The low-order bit corresponds to the first register to be transferred; the high-order bit corresponds to the last register to be transferred. Thus, for both control mode and postincrement mode addresses, the mask correspondence is:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1
A7	A6	A5	A4	A3	A2	A1	A0	D7	D6	D5	D4	D3	D2	D1

For the predecrement mode addresses, the mask correspondence is reversed:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1
D0	D1	D2	D3	D4	D5	D6	D7	A0	A1	A2	A3	A4	A5	A6

Syntax: MOVEP (d16,Ay),Dx

Attributes: Size = (Word, Long)

Description: Moves data between a data register and alternate bytes within the space starting at the location specified and incrementing by two. The high-order byte of the data register is transferred first, and the low-order byte is transferred last. The memory address is specified in the address register indirect plus 16-bit displacement addressing mode. This instruction was originally designed for interfacing with peripheral devices on a 16-bit data bus, such as the MC68000 bus. Although supported on the MC68020, MC68030, and MC68040, this instruction is not useful for those processors with an external 32-bit bus.

Example: Long transfer to/from an even address.

Byte Organization in Register

31	24	23	16	15	8	7	0
HIGH ORDER	MID UPPER		MID LOWER		LOW ORDER		

Byte Organization in 16-Bit Memory (Low Address at Top)

15	8	7	0
HIGH ORDER			
MID UPPER			
MID LOWER			
LOW ORDER			

HIGH ORDER		MID UPPER	
MID LOWER		LOW ORDER	

or

31	24	23	16	15	8	7	0
				HIGH ORDER			
	MID UPPER			MID LOWER			
	LOW ORDER						

Example: Word transfer to/from (odd address).

Byte Organization in Register

31	24	23	16	15	8	7	0
				HIGH ORDER		LOW ORDER	

Byte Organization in 16-Bit Memory (Low Address at Top)

15	8	7	0
		HIGH ORDER	
		LOW ORDER	

Byte Organization in 32-Bit Memory

31	24	23	16	15	8	7	0
						HIGH ORDER	
	LOW ORDER						

or

31	24	23	16	15	8	7	0
		HIGH ORDER				LOW ORDER	

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2
0	0	0	0	DATA REGISTER			OPMODE			0	0	1	ADDRESS
16-BIT DISPLACEMENT													

Instruction Fields:

Data Register field—Specifies the data register for the instruction.

Opmode field—Specifies the direction and size of the operation.

100—Transfer word from memory to register.

101—Transfer long from memory to register.

110—Transfer word from register to memory.

111—Transfer long from register to memory.

Address Register field—Specifies the address register which is used in the register indirect plus displacement addressing mode.

Displacement field—Specifies the displacement used in the operand address.

Syntax: MOVEQ # < data > ,Dn

Attributes: Size = (Long)

Description: Moves a byte of immediate data to a 32-bit data register. The data in the field within the operation word is sign-extended to a long operand in the data register as it is transferred.

Condition Codes:

X	N	Z	V	C
—	*	*	0	0

X — Not affected.

N — Set if the result is negative; cleared otherwise.

Z — Set if the result is zero; cleared otherwise.

V — Always cleared.

C — Always cleared.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1
0	1	1	1	REGISTER			0	DATA						

Instruction Fields:

Register field—Specifies the data register to be loaded.

Data field—Eight bits of data, which are sign-extended to a long operand.

Syntax: *MULS.L < ea > ,DI 32 x 32 → 32
 *MULS.L < ea > ,Dh – DI 32 x 32 → 64
 *Applies to MC68020, MC68030, MC68040, CPU32

Attributes: Size = (Word, Long)

Description: Multiplies two signed operands yielding a signed result. This instruction uses a word operand form and a long operand form.

In the word form, the multiplier and multiplicand are both word operands, and the result is a long-word operand. A register operand is the low-order word; the upper word of the register is ignored. All 32 bits of the product are saved in the destination data register.

In the long form, the multiplier and multiplicand are both long-word operands, and the result is either a long word or a quad word. The long-word result is the low-order word of the quad-word result; the high-order 32 bits of the product are discarded.

Condition Codes:

X	N	Z	V	C
—	*	*	*	0

- X — Not affected.
- N — Set if the result is negative; cleared otherwise.
- Z — Set if the result is zero; cleared otherwise.
- V — Set if overflow; cleared otherwise.
- C — Always cleared.

NOTE

Overflow ($V = 1$) can occur only when multiplying 32-bit operands to yield a 32-bit result. Overflow occurs if the high-order 32 bits of the quad-word product are not the sign extension of the low-order 32 bits.

*Can be used with CPU32.

Register DI field—Specifies a data register for the destination operand. The high-order 32 bits of the multiplicand comes from this register, and the low-order 32 bits of the product are loaded into this register.

Size field—Selects a 32- or 64-bit product.

- 0 — 32-bit product to be returned to register DI.
- 1 — 64-bit product to be returned to Dh – DI.

Register Dh field—If size is one, specifies the data register into which the high-order 32 bits of the product are loaded. If Dh = DI and size is one, the result of the operation are undefined. Otherwise, this field is unused.

Syntax:

*MULU.L < ea > ,DI 32 x 32 → 32

*MULU.L < ea > ,Dh – DI 32 x 32 → 64

*Applies to MC68020, MC68030, MC68040, CPU32 only

Attributes:

Size = (Word, Long)

Description: Multiplies two unsigned operands yielding an unsigned result. This instruction has a word operand form and a long operand form.

In the word form, the multiplier and multiplicand are both word operands, and the result is a long-word operand. A register operand is the low-order word; the upper word of the register is ignored. All 32 bits of the product are saved in the destination data register.

In the long form, the multiplier and multiplicand are both long-word operands, and the result is either a long word or a quad word. The long-word result is the low-order word of the quad-word result; the high-order 32 bits of the product are discarded.

Condition Codes:

X	N	Z	V	C
—	*	*	*	0

X — Not affected.

N — Set if the result is negative; cleared otherwise.

Z — Set if the result is zero; cleared otherwise.

V — Set if overflow; cleared otherwise.

C — Always cleared.

NOTE

Overflow ($V = 1$) can occur only when multiplying 32-bit operands to yield a 32-bit result. Overflow occurs if any of the high-order 32 bits of the quad-word product are not equal to zero.

*Can be used with CPU32.

Register DI field—Specifies a data register for the destination operand. The multiplicand comes from this register, and the low-order 32 bits of the product are loaded into this register.

Size field—Selects a 32- or 64-bit product.

- 0 — 32-bit product to be returned to register DI.
- 1 — 64-bit product to be returned to Dh – DI.

Register Dh field—If size is one, specifies the data register into which the high-order 32 bits of the product are loaded. If Dh = DI and size is one, the result of the operation are undefined. Otherwise, this field is unused.

Syntax: NBCD < ea >

Attributes: Size = (Byte)

Description: Subtracts the destination operand and the extend bit from zero. The is performed using binary-coded decimal arithmetic. The packed binary-code result is saved in the destination location. This instruction produces complement of the destination if the extend bit is zero or the nines complement extend bit is one. This is a byte operation only.

Condition Codes:

X	N	Z	V	C
*	U	*	U	*

X — Set the same as the carry bit.

N — Undefined.

Z — Cleared if the result is nonzero; unchanged otherwise.

V — Undefined.

C — Set if a decimal borrow occurs; cleared otherwise.

NOTE

Normally the Z condition code bit is set via programming before the start of the operation. This allows successful tests for zero results upon completion of multiple-precision operations.

Instruction Fields:

Effective Address field—Specifies the destination operand. Only data addressing modes can be used as listed in the following tables:

Addressing Mode	Mode	Register
Dn	000	reg. number:Dn

*Can be used with CPU32.

Syntax: NOP

Attributes: Unsized

Description: Performs no operation. The processor state, other than the program counter, is unaffected. Execution continues with the instruction following the NOP instruction. The NOP instruction does not begin execution until all pending bus cycles are completed. This synchronizes the pipeline and prevents instruction overlap.

Condition Codes:

Not affected.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2
0	1	0	0	1	1	1	0	0	1	1	1	0	0

Syntax: NOT < ea >

Attributes: Size = (Byte, Word, Long)

Description:Calculates the ones complement of the destination operand and stores the result in the destination location. The size of the operation is specified as byte, word, or long.

Condition Codes:

X	N	Z	V	C
—	*	*	0	0

X — Not affected.

NOTE

If the destination is a data register, it must be specified using the destination Dn mode, not the destination < ea > mode.

Most assemblers use ORI when the source is immediate data.

Syntax: ORI # < data > , < ea >

Attributes: Size = (Byte, Word, Long)

Description: Performs an inclusive-OR operation on the immediate data destination operand and stores the result in the destination location. The operation is specified as byte, word, or long. The size of the immediate data is the operation size.

Condition Codes:

X	N	Z	V	C
—	*	*	0	0

X — Not affected.

N — Set if the most significant bit of the result is set; cleared otherwise.

Z — Set if the result is zero; cleared otherwise.

V — Always cleared.

C — Always cleared.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2
0	0	0	0	0	0	0	0	SIZE		EFFECTIVE ADDRESS			
										MODE		REG	
16-BIT WORD DATA								8-BIT BYTE DATA					
32-BIT LONG DATA													

- 00— Byte operation
- 01— Word operation
- 10— Long operation

Effective Address field—Specifies the destination operand. Only data addressing modes can be used as listed in the following tables:

Addressing Mode	Mode	Register
Dn	000	reg. number:Dn
An	—	—
(An)	010	reg. number:An
(An) +	011	reg. number:An

([bd,An],Xn,od)	110	reg. number:An

(bd,PC,Xn)*	—	—
([bd,PC,Xn],od)	—	—
([bd,PC],Xn,od)	—	—

*Can be used with CPU32.

Immediate field—Data immediately following the instruction.

If size = 00, the data is the low-order byte of the immediate word.

If size = 01, the data is the entire immediate word.

If size = 10, the data is the next two immediate words.

Operation: Source V CCR → CCR

Assembler

Syntax: ORI # < data > ,CCR

Attributes: Size = (Byte)

Description: Performs an inclusive-OR operation on the immediate operand condition codes and stores the result in the condition code register (low-order the status register). All implemented bits of the condition code register are af

Condition Codes:

X	N	Z	V	C
*	*	*	*	*

X — Set if bit 4 of immediate operand is one; unchanged otherwise.

N — Set if bit 3 of immediate operand is one; unchanged otherwise.

Z — Set if bit 2 of immediate operand is one; unchanged otherwise.

V — Set if bit 1 of immediate operand is one; unchanged otherwise.

C — Set if bit 0 of immediate operand is one; unchanged otherwise.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2
0	0	0	0	0	0	0	0	0	0	1	1	1	1
0	0	0	0	0	0	0	0	8-BIT BYTE DATA					

Syntax: PACK Dx,Dy,# < adjustment >

Attributes: Unsize

Description: Adjusts and packs the lower four bits of each of two bytes into a single

When both operands are data registers, the adjustment is added to the value contained in the source register. Bits 11 – 8 and 3 – 0 of the intermediate result are concatenated and placed in bits 7 – 0 of the destination register. The remainder of the destination register is unaffected.

Source:

Add Adjustment Word:

Resulting in:

Destination:

When the predecrement addressing mode is specified, two bytes from the source are fetched and concatenated. The adjustment word is added to the concatenated value. Bits 3 – 0 of each byte are extracted. These eight bits are concatenated to form a single byte which is then written to the destination.

x	x	x	x	a	b	c	d
x	x	x	x	e	f	g	h
Ax							

Concatenated Word:

15	14	13	12	11	10	9	8	7	6	5	4	3	2
x	x	x	x	a	b	c	d	x	x	x	x	e	f

Add Adjustment Word:

15	16-BIT EXTENSION												
----	------------------	--	--	--	--	--	--	--	--	--	--	--	--

Destination:

7	6	5	4	3	2	1	0
a'	b'	c'	d'	e'	f'	g'	h'
Ay							

Condition Codes:

Not affected.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2
1	0	0	0	REGISTER Dy/Ay			1	0	1	0	0	R/M	REGIST
16-BIT ADJUSTMENT EXTENSION:													

If R/M = 0, specifies a data register.

If R/M = 1, specifies an address register in the predecrement addressing mode.

R/M field—Specifies the operand addressing mode.

0 — The operation is data register to data register.

1 — The operation is memory to memory.

Register Dx/Ax field—Specifies the source register.

If R/M = 0, specifies a data register.

If R/M = 1, specifies an address register in the predecrement addressing mode.

Adjustment field—Immediate data word that is added to the source operand. The value is zero to pack ASCII or EBCDIC codes. Other values can be used for other codes.

Syntax: PEA < ea >

Attributes: Size = (Long)

Description: Computes the effective address and pushes it onto the stack. The address is a long address.

Condition Codes:

Not affected.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2
0	1	0	0	1	0	0	0	0	1	EFFECTIVE ADDRESS MODE			REG

Instruction Field:

Effective Address field—Specifies the address to be pushed onto the stack. The control addressing modes can be used as listed in the following tables:

Addressing Mode	Mode	Register
Dn	—	—
An	—	—
(An)	010	reg. number:An

*Can be used with CPU32.

Syntax: R0d # < data > ,Dy R0d < ea > where d is direction, L or R

Attributes: Size = (Byte, Word, Long)

Description: Rotates the bits of the operand in the direction specified (L or R). The carry bit is not included in the rotation. The rotate count for the rotation of a register is specified in either of two ways:

1. Immediate—The rotate count (1 – 8) is specified in the instruction.
2. Register—The rotate count is the value in the data register specified in the instruction, modulo 64.

The size of the operation for register destinations is specified as byte, word, or long. The contents of memory, (R0d < ea >), can be rotated one bit only, and operand size is restricted to a word.

The ROL instruction rotates the bits of the operand to the left; the rotate count determines the number of bit positions rotated. Bits rotated out of the high-order bit position go to the carry bit and also back into the low-order bit.

The ROR instruction rotates the bits of the operand to the right; the rotate count determines the number of bit positions rotated. Bits rotated out of the low-order bit position go to the carry bit and also back into the high-order bit.

—	*	*	0	*
---	---	---	---	---

X — Not affected.

N — Set if the most significant bit of the result is set; cleared otherwise.

Z — Set if the result is zero; cleared otherwise.

V — Always cleared.

C — Set according to the last bit rotated out of the operand; cleared when count is zero.

Instruction Format:

REGISTER ROTATE

15	14	13	12	11	10	9	8	7	6	5	4	3	2
1	1	1	0	COUNT/ REGISTER		dr	SIZE		i/r	1	1	REG	

Instruction Fields:

Count/Register field:

If $i/r = 0$, this field contains the rotate count. The values 1 – 7 represent counts of 1 – 7, and zero specifies a count of eight.

If $i/r = 1$, this field specifies a data register that contains the rotate count (most significant bit first).

dr field—Specifies the direction of the rotate.

0 — Rotate right

1 — Rotate left

Size field—Specifies the size of the operation.

00 — Byte operation

01 — Word operation

10 — Long operation

i/r field—Specifies the rotate count location.

If $i/r = 0$, immediate rotate count.

If $i/r = 1$, register rotate count.

Register field—Specifies a data register to be rotated.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1

*Can be used with CPU32.

Syntax: ROXd # < data > ,Dy
 ROXd < ea >
 where d is direction, L or R

Attributes: Size = (Byte, Word, Long)

Description: Rotates the bits of the operand in the direction specified (L or R). The carry bit is included in the rotation. The rotate count for the rotation of a register is in either of two ways:

1. Immediate—The rotate count (1 – 8) is specified in the instruction.
2. Register—The rotate count is the value in the data register specified in the instruction, modulo 64.

The size of the operation for register destinations is specified as byte, word, or long. The contents of memory, < ea > , can be rotated one bit only, and operation is restricted to a word. The ROXL instruction rotates the bits of the operand to the left; the rotate count determines the number of bit positions rotated. Bits rotated out of the high-order bit go to the carry bit and the extend bit; the previous value of the extend bit rotates into the low-order bit.

The ROXR instruction rotates the bits of the operand to the right; the rotate count determines the number of bit positions rotated. Bits rotated out of the low-order bit go to the carry bit and the extend bit; the previous value of the extend bit rotates into the high-order bit.

*	*	*	0	*
---	---	---	---	---

- X — Set to the value of the last bit rotated out of the operand; unaffected when rotate count is zero.
- N — Set if the most significant bit of the result is set; cleared otherwise.
- Z — Set if the result is zero; cleared otherwise.
- V — Always cleared.
- C — Set according to the last bit rotated out of the operand; when the rotate count is zero, set to the value of the extend bit.

Instruction Format:

REGISTER ROTATE														
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1
1	1	1	0	COUNT/ REGISTER			dr	SIZE		i/r	1	0	REGIS	

Instruction Fields:

Count/Register field:

If $i/r = 0$, this field contains the rotate count. The values 1 – 7 represent counts of 1 – 7, and zero specifies a count of eight.

If $i/r = 1$, this field specifies a data register that contains the rotate count (modulo 8).

dr field—Specifies the direction of the rotate.

0 — Rotate right

1 — Rotate left

i/r field—Specifies the rotate count location.

If i/r = 0, immediate rotate count.

If i/r = 1, register rotate count.

Register field—Specifies a data register to be rotated.

Instruction Format:

MEMORY ROTATE										EFFECTIVE ADDRESS			
15	14	13	12	11	10	9	8	7	6	5	4	3	2
1	1	1	0	0	1	0	dr	1	1	MODE			REG

Instruction Fields:

dr field—Specifies the direction of the rotate.

0 — Rotate right

1 — Rotate left

Effective Address field—Specifies the operand to be rotated. Only memory addressing modes can be used as listed in the following tables:

Addressing Mode	Mode	Register
Dn	—	—
An	—	—
(An)	010	reg. number:An

(bd,An,Xn)*	110	reg. number:An
([bd,An,Xn],od)	110	reg. number:An
([bd,An],Xn,od)	110	reg. number:An

(bd,PC,Xn)*	—	
([bd,PC,Xn],od)	—	
([bd,PC],Xn,od)	—	

*Can be used with CPU32.

Syntax: RTD # < displacement >

Attributes: Unsized

Description: Pulls the program counter value from the stack and adds the sign-extended 16-bit displacement value to the stack pointer. The previous program counter value is lost.

Condition Codes:

Not affected.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	0	0	1	1	1	0	0	1	1	1	0	1	0	0
16-BIT DISPLACEMENT															

Instruction Field:

Displacement field—Specifies the two's complement integer to be sign-extended and added to the stack pointer.

Syntax: RTM Rn

Attributes: Unsized

Description: A previously saved module state is reloaded from the top of stack. module state is retrieved from the top of the stack, the caller's stack pointer is incremented by the argument count value in the module state.

Condition Codes:

Set according to the content of the word on the stack.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2
0	0	0	0	0	1	1	0	1	1	0	0	D/A	REG

Instruction Fields:

D/A field—Specifies whether the module data pointer is in a data or an address register
0 — the register is a data register
1 — the register is an address register

Register field—Specifies the register number for the module data area pointer restored from the saved module state. If the register specified is A7, the updated value of the register reflects the stack pointer operations, and the module data area pointer is lost.

Syntax: RTR

Attributes: Unsized

Description: Pulls the condition code and program counter values from the stack. The previous condition code and program counter values are lost. The supervisor of the status register is unaffected.

Condition Codes:

Set to the condition codes from the stack.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1
0	1	0	0	1	1	1	0	0	1	1	1	0	1	1

Syntax: RTS

Attributes: Unsized

Description: Pulls the program counter value from the stack. The previous program counter value is lost.

Condition Codes:

Not affected.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2
0	1	0	0	1	1	1	0	0	1	1	1	0	1

Syntax: SBCD – (Ax), – (Ay)

Attributes: Size = (Byte)

Description: Subtracts the source operand and the extend bit from the destination and stores the result in the destination location. The subtraction is performed using binary-coded decimal arithmetic; the operands are packed binary-coded decimal numbers. The instruction has two modes:

1. Data register to data register—the data registers specified in the instruction contain the operands.
2. Memory to memory—the address registers specified in the instruction contain the operands from memory using the predecrement addressing mode.

This operation is a byte operation only.

Condition Codes:

X	N	Z	V	C
*	U	*	U	*

X — Set the same as the carry bit.

N — Undefined.

Z — Cleared if the result is nonzero; unchanged otherwise.

V — Undefined.

C — Set if a borrow (decimal) is generated; cleared otherwise.

NOTE

Normally the Z condition code bit is set via programming before the start of an operation. This allows successful tests for zero results upon completion of multiple-precision operations.

1	0	0	0	REGISTER Dy/Ay	1	0	0	0	0	R/M	REGIST
---	---	---	---	----------------	---	---	---	---	---	-----	--------

Instruction Fields:

Register Dy/Ay field—Specifies the destination register.

If R/M = 0, specifies a data register.

If R/M = 1, specifies an address register for the predecrement addressing

R/M field—Specifies the operand addressing mode.

0 — The operation is data register to data register.

1 — The operation is memory to memory.

Register Dx/Ax field—Specifies the source register.

If R/M = 0, specifies a data register.

If R/M = 1, specifies an address register for the predecrement addressing

Assembler**Syntax:** Scc < ea >**Attributes:** Size = (Byte)

Description: Tests the specified condition code; if the condition is true, sets the status flag specified by the effective address to TRUE (all ones). Otherwise, sets that flag to FALSE (all zeros). Condition code cc specifies one of the following conditions (refer to Table 3-19 for more information on these conditional tests):

Mnemonic	Condition	Mnemonic	Condition
CC(HI)	Carry Clear	LS	Low or Same
CS(LO)	Carry Set	LT	Less Than
EQ	Equal	MI	Minus
F	False	NE	Not Equal
GE	Greater or Equal	PL	Plus
GT	Greater Than	T	True
HI	High	VC	Overflow Clear
LE	Less or Equal	VS	Overflow Set

Condition Codes:

Not affected.

0	1	0	1	CONDITION	1	1	EFFECTIVE ADDRESS MODE	REG
---	---	---	---	-----------	---	---	---------------------------	-----

Instruction Fields:

Condition field—The binary code for one of the conditions listed in the table.

Effective Address field—Specifies the location in which the TRUE/FALSE byte is stored. Only data alterable addressing modes can be used as listed in the following tables:

Addressing Mode	Mode	Register
Dn	000	reg. number:Dn
An	—	—
(An)	010	reg. number:An
(An) +	011	reg. number:An
– (An)	100	reg. number:An
(d ₁₆ ,An)	101	reg. number:An
(d ₈ ,An,Xn)	110	reg. number:An

Addressing Mode	Mode	REG
(xxx).W	111	
(xxx).L	111	
#<data>	—	
(d ₁₆ ,PC)	—	
(d ₈ ,PC,Xn)	—	

MC68020, MC68030, and MC68040 only

(bd,An,Xn)*	110	reg. number:An
([bd,An,Xn],od)	110	reg. number:An
([bd,An],Xn,od)	110	reg. number:An

(bd,PC,Xn)*	—	
([bd,PC,Xn],od)	—	
([bd,PC],Xn,od)	—	

*Can be used with CPU32.

NOTE

A subsequent NEG.B instruction with the same effective address can be used to change the Scc result from TRUE or FALSE to the equivalent arithmetic value (TRUE = 1, FALSE = 0). In the MC68000 and MC68008, a memory destination is read before it is written.

Syntax: SUB Dn, < ea >

Attributes: Size = (Byte, Word, Long)

Description: Subtracts the source operand from the destination operand and stores the result in the destination. The size of the operation is specified as byte, word, or long. The mode of the instruction indicates which operand is the source, which is the destination, and which is the operand size.

Condition Codes:

X	N	Z	V	C
*	*	*	*	*

- X — Set to the value of the carry bit.
- N — Set if the result is negative; cleared otherwise.
- Z — Set if the result is zero; cleared otherwise.
- V — Set if an overflow is generated; cleared otherwise.
- C — Set if a borrow is generated; cleared otherwise.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1
1	0	0	1	REGISTER			OPMODE			EFFECTIVE ADDRESS				
											MODE			REGI

Opmode field

Byte	Word	Long	Operation
000	001	010	$D_n - \langle ea \rangle \rightarrow D_n$
100	101	110	$\langle ea \rangle - D_n \rightarrow \langle ea \rangle$

Effective Address field—Determines the addressing mode. If the location specifies a source operand, all addressing modes can be used as listed in the tables:

Addressing Mode	Mode	Register	Addressing Mode	Mode	Register
D_n	000	reg. number: D_n	$(xxx).W$	111	
A_n^*	001	reg. number: A_n	$(xxx).L$	111	
(A_n)	010	reg. number: A_n	$\# \langle data \rangle$	111	
$(A_n) +$	011	reg. number: A_n			
$-(A_n)$	100	reg. number: A_n			
(d_{16}, A_n)	101	reg. number: A_n	(d_{16}, PC)	111	
(d_8, A_n, X_n)	110	reg. number: A_n	(d_8, PC, X_n)	111	

MC68020, MC68030, and MC68040 only

$(bd, A_n, X_n)^{**}$	110	reg. number: A_n	$(bd, PC, X_n)^{**}$	111	
$([bd, A_n, X_n], od)$	110	reg. number: A_n	$([bd, PC, X_n], od)$	111	
$([bd, A_n], X_n, od)$	110	reg. number: A_n	$([bd, PC], X_n, od)$	111	

*For byte-sized operation, address register direct is not allowed.

**Can be used with CPU32.

Addressing Mode	Mode	Register

(bd,PC,Xn)*	—	.
([bd,PC,Xn],od)	—	.
([bd,PC],Xn,od)	—	.

*Can be used with CPU32.

NOTE

If the destination is a data register, it must be specified as a destination Dn address, not as a destination < ea > address.

Most assemblers use SUBA when the destination is an address register and SUBI or SUBQ when the source is immediate data.

Syntax: SUBA < ea > ,An

Attributes: Size = (Word, Long)

Description: Subtracts the source operand from the destination address register and places the result in the address register. The size of the operation is specified as word or long. Word-sized source operands are sign-extended to 32-bit quantities prior to subtraction.

Condition Codes:

Not affected.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2
1	0	0	1	REGISTER			OPMODE			EFFECTIVE ADDRESS MODE REG			

Instruction Fields:

Register field—Specifies the destination, any of the eight address registers.

Opmode field—Specifies the size of the operation.

011—Word operation. The source operand is sign-extended to a long operand. If the operation is performed on the address register using all 32 bits.

111—Long operation.

Addressing Mode	Mode	Register
Dn	000	reg. number:Dn
An	001	reg. number:An
(An)	010	reg. number:An
(An) +	011	reg. number:An
– (An)	100	reg. number:An
(d ₁₆ ,An)	101	reg. number:An
(d ₈ ,An,Xn)	110	reg. number:An

Addressing Mode	Mode	Reg
(xxx).W	111	C
(xxx).L	111	C
#<data>	111	1
(d ₁₆ ,PC)	111	C
(d ₈ ,PC,Xn)	111	C

MC68020, MC68030, and MC68040 only

(bd,An,Xn)*	110	reg. number:An
([bd,An,Xn],od)	110	reg. number:An
([bd,An],Xn,od)	110	reg. number:An

(bd,PC,Xn)*	111	C
([bd,PC,Xn],od)	111	C
([bd,PC],Xn,od)	111	C

*Can be used with CPU32.

Syntax: SUBI # < data > , < ea >

Attributes: Size = (Byte, Word, Long)

Description: Subtracts the immediate data from the destination operand and result in the destination location. The size of the operation is specified as byte or long. The size of the immediate data matches the operation size.

Condition Codes:

X	N	Z	V	C
*	*	*	*	*

- X — Set to the value of the carry bit.
- N — Set if the result is negative; cleared otherwise.
- Z — Set if the result is zero; cleared otherwise.
- V — Set if an overflow occurs; cleared otherwise.
- C — Set if a borrow occurs; cleared otherwise.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2
0	0	0	0	0	1	0	0	SIZE		EFFECTIVE ADDRESS			
										MODE		REG	
16-BIT WORD DATA								8-BIT BYTE DATA					
32-BIT LONG DATA													

- 00 — Byte operation
- 01 — Word operation
- 10 — Long operation

Effective Address field—Specifies the destination operand. Only data addressing modes can be used as listed in the following tables:

Addressing Mode	Mode	Register
Dn	000	reg. number:Dn
An	—	—
(An)	010	reg. number:An
(An) +	011	reg. number:An
– (An)	100	reg. number:An
(d ₁₆ ,An)	101	reg. number:An
(d ₈ ,An,Xn)	110	reg. number:An

Addressing Mode	Mode	Reg
(xxx).W	111	0
(xxx).L	111	0
#<data>	—	—

MC68020, MC68030, and MC68040 only

(bd,An,Xn)*	110	reg. number:An
([bd,An,Xn],od)	110	reg. number:An
([bd,An],Xn,od)	110	reg. number:An

(bd,PC,Xn)*	—	—
([bd,PC,Xn],od)	—	—
([bd,PC],Xn,od)	—	—

*Can be used with CPU32.

Immediate field—Data immediately following the instruction.

If size = 00, the data is the low-order byte of the immediate word.

If size = 01, the data is the entire immediate word.

If size = 10, the data is the next two immediate words.

Syntax: SUBQ # < data > , < ea >

Attributes: Size = (Byte, Word, Long)

Description: Subtracts the immediate data (1 – 8) from the destination operand. The operation size of the operation is specified as byte, word, or long. Only word and long operations can be used with address registers, and the condition codes are not affected. When subtracting from address registers, the entire destination address register is updated despite the operation size.

Condition Codes:

X	N	Z	V	C
*	*	*	*	*

- X — Set to the value of the carry bit.
- N — Set if the result is negative; cleared otherwise.
- Z — Set if the result is zero; cleared otherwise.
- V — Set if an overflow occurs; cleared otherwise.
- C — Set if a borrow occurs; cleared otherwise.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2
0	1	0	1	DATA			1	SIZE		EFFECTIVE ADDRESS			
											MODE		REG

and zero represents eight.

Size field—Specifies the size of the operation.

- 00 — Byte operation
- 01 — Word operation
- 10 — Long operation

Effective Address field—Specifies the destination location. Only alterable addressing modes can be used as listed in the following tables:

Addressing Mode	Mode	Register
Dn	000	reg. number:Dn
An*	001	reg. number:An
(An)	010	reg. number:An
(An) +	011	reg. number:An
– (An)	100	reg. number:An
(d ₁₆ ,An)	101	reg. number:An
(d ₈ ,An,Xn)	110	reg. number:An

MC68020, MC68030, and MC68040 only

(bd,An,Xn)**	110	reg. number:An
([bd,An,Xn],od)	110	reg. number:An
([bd,An],Xn,od)	110	reg. number:An

(bd,PC,Xn)**	—	—
([bd,PC,Xn],od)	—	—
([bd,PC],Xn,od)	—	—

*Word and long only.

**Can be used with CPU32.

Syntax: SUBX – (Ax), – (Ay)

Attributes: Size = (Byte, Word, Long)

Description: Subtracts the source operand and the extend bit from the destination and stores the result in the destination

location. The instruction has two modes:

1. Data register to data register—the data registers specified in the instruction contain the operands.
2. Memory to memory—the address registers specified in the instruction contain the operands from memory using the predecrement addressing mode.

The size of the operand is specified as byte, word, or long.

Condition Codes:

X	N	Z	V	C
*	*	*	*	*

X — Set to the value of the carry bit.

N — Set if the result is negative; cleared otherwise.

Z — Cleared if the result is nonzero; unchanged otherwise.

V — Set if an overflow occurs; cleared otherwise.

C — Set if a borrow occurs; cleared otherwise.

NOTE

Normally the Z condition code bit is set via programming before the start of an operation. This allows successful tests for zero results upon completion of multiple-precision operations.

1	0	0	1	REGISTER Dy/Ay	1	SIZE	0	0	R/M	REGISTE
---	---	---	---	----------------	---	------	---	---	-----	---------

Instruction Fields:

Register Dy/Ay field—Specifies the destination register.

If R/M = 0, specifies a data register.

If R/M = 1, specifies an address register for the predecrement addressing mode.

Size field—Specifies the size of the operation.

00 — Byte operation

01 — Word operation

10 — Long operation

R/M field—Specifies the operand addressing mode.

0 — The operation is data register to data register.

1 — The operation is memory to memory.

Register Dx/Ax field—Specifies the source register:

If R/M = 0, specifies a data register.

If R/M = 1, specifies an address register for the predecrement addressing mode.

Syntax: SWAP Dn

Attributes: Size = (Word)

Description: Exchange the 16-bit words (halves) of a data register.

Condition Codes:

X	N	Z	V	C
—	*	*	0	0

X — Not affected.

N — Set if the most significant bit of the 32-bit result is set; cleared otherwise.

Z — Set if the 32-bit result is zero; cleared otherwise.

V — Always cleared.

C — Always cleared.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	
0	1	0	0	1	0	0	0	0	1	0	0	0		REG

Instruction Field:

Register field—Specifies the data register to swap.

Syntax: TAS < ea >

Attributes: Size = (Byte)

Description: Tests and sets the byte operand addressed by the effective address of the instruction. The instruction tests the current value of the operand and sets the N and Z condition codes appropriately. TAS also sets the high-order bit of the operand. The operation is used in a locked or read-modify-write transfer sequence. This instruction supports use with a semaphore to coordinate several processors.

Condition Codes:

X	N	Z	V	C
—	*	*	0	0

X — Not affected.

N — Set if the most significant bit of the operand is currently set; cleared otherwise.

Z — Set if the operand was zero; cleared otherwise.

V — Always cleared.

C — Always cleared.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1
0	1	0	0	1	0	1	0	1	1	EFFECTIVE ADDRESS				
										MODE		REGISTER		

alterable addressing modes can be used as listed in the following table:

Addressing Mode	Mode	Register
Dn	000	reg. number:Dn
An	—	—
(An)	010	reg. number:An
(An) +	011	reg. number:An
– (An)	100	reg. number:An
(d ₁₆ ,An)	101	reg. number:An
(d ₈ ,An,Xn)	110	reg. number:An

Addressing Mode	Mode	Register
(xxx).W	111	
(xxx).L	111	
#<data>	—	
(d ₁₆ ,PC)	—	
(d ₈ ,PC,Xn)	—	

MC68020, MC68030, and MC68040 only

(bd,An,Xn)*	110	reg. number:An
([bd,An,Xn],od)	110	reg. number:An
([bd,An],Xn,od)	110	reg. number:An

(bd,PC,Xn)*	—	
([bd,PC,Xn],od)	—	
([bd,PC],Xn,od)	—	

*Can be used with CPU32.

SR → (SSP); Vector Address → PC

*The MC68000 and MC68008 do not write vector offset or format code to the system stack.

Assembler

Syntax: TRAP # < vector >

Attributes: Unsized

Description: Causes a TRAP # < vector > exception. The instruction adds the immediate operand (vector) of the instruction to 32 to obtain the vector number. The valid vector values is 0 – 15, which provides 16 vectors.

Condition Codes:

Not affected.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1
0	1	0	0	1	1	1	0	0	1	0	0			VECTOR

Instruction Fields:

Vector field—Specifies the trap vector to be taken.

Assembler TRAPcc
Syntax: TRAPcc.W # < data >
 TRAPcc.L # < data >

Attributes: Unsized or Size = (Word, Long)

Description: If the specified condition is true, causes a TRAPcc exception with number 7. The processor pushes the address of the next instruction word (current program counter) onto the stack. If the condition is not true, the processor performs no operation, and execution continues with the next instruction. The immediate operand should be placed in the next word(s) following the operation word available to the trap handler. Condition code cc specifies one of the conditional tests (refer to Table 3-19 for more information on these conditions).

Mnemonic	Condition	Mnemonic	Condition
CC(HI)	Carry Clear	LS	Low or Same
CS(LO)	Carry Set	LT	Less Than
EQ	Equal	MI	Minus
F	False	NE	Not Equal
GE	Greater or Equal	PL	Plus
GT	Greater Than	T	True
HI	High	VC	Overflow Clear
LE	Less or Equal	VS	Overflow Set

Condition Codes:

Not affected.

0	1	0	1	CONDITION	1	1	1	1	1	OPM
OPTIONAL WORD										
OR LONG WORD										

Instruction Fields:

Condition field—The binary code for one of the conditions listed in the table.

Opmode field—Selects the instruction form.

010—Instruction is followed by word-sized operand.

011—Instruction is followed by long-word-sized operand.

100—Instruction has no operand.

Assembler**Syntax:** TRAPV**Attributes:** Unsized

Description: If the overflow condition is set, causes a TRAPV exception with number 7. If the overflow condition is not set, the processor performs no operation and execution continues with the next instruction.

Condition Codes:

Not affected.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2
0	1	0	0	1	1	1	0	0	1	1	1	0	1

Syntax: TST < ea >

Attributes: Size = (Byte, Word, Long)

Description: Compares the operand with zero and sets the condition codes according to the results of the test. The size of the operation is specified as byte, word, or long.

Condition Codes:

X	N	Z	V	C
—	*	*	0	0

X — Not affected.

N — Set if the operand is negative; cleared otherwise.

Z — Set if the operand is zero; cleared otherwise.

V — Always cleared.

C — Always cleared.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1
0	1	0	0	1	0	1	0	SIZE		EFFECTIVE ADDRESS MODE			REGIS	

- 00 — Byte operation
- 01 — Word operation
- 10 — Long operation

Effective Address field—Specifies the addressing mode for the destination of the instruction listed in the following tables:

Addressing Mode	Mode	Register
Dn	000	reg. number:Dn
An*	001	reg. number:An
(An)	010	reg. number:An
(An) +	011	reg. number:An
– (An)	100	reg. number:An
(d ₁₆ ,An)	101	reg. number:An
(d ₈ ,An,Xn)	110	reg. number:An

Addressing Mode	Mode	Register
(xxx).W	111	
(xxx).L	111	
#<data>*	111	
(d ₁₆ ,PC)**	111	
(d ₈ ,PC,Xn)**	111	

MC68020, MC68030, and MC68040 only

(bd,An,Xn)***	110	reg. number:An
([bd,An,Xn],od)	110	reg. number:An
([bd,An],Xn,od)	110	reg. number:An

(bd,PC,Xn)***	111	
([bd,PC,Xn],od)	111	
([bd,PC],Xn,od)	111	

*MC68020, MC68030, MC68040, and CPU32. Address register direct allowed only for word and long.

**PC relative addressing modes do not apply to MC68000, MC680008, or MC68010.

***Can be used with CPU32.

Syntax: UNLK An

Attributes: Unsized

Description: Loads the stack pointer from the specified address register, then loads the address register with the long word pulled from the top of the stack.

Condition Codes:

Not affected.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1
0	1	0	0	1	1	1	0	0	1	0	1	1		REGIS

Instruction Field:

Register field—Specifies the address register for the instruction.

Syntax: UNPK Dx,Dy,# < adjustment >

Attributes: Unsized

Description: Places the two binary-coded decimal digits in the source operand by the lower four bits of two bytes and places zero bits in the upper four bits of both bytes. Adds the adjustment value to this unpacked value. Condition codes are not affected.

When both operands are data registers, the instruction unpacks the source operand, adds the extension word, and places the result in the destination register. The high word of the destination register is unaffected.

1	0	0	0	REGISTER Dy/Ay			1	1	0	0	0	R/M	REGISTE	
16-BIT EXTENSION: ADJUSTMENT														

If R/M = 0, specifies a data register.

If R/M = 1, specifies an address register in the predecrement addressing mode.

R/M field—Specifies the operand addressing mode.

0 — The operation is data register to data register.

1 — The operation is memory to memory.

Register Dx/Ax field—Specifies the data register.

If R/M = 0, specifies a data register.

If R/M = 1, specifies an address register in the predecrement addressing mode.

Adjustment field—Immediate data word that is added to the source operand.

Appropriate constants can be used as the adjustment to translate from binary-coded decimal to the desired code. The constant used for ASCII is \$0F0F, for EBCDIC, \$F0F0.

SECTION 5 FLOATING POINT INSTRUCTIONS

This section contains information about the floating-point instructions for the MC68881, MC68882, and MC68040. In this section, all references to the MC68040 do not include the MC68LC040 and MC68EC040. Each instruction is described in detail, and the instructions descriptions are arranged in alphabetical order by instruction mnemonic.

All floating-point instructions apply to the MC68881 and MC68882 processors. The MC68040 directly supports part of the floating-point instructions through hardware, and indirectly supports the remainder by providing special traps and/or stack frame adjustments for unimplemented instructions and data types. The following identification is noted for each instruction title for the MC68040:

Directly Supported—(MC6888X, MC68040)

Software Supported—(MC6888X, MC68040FPSW)

For all MC68040 floating-point instructions, the coprocessor ID field must be 001.

Table 5-1 lists the floating-point instructions directly supported by the MC68040, and Table 5-2 lists the floating-point instructions indirectly supported.

FDBcc	Floating-Point Branch Conditionally
FCMP	Floating-Point Compare
FDBcc	Floating-Point Test Condition, Decrement, and Branch
FDIV	Floating-Point Divide
FMOVE	Move Floating-Point Data Register
FMOVE	Move Floating-Point System Control Register
FMOVEM	Move Multiple Floating-Point System Data Register
FMOVEM	Move Multiple Floating-Point Control Data Register
FMUL	Floating-Point Multiply
FNEG	Floating-Point Negate
FNOP	No Operation
FRESTORE*	Restore Internal Floating-Point State*
FSAVE*	Save Internal Floating-Point State*
FSc	Set According to Floating-Point Condition
FSORT	Floating-Point Square Root
FSUB	Floating-Point Subtract
FSGLDIV	Floating-Point Single-Precision Divide
FSFLMUL	Floating-Point Single-Precision Multiply
FTRAPcc	Trap on Floating-Point Condition
FTST	Test Floating-Point Operand

*These are privileged instructions; refer to **Section 6 Supervisor (Privileged) Instructions** for detailed information.

FATANH	Floating-Point Hyperbolic Arc Tangent
FCOS	Floating-Point Cosine
FCOSH	Floating-Point Hyperbolic Cosine
FETOX	Floating-Point e^x
FETOXM1	Floating-Point $e^x - 1$
FGETEXP	Floating-Point Get Exponent
FGETMAN	Floating-Point Get Mantissa
FINT	Floating-Point Integer Part
FINTRZ	Floating-Point Integer Part, Round-to- Zero
FLOG10	Floating-Point Log ₁₀
FLOG2	Floating-Point Log ₂
FLOGN	Floating-Point Log _e
FLOGNP1	Floating-Point Log _e ^(x + 1)
FMOD	Floating-Point Modulo Remainder
FMOVECR	Floating-Point Move Constant ROM
FREM	Floating-Point IEEE Remainder
FSCALE	Floating-Point Scale Exponent
FSIN	Floating-Point Sine
FSINCOS	Floating-Point Simultaneous Sine and Cosine
FSINH	Floating-Point Hyperbolic Sine
FTAN	Floating-Point Tangent
FTANH	Floating-Point Hyperbolic Tangent
FTENTOX	Floating-Point 10^x
FTWOTOX	Floating-Point 2^x

Syntax:

FABS. < fmt > < ea > ,FPn
 FABS.X FPm,FPn
 FABS.X FPn
 *FrABS. < fmt > < ea > ,FPn
 *FrABS.X FPm,FPn
 *FrABS.X Pn

where r is rounding precision, S or D

*Supported by MC68040 only.

Attributes:

Format = (Byte, Word, Long, Single, Quad, Extended, Packed)

Description: Converts the source operand to extended precision (if necessary) and stores the absolute value of that number in the destination floating-point data register.

FABS will round the result to the precision selected in the floating-point control register. FSABS and FDABS will round the result to single or double precision, respectively, regardless of the rounding precision selected in the floating-point control register.

Operation Table:

DESTINATION	SOURCE		
	+ In Range	- + Zero	- + Infinity
Result	Absolute Value	Absolute Value	Absolute Value

NOTE: If the source operand is a NAN, refer to **1.6.5 Not-A-Numbers** for more information

Quotient Byte:	Not affected.
Exception Byte:	BSUN Cleared
	SNAN Refer to 1.6.5 Not-A-Numbers
	OPERR Cleared
	OVFL Cleared
	UNFL If the source is an extended-denormalized number, refer to processing in the appropriate user's manual; cleared otherwise.
	DZ Cleared
	INEX2 Cleared
INEX1 If < fmt > is packed, refer to processing in the appropriate user's manual; cleared otherwise.	
Accrued Exception Byte:	Affected as described in exception processing; refer to appropriate user's manual.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2
1	1	1	1	COPROCESSOR ID		0	0	0	EFFECTIVE ADDRESS MODE		REG		
0	R/M	0	SOURCE SPECIFIER		DESTINATION REGISTER		OPMODE						

If R/M = 0, this field is unused and should be all zeros.
 If R/M = 1, this field specifies the location of the source operand. Only data addressing modes can be used as listed in the following table:

Addressing Mode	Mode	Register
Dn	000	reg. number:Dn
An	—	—
(An)	010	reg. number:An
(An) +	011	reg. number:An
– (An)	100	reg. number:An
(d ₁₆ ,An)	101	reg. number:An
(d ₈ ,An,Xn)	110	reg. number:An
(bd,An,Xn)	110	reg. number:An
([bd,An,Xn],od)	110	reg. number:An
([bd,An],Xn,od)	110	reg. number:An

Addressing Mode	Mode
(xxx).W	111
(xxx).L	111
# < data >	111
(d ₁₆ ,PC)	111
(d ₈ ,PC,Xn)	111
(bd,PC,Xn)	111
([bd,PC,Xn],od)	111
([bd,PC],Xn,od)	111

*Only if < fmt > is byte, word, long, or single.

R/M field—Specifies the source operand address mode.

- 0 — The operation is register to register.
- 1 — The operation is < ea > to register.

- 000 — Long-Word Integer (L)
- 001 — Single-Precision Real (S)
- 010 — Extended-Precision Real (X)
- 011 — Packed-Decimal Real (P)*
- 100 — Word Integer (W)
- 101 — Double-Precision Real (D)
- 110 — Byte Integer (B)

*This encoding will cause an unimplemented data type exception in the MC68040 to allow emulation in software.

Destination Register field—Specifies the destination floating- point data register.

Opmode field—Specifies the instruction and rounding precision.

0011000	FABS	Rounding precision specified by the floating-point control register.
1011000	FSABS	Single-precision rounding specified.
1011100	FDABS	Double-precision rounding specified.

1	1	1	1	COPROCESSOR ID			0	0	0	EFFECTIVE ADDRESS MODE			REG
0	R/M	0	SOURCE SPECIFIER			DESTINATION REGISTER			0	0	1	1	1

Instruction Fields:

Coprocessor ID field—Specifies which coprocessor in the system is to execute the instruction. Motorola assemblers default to ID = 1 for the floating-point coprocessor.

Effective Address field—Determines the addressing mode for external operations.
 If R/M = 0, this field is unused and should be all zeros.
 If R/M = 1, this field is encoded with an M68000 family addressing mode as shown in the following table:

Addressing Mode	Mode	Register
Dn*	000	reg. number:Dn
An	—	—
(An)	010	reg. number:An
(An) +	011	reg. number:An
– (An)	100	reg. number:An
(d ₁₆ ,An)	101	reg. number:An
(d ₈ ,An,Xn)	110	reg. number:An
(bd,An,Xn)	110	reg. number:An
([bd,An,Xn],od)	110	reg. number:An
([bd,An],Xn,od)	110	reg. number:An

Addressing Mode	Mode
(xxx).W	111
(xxx).L	111
# < data >	111
(d ₁₆ ,PC)	111
(d ₈ ,PC,Xn)	111
(bd,PC,Xn)	111
([bd,PC,Xn],od)	111
([bd,PC],Xn,od)	111

*Only if < fmt > is byte, word, long, or single.

R/M field—Specifies the source operand address mode.

0 — The operation is register to register.

1 — The operation is < ea > to register.

If R/M = 1, specifies the source data format:

- 000 — Long-Word Integer (L)
- 001 — Single-Precision Real (S)
- 010 — Extended-Precision Real (X)
- 011 — Packed-Decimal Real (P)
- 100 — Word Integer (W)
- 101 — Double-Precision Real (D)
- 110 — Byte Integer (B)

Destination Register field—Specifies the destination floating-point data register. If M = 0 and the source and destination fields are equal, then the input operand is taken from the specified floating-point data register, and the result is then stored into the same register. If the single register syntax is used, Motorola assigns and sets the source and destination fields to the same value.

Syntax: FADD.X FPm,FPn
 *FrADD. < fmt > < ea > ,FPn
 *FrADD.X FPm,FPn
 where r is rounding precision, S or D
 *Supported by MC68040 only.

Attributes: Format = (Byte, Word, Long, Single, Double, Extended, Pack

Description: Converts the source operand to extended precision (if necessary) that number to the number contained in the destination floating-point data register. Stores the result in the destination floating-point data register.

FADD will round the result to the precision selected in the floating-point control register. FSADD and FDADD will round the result to single or double-precision, respectively, regardless of the rounding precision selected in the floating-point control register.

Operation Table:

DESTINATION	SOURCE ¹			
		In Range	Zero	Infinity
In Range	+	Add	Add	+ inf
	-	Add	Add	+ inf
Zero	+	Add	+ 0.0	0.0 ²
	-	Add	0.0 ²	- 0.0
Infinity	+	+ inf	+ inf	+ inf
	-	- inf	- inf	NAN [‡]

1. If either operand is a NAN, refer to **1.6.5 Not-A-Numbers** for more information.
2. Returns + 0.0 in rounding modes RN, RZ, and RP; returns - 0.0 in RM.
3. Sets the OPERR bit in the floating-point status register exception byte.

Quotient Byte:	Not affected.
Exception Byte:	BSUN Cleared
	SNAN Refer to 1.6.5 Not-A-Numbers.
	OPERR Set if the source and the destination are opposite-signed infinities; cleared otherwise.
	OVFL Refer to exception processing in the appropriate user's manual.
	UNFL Refer to exception processing in the appropriate user's manual.
	DZ Cleared
	INEX2 Refer to exception processing in the appropriate user's manual.
	INEX1 If < fmt > is packed, refer to exception processing in the appropriate user's manual; cleared otherwise.

Accrued Exception Byte: Affected as described in exception processing in the appropriate user's manual.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1
1	1	1	1	COPROCESSOR ID			0	0	0	EFFECTIVE ADDRESS MODE			REGISTER	
0	R/M	0	SOURCE SPECIFIER			DESTINATION REGISTER			OPMODE					

Instruction Fields:

Effective Address field—Determines the addressing mode for external operands.
If R/M = 0, this field is unused and should be all zeros.

Addressing Mode	Mode	Register
Dn	000	reg. number:Dn
An	—	—
(An)	010	reg. number:An
(An) +	011	reg. number:An
– (An)	100	reg. number:An
(d ₁₆ ,An)	101	reg. number:An
(d ₈ ,An,Xn)	110	reg. number:An
(bd,An,Xn)	110	reg. number:An
([bd,An,Xn],od)	110	reg. number:An
([bd,An],Xn,od)	110	reg. number:An

Addressing Mode	Mode
(xxx).W	111
(xxx).L	111
# < data >	111
(d ₁₆ ,PC)	111
(d ₈ ,PC,Xn)	111
(bd,PC,Xn)	111
([bd,PC,Xn],od)	111
([bd,PC],Xn,od)	111

*Only if < fmt > is byte, word, long, or single.

R/M field—Specifies the source operand address mode.

- 0 — The operation is register to register.
- 1 — The operation is < ea > to register.

Source Specifier field—Specifies the source register or data format.

If R/M = 0, specifies the source floating-point data register.

If R/M = 1, specifies the source data format:

- 000 — Long-Word Integer (L)
- 001 — Single-Precision Real (S)
- 010 — Extended-Precision Real (X)
- 011 — Packed-Decimal Real (P)*
- 100 — Word Integer (W)
- 101 — Double-Precision Real (D)
- 110 — Byte Integer (B)

*This encoding will cause an unimplemented data type exception to allow emulation in software.

Destination Register field—Specifies the destination floating-point data register.

Opmode field—Specifies the instruction and rounding precision.

- 0100010 FADD Rounding precision specified by the floating-point control register.
- 1100010 FSADD Single-precision rounding specified.
- 1100110 FDADD Double-precision rounding specified.

Syntax: FASIN.X FPM,FPn
 FASIN.X FPn

Attributes: Format = (Byte, Word, Long, Single, Double, Extended, Packed)

Description: Converts the source operand to extended precision (if necessary) and calculates the arc sine of the number. Stores the result in the destination floating-point data register. This function is not defined for source operands outside of the range $[-1... + 1]$; if the source is not in the correct range, a NAN is returned as the result and the OPERR bit is set in the floating-point status register. If the source is in the correct range, the result is in the range of $[-\pi/2... + \pi/2]$.

Operation Table:

DESTINATION	SOURCE ¹								
	+	In Range	-	+	Zero	-	+	Infinity	
Result		Arc Sine		+	0.0		-	0.0	NAN ²

NOTES:

1. If the source operand is a NAN, refer to **1.6.5 Not-A-Numbers** for more information.
2. Sets the OPERR bit in the floating-point status register exception byte.

Quotient Byte:	Not affected.
Exception Byte:	BSUN Cleared
	SNAN Refer to 1.6.5 Not-A-Numbers .
	OPERR Set if the source is infinity, > + 1 cleared otherwise
	OVFL Cleared
	UNFL Can be set for an underflow condition
	DZ Cleared
	INEX2 Refer to inexact result in the appropriate user's manual.
	INEX1 If < fmt > is packed, refer to inexact result in the appropriate user's manual; cleared otherwise.
Accrued Exception Byte:	Affected as described in IEEE exception and trap handling capability in the appropriate user's manual.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2
1	1	1	1	COPROCESSOR ID			0	0	0	EFFECTIVE ADDRESS			
										MODE		REG	
0	R/M	0	SOURCE SPECIFIER			DESTINATION REGISTER			0	0	0	1	1

Instruction Fields:

Coprocessor ID field—Specifies which coprocessor in the system is to execute the instruction. Motorola assemblers default to ID = 1 for the floating-point coprocessor.

If R/M = 1, this field is encoded with an M68000 family addressing mode as shown in the following table:

Addressing Mode	Mode	Register
Dn*	000	reg. number:Dn
An	—	—
(An)	010	reg. number:An
(An) +	011	reg. number:An
– (An)	100	reg. number:An
(d ₁₆ ,An)	101	reg. number:An
(d ₈ ,An,Xn)	110	reg. number:An
(bd,An,Xn)	110	reg. number:An
([bd,An,Xn],od)	110	reg. number:An
([bd,An],Xn,od)	110	reg. number:An

Addressing Mode	Mode
(xxx).W	111
(xxx).L	111
# < data >	111
(d ₁₆ ,PC)	111
(d ₈ ,PC,Xn)	111
(bd,PC,Xn)	111
([bd,PC,Xn],od)	111
([bd,PC],Xn,od)	111

*Only if < fmt > is byte, word, long, or single.

R/M field—Specifies the source operand address mode.

- 0 — The operation is register to register.
- 1 — The operation is < ea > to register.

Source Specifier field—Specifies the source register or data format.

If R/M = 0, specifies the source floating-point data register.

If R/M = 1, specifies the source data format:

- 000 — Long-Word Integer (L)
- 001 — Single-Precision Real (S)
- 010 — Extended-Precision Real (X)
- 011 — Packed-Decimal Real (P)
- 100 — Word Integer (W)
- 101 — Double-Precision Real (D)
- 110 — Byte Integer (B)

Destination Register field—Specifies the destination floating-point data register.

If M = 0 and the source and destination fields are equal, then the input operand is taken from the specified floating-point data register, and the result is then stored into the same register. If the single register syntax is used, Motorola assumes that you set the source and destination fields to the same value.

Syntax: FATAN.X FPm,FPn
 FATAN.X FPm,FPnz

Attributes: Format = (Byte, Word, Long, Single, Double, Extended, Packed)

Description: Converts the source operand to extended precision (if necessary) and calculates the arc tangent of that number. Stores the result in the destination floating-point data register. The result is in the range of $[-\pi/2 \dots +\pi/2]$.

Operation Table:

DESTINATION	SOURCE				
	+ In Range	- + Zero	- + Infinity		
Result	Arc Tangent	+ 0.0	- 0.0	+ $\pi/2$	

NOTE: If the source operand is a NAN, refer to **1.6.5 Not-A-Numbers** for more information.

Floating-Point Status Register:

Condition Codes: Affected as described in **3.6.2 Conditional Test**

Quotient Byte: Not affected.

Exception Byte:

- BSUN Cleared
- SNAN Refer to **1.6.5 Not-A-Numbers**.
- OPERR Cleared
- OVFL Cleared
- UNFL Refer to underflow in the appropriate user's manual.
- DZ Cleared
- INEX2 Refer to inexact result in the appropriate user's manual.
- INEX1 If < fmt > is packed, refer to inexact result in the appropriate user's manual; cleared otherwise.

Accrued Exception Byte: Affected as described in IEEE exception and trap handling in the appropriate user's manual.

1	1	1	1	COPROCESSOR ID		0	0	0	EFFECTIVE ADDRESS MODE			REGIS
0	R/M	0	SOURCE SPECIFIER		DESTINATION REGISTER		0	0	0	1	1	0

Instruction Fields:

Coprocessor ID field—Specifies which coprocessor in the system is to execute the instruction. Motorola assemblers default to ID = 1 for the floating point coprocessor.

Effective Address field—Determines the addressing mode for external operands. If R/M = 0, this field is unused and should be all zeros. If R/M = 1, this field is encoded with an M68000 family addressing mode as shown in the following table:

Addressing Mode	Mode	Register
Dn*	000	reg. number:Dn
An	—	—
(An)	010	reg. number:An
(An) +	011	reg. number:An
– (An)	100	reg. number:An
(d ₁₆ ,An)	101	reg. number:An
(d ₈ ,An,Xn)	110	reg. number:An
(bd,An,Xn)	110	reg. number:An
([bd,An,Xn],od)	110	reg. number:An
([bd,An],Xn,od)	110	reg. number:An

Addressing Mode	Mode
(xxx).W	111
(xxx).L	111
# < data >	111
(d ₁₆ ,PC)	111
(d ₈ ,PC,Xn)	111
(bd,PC,Xn)	111
([bd,PC,Xn],od)	111
([bd,PC],Xn,od)	111

*Only if < fmt > is byte, word, long, or single.

R/M field—Specifies the source operand address mode.

0 — The operation is register to register.

1 — The operation is < ea > to register.

If R/M = 1, specifies the source data format:

- 000 — Long-Word Integer (L)
- 001 — Single-Precision Real (S)
- 010 — Extended-Precision Real (X)
- 011 — Packed-Decimal Real (P)
- 100 — Word Integer (W)
- 101 — Double-Precision Real (D)
- 110 — Byte Integer (B)

Destination Register field—Specifies the destination floating-point data register. If M = 0 and the source and destination fields are equal, then the input operand is taken from the specified floating-point data register, and the result is stored back into the same register. If the single register syntax is used, Motorola assembler will set the source and destination fields to the same value.

Syntax: FATANH.X FPM,FPn
 FATANH.X FPN

Attributes: Format = (Byte, Word, Long, Single, Double, Extended, Packed)

Description: Converts the source operand to extended precision (if necessary) and calculates the hyperbolic arc tangent of that value. Stores the result in the destination floating-point data register. This function is not defined for source operands outside of the range (- 1... + 1); and the result is equal to - infinity or + infinity if the source operand is equal to + 1 or - 1, respectively. If the source is outside of the range [- 1... + 1], the source is returned as the result, and the OPERR bit is set in the floating-point status register.

Operation Table:

DESTINATION	SOURCE ¹								
	+	In Range	-	+	Zero	-	+	Infinity	
Result		Hyperbolic Arc Tangent		+	0.0		-	0.0	NAN ²

NOTES:

1. If the source operand is a NAN, refer to **1.6.5 Not-A-Numbers** for more information.
2. Sets the OPERR bit in the floating-point status register exception byte.

Floating-Point Status Register:

Condition Codes: Affected as described in **3.6.2 Conditional Testing**

Quotient Byte: Not affected.

OPERR	Set if the source is $> + 1$ or $< - 1$ otherwise.
OVFL	Cleared
UNFL	Refer to underflow in the appropriate user's manual.
DZ	Set if the source is equal to $+ 1$ or $- 1$ otherwise.
INEX2	Refer to inexact result in the appropriate user's manual.
INEX1	If $\langle \text{fmt} \rangle$ is packed, refer to inexact decimal input in the appropriate user's manual; cleared otherwise.

Accrued Exception Byte: Affected as described in IEEE exception and trap handling capability in the appropriate user's manual.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2
1	1	1	1	COPROCESSOR ID			0	0	0	EFFECTIVE ADDRESS MODE			
0	R/M	0	SOURCE SPECIFIER			DESTINATION REGISTER			0	0	0	1	1

Instruction Fields:

Coprocessor ID field—Specifies which coprocessor in the system is to execute the instruction. Motorola assemblers default to ID = 1 for the floating-point coprocessor.

If R/M = 1, this field is encoded with an M68000 family addressing mode as the following table:

Addressing Mode	Mode	Register
Dn*	000	reg. number:Dn
An	—	—
(An)	010	reg. number:An
(An) +	011	reg. number:An
– (An)	100	reg. number:An
(d ₁₆ ,An)	101	reg. number:An
(d ₈ ,An,Xn)	110	reg. number:An
(bd,An,Xn)	110	reg. number:An
([bd,An,Xn],od)	110	reg. number:An
([bd,An],Xn,od)	110	reg. number:An

Addressing Mode	Mode
(xxx).W	111
(xxx).L	111
# < data >	111
(d ₁₆ ,PC)	111
(d ₈ ,PC,Xn)	111
(bd,PC,Xn)	111
([bd,PC,Xn],od)	111
([bd,PC],Xn,od)	111

*Only if < fmt > is byte, word, long, or single.

R/M field—Specifies the source operand address mode.

- 0 — The operation is register to register.
- 1 — The operation is < ea > to register.

Source Specifier field—Specifies the source register or data format.

If R/M = 0, specifies the source floating-point data register.

If R/M = 1, specifies the source data format:

- 000 — Long-Word Integer (L)
- 001 — Single-Precision Real (S)
- 010 — Extended-Precision Real (X)
- 011 — Packed-Decimal Real (P)
- 100 — Word Integer (W)
- 101 — Double-Precision Real (D)
- 110 — Byte Integer (B)

Destination Register field—Specifies the destination floating-point data register.

M = 0 and the source and destination fields are equal, then the input operand is taken from the specified floating-point data register, and the result is then stored into the same register. If the single register syntax is used, Motorola assumes that you set the source and destination fields to the same value.

Assembler:**Syntax:** FBcc. < size > , < label >**Attributes:** Size = (Word, Long)

Description: If the specified floating-point condition is met, program execution continues at the location (PC) + displacement. The displacement is a two's-complement integer that counts the relative distance in bytes. The value of the program counter when the instruction is fetched to calculate the destination address is the address of the branch instruction plus the displacement. If the displacement size is byte, then an 8-bit displacement is stored in the word immediately following the instruction operation word. If the displacement size is word, then a 16-bit displacement is stored in the two words immediately following the instruction operation word. If the displacement size is long, then a 32-bit displacement is stored in the four words immediately following the instruction operation word. The conditional specifier cc selects any one of the floating-point conditional tests as described in **3.6.2 Conditional Testing**.

Floating-Point Status Register:

Condition Codes:	Not affected.	
Quotient Byte:	Not affected.	
Exception Byte:	BSUN	Set if the NAN condition code is selected and the condition selected is an IEEE nonavailing condition.
	SNAN	Not Affected.
	OPERR	Not Affected.
	OVF	Not Affected.
	UNFL	Not Affected.
	DZ	Not Affected.
	INEX2	Not Affected.
	INEX1	Not Affected.
Accrued Exception Byte:	The IOP bit is set if the BSUN bit is set in the exception byte. No other bit is affected.	

1	1	1	1	COPROCESSOR ID	0	1	SIZE	CONDITIONAL PREDICAT
16-BIT DISPLACEMENT OR MOST SIGNIFICANT WORD OF 32-BITDISPLACEMENT								
LEAST SIGNIFICANT WORD OF 32-BIT DISPLACEMENT (IF NEEDED)								

Instruction Fields:

Size field—Specifies the size of the signed displacement.

If Format = 0, then the displacement is 16 bits and is sign- extended before

If Format = 1, then the displacement is 32 bits.

Conditional Predicate field—Specifies one of 32 conditional tests as defined

3-23 Floating-Point Conditional Tests.

NOTE

When a BSUN exception occurs, the main processor takes a preinstruction exception. If the exception handler returns without modifying the image of the program counter on the stack frame (to point to the instruction following the FBcc), then it must clear the cause of the exception (by clearing the NAN bit or disabling the BSUN trap), or the exception will occur again immediately upon return to the routine that caused the exception.

Syntax: FCMP.X FpM,FPn

Attributes: Format = (Byte, Word, Long, Single, Double, Extended, Pack

Description: Converts the source operand to extended precision (if necessary) and subtracts the operand from the destination floating-point data register. The result of the subtraction is not retained, but it is used to set the floating-point condition codes described in **3.6.2 Conditional Testing**.

Operation Table: The entries in this operation table differ from those of the tables describing most of the floating-point instructions. For each combination of operand types, the condition code bits that may be set are indicated. If the name of a condition code bit is given and is not enclosed in brackets, then it is always set by the operation. If the name of a condition code bit is enclosed in brackets, then that bit is either set or cleared, as appropriate. If the name of a condition code bit is not given, then it is always cleared by the operation. The infinity bit is always cleared by this instruction since it is not used by any of the conditional predicate equations. The NAN bit is not shown since NANs are always handled in the same manner as described in **1.6.5 Not-A-Numbers**).

DESTINATION	SOURCE							
	+	In Range	-	+	Zero	-	+	Infinity
In Range	+	{NZ}	none	none		none	N	
	-	N	{NZ}	N		N	N	
Zero	+	N	none	Z		Z	N	
	-	N	none	NZ		NZ	N	
Infinity	+	none	none	none		none	Z	
	-	N	N	N		N	N	

NOTE: If the source operand is a NAN, refer to **1.6.5 Not-A-Numbers** for more information.

Quotient Byte: Not affected.

Exception Byte:

BSUN	Cleared
SNAN	Refer to 1.6.5 Not-A-Numbers .
OPERR	Cleared
OVFL	Cleared
UNFL	Cleared
DZ	Cleared
INEX2	Cleared
INEX1	If < fmt > is packed, refer to exception processing in the appropriate user's manual; otherwise, cleared.

Accrued Exception Byte: Affected as described in exception processing in the appropriate user's manual.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1
1	1	1	1	COPROCESSOR ID			0	0	0	EFFECTIVE ADDRESS MODE			REGISTER	
0	R/M	0	SOURCE SPECIFIER			DESTINATION REGISTER			0	0	0	1	1	0

If R/M = 0, this field is unused and should be all zeros.
 If R/M = 1, specifies the location of the source operand location. Only data addressing modes can be used as listed in the following table:

Addressing Mode	Mode	Register
Dn*	000	reg. number:Dn
An	—	—
(An)	010	reg. number:An
(An) +	011	reg. number:An
– (An)	100	reg. number:An
(d ₁₆ ,An)	101	reg. number:An
(d ₈ ,An,Xn)	110	reg. number:An
(bd,An,Xn)	110	reg. number:An
([bd,An,Xn],od)	110	reg. number:An
([bd,An],Xn,od)	110	reg. number:An

Addressing Mode	Mode
(xxx).W	111
(xxx).L	111
# < data >	111
(d ₁₆ ,PC)	111
(d ₈ ,PC,Xn)	111
(bd,PC,Xn)	111
([bd,PC,Xn],od)	111
([bd,PC],Xn,od)	111

*Only if < fmt > is byte, word, long, or single.

R/M field—Specifies the source operand address mode.

- 0 — The operation is register to register.
- 1 — The operation is < ea > to register.

Source Specifier field—Specifies the source register or data format.

If R/M = 0, specifies the source floating-point data register.

If R/M = 1, specifies the source data format:

- 000 — Long-Word Integer (L)
- 001 — Single-Precision Real (S)
- 010 — Extended-Precision Real (X)
- 011 — Packed-Decimal Real (P)*
- 100 — Word Integer (W)
- 101 — Double-Precision Real (D)
- 110 — Byte Integer (B)

*This encoding in the MC68040 will cause an unimplemented data type exception to allow emulation in software.

Destination Register field—Specifies the destination floating- point data register.

Syntax: FCOS.X FpM,FPn FCOS.X FPn

Attributes: Format = (Byte, Word, Long, Single, Double, Extended, Packed)

Description: Converts the source operand to extended precision (if necessary) and calculates the cosine of that number. Stores the result in the destination floating-point data register. This function is not defined for source operands of \pm infinity. If the source operand is not in the range of $[-2\pi \dots +2\pi]$, then the argument is reduced to within that range before the cosine is calculated. However, large arguments may lose accuracy during reduction, and very large arguments (greater than approximately 10^{20}) may lose accuracy. The result is in the range of $[-1 \dots +1]$.

Operation Table:

DESTINATION	SOURCE ¹					
	+	In Range	- +	Zero - + Infinity		
Result		Cosine		+ 1.0		NAN ²

NOTES:

1. If the source operand is a NAN, refer to **1.6.5 Not-A-Numbers** for more information.
2. Sets the OPERR bit in the floating-point status register exception byte.

Quotient Byte:	Not affected
Exception Byte:	BSUN Cleared
	SNAN Refer to 1.6.5 Not-A-Numbers .
	OPERR Set if the source operand is \pm infinity otherwise.
	OVFL Cleared
	UNFL Cleared
	DZ Cleared
	INEX2 Refer to inexact result in the appropriate user's manual.
	INEX1 If < fmt > is packed, refer to inexact result in the appropriate user's manual; cleared otherwise.
Accrued Exception Byte:	Affected as described in IEEE exception and trap handling capability in the appropriate user's manual.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	
1	1	1	1	COPROCESSOR ID		0	0	0	EFFECTIVE ADDRESS MODE					REG
0	R/M	0	SOURCE SPECIFIER		DESTINATION REGISTER			0	0	1	1	1		

Instruction Fields:

Coprocessor ID field—Specifies which coprocessor in the system is to execute the instruction. Motorola assemblers default to ID = 1 for the floating-point coprocessor.

the following table:

Addressing Mode	Mode	Register
Dn*	000	reg. number:Dn
An	—	—
(An)	010	reg. number:An
(An) +	011	reg. number:An
– (An)	100	reg. number:An
(d ₁₆ ,An)	101	reg. number:An
(d ₈ ,An,Xn)	110	reg. number:An
(bd,An,Xn)	110	reg. number:An
([bd,An,Xn],od)	110	reg. number:An
([bd,An],Xn,od)	110	reg. number:An

Addressing Mode	Mode
(xxx).W	111
(xxx).L	111
# < data >	111
(d ₁₆ ,PC)	111
(d ₈ ,PC,Xn)	111
(bd,PC,Xn)	111
([bd,PC,Xn],od)	111
([bd,PC],Xn,od)	111

*Only if < fmt > is byte, word, long, or single.

R/M field—Specifies the source operand address mode.

- 0 — The operation is register to register.
- 1 — The operation is < ea > to register.

Source Specifier field—Specifies the source register or data format.

If R/M = 0, specifies the source floating-point data register.

If R/M = 1, specifies the source data format:

- 000 — Long-Word Integer (L)
- 001 — Single-Precision Real (S)
- 010 — Extended-Precision Real (X)
- 011 — Packed-Decimal Real (P)
- 100 — Word Integer (W)
- 101 — Double-Precision Real (D)
- 110 — Byte Integer (B)

Destination Register field—Specifies the destination floating-point data register.

M = 0 and the source and destination fields are equal, then the input operand is taken from the specified floating-point data register, and the result is written to the same register. If the single register syntax is used, Motorola assembler copies the source and destination fields to the same value.

Syntax: FCOSH.X FPM,FPn FCOSH.X FPn

Attributes: Format = (Byte, Word, Long, Single, Double, Extended, Pack

Description: Converts the source operand to extended precision (if necessary) and calculates the hyperbolic cosine of that number. Stores the result in the destination floating-point data register.

Operation Table:

DESTINATION	SOURCE							
	+	In Range	-	+	Zero	-	+	Infinity
Result		Hyperbolic Cosine			+ 1.0			+ inf

NOTE: If the source operand is a NAN, refer to **1.6.5 Not-A-Numbers** for more information.

Floating-Point Status Register:

Condition Codes: Affected as described in **3.6.2 Conditional Test**

Quotient Byte: Not affected.

Exception Byte:

BSUN	Cleared
SNAN	Refer to 1.6.5 Not-A-Numbers .
OPERR	Cleared
OVFL	Refer to overflow in the appropriate user's manual.
UNFL	Cleared
DZ	Cleared
INEX2	Refer to inexact result in the appropriate user's manual.
INEX1	If < fmt > is packed, refer to inexact result in the appropriate user's manual; cleared otherwise.

Accrued Exception Byte: Affected as described in IEEE exception and trap handling in the appropriate user's manual.

1	1	1	1	COPROCESSOR ID		0	0	0	EFFECTIVE ADDRESS			REGIS
0	R/M	0	SOURCE SPECIFIER		DESTINATION REGISTER		0	0	1	1	1	0

Instruction Fields:

Coprocessor ID field—Specifies which coprocessor in the system is to execute instruction. Motorola assemblers default to ID = 1 for the floating-point coprocessor.

Effective Address field—Determines the addressing mode for external operands. If R/M = 0, this field is unused and should be all zeros.

If R/M = 1, this field is encoded with an M68000 family addressing mode as shown in the following table:

Addressing Mode	Mode	Register
Dn*	000	reg. number:Dn
An	—	—
(An)	010	reg. number:An
(An) +	011	reg. number:An
– (An)	100	reg. number:An
(d ₁₆ ,An)	101	reg. number:An
(d ₈ ,An,Xn)	110	reg. number:An
(bd,An,Xn)	110	reg. number:An
([bd,An,Xn],od)	110	reg. number:An
([bd,An],Xn,od)	110	reg. number:An

Addressing Mode	Mode
(xxx).W	111
(xxx).L	111
# < data >	111
(d ₁₆ ,PC)	111
(d ₈ ,PC,Xn)	111
(bd,PC,Xn)	111
([bd,PC,Xn],od)	111
([bd,PC],Xn,od)	111

*Only if < fmt > is byte, word, long, or single.

Source Specifier field—Specifies the source register or data format.

If R/M = 0, specifies the source floating-point data register.

If R/M = 1, specifies the source data format:

000 — Long-Word Integer (L)

001 — Single-Precision Real (S)

010 — Extended-Precision Real (X)

011 — Packed-Decimal Real (P)

100 — Word Integer (W)

101 — Double-Precision Real (D)

110 — Byte Integer (B)

Destination Register field—Specifies the destination floating-point data register.

If R/M = 0 and the source and destination fields are equal, then the input operand is taken from the specified floating-point data register, and the result is written to the same register. If the single register syntax is used, Motorola assembler automatically sets the source and destination fields to the same value.

```

Else Dn - 1 → Dn
  If Dn ≠ - 1
    Then PC + dn → PC
  Else Execute Next Instruction

```

Assembler

Syntax: FDBcc Dn, < label >

Attributes: Unsized

Description: This instruction is a looping primitive of three parameters: a floating-point condition, a counter (data register), and a 16-bit displacement. The instruction first tests the condition to determine if the termination condition for the loop has been met. If so, execution continues with the next instruction in the instruction stream. If the termination condition is not true, the low-order 16 bits of the counter register are decremented by one. If the result is - 1, the count is exhausted, and execution continues with the next instruction. If the result is not equal to - 1, execution continues at the location specified by the current value of the program counter plus the sign-extended 16-bit displacement. The value of the program counter used in the address calculation is the address of the displacement word.

The conditional specifier cc selects any one of the 32 floating-point conditions as described in **3.6.2 Conditional Testing**.

Floating-Point Status Register:

Condition Codes:	Not affected.	
Quotient Byte:	Not affected.	
Exception Byte:	BSUN	Set if the NAN condition code is set and the condition selected is an IEEE nonaw...
	SNAN	Not Affected.
	OPERR	Not Affected.
	OVFL	Not Affected.
	UNFL	Not Affected.
	DZ	Not Affected.
	NEX2	Not Affected.
	INEX1	Not Affected.
Accrued Exception Byte:	The IOP bit is set if the BSUN bit is set in the exception byte. No other bit is affected.	

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	COPROCESSOR ID			0	0	1	0	0	1	CO REG		
0	0	0	0	0	0	0	0	0	0	CONDITIONAL PREDICA					
16-BIT DISPLACEMENT															

Instruction Fields:

Count Register field—Specifies data register that is used as the counter.

Conditional Predicate field—Specifies one of the 32 floating-point conditional predicates described in **3.6.2 Conditional Testing**.

Displacement field—Specifies the branch distance (from the address of the instruction plus two) to the destination in bytes.

NOTE

The terminating condition is like that defined by the UNTIL loop constructs of high-level languages. For example: FDBOLT can be stated as "decrement and branch until ordered less than".

There are two basic ways of entering a loop: at the beginning or by branching to the trailing FDBcc instruction. If a loop structure terminated with FDBcc is entered at the beginning, the control counter must be one less than the number of loop executions desired. This count is useful for indexed addressing modes and dynamically specified bit operations. However, when entering a loop by branching directly to the trailing FDBcc instruction, the count should equal the loop execution count. In this case, if the counter is zero when the loop is entered, the FDBcc instruction does not branch, causing a complete bypass of the main loop.

When a BSUN exception occurs, a preinstruction exception is taken by the main processor. If the exception handler returns without modifying the image of the program counter on the stack frame (to point to the instruction following the FDBcc), then it must clear the cause of the exception (by clearing the NAN bit or disabling the BSUN trap), or the exception will occur again immediately upon return to the routine that caused the exception.

Syntax:FDIV.X F_{Pm},F_{Pn}*FrDIV. < fmt > < ea > ,F_{Pn}*FrDIV.X F_{Pm},F_{Pn}

where r is rounding precision, S or D

*Supported by MC68040 only

Attributes:

Format = (Byte, Word, Long, Single, Double, Extended, Packed)

Description: Converts the source operand to extended precision (if necessary) and that number into the number in the destination floating-point data register. Stores the result in the destination floating-point data register.

FDIV will round the result to the precision selected in the floating-point control register. FSDIV and FDDIV will round the result to single or double precision, respectively, regardless of the rounding precision selected in the floating-point control register.

Operation Table:

DESTINATION	SOURCE ¹						
		In Range		Zero		Infinity	
	+	-	+	-	+	-	
In Range	+	Divide		+ inf ²	- inf ²	+ 0.0	-
	-			- inf ²	+ inf ²	- 0.0	+
Zero	+	+ 0.0	+ 0.0	NAN ³		+ 0.0	-
	-	- 0.0	+ 0.0			- 0.0	+
Infinity	+	+ inf	- inf	+ inf	- inf	NAN‡	
	-	- inf	+ inf	- inf	+ inf		

NOTES:

1. If the source operand is a NAN, refer to **1.6.5 Not-A-Numbers** for more information.
2. Sets the DZ bit in the floating-point status register exception byte.
3. Sets the OPERR bit in the floating-point status register exception byte.

Quotient Byte:	Not affected.
Exception Byte:	BSUN Cleared
	SNAN Refer to 1.6.5 Not-A-Numbers .
	OPERR Set for $0 \div 0$ or $\text{infinity} \div \text{infinity}$ otherwise.
	OVFL Refer to exception processing appropriate user's manual.
	UNFL Refer to exception processing appropriate user's manual.
	DZ Set if the source is zero and the destination is in range; cleared otherwise.
	INEX2 Refer to exception processing appropriate user's manual.
	INEX1 If <code>< fmt ></code> is packed, refer to exception processing in the appropriate user's manual; cleared otherwise.
Accrued Exception Byte:	Affected as described in exception processing in the appropriate user's manual.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	
1	1	1	1	COPROCESSOR ID		0	0	0	EFFECTIVE ADDRESS MODE					REG
0	R/M	0	SOURCE SPECIFIER		DESTINATION REGISTER			OPMODE						

If R/M = 0, this field is unused and should be all zeros.
 If R/M = 1, specifies the location of the source operand location. Only data addressing modes can be used as listed in the following table:

Addressing Mode	Mode	Register	Addressing Mode	Mode
Dn*	000	reg. number:Dn	(xxx).W	111
An	—	—	(xxx).L	111
(An)	010	reg. number:An	# < data >	111
(An) +	011	reg. number:An		
– (An)	100	reg. number:An		
(d ₁₆ ,An)	101	reg. number:An	(d ₁₆ ,PC)	111
(d ₈ ,An,Xn)	110	reg. number:An	(d ₈ ,PC,Xn)	111
(bd,An,Xn)	110	reg. number:An	(bd,PC,Xn)	111
([bd,An,Xn],od)	110	reg. number:An	([bd,PC,Xn],od)	111
([bd,An],Xn,od)	110	reg. number:An	([bd,PC],Xn,od)	111

*Only if < fmt > is byte, word, long, or single.

R/M field—Specifies the source operand address mode.

0 — The operation is register to register.

1 — The operation is < ea > to register.

Source Specifier field—Specifies the source register or data format.

If R/M = 0, specifies the source floating-point data register.

If R/M = 1, specifies the source data format:

000 — Long-Word Integer (L)

001 — Single-Precision Real (S)

010 — Extended-Precision Real (X)

011 — Packed-Decimal Real (P)*

100 — Word Integer (W)

101 — Double-Precision Real (D)

110 — Byte Integer (B)

*This encoding in the MC68040 will cause an unimplemented data type exception to allow emulation in software.

0100000	FDIV	Rounding precision specified by the floating- point control register.
1100000	FSDIV	Single-precision rounding specified.
1100100	FDDIV	Double-precision rounding specified.

Syntax: FETOX.X Fp_m,Fp_n
Syntax: FETOX.X Fp_n

Attributes: Format = (Byte, Word, Long, Single, Double, Extended, Packed)

Description: Converts the source operand to extended precision (if necessary) and calculates e to the power of that number. Stores the result in the destination floating-point data register.

Operation Table:

DESTINATION	SOURCE							
	+	In Range	-	+	Zero	-	+	Infinity
Result		e ^x			+ 1.0			+ inf

NOTE: If the source operand is a NAN, refer to **1.6.5 Not-A-Numbers** for more information.

Floating-Point Status Register:

Condition Codes: Affected as described in **3.6.2 Conditional Testing**

Quotient Byte: Not affected.

Exception Byte:

- BSUN Cleared
- SNAN Refer to **1.6.5 Not-A-Numbers**.
- OPERR Cleared
- OVFL Refer to overflow in the appropriate user's manual.
- UNFL Refer to underflow in the appropriate user's manual.
- DZ Cleared
- INEX2 Refer to inexact result in the appropriate user's manual.
- INEX1 If < fmt > is packed, refer to inexact result in the appropriate user's manual; decimal input in the appropriate user's manual; cleared otherwise.

Accrued Exception Byte: Affected as described in IEEE exception and trap capability in the appropriate user's manual.

1	1	1	1	COPROCESSOR ID		0	0	0	EFFECTIVE ADDRESS			REG
0	R/M	0	SOURCE SPECIFIER		DESTINATION REGISTER		0	0	0	1	1	

Instruction Fields:

Coprocessor ID field—Specifies which coprocessor in the system is to execute the instruction. Motorola assemblers default to ID = 1 for the floating-point coprocessor.

Effective Address field—Determines the addressing mode for external operations.
 If R/M = 0, this field is unused and should be all zeros.
 If R/M = 1, this field is encoded with an M68000 family addressing mode as shown in the following table:

Addressing Mode	Mode	Register
Dn*	000	reg. number:Dn
An	—	—
(An)	010	reg. number:An
(An) +	011	reg. number:An
– (An)	100	reg. number:An
(d ₁₆ ,An)	101	reg. number:An
(d ₈ ,An,Xn)	110	reg. number:An
(bd,An,Xn)	110	reg. number:An
([bd,An,Xn],od)	110	reg. number:An
([bd,An],Xn,od)	110	reg. number:An

Addressing Mode	Mode
(xxx).W	111
(xxx).L	111
# < data >	111
(d ₁₆ ,PC)	111
(d ₈ ,PC,Xn)	111
(bd,PC,Xn)	111
([bd,PC,Xn],od)	111
([bd,PC],Xn,od)	111

*Only if < fmt > is byte, word, long, or single.

Source Specifier Field—Specifies the source register or data format.

If R/M = 0, specifies the source floating-point data register.

If R/M = 1, specifies the source data format:

000 — Long-Word Integer (L)

001 — Single-Precision Real (S)

010 — Extended-Precision Real (X)

011 — Packed-Decimal Real (P)*

100 — Word Integer (W)

101 — Double-Precision Real (D)

110 — Byte Integer (B)

Destination Register field—Specifies the destination floating-point data register.

M = 0 and the source and destination fields are equal, then the input operand is taken from the specified floating-point data register, and the result is written to the same register. If the single register syntax is used, Motorola assembler interprets the source and destination fields to the same value.

Syntax: FETOXM1.X Fp_m,FP_n
FETOXM1.X FP_n

Attributes: Format = (Byte, Word, Long, Single, Double, Extended, Pack

Description: Converts the source operand to extended precision (if necessary) and calculates e to the power of that number. Subtracts one from the value and stores the result in the destination floating-point data register.

Operation Table:

DESTINATION	SOURCE								
	+	In Range	-	+	Zero	-	+	Infinity	
Result		$e^x - 1$			+ 0.0			- 0.0	+ inf

NOTE: If the source operand is a NAN, refer to **1.6.5 Not-A-Numbers** for more information.

Floating-Point Status Register:

Condition Codes: Affected as described in **3.6.2 Conditional Test**

Quotient Byte: Not affected.

Exception Byte:

- BSUN Cleared
- SNAN Refer to **1.6.5 Not-A-Numbers**.
- OPERR Cleared
- OVFL Refer to overflow in the appropriate user's manual.
- UNFL Refer to underflow in the appropriate user's manual.
- DZ Cleared
- INEX2 Refer to inexact result in the appropriate user's manual.
- INEX1 If < fmt > is packed, refer to inexact result in the appropriate user's manual; cleared otherwise.

Accrued Exception Byte: Affected as described in IEEE exception and trap handling in the appropriate user's manual.

1	1	1	1	COPROCESSOR ID		0	0	0	EFFECTIVE ADDRESS MODE			REGIS
0	R/M	0	SOURCE SPECIFIER		DESTINATION REGISTER		0	0	0	1	1	0

Instruction Fields:

Coprocessor ID field—Specifies which coprocessor in the system is to execute the instruction. Motorola assemblers default to ID = 1 for the floating-point coprocessor.

Effective Address field—Determines the addressing mode for external operands. If R/M = 0, this field is unused and should be all zeros.

If R/M = 1, this field is encoded with an M68000 family addressing mode as shown in the following table:

Addressing Mode	Mode	Register
Dn*	000	reg. number:Dn
An	—	—
(An)	010	reg. number:An
(An) +	011	reg. number:An
– (An)	100	reg. number:An
(d ₁₆ ,An)	101	reg. number:An
(d ₈ ,An,Xn)	110	reg. number:An
(bd,An,Xn)	110	reg. number:An
([bd,An,Xn],od)	110	reg. number:An
([bd,An],Xn,od)	110	reg. number:An

Addressing Mode	Mode
(xxx).W	111
(xxx).L	111
# < data >	111
(d ₁₆ ,PC)	111
(d ₈ ,PC,Xn)	111
(bd,PC,Xn)	111
([bd,PC,Xn],od)	111
([bd,PC],Xn,od)	111

*Only if < fmt > is byte, word, long, or single.

Source Specifier Field—Specifies the source register or data format.

If R/M = 0, specifies the source floating-point data register.

If R/M = 1, specifies the source data format:

000 — Long-Word Integer (L)

001 — Single-Precision Real (S)

010 — Extended-Precision Real (X)

011 — Packed-Decimal Real (P)

100 — Word Integer (W)

101 — Double-Precision Real (D)

110 — Byte Integer (B)

Destination Register field—Specifies the destination floating-point data register.

If R/M = 0 and the source and destination fields are equal, then the input operand is taken from the specified floating-point data register, and the result is written to the same register. If the single register syntax is used, Motorola assembler concatenates the source and destination fields to the same value.

Syntax: FGETEXP.X FPM,FPn
FGETEXP.X FPN

Attributes: Format = (Byte, Word, Long, Single, Double, Extended, Packed)

Description: Converts the source operand to extended precision (if necessary) and extracts the binary exponent. Removes the exponent bias, converts the exponent to an extended-precision floating-point number, and stores the result in the destination floating-point data register.

Operation Table:

DESTINATION	SOURCE ¹									
	+	In Range	-	+	Zero	-	+	Infinity		
Result		Exponent		+	0.0		-	0.0		NAN ²

NOTES:

1. If the source operand is a NAN, refer to **1.6.5 Not-A-Numbers** for more information.
2. Sets the OPERR bit in the floating-point status register exception byte.

Floating-Point Status Register:

Condition Codes: Affected as described in **3.6.2 Conditional Testing**

Quotient Byte: Not affected.

Exception Byte:

BSUN	Cleared
SNAN	Refer to 1.6.5 Not-A-Numbers .
OPERR	Set if the source is \pm infinity; otherwise.

([bd,PC,Xn],od)	111
([bd,PC],Xn,od)	111

*Only if < fmt > is byte, word, long, or single.

R/M field—Specifies the source operand address mode.

0 — The operation is register to register.

1 — The operation is < ea > to register.

- 000 — Long-Word Integer (L)
- 001 — Single-Precision Real (S)
- 010 — Extended-Precision Real (X)
- 011 — Packed-Decimal Real (P)
- 100 — Word Integer (W)
- 101 — Double-Precision Real (D)
- 110 — Byte Integer (B)

Destination Register field—Specifies the destination floating-point data register. If $M = 0$ and the source and destination fields are equal, then the input operand is taken from the specified floating-point data register, and the result is written to the same register. If the single register syntax is used, Motorola assembler sets both the source and destination fields to the same value.

Syntax: FGETMAN.X FPm,FPn
FGETMAN.X FPn

Attributes: Format = (Byte, Word, Long, Single, Double, Extended, Pack

Description: Converts the source operand to extended precision (if necessary) and extracts the mantissa. Converts the mantissa to an extended-precision value and stores the result in the destination floating-point data register. The result is in the range [1.0...2.0] with the sign of the source mantissa, zero, or a NAN.

Operation Table:

DESTINATION	SOURCE ¹									
	+	In Range	-	+	Zero	-	+	Infinity		
Result		Mantissa		+	0.0		-	0.0		NAN ²

NOTES:

1. If the source operand is a NAN, refer to **1.6.5 Not-A-Numbers** for more information.
2. Sets the OPERR bit in the floating-point status register exception byte.

Floating-Point Status Register:

Condition Codes: Affected as described in **3.6.2 Conditional Test**

Quotient Byte: Not affected.

Exception Byte:

BSUN	Cleared

(xxx).L	111
# < data >	111
(d ₁₆ ,PC)	111
(d ₈ ,PC,Xn)	111
(bd,PC,Xn)	111
([bd,PC,Xn],od)	111
([bd,PC],Xn,od)	111

*Only if < fmt > is byte, word, long, or single.

R/M field—Specifies the source operand address mode.

0 — The operation is register to register.

1 — The operation is < ea > to register.

- 000 — Long-Word Integer (L)
- 001 — Single-Precision Real (S)
- 010 — Extended-Precision Real (X)
- 011 — Packed-Decimal Real (P)
- 100 — Word Integer (W)
- 101 — Double-Precision Real (D)
- 110 — Byte Integer (B)

Destination Register field—Specifies the destination floating-point data register. If $M = 0$ and the source and destination fields are equal, then the input is taken from the specified floating-point data register, and the result is written to the same register. If the single register syntax is used, Motorola assembler sets the source and destination fields to the same value.

Syntax: FINT.X FPm,FPn
 FINT.X FPn

Attributes: Format = (Byte, Word, Long, Single, Double, Extended, Packed)

Description: Converts the source operand to extended precision (if necessary), the integer part, and converts it to an extended-precision floating-point number and stores the result in the destination floating-point data register. The integer part is extracted, and the extended-precision number is rounded to an integer using the current rounding mode selected in the floating-point control register mode control byte. Thus, the integer part returned is the number that is to the left of the radix point when the exponent is adjusted after rounding. For example, the integer part of 137.57 is 137.0 for the round-to-zero and round-to-negative infinity modes and 138.0 for the round-to-nearest and round-to-positive infinity modes. Note that the result of this operation is a floating-point number.

Operation Table:

DESTINATION	SOURCE										
	+	In Range	-	+	Zero	-	+	Infinity			
Result		Integer		+	0.0		-	0.0		+	inf - inf

NOTE: If the source operand is a NAN, refer to **1.6.5 Not-A-Numbers** for more information.

Quotient Byte:	Not affected.
Exception Byte:	BSUN Cleared
	SNAN Refer to 1.6.5 Not-A-Numbers .
	OPERR Cleared
	OVFL Cleared
	UNFL Cleared
	DZ Cleared
	INEX2 Refer to inexact result in the appropriate user's manual.
INEX1 If < fmt > is packed, refer to inexact result in the appropriate user's manual; cleared otherwise.	
Accrued Exception Byte:	Affected as described in IEEE exception and trap handling capability in the appropriate user's manual.

(bd,PC,Xn)	111
([bd,PC,Xn],od)	111
([bd,PC],Xn,od)	111

*Only if < fmt > is byte, word, long, or single.

R/M field—Specifies the source operand address mode.

- 0 — The operation is register to register.
- 1 — The operation is < ea > to register.

Source Specifier field—Specifies the source register or data format.

If R/M = 0, specifies the source floating-point data register.

If R/M = 1, specifies the source data format:

- 000 — Long-Word Integer (L)
- 001 — Single-Precision Real (S)
- 010 — Extended-Precision Real (X)
- 011 — Packed-Decimal Real (P)
- 100 — Word Integer (W)
- 101 — Double-Precision Real (D)
- 110 — Byte Integer (B)

Destination Register field—Specifies the destination floating-point data register.

M = 0 and the source and destination fields are equal, then the input operand is taken from the specified floating-point data register, and the result is written to the same register. If the single register syntax is used, Motorola assembler copies the source and destination fields to the same value.

Syntax: FINTRZ.X FPm,FPn
FINTRZ.X FPn

Attributes: Format = (Byte, Word, Long, Single, Double, Extended, Pack)

Description: Converts the source operand to extended precision (if necessary) and extracts the integer part and converts it to an extended-precision floating-point number. Stores the result in the destination floating-point data register. The integer part is extracted by rounding the extended-precision number to an integer using the round-to-zero mode, regardless of the rounding mode selected in the floating-point data register mode control byte (making it useful for FORTRAN assignments). The integer part returned is the number that is to the left of the radix point if the exponent is zero. For example, the integer part of 137.57 is 137.0; the integer part of 0.1245×10^2 is 12.0. Note that the result of this operation is a floating-point number.

Operation Table:

DESTINATION	SOURCE									
	+	In Range	-	+	Zero	-	+	Infinity		
Result		Integer, Forced Round-to- Zero		+	0.0		-	0.0	+	inf

NOTE: If the source operand is a NAN, refer to **1.6.5 Not-A-Numbers** for more information.

Quotient Byte:	Not affected.
Exception Byte:	BSUN Cleared
	SNAN Refer to 1.6.5 Not-A-Numbers .
	OPERR Cleared
	OVFL Cleared
	UNFL Cleared
	DZ Cleared
	INEX2 Refer to inexact result in the appropriate user's manual.
	INEX1 If < fmt > is packed, refer to inexact result in the appropriate user's manual; cleared otherwise.
Accrued Exception Byte:	Affected as described in IEEE exception and trap capability in the appropriate user's manual.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1
1	1	1	1	COPROCESSOR ID			0	0	0	EFFECTIVE ADDRESS MODE			REGIS	
0	R/M	0	SOURCE SPECIFIER			DESTINATION REGISTER			0	0	0	0	0	1

Instruction Fields:

Coprocessor ID field—Specifies which coprocessor in the system is to execute the instruction. Motorola assemblers default to ID = 1 for the floating-point coprocessor.

the following table:

Addressing Mode	Mode	Register
Dn*	000	reg. number:Dn
An	—	—
(An)	010	reg. number:An
(An) +	011	reg. number:An
– (An)	100	reg. number:An
(d ₁₆ ,An)	101	reg. number:An
(d ₈ ,An,Xn)	110	reg. number:An
(bd,An,Xn)	110	reg. number:An
([bd,An,Xn],od)	110	reg. number:An
([bd,An],Xn,od)	110	reg. number:An

Addressing Mode	Mode
(xxx).W	111
(xxx).L	111
# < data >	111
(d ₁₆ ,PC)	111
(d ₈ ,PC,Xn)	111
(bd,PC,Xn)	111
([bd,PC,Xn],od)	111
([bd,PC],Xn,od)	111

*Only if < fmt > is byte, word, long, or single.

R/M field—Specifies the source operand address mode.

- 0 — The operation is register to register.
- 1 — The operation is < ea > to register.

Source Specifier field—Specifies the source register or data format.

- If R/M = 0, specifies the source floating-point data register.
- If RM = 1, specifies the source data format:

- 000 — Long-Word Integer (L)
- 001 — Single-Precision Real (S)
- 010 — Extended-Precision Real (X)
- 011 — Packed-Decimal Real (P)
- 100 — Word Integer (W)
- 101 — Double-Precision Real (D)
- 110 — Byte Integer (B)

Destination Register field—Specifies the destination floating-point data register.

If R/M = 0 and the source and destination fields are equal, then the input operand is taken from the specified floating-point data register, and the result is written to the same register. If the single register syntax is used, Motorola assembles the source and destination fields to the same value.

Syntax: FLOG10.X Fm,FPn
FLOG10.X FPn

Attributes: Format = (Byte, Word, Long, Single, Double, Extended, Packed)

Description: Convert the source operand to extended precision (if necessary) and calculates the logarithm of that number using base 10 arithmetic. Stores the result in the destination floating-point data register. This function is not defined for inputs less than zero.

Operation Table:

DESTINATION	SOURCE ¹							
	+	In Range	-	+	Zero	-	+	Infinity
Result	Log ₁₀		NAN ²		- inf ³		+ inf	

NOTES:

1. If the source operand is a NAN, refer to **1.6.5 Not-A-Numbers** for more information.
2. Sets the OPERR bit in the floating-point status register exception byte.
3. Sets the DZ bit in the floating-point status register exception byte.

Floating-Point Status Register:

Condition Codes: Affected as described in **3.6.2 Conditional Testing**

Quotient Byte: Not affected.

Exception Byte:

BSUN	Cleared
SNAN	Refer to 1.6.5 Not-A-Numbers .
OPERR	Set if the source operand is < 0; otherwise.
OVFL	Cleared
UNFL	Cleared
DZ	Set if the source is ± 0; cleared otherwise.
INEX2	Refer to inexact result in the appropriate user's manual.
INEX1	If < fmt > is packed, refer to inexact result in the appropriate user's manual; cleared otherwise.

Accrued Exception Byte: Affected as described in IEEE exception and trap capability in the appropriate user's manual.

1	1	1	1	COPROCESSOR ID		0	0	0	EFFECTIVE ADDRESSING MODE			REG
0	R/M	0	SOURCE SPECIFIER		DESTINATION REGISTER		0	0	1	0	1	

Instruction Fields:

Coprocessor ID field—Specifies which coprocessor in the system is to execute the instruction. Motorola assemblers default to ID = 1 for the floating-point coprocessor.

Effective Address field—Determines the addressing mode for external operations.
 If R/M = 0, this field is unused and should be all zeros.
 If R/M = 1, this field is encoded with an M68000 family addressing mode as shown in the following table:

Addressing Mode	Mode	Register
Dn*	000	reg. number:Dn
An	—	—
(An)	010	reg. number:An

([bd,PC,Xn],od)	111
([bd,PC],Xn,od)	111

*Only if < fmt > is byte, word, long, or single.

Source Specifier field—Specifies the source register or data format.

If R/M = 0, specifies the source floating-point data register.

If R/M = 1, specifies the source data format:

000 — Long-Word Integer (L)

001 — Single-Precision Real (S)

010 — Extended-Precision Real (X)

011 — Packed-Decimal Real (P)

100 — Word Integer (W)

101 — Double-Precision Real (D)

110 — Byte Integer (B)

Destination Register field—Specifies the destination floating-point data register.

M = 0 and the source and destination fields are equal, then the input operand is taken from the specified floating-point data register, and the result is written to the same register. If the single register syntax is used, Motorola assembler sets both the source and destination fields to the same value.

Syntax: FLOG2.X Fp_m,Fp_n
FLOG2.X Fp_n

Attributes: Format = (Byte, Word, Long, Single, Double, Extended, Packed)

Description: Converts the source operand to extended precision (if necessary) and calculates the logarithm of that number using base two arithmetic. Stores the result in the destination floating-point data register. This function is not defined for inputs less than zero.

Operation Table:

DESTINATION	SOURCE ¹			
	+ In Range	-	+ Zero	- + Infinity
Result	Log ₂	NAN ²	- inf ³	+ inf

NOTES:

1. If the source operand is a NAN, refer to **1.6.5 Not-A-Numbers** for more information.
2. Sets the OPERR bit in the floating-point status register exception byte.
3. Sets the DZ bit in the floating-point status register exception byte.

(d ₁₆ ,PC)	111
(d ₈ ,PC,Xn)	111
(bd,PC,Xn)	111
([bd,PC,Xn],od)	111
([bd,PC],Xn,od)	111

*Only if < fmt > is byte, word, long, or single.

Source Specifier field—Specifies the source register or data format.

If R/M = 0, specifies the source floating-point data register.

If R/M = 1, specifies the source data format:

000 — Long-Word Integer (L)

001 — Single-Precision Real (S)

010 — Extended-Precision Real (X)

011 — Packed-Decimal Real (P)

100 — Word Integer (W)

101 — Double-Precision Real (D)

110 — Byte Integer (B)

Destination Register field—Specifies the destination floating-point data register.

If R/M = 0 and the source and destination fields are equal, then the input operand is taken from the specified floating-point data register, and the result is written to the same register. If the single register syntax is used, Motorola assembler automatically sets the source and destination fields to the same value.

Syntax: FLOGN.X FPm,FPn
FLOGN.X FPn

Attributes: Format = (Byte, Word, Long, Single, Double, Extended, Packed)

Description: Converts the source operand to extended precision (if necessary) and calculates the natural logarithm of that number. Stores the result in the destination floating-point data register. This function is not defined for input values less than or equal to zero.

Operation Table:

DESTINATION	SOURCE ¹							
	+	In Range	-	+	Zero	-	+	Infinity
Result	ln(x)		NAN ²		- inf ³		+ inf	

NOTES:

1. If the source operand is a NAN, refer to **1.6.5 Not-A-Numbers** for more information.
2. Sets the OPERR bit in the floating-point status register exception byte.
3. Sets the DZ bit in the floating-point status register exception byte.

Floating-Point Status Register:

Condition Codes: Affected as described in **3.6.2 Conditional Testing**

Quotient Byte: Not affected.

Exception Byte:

(d ₁₆ ,PC)	111
(d ₈ ,PC,Xn)	111
(bd,PC,Xn)	111
([bd,PC,Xn],od)	111
([bd,PC],Xn,od)	111

*Only if < fmt > is byte, word, long, or single.

Source Specifier field—Specifies the source register or data format.

If R/M = 0, specifies the source floating-point data register.

If R/M = 1, specifies the source data format:

000 — Long-Word Integer (L)

001 — Single-Precision Real (S)

010 — Extended-Precision Real (X)

011 — Packed-Decimal Real (P)

100 — Word Integer (W)

101 — Double-Precision Real (D)

110 — Byte Integer (B)

Destination Register field—Specifies the destination floating-point data register.

M = 0 and the source and destination fields are equal, then the input operand is taken from the specified floating-point data register, and the result is written to the same register. If the single register syntax is used, Motorola assembler sets both the source and destination fields to the same value.

Syntax: FLOGNP1.X Fp_m, Fp_n
FLOGNP1.X Fp_n

Attributes: Format = (Byte, Word, Long, Single, Double, Extended, Pack

Description: Converts the source operand to extended precision (if necessary), to that value, and calculates the natural logarithm of that intermediate result. S result in the destination floating-point data register. This function is not defined values less than -1 .

Operation Table:

DESTINATION	SOURCE ¹											
	+	In Range	-	+	Zero	-	+	Infinity				
Result	$\ln(x + 1)$	$\ln(x + 1)^2$		+	0.0		-	0.0	+	inf		N

NOTES:

1. If the source operand is a NAN, refer to **1.6.5 Not-A-Numbers** for more information.
2. If the source is -1 , sets the DZ bit in the floating-point status register exception byte and returns a NAN. If the source is < -1 , sets the OPERR bit in the floating-point status register exception byte and returns a NAN.
3. Sets the OPERR bit in the floating-point status register exception byte.

Floating-Point Status Register:

Condition Codes: Affected as described in **3.6.2 Conditional Testi**

Quotient Byte: Not affected.

OPERR	Set if the source operand is ≤ -1 , otherwise.
OVFL	Cleared
UNFL	Refer to underflow in the appropriate manual.
DZ	Set if the source operand is -1 ; otherwise
INEX2	Refer to inexact result in the appropriate user's manual.
INEX1	If < fmt > is packed, refer to inexact result in the appropriate manual; decimal input in the appropriate manual; cleared otherwise.

Accrued Exception Byte: Affected as described in IEEE exception and trap capability in the appropriate user's manual.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1
1	1	1	1	COPROCESSOR ID			0	0	0	EFFECTIVE ADDRESS MODE			REGISTER	
0	R/M	0	SOURCE SPECIFIER			DESTINATION REGISTER			0	0	0	0	1	1

Instruction Fields:

Coprocessor ID field—Specifies which coprocessor in the system is to execute the instruction. Motorola assemblers default to ID = 1 for the floating-point coprocessor.

the following table:

Addressing Mode	Mode	Register
Dn*	000	reg. number:Dn
An	—	—
(An)	010	reg. number:An
(An) +	011	reg. number:An
– (An)	100	reg. number:An
(d ₁₆ ,An)	101	reg. number:An
(d ₈ ,An,Xn)	110	reg. number:An
(bd,An,Xn)	110	reg. number:An
([bd,An,Xn],od)	110	reg. number:An
([bd,An],Xn,od)	110	reg. number:An

Addressing Mode	Mode
(xxx).W	111
(xxx).L	111
# < data >	111
(d ₁₆ ,PC)	111
(d ₈ ,PC,Xn)	111
(bd,PC,Xn)	111
([bd,PC,Xn],od)	111
([bd,PC],Xn,od)	111

*Only if < fmt > is byte, word, long, or single.

R/M field—Specifies the source operand address mode.

- 0 — The operation is register to register.
- 1 — The operation is < ea > to register.

Source Specifier field—Specifies the source register or data format.

If R/M = 0, specifies the source floating-point data register.

If R/M = 1, specifies the source data format:

- 000 — Long-Word Integer (L)
- 001 — Single-Precision Real (S)
- 010 — Extended-Precision Real (X)
- 011 — Packed-Decimal Real (P)
- 100 — Word Integer (W)
- 101 — Double-Precision Real (D)
- 110 — Byte Integer (B)

Destination Register field—Specifies the destination floating-point data register.

If R/M = 0 and the source and destination fields are equal, then the input operand is taken from the specified floating-point data register, and the result is written to the same register. If the single register syntax is used, Motorola assembler will equate the source and destination fields to the same value.

Syntax: FMOD.X Fp_m,FP_n

Attributes: Format = (Byte, Word, Long, Single, Double, Extended, Packed)

Description: Converts the source operand to extended precision (if necessary) and calculates the modulo remainder of the number in the destination floating-point register, using the source operand as the modulus. Stores the result in the destination floating-point data register and stores the sign and seven least significant bits of the quotient in the floating-point status register quotient byte (the quotient is the FP_n ÷ Source). The modulo remainder function is defined as:

$$FP_n - (\text{Source} \times N)$$

where $N = \text{INT}(FP_n \div \text{Source})$ in the round-to-zero mode.

The FMOD function is not defined for a source operand equal to zero or for a destination operand equal to infinity. Note that this function is not the same as the FREM instruction which uses the round-to-nearest mode and thus returns the remainder that is required by the IEEE *Specification for Binary Floating-Point Arithmetic*.

Operation Table:

DESTINATION	SOURCE ¹							
	+	In Range	-	+	Zero#	-	+	Infinity
In Range	+	Modulo Remainder	-	+	Zero#	-	+	Infinity
	-							
Zero	+	+ 0.0	-	+	Zero#	-	+	Infinity
	-	- 0.0						
Infinity	+	NAN ²	-	+	Zero#	-	+	Infinity
	-							

NOTES:

1. If the source operand is a NAN, refer to **1.6.5 Not-A-Numbers** for more information.
2. Sets the OPERR bit in the floating-point status register exception byte.
3. Returns the value of FP_n before the operation. However, the result is processed by the normal instruction termination procedure to round it as required. Thus, an overflow and/or inexact result may occur if the rounding precision has been changed to a smaller size since the FP_n value was loaded

Quotient Byte:

Loaded with the sign and least significant seven bits of the quotient (FPn ÷ Source). The sign of the quotient is the exclusive-OR of the sign bits of the source and destination operands.

Exception Byte:

BSUN Cleared
SNAN Refer to **1.6.5 Not-A-Numbers**.
OPERR Set if the source is zero or the destination is infinity; cleared otherwise.
OVFL Cleared
UNFL Refer to underflow in the appropriate user's manual.
DZ Cleared
INEX2 Refer to inexact result in the appropriate user's manual.
INEX1 If < fmt > is packed, in the appropriate user's manual for inexact result on decimal operations; cleared otherwise.

Accrued Exception Byte: Affected as described in IEEE exception and trap handling capability in the appropriate user's manual.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2
1	1	1	1	COPROCESSOR ID		0	0	0	EFFECTIVE ADDRESS				
0	R/M	0	SOURCE SPECIFIER		DESTINATION REGISTER			0	1	0	1	1	

Instruction Fields:

Coprocessor ID field—Specifies which coprocessor in the system is to execute the instruction. Motorola assemblers default to ID = 1 for the floating-point coprocessor.

the following table:

Addressing Mode	Mode	Register
Dn	000	reg. number:Dn
An	—	—

([bd,PC,Xn],od)	111
([bd,PC],Xn,od)	111

*Only if < fmt > is byte, word, long, or single.

R/M field—Specifies the source operand address mode.

- 0 — The operation is register to register.
- 1 — The operation is < ea > to register.

Source Specifier field—Specifies the source register or data format.

If R/M = 0, specifies the source floating-point data register.

If R/M = 1, specifies the source data format:

- 000 — Long-Word Integer (L)
- 001 — Single-Precision Real (S)
- 010 — Extended-Precision Real (X)
- 011 — Packed-Decimal Real (P)
- 100 — Word Integer (W)
- 101 — Double-Precision Real (D)
- 110 — Byte Integer (B)

Destination Register field—Specifies the destination floating-point data register.

Syntax:

FMOVE. < fmt > FPm, < ea >
FMOVE.P FPm, < ea > {Dn}
FMOVE.P FPm, < ea > {k}
*FrMOVE. < fmt > < ea > ,FPn
where r is rounding precision, S or D
*Supported by MC68040 only

Attributes:

Format = (Byte, Word, Long, Single, Double, Extended, Pack

Description:

Moves the contents of the source operand to the destination. Although the primary function of this instruction is data movement, it is also considered an arithmetic instruction since conversions from the source operand format to the destination operand format are performed implicitly during the move operation. If the source operand is rounded according to the selected rounding precision and

Unlike the MOVE instruction, the FMOVE instruction does not support a memory-to-memory format. For such transfers, it is much faster to utilize the MOVE instruction to transfer the floating-point data than to use the FMOVE instruction. The FMOVE instruction only supports memory-to-register, register-to-register, and register-to-memory operations (in this context, memory may refer to an integer data register). The data format is byte, word, long, or single). The memory-to-register and register-to-memory operation uses a command word encoding distinctly different from that of the register-to-memory operation; these two operation classes are described separately.

Memory-to-Register and Register-to-Register Operation:

Converts the source operand to an extended-precision floating-point number (if necessary) and stores the result in the destination floating-point data register. FMOVE will round the result to the precision selected in the floating-point control register. FMOVE and FDMOVE will round the result to single or double precision, respectively, regardless of the rounding precision selected in the floating-point control register. Depending on the source data format and the rounding precision, some operations may produce an inexact result. In the following table, combinations that can produce an inexact result are marked with a dot. All other combinations produce an exact result.

Single		
Double						.	.
Extended							.

Floating-Point Status Register (< ea > to Register):

Condition Codes:	Affected as described in 3.6.2 Conditional Testin	
Quotient Byte:	Not affected.	
Exception Byte:	BSUN	Cleared
	SNAN	Refer to 1.6.5 Not-A-Numbers.
	OPERR	Cleared
	OVFL	Cleared
	UNFL	Refer to exception processing appropriate user's manual if the sou extended-precision denormalized cleared otherwise.
	DZ	Cleared
	INEX2	Refer to exception processing appropriate user's manual if < fmt > i X; cleared otherwise.
	INEX1	Refer to exception processing appropriate user's manual if < fmt > cleared otherwise.
Accrued Exception Byte:	Affected as described in exception processing in th priate user's manual.	

15	14	13	12	11	10	9	8	7	6	5	4	3	2
1	1	1	1	COPROCESSOR ID			0	0	0	EFFECTIVE ADDRESS MODE			
0	R/M	0	SOURCE SPECIFIER		DESTINATION REGISTER			OPMODE					

Instruction Fields:

Effective Address field—Determines the addressing mode for external operation.

If R/M = 0, this field is unused and should be all zeros.

If R/M = 1, specifies the location of the source operand. Only data addressing modes can be used as listed in the following table:

Addressing Mode	Mode	Register
Dn*	000	reg. number:Dn
An	—	—
(An)	010	reg. number:An
(An) +	011	reg. number:An
– (An)	100	reg. number:An
(d ₁₆ ,An)	101	reg. number:An
(d ₈ ,An,Xn)	110	reg. number:An
(bd,An,Xn)	110	reg. number:An
([bd,An,Xn],od)	110	reg. number:An
([bd,An],Xn,od)	110	reg. number:An

Addressing Mode	Mode
(xxx).W	111
(xxx).L	111
# < data >	111
(d ₁₆ ,PC)	111
(d ₈ ,PC,Xn)	111
(bd,PC,Xn)	111
([bd,PC,Xn],od)	111
([bd,PC],Xn,od)	111

*Only if < fmt > is byte, word, long, or single.

R/M field—Specifies the source operand address mode.

0 — The operation is register to register.

1 — The operation is < ea > to register.

- 000 — Long-Word Integer (L)
- 001 — Single-Precision Real (S)
- 010 — Extended-Precision Real (X)
- 011 — Packed-Decimal Real (P)*
- 100 — Word Integer (W)
- 101 — Double-Precision Real (D)
- 110 — Byte Integer (B)

*This encoding in the MC68040 will cause an unimplemented data type exception to allow emulation in software.

Destination Register field—Specifies the destination floating-point data register.

Opmode field—Specifies the instruction and rounding precision.

- 0000000 FMOVE Rounding precision specified by the floating-point control register.
- 1000000 FSMOVE Single-precision rounding specified.
- 1000100 FDMOVE Double-precision rounding specified.

Register-to-Memory Operation: Rounds the source operand to the size of the destination format and stores it at the destination effective address. If the destination is packed decimal, a third operand is required to specify the format resultant string. This operand, called the k-factor, is a 7-bit signed integer (two's complement) and may be specified as an immediate value or in an integer register. If a data register contains the k-factor, only the least significant seven bits are used, and the rest of the register is ignored.

Quotient Byte:	Not affected.	
Exception Byte:	BSUN Cleared	
< fmt > is B, W, or L	SNAN Refer to 1.6.5 Not-A-Numbers .	
	OPERR Set if the source operand is infinity destination size is exceeded after c and rounding; cleared otherwise.

([bd,An],Xn,od)	110	reg. number:An	([bd,PC],Xn,od)	—

*Only if < fmt > is byte, word, long, or single.

Destination Format field—Specifies the data format of the destination operand.

- 000 — Long-Word Integer (L)
- 001 — Single-Precision Real (S)
- 010 — Extended-Precision Real (X)
- 011 — Packed-Decimal Real with Static k-Factor (P{#k})*
- 100 — Word Integer (W)
- 101 — Double-Precision Real (D)
- 110 — Byte Integer (B)
- 111 — Packed-Decimal Real with Dynamic k-Factor (P{Dn})*

*This encoding will cause an unimplemented data type exception in the MC68040 to allow emulation in software.

of the decimal string. For any other destination format, this field should be all zeros. For a static k-factor, this field is encoded with a twos-complement integer where the value defines the format as follows:

- 64 to 0—Indicates the number of significant digits to the right of the point (FORTRAN "F" format).
- + 1 to + 17—Indicates the number of significant digits in the mantissa (FORTRAN "E" format).
- + 18 to + 63—Sets the OPERR bit in the floating-point status register to 1 and treated as + 17.

The format of this field for a dynamic k-factor is:

r r r 0 0 0 0

where "rrr" is the number of the main processor data register that contains the value.

The following table gives several examples of how the k-factor value affects the format of the decimal string that is produced by the floating-point coprocessor. The format of the string that is generated is independent of the source of the k-factor (static or dynamic).

k- Factor	Source Operand Value	Destination String
– 5	+ 12345.678765	+ 1.234567877E + 4
– 3	+ 12345.678765	+ 1.2345679E + 4
– 1	+ 12345.678765	+ 1.23457E + 4
0	+ 12345.678765	+ 1.2346E + 4
+ 1	+ 12345.678765	+ 1.E + 4
+ 3	+ 12345.678765	+ 1.23E + 4
+ 5	+ 12345.678765	+ 1.2346E + 4

Assembler FMOVE.L < ea > ,FPCR
Syntax: FMOVE.L FPCR, < ea >

Attributes: Size = (Long)

Description: Moves the contents of a floating-point system control register (floating-point control register, floating-point status register, or floating-point instruction register) to or from an effective address. A 32-bit transfer is always performed, though the system control register may not have 32 implemented bits. Unimplemented bits of a control register are read as zeros and are ignored during writes (must be for compatibility with future devices). For the MC68881, this instruction does not depend on pending exceptions (other than protocol violations) to be reported. Furthermore, the floating-point control register exception enable byte or the floating-point instruction register exception status byte cannot generate a new exception, regardless of the value written.

Floating-Point Status Register: Changed only if the destination is the floating-point instruction register, in which case all bits are modified to reflect the value of the source operand.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1
1	1	1	1	COPROCESSOR ID			0	0	0	EFFECTIVE ADDRESS MODE			REGISTER	
1	0	dr	REGISTER SELECT		0	0	0	0	0	0	0	0	0	0

Effective Address field—(Memory-to-Register) All addressing modes can be listed in the following table:

Addressing Mode	Mode	Register
Dn	000	reg. number:Dn
An*	001	reg. number:An
(An)	010	reg. number:An
(An) +	011	reg. number:An

(d ₁₆ ,PC)	—
(d ₈ ,PC,Xn)	—
(bd,PC,Xn)	—
([bd,PC,Xn],od)	—
([bd,PC],Xn,od)	—

*Only if the source register is the floating-point instruction address register.

1 — From the specified system control register to < ea > .

Register Select field—Specifies the system control register to be moved:

100 Floating-Point Control Register

010 Floating-Point Status Register

001 Floating-Point Instruction Address Register

Syntax: FMOVECR.X # < ccc > ,FPn

Attributes: Format = (Extended)

Description: Fetches an extended-precision constant from the floating-point coprocessor on-chip ROM, rounds the mantissa to the precision specified in the floating-point control register mode control byte, and stores it in the destination floating-point register. The constant is specified by a predefined offset into the constant ROM. Values of the constants contained in the ROM are shown in the offset table at the end of this description.

Floating-Point Status Register:

Condition Codes: Affected as described in **3.6.2 Conditional Testing**

Quotient Byte: Not affected.

Exception Byte: BSUN Cleared

SNAN Cleared

OPERR Cleared

OVFL Cleared

UNFL Cleared

DZ Cleared

INEX2 Refer to inexact result in the appropriate user's manual.

INEX1 Cleared

Accrued Exception Byte: Affected as described in IEEE exception and trap handling capability in the appropriate user's manual.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2
1	1	1	1	COPROCESSOR ID			0	0	0	0	0	0	0
0	1	0	1	1	1	DESTINATION REGISTER			ROM OFFSET				

instruction. Motorola assemblers default to ID = 1 for the floating-point coprocessor.

Destination Register field—Specifies the destination floating-point data register.

ROM Offset field—Specifies the offset into the floating-point coprocessor constant ROM where the desired constant is located. The offsets for the constants are as follows:

Offset	Constant
\$00	π
\$0B	$\text{Log}_{10}(2)$
\$0C	e
\$0D	$\text{Log}_2(e)$
\$0E	$\text{Log}_{10}(e)$
\$0F	0.0
\$30	$1_n(2)$
\$31	$1_n(10)$
\$32	100
\$33	10^1
\$34	10^2
\$35	10^4
\$36	10^8
\$37	10^{16}
\$38	10^{32}
\$39	10^{64}
\$3A	10^{128}
\$3B	10^{256}
\$3C	10^{512}
\$3D	10^{1024}
\$3E	10^{2048}
\$3F	10^{4096}

The on-chip ROM contains other constants useful only to the on-chip microcontroller. The values contained at offsets other than those defined above are reserved for the use of Motorola and may be different on various mask sets of the floating-point coprocessor. These undefined values yield the value 0.0 in the M68040FPSP.

Assembler FMOVEM.X < list > , < ea >
Syntax: FMOVEM.X Dn, < ea >
FMOVEM.X < ea > , < list > FMOVEM.X < ea > ,Dn

Attributes: Format = (Extended)

Description: Moves one or more extended-precision numbers to or from a list of floating-point data registers. No conversion or rounding is performed during this operation; the floating-point status register is not affected by the instruction. For the MC68000, this instruction does not cause pending exceptions (other than protocol violations) to be reported. Furthermore, a write to the floating-point control register exception status byte or the floating-point status register exception status byte cannot generate an exception, despite the value written.

Any combination of the eight floating-point data registers can be transferred to or from the selected registers specified by a user-supplied mask. This mask is an 8-bit value where each bit corresponds to one register; if a bit is set in the mask, that register is moved. The register select mask may be specified as a static value contained in the instruction or a dynamic value in the least significant eight bits of an integer register (the remaining bits of the register are ignored).

FMOVEM allows three types of addressing modes: the control modes, the preincrement mode, or the postincrement mode. If the effective address is one of the control addressing modes, the registers are transferred between the processor and memory starting at the specified address and up through higher addresses. The order of transfer is from FP0 – FP7.

address register and down through lower addresses. Before each register is stored, the address register is decremented by 12 (the size of an extended-precision number in memory) and the floating-point data register is then stored at the resultant address. When the operation is complete, the address register points to the image of the last floating-point data register stored. The order of the transfer is from FP7 – FP0.

If the effective address is the postincrement mode, only a memory-to-register transfer is allowed. The registers are loaded starting at the specified address and moving through higher addresses. After each register is stored, the address register is incremented by 12 (the size of an extended-precision number in memory). When the operation is complete, the address register points to the byte immediately following the image of the last floating-point data register loaded. The order of the transfer is the same as for the control addressing modes: FP0 – FP7.

Floating-Point Status Register: Not Affected. Note that the FMOVE instruction is the only mechanism for moving a floating-point data item between the floating-point unit and memory without performing any data conversions or affecting the condition code and exception status bits.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	
1	1	1	1	COPROCESSOR ID			0	0	0	EFFECTIVE ADDRESS MODE REGISTER LIST					
1	1	dr	MODE		0	0	0								

Effective Address field—(Memory-to-Register) Only control alterable addressing modes or the postincrement addressing mode can be used as listed in the following table:

Addressing Mode	Mode	Register
Dn	—	—
An	—	—
(An)	010	reg. number:An
(An) +	011	reg. number:An

([bd,An,Xn],od)	110	reg. number:An
([bd,An],Xn,od)	110	reg. number:An

Addressing Mode	Mode
(xxx).W	111
(xxx).L	111
# < data >	—
(d ₁₆ ,PC)	—
(d ₈ ,PC,Xn)	—
(bd,PC,Xn)	—
([bd,PC,Xn],od)	—
([bd,PC],Xn,od)	—

1 — Move the listed registers from the floating-point unit to memory.

Mode field—Specifies the type of the register list and addressing mode.

00 — Static register list, predecrement addressing mode.

01 — Dynamic register list, predecrement addressing mode.

10 — Static register list, postincrement or control addressing mode.

11 — Dynamic register list, postincrement or control addressing mode.

Register List field:

Static list—contains the register select mask. If a register is to be moved, the corresponding bit in the mask is set as shown below; otherwise it is clear.

Dynamic list—contains the integer data register number, rrr, as listed in the following table:

List Type	Register List Format							
Static, – (An)	FP7	FP6	FP5	FP4	FP3	FP2	FP1	FP0
Static, (An) + , or Control	FP0	FP1	FP2	FP3	FP4	FP5	FP6	FP7
Dynamic	0	r	r	r	0	0	0	0

The format of the dynamic list mask is the same as for the static list and is contained in the least significant eight bits of the specified main processor data register.

Programming Note: This instruction provides a very useful feature, dynamic register specification, that can significantly enhance system performance. If the conventions used for procedure calls utilize the dynamic register list feature, the number of floating-point data registers saved and restored can be reduced.

To utilize the dynamic register specification feature of the FMOVEM instruction, the calling and the called procedures must be written to communicate information about register usage. When one procedure calls another, a register mask is passed to the called procedure to indicate which registers must not be altered on return to the calling procedure. The called procedure then saves only those registers that are modified and are already in use. Several techniques can be used to utilize this mechanism, and an example follows.

cedure. Bits 15 – 8 identify the registers in the order FP0 – FP7, and bits 7 – 0 identify the registers in the order FP7 – FP0 (the two masks are required due to the different order used by the predecrement and postincrement addressing modes). The mask used by the calling procedure consists of simply moving the mask (which is generated at compile time) for the floating-point data registers currently in use into D7:

Calling procedure...

MOVE.W	#ACTIVE,D7	Load the list of FP registers that are currently in use.
BSR	PROC_2	

The entry code for all other procedures computes two masks. The first mask identifies the registers in use by the calling procedure that are used by the called procedure (and therefore saved and restored by the called procedure). The second mask identifies the registers in use by the calling procedure that are used by the called procedure but are therefore not saved on entry). The appropriate registers are then stored along with the two masks:

Called procedure...

MOVE.W	D7,D6	Copy the list of active registers.
AND.W	#WILL_USE,D7	Generate the list of doubly-used registers.
FMOVEM	D7, – (A7)	Save those registers.
MOVE.W	D7, – (A7)	Save the register list.
EOR.W	D7,D6	Generate the list of not saved active registers.
MOVE.W	D6, – (A7)	Save it for later use.

If the second procedure calls a third procedure, a register mask is passed to the third procedure that indicates which registers must not be altered by the third procedure. This mask identifies any registers in the list from the first procedure that were not altered by the second procedure, plus any registers used by the second procedure that must not be altered by the third procedure.

Nested calling sequence...

MOVE.W	UNSAVED (A7),D7	Load the list of active registers not saved at entry.
OR.W	#WILL_USE,D7	Combine with those active at this t
BSR	PROC_3	

Upon return from a procedure, the restoration of the necessary registers follows the same convention, and the register mask generated during the save operation is used to restore the required floating-point data registers:

Return to caller...

ADDQ.L	#2,A7	Discard the list of registers not saved.
MOVE.B	(A7) + ,D7	Get the saved register list (pop word, use byte).
FMOVEM	(A7) + ,D7	Restore the registers.
	*	
	*	
	*	
RTS		Return to the calling routine.

Assembler FMOVEM.L < list > , < ea >
Syntax: FMOVEM.L < ea > , < list >

Attributes: Size = (Long)

Description: Moves one or more 32-bit values into or out of the specified system registers. Any combination of the three system control registers may be specified; the system control registers are always moved in the same order, regardless of the addressing mode used; the floating-point control register is moved first, followed by the floating-point status register, and the floating-point instruction address register is moved last. If the floating-point instruction address register is not selected for the transfer, the relative order of the transfer of the other registers is the same. The first register is transferred between the floating-point instruction address register and the specified address, with successive registers located up through higher addresses.

For the MC68881, this instruction does not cause pending exceptions (other than protocol violations) to be reported. Furthermore, a write to the floating-point control register exception enable byte or the floating-point status register exception status register cannot generate a new exception, despite the value written.

When more than one register is moved, the memory or memory-alterable addressing modes can be used as shown in the addressing mode tables. If the addressing mode is predecrement, the address register is first decremented by the total size of the register images to be moved (i.e., four times the number of registers), and then the registers are transferred starting at the resultant address. For the postincrement addressing mode, the selected registers are transferred to or from the specified address, and the address register is incremented by the total size of the register images transferred. If a single system control register is selected, the data register direct addressing mode may be used; if the only register selected is the floating-point instruction address register, then the address register direct addressing mode is allowed. Note that if the floating-point instruction address register is selected, the opcode generated is the same as for the FMOVE single system control register instruction.

register image.

Instruction Format:

Attributes:

Format = (Byte, Word, Long, Single, Double, Extended, Packed)

Description: Converts the source operand to extended precision (if necessary) and multiplies that number by the number in the destination floating-point data register. Stores the result in the destination floating-point data register.

FMUL will round the result to the precision selected in the floating-point control register. FSMUL and FDMUL will round the result to single or double precision, respectively, regardless of the rounding precision selected in the floating-point control register.

Operation Table:

DESTINATION	SOURCE ¹					
	+ In Range	- In Range	+ Zero	- Zero	+ Infinity	- Infinity
In Range	+ -	Multiply	+ 0.0 - 0.0	- 0.0 + 0.0	+ inf - inf	
Zero	+ -	+ 0.0 - 0.0	- 0.0 + 0.0	+ 0.0 - 0.0	- 0.0 + 0.0	NAN ²
Infinity	+ -	+ inf - inf	- inf + inf	NAN ²	+ inf - inf	

NOTES:

1. If the source operand is a NAN, refer to **1.6.5 Not-A-Numbers** for more information.
2. Sets the OPERR bit in the floating-point status register exception byte.

Quotient Byte:	Not affected.
Exception Byte:	BSUN Cleared
	SNAN Refer to 1.6.5 Not-A-Numbers .
	OPERR Set for 0 x infinity; cleared otherwise.
	OVFL Refer to exception processing appropriate user's manual.
	UNFL Refer to exception processing appropriate user's manual.
	DZ Cleared
	INEX2 Refer to exception processing appropriate user's manual.
	INEX1 If < fmt > is packed, refer to exception processing in the appropriate user's manual; cleared otherwise.
Accrued Exception Byte:	Affected as described in exception processing in the appropriate user's manual.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2
1	1	1	1	COPROCESSOR ID		0	0	0	EFFECTIVE ADDRESS MODE				REG
0	R/M	0	SOURCE SPECIFIER		DESTINATION REGISTER		OPMODE						

If R/M = 0, this field is unused and should be all zeros.
 If R/M = 1, specifies the location of the source operand location. Only data addressing modes can be used as listed in the following table:

Addressing Mode	Mode	Register
Dn*	000	reg. number:Dn
An	—	—
(An)	010	reg. number:An
(An) +	011	reg. number:An
– (An)	100	reg. number:An
(d ₁₆ ,An)	101	reg. number:An
(d ₈ ,An,Xn)	110	reg. number:An
(bd,An,Xn)	110	reg. number:An
([bd,An,Xn],od)	110	reg. number:An
([bd,An],Xn,od)	110	reg. number:An

Addressing Mode	Mode
(xxx).W	111
(xxx).L	111
# < data >	111
(d ₁₆ ,PC)	111
(d ₈ ,PC,Xn)	111
(bd,PC,Xn)	111
([bd,PC,Xn],od)	111
([bd,PC],Xn,od)	111

*Only if < fmt > is byte, word, long, or single.

R/M field—Specifies the source operand address mode.

- 0 — The operation is register to register.
- 1 — The operation is < ea > to register.

Source Specifier field—Specifies the source register or data format.

If R/M = 0, specifies the source floating-point data register.

If R/M = 1, specifies the source data format:

- 000 — Long-Word Integer (L)
- 001 — Single-Precision Real (S)
- 010 — Extended-Precision Real (X)
- 011 — Packed-Decimal Real (P)*
- 100 — Word Integer (W)
- 101 — Double-Precision Real (D)
- 110 — Byte Integer (B)

*This encoding will cause an unimplemented data type exception in the MC68040 to allow emulation in software.

0100011	FMUL	Rounding precision specified by the floating-point control register.
1100011	FSMUL	Single-precision rounding specified.
1100111	FDMUL	Double-precision rounding specified.

Syntax: FNEG.X FPm,FPn
 FNEG.X FPn
 *FrNEG. < fmt > < ea > ,FPn
 *FrNEG.X FPm,FPn
 *FrNEG.X FPn
 where r is rounding precision, S or D
 *Supported by MC68040 only

Attributes: Format = (Byte, Word, Long, Single, Double, Extended, Packed)

Description: Converts the source operand to extended precision (if necessary) and the sign of the mantissa. Stores the result in the destination floating-point data register.

FNEG will round the result to the precision selected in the floating-point control register. FSNEG and FDNEG will round the result to single or double precision, respectively, regardless of the rounding precision selected in the floating-point control register.

Operation Table:

DESTINATION	SOURCE										
	+	In Range	-	+	Zero	-	+	Infinity			
Result		Negate		-	0.0		+	0.0		-	inf

NOTE: If the source operand is a NAN, refer to **1.6.5 Not-A-Numbers** for more information.

Quotient Byte:	Not affected.
Exception Byte:	BSUN Cleared
	SNAN Refer to 1.6.5 Not-A-Numbers.
	OPERR Cleared
	OVFL Cleared
	UNFL If source is an extended-denormalized number, refer to exception processing in the appropriate user's manual. Cleared otherwise.
	DZ Cleared
	INEX2 Cleared
INEX1 If < fmt > is packed, refer to exception processing in the appropriate user's manual. Cleared otherwise.	
Accrued Exception Byte:	Affected as described in exception processing in the appropriate user's manual.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2
1	1	1	1	COPROCESSOR ID		0	0	0	EFFECTIVE ADDRESS MODE		REG		
0	R/M	0	SOURCE SPECIFIER		DESTINATION REGISTER		OPMODE						

If R/M = 0, this field is unused and should be all zeros.
 If R/M = 1, specifies the location of the source operand. Only data addressing modes can be used as listed in the following table:

Addressing Mode	Mode	Register
Dn*	000	reg. number:Dn
An	—	—
(An)	010	reg. number:An
(An) +	011	reg. number:An
– (An)	100	reg. number:An
(d ₁₆ ,An)	101	reg. number:An
(d ₈ ,An,Xn)	110	reg. number:An
(bd,An,Xn)	110	reg. number:An
([bd,An,Xn],od)	110	reg. number:An
([bd,An],Xn,od)	110	reg. number:An

Addressing Mode	Mode
(xxx).W	111
(xxx).L	111
# < data >	111
(d ₁₆ ,PC)	111
(d ₈ ,PC,Xn)	111
(bd,PC,Xn)	111
([bd,PC,Xn],od)	111
([bd,PC],Xn,od)	111

*Only if < fmt > is byte, word, long, or single.

R/M field—Specifies the source operand address mode.

- 0 — The operation is register to register.
- 1 — The operation is < ea > to register.

Source Specifier field—Specifies the source register or data format.

If R/M = 0, specifies the source floating-point data register.

If R/M = 1, specifies the source data format:

- 000 — Long-Word Integer (L)
- 001 — Single-Precision Real (S)
- 010 — Extended-Precision Real (X)
- 011 — Packed-Decimal Real (P)*
- 100 — Word Integer (W)
- 101 — Double-Precision Real (D)
- 110 — Byte Integer (B)

*This encoding will cause an unimplemented data type exception to allow emulation in software.

the same register. If the single register syntax is used, Motorola assembles the source and destination fields to the same value.

Opmode field—Specifies the instruction and rounding precision.

0011010	FNEG	Rounding precision specified by the floating-point control register.
1011010	FSNEG	Single-precision rounding specified.
1011110	FDNEG	Double-precision rounding specified.

Syntax: FNOP

Attributes: Unsize

Description: This instruction does not perform any explicit operation. However, it is used to force synchronization of the floating-point unit with an integer unit or to process pending exceptions. For most floating-point instructions, the integer unit is allowed to continue with the execution of the next instruction once the floating-point unit has any operands needed for an operation, thus supporting concurrent execution of floating-point and integer instructions. The FNOP instruction synchronizes the floating-point unit and the integer unit by causing the integer unit to wait until previous floating-point instructions have completed. Execution of FNOP also forces any exceptions pending from the execution of a previous floating-point instruction to be processed as a preinstruction exception.

The MC68882 may not wait to begin execution of another floating-point instruction until it has completed execution of the current instruction. The FNOP instruction synchronizes the coprocessor and microprocessor unit by causing the microprocessor to wait until the current instruction (or both instructions) have completed.

The FNOP instruction also forces the processing of exceptions pending from the execution of previous instructions. This is also inherent in the way that the floating-point coprocessor utilizes the M68000 family coprocessor interface. Once the floating-point coprocessor has received the input operand for an arithmetic instruction, it releases the main processor to execute the next instruction (regardless of whether or not concurrent execution is prevented for the instruction due to tracing) without delaying the exception during the execution of that instruction. Then, when the main processor attempts to initiate the execution of the next floating-point coprocessor instruction, a preinstruction exception may be reported to initiate exception processing of the exception that occurred during a previous instruction. By using the FNOP instruction, the user can force any pending exceptions to be processed without performing other operations.

Floating-Point Status Register: Not Affected.

1	1	1	1	COPROCESSOR ID			0	1	0	0	0	0	0	0
0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Instruction Fields:

Coprocessor ID field—Specifies which coprocessor in the system is to execute the instruction. Motorola assemblers default to ID = 1 for the floating-point coprocessor.

NOTE

FNOP uses the same opcode as the FBcc.W < label > instruction, with cc = F (nontrapping false) and < label > = + 2 (which results in a displacement of 0).

Syntax: FREM.X FPm,FPn

Attributes: Format = (Byte, Word, Long, Single, Double, Extended, Packed)

Description: Converts the source operand to extended precision (if necessary) and calculates the modulo remainder of the number in the destination floating-point register, using the source operand as the modulus. Stores the result in the destination floating-point data register and stores the sign and seven least significant bits of the quotient in the floating-point status register quotient byte (the quotient is the $FPn \div Source$). The IEEE remainder function is defined as:

$$FPn - (Source \times N)$$

where $N = INT (FPn \div Source)$ in the round-to-nearest mode.

The FREM function is not defined for a source operand equal to zero or for a destination operand equal to infinity. Note that this function is not the same as the FREM instruction, which uses the round-to-zero mode and thus returns a remainder that is different from the remainder required by the IEEE *Specification for Binary Floating-Point Arithmetic*.

Operation Table:

DESTINATION	SOURCE ¹							
	+	In Range	-	+	Zero#	-	+	Infinity
In Range	+	IEEE Remainder	-	+	NAN ²	-	+	FPn ²
	-							
Zero	+	+ 0.0	-	+	NAN ²	-	+	+ 0.0
	-	- 0.0						- 0.0
Infinity	+	NAN ²	-	+	NAN ²	-	+	NAN ^{†2}
	-							

NOTES:

1. If the source operand is a NAN, refer to **1.6.5 Not-A-Numbers** for more information.
2. Sets the OPERR bit in the floating-point status register exception byte.
3. Returns the value of FPn before the operation. However, the result is processed by the normal instruction termination procedure to round it as required. Thus, an overflow and/or inexact result may occur if the rounding precision has been changed to a smaller size since the FPn value was loaded.

Quotient Byte:	Loaded with the sign and least significant seven bits of the quotient (FPn ÷ Source). The sign of the quotient is the exclusive-OR of the sign bits of the source and destination operands.	
Exception Byte:	BSUN	Cleared
	SNAN	Refer to 1.6.5 Not-A-Numbers .
	OPERR	Set if the source is zero or the destination is infinity; cleared otherwise.
	OVFL	Cleared
	UNFL	Refer to underflow in the appropriate user's manual.
	DZ	Cleared
	INEX2	Cleared
	INEX1	If < fmt > is packed, refer to inexact result in the appropriate user's manual; cleared otherwise.
Accrued Exception Byte:	Affected as described in IEEE exception and trap handling in the appropriate user's manual.	

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	
1	1	1	1	COPROCESSOR ID		0	0	0	EFFECTIVE ADDRESS MODE					REG
0	R/M	0	SOURCE SPECIFIER		DESTINATION REGISTER			0	1	0	0	1		

Instruction Fields:

Coprocessor ID field—Specifies which coprocessor in the system is to execute the instruction. Motorola assemblers default to ID = 1 for the floating-point coprocessor.

the following table:

Addressing Mode	Mode	Register
Dn*	000	reg. number:Dn
An	—	—
(An)	010	reg. number:An

(d ₁₆ ,An)	101	reg. number:An
(d ₈ ,An,Xn)	110	reg. number:An
(bd,An,Xn)	110	reg. number:An
([bd,An,Xn],od)	110	reg. number:An
([bd,An],Xn,od)	110	reg. number:An

Addressing Mode	Mode
(xxx).W	111
(xxx).L	111
# < data >	111
(d ₁₆ ,PC)	111
(d ₈ ,PC,Xn)	111
(bd,PC,Xn)	111
([bd,PC,Xn],od)	111
([bd,PC],Xn,od)	111

*Only if < fmt > is byte, word, long, or single.

R/M field—Specifies the source operand address mode.

- 0 — The operation is register to register.
- 1 — The operation is < ea > to register.

Source Specifier field—Specifies the source register or data format.

If R/M = 0, specifies the source floating-point data register.

If R/M = 1, specifies the source data format:

- 000 — Long-Word Integer (L)
- 001 — Single-Precision Real (S)
- 010 — Extended-Precision Real (X)
- 011 — Packed-Decimal Real (P)
- 100 — Word Integer (W)
- 101 — Double-Precision Real (D)
- 110 — Byte Integer (B)

Destination Register field—Specifies the destination floating- point data register.

Syntax: FSCALE.X Fp_m,Fp_n

Attributes: Format = (Byte, Word, Long, Single, Double, Extended, Pack

Description: Converts the source operand to an integer (if necessary) and adds the result to the destination exponent. Stores the result in the destination floating-point register. This function has the effect of multiplying the destination by 2^{Source} , which is much faster than a multiply operation when the source is an integer value.

The floating-point coprocessor assumes that the scale factor is an integer value when the operation is executed. If not, the value is chopped (i.e., rounded using the round-to-zero mode) to an integer before it is added to the exponent. When the absolute value of the source operand is $\geq 2^{14}$, an overflow or underflow always results.

Operation Table:

DESTINATION	SOURCE ¹						
	+	In Range	-	+	Zero	-	+
In Range + -	Scale Exponent		FPn ²		NaN ³		
Zero + -	+ 0.0	- 0.0	+ 0.0	- 0.0	NaN ³		
Infinity + -	+ inf	- inf	+ inf	- inf	NaN ³		

NOTES:

1. If the source operand is a NaN, refer to **1.6.5 Not-A-Numbers** for more information.
2. Returns the value of Fp_n before the operation. However, the result is processed by the normal instruction termination procedure to round it as required. Thus, an overflow and/or inexact result may occur if the rounding precision has been changed to a smaller size since the Fp_n value was loaded.
3. Sets the OPERR bit in the floating-point status register exception byte.

Quotient Byte:	Not affected

(xxx).L	111
# < data >	—
(d ₁₆ ,PC)	—
(d ₈ ,PC,Xn)	—
(bd,PC,Xn)	—
([bd,PC,Xn],od)	—
([bd,PC],Xn,od)	—

Conditional Predicate field—Specifies one of 32 conditional tests as defined in
Conditional Testing.

NOTE

When a BSUN exception occurs, a preinstruction exception is taken. If the exception handler returns without modifying the image of the program counter on the stack frame (to point to the instruction following the FSc), then it must clear the cause of the exception (by clearing the NAN bit or disabling the BSUN trap) or the exception occurs again immediately upon return to the routine that caused the exception.

Syntax:

FSGLDIV.X

FPm,FPn

Attributes:

Format = (Byte, Word, Long, Single, Double, Extended, Packed)

Description: Converts the source operand to extended precision (if necessary) and that number into the number in the destination floating-point data register. The result is in the destination floating-point data register, rounded to single precision (if the current rounding precision is not single precision). This function is undefined for $0 \div 0$ and infinity \div infinity.

Both the source and destination operands are assumed to be representable in single-precision format. If either operand requires more than 24 bits of mantissa to be accurately represented, the extraneous mantissa bits are truncated prior to division, hence the accuracy of the result is not guaranteed. Furthermore, the result may exceed the range of single precision, regardless of the rounding precision selected in the floating-point control register mode control byte. Refer to **3.6.1 Overflow, Round, Overflow** for more information.

The accuracy of the result is not affected by the number of mantissa bits required to represent each input operand since the input operands just change to extended precision. The result mantissa is rounded to single precision, and the result exponent is rounded to extended precision, despite the rounding precision selected in the floating-point control register.

Operation Table:

DESTINATION	SOURCE ^{3,1}						
		In Range		Zero		Infinity	
In Range	+	Divide (Single Precision)		+ inf ²	- inf ²	+ 0.0	- 0.0
	-			- inf ²	+ inf ²	- 0.0	+ 0.0
Zero	+	+ 0.0	- 0.0	NaN ³		+ 0.0	- 0.0
	-	- 0.0	+ 0.0			- 0.0	+ 0.0
Infinity	+	+ inf	- inf	+ inf	- inf	NaN ³	
	-	- inf	+ inf	- inf	+ inf		

NOTES:

1. If the source operand is a NaN, refer to **1.6.5 Not-A-Numbers** for more information.
2. Sets the DZ bit in the floating-point status register exception byte.
3. Sets the OPERR bit in the floating-point status register exception byte.

Quotient Byte:	Not affected.
Exception Byte:	BSUN Cleared
	SNAN Refer to 1.6.5 Not-A-Numbers .
	OPERR Set for $0 \div 0$ or infinity \div infinity.
	OVFL Refer to overflow in the appropriate user's manual.
	UNFL Refer to underflow in the appropriate user's manual.
	DZ Set if the source is zero and the destination is not in range; cleared otherwise.
	INEX2 Refer to inexact result in the appropriate user's manual.
INEX1 If < fmt > is packed, refer to the appropriate user's manual for inexact result on packed input; cleared otherwise.	

Accrued Exception Byte: Affected as described in IEEE exception and trap handling section of the appropriate user's manual.

*Only if < fmt > is byte, word, long, or single.

R/M field—Specifies the source operand address mode.

- 0 — The operation is register to register.
- 1 — The operation is < ea > to register.

Source Specifier field—Specifies the source register or data format.

If R/M = 0, specifies the source floating-point data register.

If R/M = 1, specifies the source data format:

- 000 — Long-Word Integer (L)
- 001 — Single-Precision Real (S)
- 010 — Extended-Precision Real (X)
- 011 — Packed-Decimal Real (P)
- 100 — Word Integer (W)
- 101 — Double-Precision Real (D)
- 110 — Byte Integer (B)

Destination Register field—Specifies the destination floating- point data register.

Syntax: FSGLMUL.X FpM,FPn

Attributes: Format = (Byte, Word, Long, Single, Double, Extended, Pack

Description: Converts the source operand to extended precision (if necessary) and multiplies that number by the number in the destination floating-point data register. Stores the result in the destination floating-point data register, rounded to the current precision (regardless of the current rounding precision).

Both the source and destination operands are assumed to be representable in single-precision format. If either operand requires more than 24 bits of mantissa to be accurately represented, the extraneous mantissa bits are truncated prior to multiplication; hence, the accuracy of the result is not guaranteed. Furthermore, the exponent may exceed the range of single precision, regardless of the rounding mode selected in the floating-point control register mode control byte. Refer to **Underflow, Round, Overflow** for more information.

Operation Table:

DESTINATION	SOURCE ¹					
		In Range		Zero		Infinity
In Range	+	Multiply (Single Precision)		+ 0.0	- 0.0	+ inf
	-			- 0.0	+ 0.0	- inf
Zero	+	+ 0.0	- 0.0	+ 0.0	- 0.0	NaN ²
	-	- 0.0	+ 0.0	- 0.0	+ 0.0	
Infinity	+	+ inf	- inf	NaN		+ inf
	-	- inf	+ inf			- inf

NOTES:

1. If the source operand is a NaN, refer to **1.6.5 Not-A-Numbers** for more information.
2. Sets the OPERR bit in the floating-point status register exception byte.

NOTE

The input operand mantissas truncate to single precision before the multiply operation. The result mantissa rounds to single precision despite the rounding precision selected in the floating-point control register.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1
1	1	1	1	COPROCESSOR ID			0	0	0	EFFECTIVE ADDRESS MODE			REGISTER	
0	R/M	0	SOURCE SPECIFIER			DESTINATION REGISTER			0	1	0	0	1	1

Instruction Fields:

Coprocessor ID field—Specifies which coprocessor in the system is to execute the instruction. Motorola assemblers default to ID = 1 for the floating-point coprocessor.

the following table:

Addressing Mode	Mode	Register
Dn*	000	reg. number:Dn
An	—	—
(An)	010	reg. number:An
(An) +	011	reg. number:An
– (An)	100	reg. number:An
(d ₁₆ ,An)	101	reg. number:An
(d ₈ ,An,Xn)	110	reg. number:An
(bd,An,Xn)	110	reg. number:An
([bd,An,Xn],od)	110	reg. number:An
([bd,An],Xn,od)	110	reg. number:An

Addressing Mode	Mode
(xxx).W	111
(xxx).L	111
# < data >	111
(d ₁₆ ,PC)	111
(d ₈ ,PC,Xn)	111
(bd,PC,Xn)	111
([bd,PC,Xn],od)	111
([bd,PC],Xn,od)	111

*Only if < fmt > is byte, word, long, or single.

R/M field—Specifies the source operand address mode.

- 0 — The operation is register to register.
- 1 — The operation is < ea > to register.

Source Specifier field—Specifies the source register or data format.

If R/M = 0, specifies the source floating-point data register.

If R/M = 1, specifies the source data format:

- 000 — Long-Word Integer (L)
- 001 — Single-Precision Real (S)
- 010 — Extended-Precision Real (X)
- 011 — Packed-Decimal Real (P)
- 100 — Word Integer (W)
- 101 — Double-Precision Real (D)
- 110 — Byte Integer (B)

Destination Register field—Specifies the destination floating- point data register.

Syntax: FSIN.X FPm,FPn
 FSIN.X FPn

Attributes: Format = (Byte, Word, Long, Single, Double, Extended, Packed)

Description: Converts the source operand to extended precision (if necessary) and calculates the sine of that number. Stores the result in the destination floating-point data register. This function is not defined for source operands of \pm infinity. If the source operand is not in the range of $[-2\pi... + 2\pi]$, the argument is reduced to within that range before the sine is calculated. However, large arguments may lose accuracy during reduction, and very large arguments (greater than approximately 10^{20}) may lose accuracy. The result is in the range of $[-1... + 1]$.

Operation Table:

DESTINATION	SOURCE ¹									
	+	In Range	-	+	Zero	-	+	Infinity		
Result		Sine		+	0.0		-	0.0		NAN ²

NOTES:

1. If the source operand is a NAN, refer to **1.6.5 Not-A-Numbers** for more information.
2. Sets the OPERR bit in the floating-point status register exception byte.

Floating-Point Status Register:

Condition Codes: Affected as described in **3.6.2 Conditional Testing**

Quotient Byte: Not affected.

OPERR	Set if the source is \pm infinity, otherwise.
OVFL	Cleared
UNFL	Refer to underflow in the appropriate user's manual.
DZ	Cleared
INEX2	Refer to inexact result in the appropriate user's manual.
INEX1	If < fmt > is packed, refer to inexact decimal input in the appropriate user's manual; cleared otherwise.

Accrued Exception Byte: Affected as described in IEEE exception and trap capability in the appropriate user's manual.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2
1	1	1	1	COPROCESSOR ID			0	0	0	EFFECTIVE ADDRESS			
										MODE		REG	
0	R/M	0	SOURCE SPECIFIER			DESTINATION REGISTER			0	0	0	1	1

Instruction Fields:

Coprocessor ID field—Specifies which coprocessor in the system is to execute instruction. Motorola assemblers default to ID = 1 for the floating point coprocessor.

the following table:

Addressing Mode	Mode	Register
Dn*	000	reg. number:Dn
An	—	—
(An)	010	reg. number:An
(An) +	011	reg. number:An
– (An)	100	reg. number:An
(d ₁₆ ,An)	101	reg. number:An
(d ₈ ,An,Xn)	110	reg. number:An
(bd,An,Xn)	110	reg. number:An
([bd,An,Xn],od)	110	reg. number:An
([bd,An],Xn,od)	110	reg. number:An

Addressing Mode	Mode
(xxx).W	111
(xxx).L	111
# < data >	111
(d ₁₆ ,PC)	111
(d ₈ ,PC,Xn)	111
(bd,PC,Xn)	111
([bd,PC,Xn],od)	111
([bd,PC],Xn,od)	111

*Only if < fmt > is byte, word, long, or single.

R/M field—Specifies the source operand address mode.

- 0 — The operation is register to register.
- 1 — The operation is < ea > to register.

Source Specifier field—Specifies the source register or data format.

If R/M = 0, specifies the source floating-point data register.

If R/M = 1, specifies the source data format:

- 000 — Long-Word Integer (L)
- 001 — Single-Precision Real (S)
- 010 — Extended-Precision Real (X)
- 011 — Packed-Decimal Real (P)
- 100 — Word Integer (W)
- 101 — Double-Precision Real (D)
- 110 — Byte Integer (B)

Destination Register field—Specifies the destination floating-point data register.

M = 0 and the source and destination fields are equal, then the input operand is taken from the specified floating-point data register, and the result is written to the same register. If the single register syntax is used, Motorola assembler copies the source and destination fields to the same value.

Assembler FSINCOS. < fmt > < ea > ,FPc,FPs
Syntax: FSINCOS.X FPm,FPc,FPs

Attributes: Format = (Byte, Word, Long, Single, Double, Extended, Pack

Description: Converts the source operand to extended precision (if necessary) and calculates both the sine and the cosine of that number. Calculates both sine and cosine simultaneously; thus, this instruction is significantly faster than performing FSIN and FCOS instructions. Loads the sine and cosine results into the destination floating-point data register. Sets the condition code bits according to the sine and cosine results. If FPc and FPm are specified to be the same register, the cosine result is first loaded into the register and then is overwritten with the sine result. This function is not defined for source operands of \pm infinity.

If the source operand is not in the range of $[-2\pi \dots + 2\pi]$, the argument is reduced to within that range before the sine and cosine are calculated. However, large arguments may lose accuracy during reduction, and very large arguments (greater than approximately 10^{20}) lose all accuracy. The results are in the range of $[-1 \dots + 1]$.

Operation Table:

DESTINATION	SOURCE ¹								
	+	In Range	-	+	Zero	-	+	Infinity	
FPs		Sine		+	0.0		-	0.0	NAN ²
FPc		Cosine			+ 1.0				NAN ²

NOTES:

1. If the source operand is a NAN, refer to **1.6.5 Not-A-Numbers** for more information.
2. Sets the OPERR bit in the floating-point status register exception byte.

Quotient Byte: Not affected.

Exception Byte:

- BSUN Cleared
- SNAN Refer to **1.6.5 Not-A-Numbers**.
- OPERR Set if the source is \pm infinity; otherwise.
- OVFL Cleared
- UNFL Set if a sine underflow occurs, in which the cosine result is 1. Cosine underflow. Refer to underflow appropriate user's manual.
- DZ Cleared
- INEX2 Refer to inexact result in the appropriate user's manual.
- INEX1 If <fmt > is packed, refer to inexact result in the appropriate user's manual; cleared otherwise.

Accrued Exception Byte: Affected as described in IEEE exception and trap handling capability in the appropriate user's manual.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1
1	1	1	1	COPROCESSOR ID			0	0	0	EFFECTIVE ADDRESS MODE			0	0
0	R/M	0	SOURCE SPECIFIER			DESTINATION REGISTER, FPs			0	1	1	0	DESTINATION REGISTER	

Instruction Fields:

Coprocessor ID field—Specifies which coprocessor in the system is to execute the instruction. Motorola assemblers default to ID = 1 for the floating-point coprocessor.

the following table:

Addressing Mode	Mode	Register
Dn*	000	reg. number:Dn
An	—	—
(An)	010	reg. number:An
(An) +	011	reg. number:An
– (An)	100	reg. number:An
(d ₁₆ ,An)	101	reg. number:An
(d ₈ ,An,Xn)	110	reg. number:An
(bd,An,Xn)	110	reg. number:An
([bd,An,Xn],od)	110	reg. number:An
([bd,An],Xn,od)	110	reg. number:An

Addressing Mode	Mode
(xxx).W	111
(xxx).L	111
# < data >	111
(d ₁₆ ,PC)	111
(d ₈ ,PC,Xn)	111
(bd,PC,Xn)	111
([bd,PC,Xn],od)	111
([bd,PC],Xn,od)	111

*Only if < fmt > is byte, word, long, or single.

R/M field—Specifies the source operand address mode.

- 0 — The operation is register to register.
- 1 — The operation is < ea > to register.

Source Specifier field—Specifies the source register or data format.

If R/M = 0, specifies the source floating-point data register.

If R/M = 1, specifies the source data format:

- 000 — Long-Word Integer (L)
- 001 — Single-Precision Real (S)
- 010 — Extended-Precision Real (X)
- 011 — Packed-Decimal Real (P)
- 100 — Word Integer (W)
- 101 — Double-Precision Real (D)
- 110 — Byte Integer (B)

Destination Register, FPc field—Specifies the destination floating-point data register.

FPc. The cosine result is stored in this register.

If $R/M = 0$ and the source register field is equal to either of the destination fields, the input operand is taken from the specified floating-point data register. appropriate result is written into the same register.

Syntax: FSINH.X FPM,FPn
FSINH.X FPn

Attributes: Format = (Byte, Word, Long, Single, Double, Extended, Packed)

Description: Converts the source operand to extended precision (if necessary) and calculates the hyperbolic sine of that number. Stores the result in the destination floating-point data register.

Operation Table:

DESTINATION	SOURCE				
	+ In Range	- + Zero	- + Infinity		
Result	Hyperbolic Sine	+ 0.0	- 0.0	+ inf	

NOTE: If the source operand is a NAN, refer to **1.6.5 Not-A-Numbers** for more information.

Floating-Point Status Register:

Condition Codes: Affected as described in **3.6.2 Conditional Test Instructions**.

Quotient Byte: Not affected.

Exception Byte:

- BSUN Cleared
- SNAN Refer to **1.6.5 Not-A-Numbers**.
- OPERR Cleared
- OVFL Refer to overflow in the appropriate user's manual.
- UNFL Refer to underflow in the appropriate user's manual.
- DZ Cleared
- INEX2 Refer to inexact result in the appropriate user's manual.
- INEX1 If < fmt > is packed, refer to inexact result in the appropriate user's manual; cleared otherwise.

Accrued Exception Byte: Affected as described in IEEE exception and trap handling capability in the appropriate user's manual.

1	1	1	1	COPROCESSOR ID		0	0	0	EFFECTIVE ADDRESS MODE			REGIS
0	R/M	0	SOURCE SPECIFIER		DESTINATION REGISTER		0	0	0	0	0	1

Instruction Fields:

Coprocessor ID field—Specifies which coprocessor in the system is to execute the instruction. Motorola assemblers default to ID = 1 for the floating-point coprocessor.

Effective Address field—Determines the addressing mode for external operands. If R/M = 0, this field is unused and should be all zeros.

If R/M = 1, this field is encoded with an M68000 family addressing mode as shown in the following table:

Addressing Mode	Mode	Register
Dn*	000	reg. number:Dn
An	—	—
(An)	010	reg. number:An
(An) +	011	reg. number:An
– (An)	100	reg. number:An
(d ₁₆ ,An)	101	reg. number:An
(d ₈ ,An,Xn)	110	reg. number:An
(bd,An,Xn)	110	reg. number:An
([bd,An,Xn],od)	110	reg. number:An
([bd,An],Xn,od)	110	reg. number:An

Addressing Mode	Mode
(xxx).W	111
(xxx).L	111
# < data >	111
(d ₁₆ ,PC)	111
(d ₈ ,PC,Xn)	111
(bd,PC,Xn)	111
([bd,PC,Xn],od)	111
([bd,PC],Xn,od)	111

*Only if < fmt > is byte, word, long, or single.

Source Specifier field—Specifies the source register or data format.

If R/M = 0, specifies the source floating-point data register.

If R/M = 1, specifies the source data format:

000 — Long-Word Integer (L)

001 — Single-Precision Real (S)

010 — Extended-Precision Real (X)

011 — Packed-Decimal Real (P)

100 — Word Integer (W)

101 — Double-Precision Real (D)

110 — Byte Integer (B)

Destination Register field—Specifies the destination floating-point data register.

If R/M = 0 and the source and destination fields are equal, the input operand is read from the specified floating-point data register, and the result is written to the same register. If the single register syntax is used, Motorola assembler requires the source and destination fields to be the same value.

Syntax:

FSQRT.X FPM,FPn

FSQRT.X FPn

*FrSQRT. < fmt > < ea > ,FPn

*FrSQRT FPM,FPn

*FrSQRT FPn

where r is rounding precision, S or D

*Supported by MC68040 only

Attributes:

Format = (Byte, Word, Long, Single, Double, Extended, Packed)

Description: Converts the source operand to extended precision (if necessary) and calculates the square root of that number. Stores the result in the destination floating-point data register. This function is not defined for negative operands.

FSQRT will round the result to the precision selected in the floating-point control register. FSFSQRT and FDFSQRT will round the result to single or double precision, respectively, regardless of the rounding precision selected in the floating-point control register. Operation Table:

DESTINATION	SOURCE ¹									
	+	In Range	-	+	Zero	-	+	Infinity		
Result	\sqrt{x}		NAN ²	+	0.0	-	0.0	+	inf	N

NOTES:

1. If the source operand is a NAN, refer to **1.6.5 Not-A-Numbers** for more information.
2. Sets the OPERR bit in the floating-point status register exception byte.

Quotient Byte:	Not affected.
Exception Byte:	BSUN Cleared
	SNAN Refer to 1.6.5 Not-A-Numbers .
	OPERR Set if the source operand is not zero or negative; cleared otherwise.
	OVFL Cleared
	UNFL Cleared
	DZ Cleared
	INEX2 Refer to exception processing in the appropriate user's manual.
	INEX1 If < fmt > is packed, refer to exception processing in the appropriate user's manual; cleared otherwise.

Accrued Exception Byte: Affected as described in exception processing in the appropriate user's manual.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2
1	1	1	1	COPROCESSOR ID			0	0	0	EFFECTIVE ADDRESS MODE			
0	R/M	0	SOURCE SPECIFIER			DESTINATION REGISTER			OPMODE				

If R/M = 0, this field is unused and should be all zeros.
 If R/M = 1, specifies the location of the source operand. Only data addressing modes can be used as listed in the following table:

Addressing Mode	Mode	Register		Addressing Mode	Mode
Dn*	000	reg. number:Dn		(xxx).W	111
An	—	—		(xxx).L	111
(An)	010	reg. number:An		# < data >	111
(An) +	011	reg. number:An			
– (An)	100	reg. number:An			
(d ₁₆ ,An)	101	reg. number:An		(d ₁₆ ,PC)	111
(d ₈ ,An,Xn)	110	reg. number:An		(d ₈ ,PC,Xn)	111
(bd,An,Xn)	110	reg. number:An		(bd,PC,Xn)	111
([bd,An,Xn],od)	110	reg. number:An		([bd,PC,Xn],od)	111
([bd,An],Xn,od)	110	reg. number:An		([bd,PC],Xn,od)	111

*Only if < fmt > is byte, word, long, or single.

R/M field—Specifies the source operand address mode.

- 0 — The operation is register to register.
- 1 — The operation is < ea > to register.

Source Specifier field—Specifies the source register or data format.

If R/M = 0, specifies the source floating-point data register.

If R/M = 1, specifies the source data format:

- 000 — Long-Word Integer (L)
- 001 — Single-Precision Real (S)
- 010 — Extended-Precision Real (X)
- 011 — Packed-Decimal Real (P)*
- 100 — Word Integer (W)
- 101 — Double-Precision Real (D)
- 110 — Byte Integer (B)

*This encoding will cause an unimplemented data type exception in the MC68040 to allow emulation in software.

same register. If the single register syntax is used, Motorola assembles source and destination fields to the same value.

Opmode field—Specifies the instruction and rounding precision.

0000100	FSQRT	Rounding precision specified by the floating-point control register.
1000001	FSSQRT	Single-precision rounding specified.
1000101	FDSQRT	Double-precision rounding specified.

Syntax:

FSUB. < fmt > < ea > ,FPn
 FSUB.X Fm,FPn
 *FrSUB. < fmt > < ea > ,FPn
 *FrSUB.X Fm,FPn
 where r is rounding precision, S or D
 *Supported by MC68040 only

Attributes:

Format = (Byte, Word, Long, Single, Double, Extended, Packed)

Description: Converts the source operand to extended precision (if necessary) and subtracts that number from the number in the destination floating-point data register. Stores the result in the destination floating-point data register.

Operation Table:

DESTINATION	SOURCE ¹			
	+ In Range	- + In Range	- + Zero	- + Infinity
In Range	+ -	Subtract	Subtract	- inf
Zero	+ -	Subtract	+ 0.0 ² + 0.0	+ 0.0 + 0.0 ² - inf
Infinity	+ -	+ inf - inf	+ inf - inf	NAN ² - inf

NOTES:

1. If the source operand is a NAN, refer to **1.6.5 Not-A-Numbers** for more information.
2. Returns + 0.0 in rounding modes RN, RZ, and RP; returns - 0.0 in RM.
3. Sets the OPERR bit in the floating-point status register exception byte.

Quotient Byte:	Not affected.
Exception Byte:	BSUN Cleared
	SNAN Refer to 1.6.5 Not-A-Numbers .
	OPERR Set if both the source and destination are like-signed infinities; cleared otherwise.
	OVFL Refer to exception processing in the appropriate user's manual.
	UNFL Refer to exception processing in the appropriate user's manual.
	DZ Cleared
	INEX2 Refer to exception processing in the appropriate user's manual.
	INEX1 If < fmt > is packed, refer to exception processing in the appropriate user's manual; cleared otherwise.

Accrued Exception Byte: Affected as described in IEEE exception and trap processing in the appropriate user's manual.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2
1	1	1	1	COPROCESSOR ID			0	0	0	EFFECTIVE ADDRESS			
										MODE			REG
0	R/M	0	SOURCE SPECIFIER			DESTINATION REGISTER			OPMODE				

If R/M = 0, this field is unused and should be all zeros.
 If R/M = 1, specifies the location of the source operand. Only data addressing modes can be used as listed in the following table:

Addressing Mode	Mode	Register		Addressing Mode	Mode
Dn*	000	reg. number:Dn		(xxx).W	111
An	—	—		(xxx).L	111
(An)	010	reg. number:An		# < data >	111
(An) +	011	reg. number:An			
– (An)	100	reg. number:An			
(d ₁₆ ,An)	101	reg. number:An		(d ₁₆ ,PC)	111
(d ₈ ,An,Xn)	110	reg. number:An		(d ₈ ,PC,Xn)	111
(bd,An,Xn)	110	reg. number:An		(bd,PC,Xn)	111
([bd,An,Xn],od)	110	reg. number:An		([bd,PC,Xn],od)	111
([bd,An],Xn,od)	110	reg. number:An		([bd,PC],Xn,od)	111

*Only if < fmt > is byte, word, long, or single.

R/M field—Specifies the source operand address mode.

- 0 — The operation is register to register.
- 1 — The operation is < ea > to register.

Source Specifier field—Specifies the source register or data format.

If R/M = 0, specifies the source floating-point data register.

If R/M = 1, specifies the source data format:

- 000 — Long-Word Integer (L)
- 001 — Single-Precision Real (S)
- 010 — Extended-Precision Real (X)
- 011 — Packed-Decimal Real (P)*
- 100 — Word Integer (W)
- 101 — Double-Precision Real (D)
- 110 — Byte Integer (B)

*This encoding will cause an unimplemented data type exception in the MC68040 to allow emulation in software.

0101000	FSUB	Rounding precision specified by the floating- point control register.
1101000	FSSUB	Single-precision rounding specified.
1101100	FDSUB	Double-precision rounding specified.

Syntax: FTAN.X FPm,FPn
 FTAN.X FPn

Attributes: Format = (Byte, Word, Long, Single, Double, Extended, Packed)

Description: Converts the source operand to extended precision (if necessary) and calculates the tangent of that number. Stores the result in the destination floating-point data register. This function is not defined for source operands of \pm infinity. If the source operand is not in the range of $[-\pi/2 \dots +\pi/2]$, the argument is reduced to within that range before the tangent is calculated. However, large arguments may lose accuracy during reduction, and very large arguments (greater than approximately 10^{20}) may lose accuracy.

Operation Table:

DESTINATION	SOURCE ¹									
	+	In Range	-	+	Zero	-	+	Infinity		
Result		Tangent		+	+ 0.0		-	- 0.0		NAN ²

NOTES:

1. If the source operand is a NAN, refer to **1.6.5 Not-A-Numbers** for more information.
2. Sets the OPERR bit in the floating-point status register exception byte.

Quotient Byte:	Not affected.
Exception Byte:	BSUN Cleared
	SNAN Refer to 1.6.5 Not-A-Numbers .
	OPERR Set if the source is \pm infinity; otherwise.
	OVFL Refer to overflow in the appropriate user's manual.
	UNFL Refer to underflow in the appropriate user's manual.
	DZ Cleared
	INEX2 Refer to inexact result in the appropriate user's manual.
INEX1 If < fmt > is packed, refer to inexact result in the appropriate user's manual; cleared otherwise.	
Accrued Exception Byte:	Affected as described in IEEE exception and trap handling in the appropriate user's manual.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2
1	1	1	1	COPROCESSOR ID			0	0	0	EFFECTIVE ADDRESS			
										MODE		REG	
0	R/M	0	SOURCE SPECIFIER			DESTINATION REGISTER			0	0	0	1	1

Instruction Fields:

Coprocessor ID field—Specifies which coprocessor in the system is to execute the instruction. Motorola assemblers default to ID = 1 for the floating-point coprocessor.

the following table:

Addressing Mode	Mode	Register
Dn*	000	reg. number:Dn
An	—	—
(An)	010	reg. number:An
(An) +	011	reg. number:An
– (An)	100	reg. number:An
(d ₁₆ ,An)	101	reg. number:An
(d ₈ ,An,Xn)	110	reg. number:An
(bd,An,Xn)	110	reg. number:An
([bd,An,Xn],od)	110	reg. number:An
([bd,An],Xn,od)	110	reg. number:An

Addressing Mode	Mode
(xxx).W	111
(xxx).L	111
# < data >	111
(d ₁₆ ,PC)	111
(d ₈ ,PC,Xn)	111
(bd,PC,Xn)	111
([bd,PC,Xn],od)	111
([bd,PC],Xn,od)	111

*Only if < fmt > is byte, word, long, or single.

R/M field—Specifies the source operand address mode.

- 0 — The operation is register to register.
- 1 — The operation is < ea > to register.

Source Specifier field—Specifies the source register or data format.

If R/M = 0, specifies the source floating-point data register.

If R/M = 1, specifies the source data format:

- 000 — Long-Word Integer (L)
- 001 — Single-Precision Real (S)
- 010 — Extended-Precision Real (X)
- 011 — Packed-Decimal Real (P)
- 100 — Word Integer (W)
- 101 — Double-Precision Real (D)
- 110 — Byte Integer (B)

Destination Register field—Specifies the destination floating-point data register.

M = 0 and the source and destination fields are equal, the input operand is read from the specified floating-point data register, and the result is written to the same register. If the single register syntax is used, Motorola assemblers use the source and destination fields to the same value.

Syntax: FTANH.X Fp_m,Fp_n
FTANH.X Fp_n

Attributes: Format = (Byte, Word, Long, Single, Double, Extended, Packed)

Description: Converts the source operand to extended precision (if necessary) and calculates the hyperbolic tangent of that number. Stores the result in the destination floating-point data register.

Operation Table:

DESTINATION	SOURCE					
	+ In Range	-	+ Zero	-	+ Infinity	
Result	Hyperbolic Tangent		+ 0.0		- 0.0	+ 1.0

NOTE: If the source operand is a NAN, refer to **1.6.5 Not-A-Numbers** for more information.

Floating-Point Status Register:

Condition Codes: Affected as described in **3.6.2 Conditional Test Instructions**.

Quotient Byte: Not affected.

Exception Byte:

BSUN	Cleared
SNAN	Refer to 1.6.5 Not-A-Numbers .
OPERR	Cleared
OVFL	Cleared
UNFL	Refer to underflow in the appropriate user's manual.
DZ	Cleared
INEX2	Refer to inexact result in the appropriate user's manual.
INEX1	If < fmt > is packed, refer to inexact result in the appropriate user's manual; decimal input in the appropriate user's manual; cleared otherwise.

Accrued Exception Byte: Affected as described in IEEE exception and trap handling in the appropriate user's manual.

1	1	1	1	COPROCESSOR ID		0	0	0	EFFECTIVE ADDRESS MODE			REGIS
0	R/M	0	SOURCE SPECIFIER		DESTINATION REGISTER		0	0	0	1	0	0

Instruction Fields:

Coprocessor ID field—Specifies which coprocessor in the system is to execute the instruction. Motorola assemblers default to ID = 1 for the floating-point coprocessor.

Effective Address field—Determines the addressing mode for external operands. If R/M = 0, this field is unused and should be all zeros. If R/M = 1, this field is encoded with an M68000 family addressing mode as shown in the following table:

Addressing Mode	Mode	Register
Dn*	000	reg. number:Dn
An	—	—
(An)	010	reg. number:An
(An) +	011	reg. number:An
– (An)	100	reg. number:An
(d ₁₆ ,An)	101	reg. number:An
(d ₈ ,An,Xn)	110	reg. number:An
(bd,An,Xn)	110	reg. number:An
([bd,An,Xn],od)	110	reg. number:An

Addressing Mode	Mode
(xxx).W	111
(xxx).L	111
# < data >	111
(d ₁₆ ,PC)	111
(d ₈ ,PC,Xn)	111
(bd,PC,Xn)	111
([bd,PC,Xn],od)	111
([bd,PC],Xn,od)	111

*Only if < fmt > is byte, word, long, or single.

R/M field—Specifies the source operand address mode.

- 0 — The operation is register to register.
- 1 — The operation is < ea > to register.

- 000 — Long-Word Integer (L)
- 001 — Single-Precision Real (S)
- 010 — Extended-Precision Real (X)
- 011 — Packed-Decimal Real (P)
- 100 — Word Integer (W)
- 101 — Double-Precision Real (D)
- 110 — Byte Integer (B)

Destination Register field—Specifies the destination floating-point data register. If $M = 0$ and the source and destination fields are equal, the input operand is read from the specified floating-point data register, and the result is written to the same register. If the single register syntax is used, Motorola assembler automatically sets the source and destination fields to the same value.

Syntax: FTENTOX.X Fp_m,Fp_n
 FTENTOX.X Fp_n

Attributes: Format = (Byte, Word, Long, Single, Double, Extended, Packed)

Description: Converts the source operand to extended precision (if necessary) and calculates 10 to the power of that number. Stores the result in the destination floating-point data register.

Operation Table:

DESTINATION	SOURCE							
	+	In Range	-	+	Zero	-	+	Infinity
Result		10 ^x			+ 1.0		+ inf	

NOTE: If the source operand is a NAN, refer to **1.6.5 Not-A-Numbers** for more information.

Floating-Point Status Register:

Condition Codes: Affected as described in **3.6.2 Conditional Testing**

Quotient Byte: Not affected.

Exception Byte:

BSUN	Cleared
SNAN	Refer to 1.6.5 Not-A-Numbers .
OPERR	Cleared
OVFL	Refer to overflow in the appropriate user's manual.
UNFL	Refer to underflow in the appropriate user's manual.
DZ	Cleared
INEX2	Refer to inexact result in the appropriate user's manual.
INEX1	If < fmt > is packed, refer to the appropriate user's manual inexact result on packed input; cleared otherwise.

Accrued Exception Byte: Affected as described in IEEE exception and trap capability in the appropriate user's manual.

1	1	1	1	COPROCESSOR ID			0	0	0	EFFECTIVE ADDRESS			
0	R/M	0	SOURCE SPECIFIER			DESTINATION REGISTER			0	0	1	0	0

Instruction Fields:

Coprocessor ID field—Specifies which coprocessor in the system is to execute the instruction. Motorola assemblers default to ID = 1 for the floating-point coprocessor.

Effective Address field—Determines the addressing mode for external operations.
 If R/M = 0, this field is unused and should be all zeros.
 If R/M = 1, this field is encoded with an M68000 family addressing mode as shown in the following table:

Addressing Mode	Mode	Register
Dn*	000	reg. number:Dn
An	—	—
(An)	010	reg. number:An
(An) +	011	reg. number:An
– (An)	100	reg. number:An
(d ₁₆ ,An)	101	reg. number:An
(d ₈ ,An,Xn)	110	reg. number:An
(bd,An,Xn)	110	reg. number:An
([bd,An,Xn],od)	110	reg. number:An
([bd,An],Xn,od)	110	reg. number:An

Addressing Mode	Mode
(xxx).W	111
(xxx).L	111
# < data >	111
(d ₁₆ ,PC)	111
(d ₈ ,PC,Xn)	111
(bd,PC,Xn)	111
([bd,PC,Xn],od)	111
([bd,PC],Xn,od)	111

*Only if < fmt > is byte, word, long, or single.

Source Specifier field—Specifies the source register or data format.

If R/M = 0, specifies the source floating-point data register.

If R/M = 1, specifies the source data format:

000 — Long-Word Integer (L)

001 — Single-Precision Real (S)

010 — Extended-Precision Real (X)

011 — Packed-Decimal Real (P)

100 — Word Integer (W)

101 — Double-Precision Real (D)

110 — Byte Integer (B)

Destination Register field—Specifies the destination floating-point data register.

M = 0 and the source and destination fields are equal, the input operand is read from the specified floating-point data register, and the result is written to the same register. If the single register syntax is used, Motorola assemblers use the source and destination fields to the same value.

Assembler FTRAPcc
Syntax: FTRAPcc.W # < data >
FTRAPcc.L # < data >

Attributes: Size = (Word, Long)

Description: If the selected condition is true, the processor initiates exception processing. A vector number is generated to reference the TRAPcc exception vector. The program counter points to the next instruction. If the selected condition is not true, no operation is performed and execution continues with the next instruction in the sequence. The immediate data operand is placed in the word(s) following the conditional predicate word and is available for user definition for use within the exception handler.

The conditional specifier cc selects one of the 32 conditional tests defined in the **Conditional Testing** section.

Floating-Point Status Register:

Condition Codes:	Not affected.	
Quotient Byte:	Not affected.	
Exception Byte:	BSUN	Set if the NAN condition code is selected and the selected condition is an IEEE nonavailing condition.
	SNAN	Not Affected.
	OPERR	Not Affected.
	OVFL	Not Affected.
	UNFL	Not Affected.
	DZ	Not Affected.
	INEX2	Not Affected.
	INEX1	Not Affected.
Accrued Exception Byte:	The IOP bit is set if the BSUN bit is set in the exception byte; no other bit is affected.	

1	1	1	1	COPROCESSOR ID			0	0	1	1	1	1	MO
0	0	0	0	0	0	0	0	0	0	CONDITIONAL PREDICAT			
16-BIT OPERAND OR MOST SIGNIFICANT WORD OF 32-BIT OPERAND (IF NEEDED)													
LEAST SIGNIFICANT WORD OR 32-BIT OPERAND (IF NEEDED)													

Instruction Fields:

Mode field—Specifies the form of the instruction.
 010 — The instruction is followed by a word operand.
 011 — The instruction is followed by a long-word operand.
 100 — The instruction has no operand.

Conditional Predicate field—Specifies one of 32 conditional tests as described in **Conditional Testing**.

Operand field—Contains an optional word or long-word operand that is used for the instruction.

NOTE

When a BSUN exception occurs, a preinstruction exception is taken by the main processor. If the exception handler returns without modifying the image of the program counter on the stack frame (to point to the instruction following the FTRAPcc), it must clear the cause of the exception (by clearing the NAN bit or disabling the BSUN trap), or the exception occurs again immediately upon return to the routine that caused the exception.

Syntax: FTST.X Fpm

Attributes: Format = (Byte, Word, Long, Single, Double, Extended, Packed)

Description: Converts the source operand to extended precision (if necessary) and sets the condition code bits according to the data type of the result.

Operation Table: The contents of this table differ from the other operation tables. An entry of this table indicates that the designated condition code bit is always set for the FTST operation. All unspecified condition code bits are cleared for the operation.

DESTINATION	SOURCE							
	+	In Range	-	+	Zero	-	+	Infinity
Result	none		N	Z		NZ	I	

NOTE: If the source operand is a NAN, set the NAN condition code bit. If the source operand is an SNAN, set the SNAN bit in the floating-point status register exception byte

Floating-Point Status Register:

Condition Codes: Affected as described in **3.6.2 Conditional Testing**

Quotient Byte: Not affected.

Exception Byte:

BSUN	Cleared
SNAN	Refer to 1.6.5 Not-A-Numbers .
OPERR	Cleared
OVFL	Cleared
UNFL	Cleared
DZ	Cleared
INEX2	Cleared
INEX1	If < fmt > is packed, refer to appropriate user's manual; otherwise, cleared otherwise.

Accrued Exception Byte: Affected as described in exception processing in appropriate user's manual.

1	1	1	1	COPROCESSOR ID		0	0	0	EFFECTIVE ADDRESS MODE			REGIS
0	R/M	0	SOURCE SPECIFIER		DESTINATION REGISTER		0	1	1	1	0	1

Instruction Fields:

Effective Address field—Determines the addressing mode for external operand addressing.

If R/M = 0, this field is unused and should be all zeros.

If R/M = 1, specifies the location of the source operand. Only data addressing modes can be used as listed in the following table:

Addressing Mode	Mode	Register
Dn*	000	reg. number:Dn
An	—	—
(An)	010	reg. number:An
(An) +	011	reg. number:An
– (An)	100	reg. number:An
(d ₁₆ ,An)	101	reg. number:An
(d ₈ ,An,Xn)	110	reg. number:An
(bd,An,Xn)	110	reg. number:An
([bd,An,Xn],od)	110	reg. number:An
([bd,An],Xn,od)	110	reg. number:An

Addressing Mode	Mode
(xxx).W	111
(xxx).L	111
# < data >	111
(d ₁₆ ,PC)	111
(d ₈ ,PC,Xn)	111
(bd,PC,Xn)	111
([bd,PC,Xn],od)	111
([bd,PC],Xn,od)	111

*Only if < fmt > is byte, word, long, or single.

Source Specifier field—Specifies the source register or data format.

If R/M = 0, specifies the source floating-point data register.

If R/M = 1, specifies the source data format:

000 — Long-Word Integer (L)

001 — Single-Precision Real (S)

010 — Extended-Precision Real (X)

011 — Packed-Decimal Real (P)*

100 — Word Integer (W)

101 — Double-Precision Real (D)

110 — Byte Integer (B)

*This encoding will cause an unimplemented data type exception in the MC68040 to allow emulation in software.

Destination Register field—Since the floating-point unit uses a common word format for all of the arithmetic instructions (including FTST), the floating-point instructions are treated in the same manner for FTST as for the other arithmetic instructions, though the destination register is not modified. This field should be set to zero to maintain compatibility with future devices; however, the floating-point unit will not signal an illegal instruction trap if it is not zero.

Syntax: FTWOTOX.X Fp_m,Fp_n
FTWOTOX.X Fp_n

Attributes: Format = (Byte, Word, Long, Single, Double, Extended, Packed)

Description: Converts the source operand to extended precision (if necessary) and calculates two to the power of that number. Stores the result in the destination floating-point data register.

Operation Table:

DESTINATION	SOURCE			
	+ In Range	- Zero	+ Infinity	- Infinity
Result	2 ^x	+ 1.0	+ inf	- inf

NOTE: If the source operand is a NAN, refer to **1.6.5 Not-A-Numbers** for more information.

Floating-Point Status Register:

Condition Codes: Affected as described in **3.6.2 Conditional Testing**

Quotient Byte: Not affected.

Exception Byte:

- BSUN Cleared
- SNAN Refer to **1.6.5 Not-A-Numbers**.
- OPERR Cleared
- OVFL Refer to overflow in the appropriate user's manual.
- UNFL Refer to underflow in the appropriate user's manual.
- DZ Cleared
- INEX2 Refer to inexact result in the appropriate user's manual.
- INEX1 If < fmt > is packed, refer to inexact result in the appropriate user's manual; decimal input in the appropriate user's manual; cleared otherwise.

Accrued Exception Byte: Affected as described in IEEE exception and trap control in the appropriate user's manual.

1	1	1	1	COPROCESSOR ID			0	0	0	EFFECTIVE ADDRESSING MODE			REG
0	R/M	0	SOURCE SPECIFIER			DESTINATION REGISTER			0	0	1	0	0

Instruction Fields:

Coprocessor ID field—Specifies which coprocessor in the system is to execute the instruction. Motorola assemblers default to ID = 1 for the floating-point coprocessor.

Effective Address field—Determines the addressing mode for external operations.

If R/M = 0, this field is unused and should be all zeros.

If R/M = 1, this field is encoded with an M68000 family addressing mode according to the following table:

Addressing Mode	Mode	Register
Dn*	000	reg. number:Dn
An	—	—
(An)	010	reg. number:An
(An) +	011	reg. number:An
– (An)	100	reg. number:An
(d ₁₆ ,An)	101	reg. number:An
(d ₈ ,An,Xn)	110	reg. number:An
(bd,An,Xn)	110	reg. number:An
([bd,An,Xn],od)	110	reg. number:An
([bd,An],Xn,od)	110	reg. number:An

Addressing Mode	Mode
(xxx).W	111
(xxx).L	111
# < data >	111
(d ₁₆ ,PC)	111
(d ₈ ,PC,Xn)	111
(bd,PC,Xn)	111
([bd,PC,Xn],od)	111
([bd,PC],Xn,od)	111

*Only if < fmt > is byte, word, long, or single.

Source Specifier field—Specifies the source register or data format.

If R/M = 0, specifies the source floating-point data register.

If R/M = 1, specifies the source data format:

000 — Long-Word Integer (L)

001 — Single-Precision Real (S)

010 — Extended-Precision Real (X)

011 — Packed-Decimal Real (P)

100 — Word Integer (W)

101 — Double-Precision Real (D)

110 — Byte Integer (B)

Destination Register field—Specifies the destination floating-point data register.

M = 0 and the source and destination fields are equal, the input operand is read from the specified floating-point data register, and the result is written to the same register. If the single register syntax is used, Motorola assemblers use the source and destination fields to the same value.

SECTION 9 SUPERVISOR (PRIVILEGED) INSTRUCTIONS

This section contains information about the supervisor privileged instructions of the M68000 family. Each instruction is described in detail, and the instruction descriptions are arranged in alphabetical order by instruction mnemonic.

Any differences within the M68000 family of instructions are identified in the instruction description. If an instruction only applies to a certain processor or processors, the processor(s) to which the instruction pertains to is identified under the title of the instruction. For example:

Invalidate Cache Lines (MC68040)

All references to the MC68000, MC68020, and MC68030 include references to the corresponding embedded controllers, MC68EC000, MC68EC020, and MC68EC030. All references to the MC68040 include the MC68LC040 and MC68EC040. This applies throughout this section unless otherwise specified.

If the instruction applies to all the M68000 family but a processor or processors may have a different instruction field, instruction format, etc., the differences will be identified in a separate paragraph. For example:

MC68020, MC68030 and MC68040 only

(bd,An,Xn)*	110	reg. number: An
-------------	-----	-----------------

(bd,PC,Xn)*	—	—
-------------	---	---

*Can be used with CPU32 processors

The following instructions are listed separately for each processor due to the differences involved within the instruction:

PFLUSH	Flush ATC Entries
PMOVE	Move PMMU Register
PTEST	Test Logical Address

Appendix A Processor Instruction Summary provides a listing of all processor instructions that apply to them for quick reference.

Then Source L SR → SR
ELSE TRAP

Assembler

Syntax: ANDI # < data > ,SR

Attributes: size = (word)

Description: Performs an AND operation of the immediate operand with the contents of the status register and stores the result in the status register. All implemented bits of the status register are affected.

Condition Codes:

X	N	Z	V	C
*	*	*	*	*

X—Cleared if bit 4 of immediate operand is zero; unchanged otherwise.

N—Cleared if bit 3 of immediate operand is zero; unchanged otherwise.

Z—Cleared if bit 2 of immediate operand is zero; unchanged otherwise.

V—Cleared if bit 1 of immediate operand is zero; unchanged otherwise.

C—Cleared if bit 0 of immediate operand is zero; unchanged otherwise.

Instruction Format:

5	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	0	1	0	0	1	1	1	1	1	1	0
16-BIT WORD DATA															

Assembler

Syntax: CINVL < caches > ,(An)
CINVP < caches > ,(An)
CINVA < caches >

Where < caches > specifies the instruction cache, data cache, both caches, or neither cache.

Attributes: Unsized

Description: Invalidates selected cache lines. The data cache, instruction cache, or neither cache can be specified. Any dirty data in data cache invalidate are lost; the CPUSH instruction must be used when dirty data contained in the data cache.

Specific cache lines can be selected in three ways:

1. CINVL invalidates the cache line (if any) matching the physical address specified address register.
2. CINVP invalidates the cache lines (if any) matching the physical memory in the specified address register. For example, if 4K-byte page sizes are used and An contains \$12345000, all cache lines matching page \$12345000 validate.
3. CINVA invalidates all cache entries.

Condition Codes:

Not affected.

1	1	1	1	0	1	0	0	CACHE	0	SCOPE	REGIS
---	---	---	---	---	---	---	---	-------	---	-------	-------

Instruction Fields:

Cache field—Specifies the Cache.

- 00—No Operation
- 01—Data Cache
- 10—Instruction Cache
- 11—Data and Instruction Caches

Scope field—Specifies the Scope of the Operation.

- 00—Illegal (causes illegal instruction trap)
- 01—Line
- 10—Page
- 11—All

Register field—Specifies the address register for line and page operations. operations, the low-order bits 3–0 of the address are don't cares. Bits 11–0 of the address are don't care for 4K-byte or 8K-byte page operations respectively.

ELSE TRAP

Assembler

Syntax: cpRESTORE < ea >

Attributes: Unsized

Description: Restores the internal state of a coprocessor usually after it has been a preceding cpSAVE instruction.

Condition Codes:

Not affected.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	
1	1	1	1	COPROCESSOR ID			1	0	1	EFFECTIVE ADDRESS MODE				REG

Coprocessor ID field—Identifies the coprocessor that is to be restored. Coprocessor ID of 000 results in an F-line exception for the MC68030.

Effective Address field—Specifies the location where the internal state of the coprocessor is located. Only postincrement or control addressing modes are used as listed in the following table:

Addressing Mode	Mode	Register
Dn	—	—
An	—	—
(An)	010	reg. number:An
(An) +	011	reg. number:An
— (An)	—	—
(d ₁₆ ,An)	101	reg. number:An
(d ₈ ,An,Xn)	110	reg. number:An
(bd,An,Xn)	110	reg. number:An
([bd,An,Xn], od)	110	reg. number:An
([bd,An],Xn,od)	110	reg.number:An

Addressing Mode	Mode
(xxx).W	111
(xxx).L	111
# < data >	111
(d ₁₆ ,PC)	111
(d ₈ ,PC,Xn)	111
(bd,PC,Xn)	111
([bd,PC,Xn], od)	111
([bd,PC],Xn, od)	111

NOTE

If the format word returned by the coprocessor indicates “come again”, pending interrupts are not serviced.

Assembler

Syntax: cpSAVE < ea >

Attributes: Unsized

Description: Saves the internal state of a coprocessor in a format that can be restored by a cpRESTORE instruction.

Condition Codes:

Not affected.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	
1	1	1	1	COPROCESSOR ID			1	0	0	EFFECTIVE ADDRESS MODE				REG

Instruction Fields:

Coprocessor ID field—Identifies the coprocessor for this operation. Coprocessor ID 000 results in an F-line exception for the MC68030.

Effective Address field—Specifies the location where the internal state of the coprocessor is to be saved. Only predecrement or control alterable addressing modes can be used as listed in the following table:

Addressing Mode	Mode	Register
Dn	—	—
An	—	—
(An)	010	reg. number:An
(An) +	—	—
— (An)	100	reg. number:An
(d ₁₆ ,An)	101	reg. number:An
(d ₈ ,An,Xn)	110	reg. number:An
(bd,An,Xn)	110	reg. number:An
([bd,An,Xn], od)	110	reg. number:An
([bd,An],Xn, od)	110	reg. number:An

Addressing Mode	Mode
(xxx).W	111
(xxx).L	111
# < data >	—
(d ₁₆ ,PC)	—
(d ₈ ,PC,Xn)	—
(bd,PC,Xn)	—
([bd,PC,Xn],od)	—
([bd,PC],Xn, od)	—

Invalidate Selected Cache Lines ELSE TRAP

Assembler Syntax: CPUSHL < caches > ,(An)
 CPUSHP < caches > ,(An)
 CPUSHA < caches >

Where < caches > specifies the instruction cache, data cache, both caches, or neither cache.

Attributes: Unsized

Description: Pushes and then invalidates selected cache lines. The DATA instruction cache, both caches, or neither cache can be specified. When the data cache is specified, the selected data cache lines are first pushed to memory (if they are dirty DATA) and then invalidated. Selected instruction cache lines are invalidated.

Specific cache lines can be selected in three ways:

1. CPUSHL pushes and invalidates the cache line (if any) matching the program address in the specified address register.
2. CPUSHP pushes and invalidates the cache lines (if any) matching the program memory page in the specified address register. For example, if 4K-byte cache line sizes are selected and An contains \$12345000, all cache lines matching \$12345000 are selected.
3. CPUSHA pushes and invalidates all cache entries.

Condition Codes:

Not affected.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1
1	1	1	1	0	1	0	0	CACHE		1	SCOPE			REGIS

- 00—No Operation
- 01—Data Cache
- 10—Instruction Cache
- 11—Data and Instruction Caches

Scope field—Specifies the Scope of the Operation.

- 00—Illegal (causes illegal instruction trap)
- 01—Line
- 10—Page
- 11—All

Register field—Specifies the address register for line and page operations. For line operations, the low-order bits 3–0 of the address are don't care. Bits 11–0 of the address are don't care for 4K-byte or 8K-byte page operations, respectively.

Then Source \oplus SR \rightarrow SR
ELSE TRAP

Assembler

Syntax: EORI # < data > ,SR

Attributes: Size = (Word)

Description: Performs an exclusive-OR operation on the contents of the status register using the immediate operand and stores the result in the status register. The implemented bits of the status register are affected.

Condition Codes:

X	N	Z	V	C
*	*	*	*	*

X—Changed if bit 4 of immediate operand is one; unchanged otherwise.

N—Changed if bit 3 of immediate operand is one; unchanged otherwise.

Z—Changed if bit 2 of immediate operand is one; unchanged otherwise.

V—Changed if bit 1 of immediate operand is one; unchanged otherwise.

C—Changed if bit 0 of immediate operand is one; unchanged otherwise.

16-BIT WORD DATA															

ELSE TRAP

Assembler

Syntax: FRESTORE < ea >

Attributes: Unsized

Description: Aborts the execution of any floating-point operation in progress and loads a new floating-point unit internal state from the state frame located at the specified address. The first word at the specified address is the format word of the state frame. It specifies the size of the frame and the revision number of the floating-point unit that created it. A format word is invalid if it does not recognize the size of the frame or the revision number does not match the revision of the floating-point unit. If the format word is invalid, FRESTORE aborts, and a format exception is generated. If the format word is valid, the appropriate state frame is loaded, starting at the specified location and proceeding through higher addresses.

The FRESTORE instruction does not normally affect the programmer's model of the floating-point coprocessor, except for the NULL state size, as described in the manual. It is only for restoring the user invisible portion of the machine. The FRESTORE instruction is used with the FMOVEM instruction to perform a full context restore of the floating-point unit, including the floating-point data registers and system registers. To accomplish a complete restoration, the FMOVEM instructions are executed to load the programmer's model, followed by the FRESTORE instruction to load the internal state and continue any previously suspended operation.

STORE operation with this size state frame is equivalent to a hardware restore of the floating-point unit. The programmer's model is set to the reset state with nonsignaling NaNs in the floating-point data registers and zero in the floating-point control register, floating-point status register, and floating-point instruction address register. (Thus, it is unnecessary to load the programmer's model before this operation.)

IDLE: This state frame is 4 bytes long in the MC68040, 28 (\$1C) bytes long in the MC68881, and 60 (\$3C) bytes long in the MC68882. An FRESTORE operation with this state frame causes the floating-point unit to be restored to the idle state, waiting for the initiation of the next instruction, with no exceptions pending. The programmer's model is not affected by loading this state frame.

UNIMP: This state frame is generated only by the MC68040. It is 48 (\$30) bytes long. An FSAVE that generates this size frame indicates either an unimplemented floating-point instruction or only an E1 exception is pending. This state frame is never generated when an unsupported data type exception is pending or an E3 exception is pending. If both E1 and E3 exceptions are pending, this state frame is generated.

BUSY: This state frame is 96 (\$60) bytes long in the MC68040, 184 (\$B8) bytes long in the MC68881, and 216 (\$D8) bytes long in the MC68882. An FRESTORE operation with this size state frame causes the floating-point unit to be restored to the busy state, executing the instructions that were suspended by a previous FSAVE operation. The programmer's model is not affected by loading this type of state frame; however, the completion of the suspended instructions after the restore is executed may modify the programmer's model.

Floating-Point Status Register: Cleared if the state size is NULL; otherwise, not affected.

Assembler

Syntax: FSAVE < ea >

Attributes: Unsized

Description: FSAVE allows the completion of any floating-point operation in progress on the MC68040. It saves the internal state of the floating-point unit in a state frame located at the effective address. After the save operation, the floating-point unit is in the idle state, waiting for the execution of the next instruction. The first word written to the state frame is the format word specifying the size of the frame and the revision number of the floating-point unit.

Any floating-point operations in progress when an FSAVE instruction is encountered can be completed before the FSAVE executes, saving an IDLE state frame. Execution of instructions already in the floating-point unit pipeline continues until completion of instructions in the pipeline or generation of an exception by one of the instructions. An IDLE state frame is created by the FSAVE if no exceptions occurred; otherwise, a BUSY or an UNIMP stack frame is created.

FSAVE suspends the execution of any operation in progress and saves the current state in a state frame located at the effective address for the MC68881/MC68882. After the save operation, the floating-point coprocessor is in the idle state, waiting for the execution of the next instruction. The first word written to the state frame is the format word, specifying the size of the frame and the revision number of the floating-point coprocessor. The microprocessor unit initiates the FSAVE instruction by reading the floating-point coprocessor save CIR. The floating-point coprocessor save CIR is encoded with a format word that indicates the appropriate action to be taken by the main processor. The current implementation of the floating-point coprocessor returns one of five responses in the save CIR:

Value	Definition
\$0018	Save NULL state frame
\$0118	Not ready, come again
\$0218	Illegal, take format exception
\$XX18	Save IDLE state frame
\$XXB4	Save BUSY state frame

NOTE: XX is the floating-point coprocessor version number.

word to cause the main processor to wait while an internal operation completes, or, if possible, to allow an IDLE frame rather than a BUSY frame to be saved. The illegal word aborts an FSAVE instruction that is attempted while the floating-point processor executes a previous FSAVE instruction. All other format words cause the processor unit to save the indicated state frame at the specified address. For state frame details see state frames in the appropriate user's manual.

The following state frames apply to both the MC68040 and the MC68881/MC68882:

- NULL:** This state frame is 4 bytes long. An FSAVE instruction that generates this state frame indicates that the floating-point unit state has not been saved since the last hardware reset or FRESTORE instruction with a NULL state frame. This indicates that the programmer's model is in the reset state, with nonsignaling NaNs in the floating-point data registers and zeros in the floating-point control register, floating-point status register, and floating-point instruction address register. (Thus, it is not necessary to save the programmer's model.)
- IDLE:** This state frame is 4 bytes long in the MC68040, 28 (\$1C) bytes long in the MC68881, and 60 (\$3C) bytes long in the MC68882. An FSAVE instruction that generates this state frame indicates that the floating-point unit is in an idle condition and is without any pending exceptions waiting for the initiation of the next instruction.
- UNIMP:** This state frame is generated only by the MC68040. It is 48 (\$30) bytes long. An FSAVE that generates this size frame indicates either an unimplemented floating-point instruction or that only an E1 exception is pending. This state frame is never generated when an unsupported data type exception or an illegal instruction exception is pending. If both E1 and E3 exceptions are pending, the UNIMP state frame is generated.
- BUSY:** This state frame is 96 (\$60) bytes long in the MC68040, 184 (\$B8) bytes long in the MC68881, and 216 (\$D8) bytes long in the MC68882. An FSAVE instruction that generates this size state frame indicates that the floating-point unit encountered an exception while attempting to complete the execution of the previous floating-point instructions.

unit that includes the floating-point data registers and system control registers. To accomplish a complete context save, first execute an FSAVE instruction to suspend the current operation and save the internal state, then execute the appropriate FMOVM instructions to store the programmer's model.

Floating-Point Status Register: Not affected.

1. Any other code causes an illegal instruction exception
2. For the MC68020 and MC68030 only.

Assembler MOVES Rn, < ea >
Syntax: MOVES < ea > ,Rn

Attributes: Size = (Byte, Word, Long)

Description: This instruction moves the byte, word, or long operand from the source general register to a location within the address space specified by the destination function code (DFC) register, or it moves the byte, word, or long operand from a location within the address space specified by the source function code (SFC) register to the specified general register. If the destination is a data register, the source operand replaces the corresponding low-order bits of that data register, depending on the size of the operation. If the destination is an address register, the source operand is extended to 32 bits and then loaded into that address register.

Condition Codes:

Not affected.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1

*Available for the CPU32.

A/D field—Specifies the type of general register.

0—Data Register
 1—Address Register

Register field—Specifies the register number.

dr field—Specifies the direction of the transfer.

0—From < ea > to general register.
 1—From general register to < ea > .

examples with the same address register as both source and destination.

```
MOVES.x An,(An) +  
MOVES.x An,D(An)
```

The current implementations of the MC68010, MC68020, MC68030, and MC68040 store the incremented or decremented value of An. Check the following code sequence to determine what value is stored for each case.

```
MOVEA.L #$1000,A0  
MOVES.L A0,(A0) +  
MOVES.L A0,D(A0)
```

Because the MC68040 implements a merged instruction and data space, the MC68040's integer unit into data references (SFC/DFC = 5 or 1) translates MOVES accesses to the OinstructionO address spaces (SFC/DFC = 6 or 2). The data memory unit handles these translated accesses as normal data accesses. If the access fails due to an ATC fault or a physical bus error, the resulting access error stack frame contains the converted function code in the TM field for the faulted access. To maintain cache coherency, MOVES accesses to write the OinstructionO address space must be preceded by invalidation of the instruction cache line containing the referenced location.

Then Source V SR → SR
Else TRAP

Assembler

Syntax: ORI # < data > ,SR

Attributes: Size = (Word)

Description: Performs an inclusive-OR operation of the immediate operand and the register's contents and stores the result in the status register. All implemented bits of the status register are affected.

Condition Codes:

X	N	Z	V	C
*	*	*	*	*

X—Set if bit 4 of immediate operand is one; unchanged otherwise.

N—Set if bit 3 of immediate operand is one; unchanged otherwise.

Z—Set if bit 2 of immediate operand is one; unchanged otherwise.

V—Set if bit 1 of immediate operand is one; unchanged otherwise.

C—Set if bit 0 of immediate operand is one; unchanged otherwise.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2
0	0	0	0	0	0	0	0	0	1	1	1	1	1
16—BIT WORD DATA													

Assembler**Syntax:** PBcc. < size > < label >**Attributes:** Size = (Word, Long)

Description: If the specified paged memory management unit condition is met, execution continues at location (PC) + displacement. The displacement is a two's complement integer that counts the relative distance in bytes. The value in the program code is the address of the displacement word(s). The displacement may be either 16 or 32 bits.

The condition specifier cc indicates the following conditions:

Specifier	Description	Condition Field
BS	B set	000000
LS	L set	000010
SS	S set	000100

16-BIT DISPLACEMENT OR MOST SIGNIFICANT WORD OF 32-BIT DISPLACEMENT														
LEAST SIGNIFICANT WORD OF 32-BIT DISPLACEMENT (IF NEEDED)														

0—Displacement is 16 bits.
1—Displacement is 32 bits.

MC68851 Condition field—Specifies the coprocessor condition to be tested. This condition is passed to the MC68851, which provides directives to the main processor processing this instruction.

Word Displacement field—The shortest displacement form for MC68851 branch instructions is 16 bits.

Long-Word Displacement field—Allows a displacement larger than 16 bits.

Else No Operation
Else TRAP

Assembler

Syntax: PDBcc Dn, < label >

Attributes: Size = (Word)

Description: This instruction is a looping primitive of three parameters: an M condition, a counter (an MC68020 data register), and a 16-bit displacement. The instruction first tests the condition to determine if the termination condition for the loop has been met. If so, the main processor executes the next instruction in the instruction stream. If the termination condition is not true, the low-order 16 bits of the counter register are decremented by one. If the result is not D1, execution continues to the location specified by the current value of the program counter plus the sign-extended 16-bit displacement. The value of the program counter used in the branch address calculation is the address of the PDBcc instruction plus two.

The condition specifier cc indicates the following conditions:

Specifier	Description	Condition Field
BS	B set	000000
LS	L set	000010
SS	S set	000100

GC	G clear	001101
CC	C clear	001111

15	14	13	12	11	10	9	8	7	6	5	4	3	2
1	1	1	1	0	0	0	0	0	1	0	0	1	COUNT
0	0	0	0	0	0	0	0	0	0	MC68851 CONDITION			
16-BIT DISPLACEMENT													

Instruction Fields:

Register field—Specifies the data register in the main processor to be used as the branch target register. The register number is passed to the counter.

MC68851 Condition field—Specifies the MC68851 condition to be tested. The condition code is passed to the MC68851, which provides directives to the main processor when processing this instruction.

Displacement field—Specifies the distance of the branch in bytes.

Assembler PFLUSHA
Syntax: PFLUSH FC, MASK
PFLUSH FC, MASK, < ea >

Attributes: Unsized

Description: PFLUSH invalidates address translation cache entries. The instruction has three forms. The PFLUSHA instruction invalidates all entries. When the instruction specifies a function code and mask, the instruction invalidates all entries for a specified function code(s). When the instruction also specifies an < ea >, the instruction invalidates the page descriptor for that effective address entry in each selected cache code.

The mask operand contains three bits that correspond to the three function codes. Each bit in the mask that is set to one indicates that the corresponding bit of the FC operand applies to the operation. Each bit in the mask that is zero indicates a bit that is ignored and of the ignored function code. For example, a mask operand of 100 causes the instruction to consider only the most significant bit of the FC operand. If the FC operand is 001, function codes 000, 001, 010, and 011 are selected.

The FC operand is specified in one of the following ways:

1. Immediate—Three bits in the command word.
2. Data Register—The three least significant bits of the data register specified in the instruction.
3. Source Function Code (SFC) Register
4. Destination Function Code (DFC) Register

Condition Codes:

Not affected.

MMU Status Register:

Not affected.

1	1	1	1	0	0	0	0	0	0	EFFECTIVE ADDRESS	REG
0	0	1	MODE			0	0	MASK		FC	

Instruction Fields:

Effective Address field—Specifies a control alterable address. The address translation cache entry for this address is invalidated. Valid addressing modes are defined in the following table:

Addressing Mode	Mode	Register	Addressing Mode	Mode
Dn	—	—	(xxx).W	111
An	—	—	(xxx).L	111
(An)	010	reg. number:An	# < data >	—
(An) +	—	—		
—(An)	—	—		
(d ₁₆ ,An)	101	reg. number:An	(d ₁₆ ,PC)	—
(d ₈ ,An,Xn)	110	reg. number:An	(d ₈ ,PC,Xn)	—
(bd,An,Xn)	110	reg. number:An	(bd,PC,Xn)	—
([bd,An,Xn] ,od)	110	reg. number:An	([bd,PC,Xn] ,od)	—
([bd,An],Xn ,od)	110	reg. number:An	([bd,PC],Xn ,od)	—

NOTE

The address field must provide the memory management unit with the effective address to be flushed from the address translation cache, not the effective address describing where the PFLUSH operand is located. For example, to flush the address translation cache entry corresponding to a logical address that is temporarily stored on top of the system stack, the instruction PFLUSH [(SP)] must be used since PFLUSH (SP) would invalidate the address translation cache entry mapping the system stack (i.e., the effective address passed to the memory management unit is the effective address of the system stack, not the effective address formed by the operand located on the top of the stack).

110—Flush by function code and effective address.

Mask field—Mask for selecting function codes. Ones in the mask correspond to applicable bits; zeros are bits to be ignored. When mode is 001, mask is 000.

FC field—Function code of entries to be flushed. If the mode field is 001, FC field is 00000; otherwise:

10XXX — Function code is specified as bits XXX.

01DDD — Function code is specified as bits 2–0 of data register DDD.

00000 — Function code is specified as SFC register.

00001 — Function code is specified as DFC register.

Else TRAP

Assembler PFLUSH (An)
Syntax: PFLUSHN (An)
Syntax: PFLUSHA
Syntax: PFLUSHAN
Attributes: Unsized

Description: Invalidates address translation cache entries in both the instruction address translation caches. The instruction has two forms. The PFLUSHA instruction invalidates all entries. The PFLUSH (An) instruction invalidates the entry in the instruction address translation cache which matches the logical address in An and the function code.

The function code for PFLUSH is specified in the destination function code field. Destination function code values of 1 or 2 will result in flushing of user address translation cache entries in both address translation caches; whereas, values of 3 or 4 result in flushing of supervisor address translation cache entries. PFLUSH is used for destination function code values of 0, 3, 4, and 7 and may cause flushing of an unexpected entry.

The PFLUSHN and PFLUSHAN instructions have a global option specified in the destination field. The global bit is used to flush only nonglobal entries. For example, if only page descriptors for operating system code have the global bit set, these two PFLUSH variants can be used to flush address translation cache entries during task swaps.

Condition Codes:

Not affected.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1
1	1	1	1	0	1	0	1	0	0	0	OPMODE		REGIS	

Instruction Fields:

Opmode field—Specifies the flush operation.

Opcode	Operation	Assembler Syntax
00	Flush page entry if not global	PFLUSHN (An)
01	Flush page entry	PFLUSH (An)
10	Flush all except global entries	PFLUSHAN
11	Flush all entries	PFLUSHA

Register field—Specifies the address register containing the effective address flushed when flushing a page entry.

Assembler PFLUSH (An)
Syntax: PFLUSHN (An)

Attributes: Unsized

Description: This instruction should not be executed when using an MC68EC040. PFLUSH encoding suspends operation of the MC68EC040 for an indefinite time and subsequently continues with no adverse effects.

Condition Codes:

Not affected.

Instruction Format:

Postincrement Source and Destination

15	14	13	12	11	10	9	8	7	6	5	4	3	2
1	1	1	1	0	1	0	1	0	0	0	OPMODE		REG

Instruction Fields:

Opmode field—Specifies the flush operation.

Opcode	Operation	Assembler Syntax
00	Flush page entry if not global	PFLUSHN (An)
01	Flush page entry	PFLUSH (An)
10	Flush all except global entries	PFLUSHAN
11	Flush all entries	PFLUSHA

Register field—Specifies the address register containing the effective address flushed when flushing a page entry.

Operation: If Supervisor State
Then Address Translation Cache Entries For Destination A
Are Invalidated
Else TRAP

Assembler Syntax: PFLUSHA
PFLUSH FC, MASK
PFLUSHS FC, MASK
PFLUSH FC, MASK, < ea >
PFLUSHS FC, MASK, < ea >

Attributes: Unsigned

Description: PFLUSHA invalidates all entries in the address translation cache.

PFLUSH invalidates a set of address translation cache entries whose function code bits satisfy the relation: (address translation cache function code bits and mask bits and MASK) for all entries whose task alias matches the task alias currently active when the instruction is executed. With an additional effective address argument, PFLUSHS invalidates a set of address translation cache entries whose function code satisfies the relation above and whose effective address field matches the corresponding bit field of the evaluated effective address argument. In both of these cases, address translation cache entries whose SG bit is set will not be invalidated unless the PFLUSHS instruction is specified.

The function code for this operation may be specified as follows:

1. Immediate—The function code is four bits in the command word.
2. Data Register—The function code is in the lower four bits of the MC68000 register specified in the instruction.
3. Source Function Code (SFC) Register—The function code is in the CP register. Since the SFC of the MC68020 has only three implemented bits, only function codes \$0D\$7 can be specified in this manner.
4. Destination Function Code (DFC) Register—The function code is in the DFC register. Since the DFC of the MC68020 has only three implemented bits, only function codes \$0D\$7 can be specified in this manner.

PMMU Status Register: Not affected.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2
1	1	1	1	0	0	0	0	0	0	EFFECTIVE ADDRESS			REG
				MODE		0	MASK			FC			
0	0	1	MODE			0	MASK			FC			

Instruction Fields:

Effective Address field—Specifies an address whose page descriptor is to be fetched from (invalidated) the address translation cache. Only control alterable addressing modes can be used as listed in the following table:

Addressing Mode	Mode	Register
Dn	—	—
An	—	—
(An)	010	reg. number:An
(An) +	—	—
—(An)	—	—
(d ₁₆ ,An)	101	reg. number:An
(d ₈ ,An,Xn)	110	reg. number:An
(bd,An,Xn)	110	reg. number:An
([bd,An,Xn] ,od)	110	reg. number:An
([bd,An],Xn ,od)	110	reg. number:An

Addressing Mode	Mode
(xxx).W	111
(xxx).L	111
# < data >	—
(d ₁₆ ,PC)	—
(d ₈ ,PC,Xn)	—
(bd,PC,Xn)	—
([bd,PC,Xn] ,od)	—
([bd,PC],Xn ,od)	—

NOTE

The effective address field must provide the MC68851 with the effective address of the entry to be flushed from the address translation cache, not the effective address describing where the PFLUSH operand is located. For example, in order to flush the address translation cache entry corresponding to a logical address that is temporarily stored on the top of the system stack, the instruction PFLUSH [(SP)] must be used since PFLUSH (SP) would invalidate the address translation cache entry mapping the system stack (i.e., the effective address passed to the MC68851 is the effective address of the system stack, not the effective address formed by the operand located on the top of the stack).

Mode field—Specifies how the address translation cache is to be flushed.

001—Flush all entries.

100—Flush by function code only.

101—Flush by function code including shared entries.

110—Flush by function code and effective address.

111—Flush by function code and effective address including shared entries.

Mask field—Indicates which bits are significant in the function code comparison. A zero indicates that the bit position is not significant; a one indicates that the bit position is significant. If mode = 001 (flush all entries), mask must be 0000.

FC field—Function code of address to be flushed. If the mode field is 001 (flush all entries), function code must be 00000; otherwise:

1DDDD — Function code is specified as four bits DDDD.

01RRR — Function code is contained in CPU data register RRR.

00000 — Function code is contained in CPU SFC register.

00001 — Function code is contained in CPU DFC register.

Else TRAP

Assembler

Syntax: PFLUSHR < ea >

Attributes: Unsized

Description: The quad word pointed to by < ea > is regarded as a previously used value of the CPU root pointer register. The root pointer table entry matching this value of CPU root pointer register (if any) is flushed, and all address translation cache entries for this value of CPU root pointer register (except for those that are globally shared) are invalidated. If no entry in the root pointer table matches the operand of this instruction, no action is taken.

If the supervisor root pointer is not in use, the operating system should not execute the PFLUSHR command to destroy a task identified by the current CPU root pointer register. It should wait until the CPU root pointer register has been loaded with a new root pointer identifying the next task until using the PFLUSHR instruction. At any time after the execution of the PFLUSHR instruction for the current CPU root pointer register, the current task alias to be corrupted.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	
1	1	1	1	0	0	0	0	0	0	EFFECTIVE ADDRESS				
										MODE		REG		
1	0	1	0	0	0	0	0	0	0	0	0	0	0	

pointer register. Only memory addressing modes can be used as the following table:

Addressing Mode	Mode	Register
Dn	—	—
An	—	—
(An)	010	reg. number:An
(An) +	011	reg. number:An
—(An)	100	reg. number:An
(d ₁₆ ,An)	101	reg. number:An
(d ₈ ,An,Xn)	110	reg. number:An
(bd,An,Xn)	110	reg. number:An
([bd,An,Xn] ,od)	110	reg. number:An
([bd,An],Xn ,od)	110	reg. number:An

Addressing Mode	Mode
(xxx).W	111
(xxx).L	111
# < data >	111
(d ₁₆ ,PC)	111
(d ₈ ,PC,Xn)	111
(bd,PC,Xn)	111
([bd,PC,Xn] ,od)	111
([bd,PC],Xn ,od)	111

NOTE

The effective address usage of this instruction is different than that of other PFLUSH variants.

Else TRAP

Assembler PLOADR FC, < ea >
Syntax: PLOADW FC, < ea >
Attributes: Unsized

Description: For the MC68851, PLOAD searches the translation table for a translation entry at the specified effective address. If one is found, it is flushed from the address translation cache, and an entry is made as if a bus master had run a bus cycle. Used and dirty bits in the table are updated as part of the table search. The MC68851 ignores logical bus arbitration signals during the flush and load phases at the end of the instruction. This prevents the possibility of an entry temporarily disappearing from the address translation cache and causing a false table search.

This instruction will cause a paged memory management unit illegal operation exception (vector \$39) if the E-bit of the translation control register is clear.

The function code for this operation may be specified to be:

1. Immediate—The function code is specified as four bits in the command code.
2. Data Register—The function code is contained in the lower four bits in the MC68020 data register specified in the instruction.
3. Source Function Code (SFC) Register—The function code is in the SFC register. Since the SFC of the MC68020 has only three implemented function codes \$0D\$7 can be specified in this manner.
4. Destination Function Code (DFC) Register—The function code is in the DFC register. Since the DFC of the MC68020 has only three implemented function codes \$0D\$7 can be specified in this manner.

attempted to access that address. Sets the used and modified bits appropriately of the search. The instruction executes despite the value of the E-bit in the translation control register or the state of the MMUDIS signal.

The < function code > operand is specified in one of the following ways:

1. Immediate—Three bits in the command word.
2. Data Register—The three least significant bits of the data register specified in the instruction.
3. Source Function Code (SFC) Register
4. Destination Function Code (DFC) Register

The effective address field specifies the logical address whose translation is to be loaded.

PLOADR causes U bits in the translation tables to be updated as if a read access had occurred. PLOADW causes U and M bits in the translation tables to be updated as if a write access had occurred.

PMMU Status Register: Not affected.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1
1	1	1	1	0	0	0	0	0	0	EFFECTIVE ADDRESS				
										MODE		REGIS		
0	0	1	0	0	0	R/W	0	0	0	0	FC			

into the address translation cache. Only control alterable addressing modes are allowed as listed in the following table:

Addressing Mode	Mode	Register
Dn	—	—
An	—	—
(An)	010	reg. number:An
(An) +	—	—
—(An)	—	—
(d ₁₆ ,An)	101	reg. number:An
(d ₈ ,An,Xn)	110	reg. number:An
(bd,An,Xn)	110	reg. number:An
([bd,An,Xn] ,od)	110	reg. number:An
([bd,An],Xn ,od)	110	reg. number:An

Addressing Mode	Mode
(xxx).W	111
(xxx).L	111
# < data >	—
(d ₁₆ ,PC)	—
(d ₈ ,PC,Xn)	—
(bd,PC,Xn)	—
([bd,PC,Xn] ,od)	—
([bd,PC],Xn ,od)	—

NOTE

The effective address field must provide the MC68851 with the effective address of the entry to be loaded into the address translation cache, not the effective address describing where the PLOAD operand is located. For example, to load an address translation cache entry to map a logical address that is temporarily stored on the system stack, the instruction PLOAD [(SP)] must be used since PLOAD (SP) would load an address translation cache entry mapping the system stack (i.e., the effective address passed to the MC68851 is the effective address of the system stack, not the effective address formed by the operand located on the top of the stack).

R/W field—Specifies whether the tables should be updated for a read or a write

1—Read

0—Write

- 00000 — Function code is contained in CPU SFC register.
- 00001 — Function code is contained in CPU DFC register.

FC field (MC68030)—Function code of address corresponding to entry to be

- 10XXX — Function code is specified as bits XXX.
- 01DDD — Function code is specified as bits 2–0 of data register DDD.
- 00000 — Function code is specified as SFC register.
- 00001 — Function code is specified as DFC register.

Assembler PMOVE MRn, < ea >
Syntax: PMOVE < ea > ,MRn
PMOVEFD < ea > ,MRn

Attributes: Size = (Word, Long, Quad)

Description: Moves the contents of the source effective address to the specified management unit register or moves the contents of the memory management register to the destination effective address.

The instruction is a quad-word (8 byte) operation for the CPU root pointer, supervisor root pointer. It is a long-word operation for the translation control register and the transparent translation registers (TT0 and TT1). It is a word operation for the MMU status register.

The PMOVEFD form of this instruction sets the FD-bit to disable flushing the translation cache when a new value loads into the supervisor root pointer, CPU root pointer, TT0, TT1 or translation control register (but not the MMU status register).

Writing to the following registers has the indicated side effects:

CPU Root Pointer—When the FD-bit is zero, it flushes the address translation cache. If the operand value is invalid for a root pointer descriptor, the instruction takes a memory management unit configuration error exception after moving the operand to the CPU root pointer.

Supervisor Root Pointer—When the FD-bit is zero, it flushes the address translation cache. If the operand value is invalid as a root pointer descriptor, the instruction takes a memory management unit configuration error exception after moving the operand to the supervisor root pointer.

Translation Control Register—When the FD-bit is zero, it flushes the address translation cache. If the E-bit = 1, consistency checks are performed on the PS and the operand. If the checks fail, the instruction takes a memory management unit configuration error exception after moving the operand to the translation control register. If the checks pass, the translation control register is loaded with the operand and the E-bit is set to 1.

TT0, TT1—When the FD-bit is zero, it flushes the address translation cache. If the E-bit = 1, or disables the transparent translation register according to the E-bit written to the register. If the E-bit = 1, the transparent translation register is enabled. If the E-bit = 0, the register is disabled.

MMU Status Register:

Not affected (unless the MMU status register is specified as the destination of the instruction)

Instruction Format:

0—Address translation cache is flushed.

1—Address translation cache does not flush.

Assembler PMOVE MRn, < ea >
Syntax: PMOVE < ea > ,MRn

Attributes: Size = (Word, Long, Quad)

Description: Moves the contents of the source effective address to an access control register or moves the contents of an access control register to the destination address.

The instruction is a long-word operation for the access control registers (AC0-AC15). It is a word operation for the access control unit status register (ACUSR).

Writing to the ACx registers enables or disables the access control register according to the E-bit written. If the E-bit = 1, the access control register is enabled. If the E-bit = 0, the register is disabled.

Condition Codes:

Not affected.

ACUSR:

Not affected unless the ACUSR is specified as the destination operand.

Instruction Format:

ACUSR													
15	14	13	12	11	10	9	8	7	6	5	4	3	2

011—Access Control Register 1

R/W field—Specifies the direction of transfer.

0—Memory to ACUSR

1—ACUSR to memory

Else TRAP

Assembler PMOVE < PMMU Register > , < ea >

Syntax: PMOVE < ea > , < PMMU Register >

Attributes: Size = (Byte, Word, Long, Double Long)

Description: The contents of the MC68851 register copies to the address specified by < ea > , or the data at < ea > copies into the MC68851 register.

The instruction is a quad-word operation for CPU root pointer, supervisor root pointer, and DMA root pointer registers. It is a long-word operation for the translation control register and a word operation for the breakpoint acknowledge control, breakpoint acknowledge data, access control, PMMU status, and PMMU cache status registers. PMOVE is a byte operation for the current access level, valid access level, and change control registers.

The following side effects occur when data is read into certain registers:

CPU Root Pointer—Causes the internal root pointer table to be searched for a new value. If there is no matching value, an entry in the root pointer table is replaced, and all address translation cache entries associated with the replaced entry are invalidated.

Supervisor Root Pointer—Causes all entries in the address translation cache that were formed with the supervisor root pointer (even globally shared entries) to be invalidated.

DMA Root Pointer—Causes all entries in the address translation cache that were formed with the DMA root pointer (even globally shared entries) to be invalidated.

Translation Control Register—If data written to the translation control register attempts to set the E-bit and the E-bit is currently clear, a consistency check is performed on the IS, TIA, TIB, TIC, TID, and PS fields.

Instruction Format 1:

PMOVE to/from TC, CRP, DRP, SRP, CAL, VAL, SCC, AC

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1

Instruction Fields:

Effective Address field—Same as format 1.

P Register field—Specifies the MC68851 register.

000 — PMMU Status Register

001 — PMMU Cache Status Register

R/W field—Specifies direction of transfer.

0—Transfer < ea > to MC68851 register.

1—Transfer MC68851 register to < ea > (must be one to access PMMU cache status register using this format).

Else TRAP

Assembler

Syntax: PRESTORE < ea >

Attributes: UnsizeD, Privileged

Description: The MC68851 aborts execution of any operation in progress. The state of the programmer registers and internal states are loaded from the state frame located at the effective address. The first word at the specified address is the format word of the state frame, specifying the size of the frame and the revision number of the MC68851 that created it. The MC68020 writes the first word to the MC68851 restore coprocessor interface register, initiating the restore operation. Then it reads the coprocessor interface register to verify that the MC68851 recognizes the format word as valid. The format is invalid if the MC68851 does not recognize the frame size or the revision number does not match. If the format is invalid, the MC68020 takes a bus error exception, and the MC68851 returns to the idle state with its user visible state unchanged. However, if the format is valid, then the appropriate state frame is restored, starting at the specified location and proceeding up through the higher addresses.

The PRESTORE instruction restores the nonuser visible state of the MC68851, including the PMMU status register, CPU root pointer, supervisor root pointer, current privilege level, valid access level, and stack change control registers of the user program model. In addition, if any breakpoints are enabled, all breakpoint acknowledgment and breakpoint acknowledge data registers are restored. This instruction is the first instruction of the PSAVE instruction.

The current implementation of the MC68851 supports four state frame sizes:

NULL: This state frame is 4 bytes long, with a format word of \$0. A PRESTORE with this size state frame places the MC68851 in the idle state with no coprocessor or module operations in progress.

IDLE: This state frame is 36 (\$24) bytes long. A PRESTORE with this size state frame causes the MC68851 to place itself in an idle state with no coprocessor operations in progress and no breakpoints enabled. A module may or may not be in progress. This state frame restores the minimum state of the MC68851 registers.

BREAKPOINTS ENABLED: This state frame is 76 (\$4C) bytes long. A PRE with this size state frame restores all breakpoint registers, along with states. A coprocessor operation may or may not be in progress.

PMMU Status Register: Set according to restored data.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1
1	1	1	1	0	0	0	1	0	1	EFFECTIVE ADDRESS MODE				
										REGIS				

Instruction Fields:

Effective Address field—Specifies the source location. Only control or post-in addressing modes can be used as listed in the following table:

Addressing Mode	Mode	Register
Dn	—	—
An	—	—
(An)	010	reg. number:An
(An) +	011	reg. number:An
—(An)	—	—
(d ₁₆ ,An)	101	reg. number:An
(d ₈ ,An,Xn)	110	reg. number:An
(bd,An,Xn)	110	reg. number:An

([bd,PC],Xn ,od)	111

Else TRAP

Assembler

Syntax: PSAVE < ea >

Attributes: Unsized, Privileged

Description: The MC68851 suspends execution of any operation that it is performing. It saves its internal state and some programmer registers in a state frame located at the effective address. The following registers are copied: PMMU status, coprocessor pointer, supervisor root pointer, current access level, valid access level, and change control. If any breakpoint is enabled, all breakpoint acknowledge coprocessor and breakpoint acknowledge data registers are copied. After the save operation, the MC68851 is in an idle state waiting for another operation to be requested. Program registers are not changed.

The state frame format saved by the MC68851 depends on its state at the time of the PSAVE operation. In the current implementation, three state frames are possible:

IDLE: This state frame is 36 (\$24) bytes long. A PSAVE of this size state frame indicates that the MC68851 was in an idle state with no coprocessor operation in progress and no breakpoints enabled. A module call operation may or may not have been in progress when this state frame was saved.

MID-COPROCESSOR: This state frame is 44 (\$2C) bytes long. A PSAVE of this size state frame indicates that the MC68851 was in a state with a coprocessor operation in progress and no breakpoints enabled.

BREAKPOINTS ENABLED: This state frame is 76 (\$4C) bytes long. A PSAVE of this size state frame indicates that one or more breakpoints were enabled. A coprocessor or module call operation may or may not have been in progress.

PMMU Status Register: Not affected

Instruction Fields:

Effective Address field—Specifies the destination location. Only constant and predecrement addressing modes can be used as listed in the following table.

Addressing Mode	Mode	Register
Dn	—	—
An	—	—

MC68851 Condition field—Specifies the coprocessor condition to be tested. This field is passed to the MC68851, which provides directives to the main processor processing this instruction.

Assembler PTESTR FC, < ea > ,# < level >
Syntax: PTESTR FC, < ea > ,# < level > ,An
PTESTW FC, < ea > ,# < level >
PTESTW FC, < ea > ,# < level > ,An

Attributes: Unsized

Description: This instruction searches the address translation cache or the translation tables to a specified level. Searching for the translation descriptor corresponding to the < ea > field, it sets the bits of the MMU status register according to the status of the translation descriptor. Optionally, PTEST stores the physical address of the last translation table accessed during the search in the specified address register. The PTEST instruction searches the address translation cache or the translation tables to obtain the requested information, but alters neither the used or modified bits of the translation table nor the address translation cache. When the level operand is zero, only the translation of either read or write accesses causes the operations of the PTEST or PTESTW to return different results.

The < function code > operand is specified as one of the following:

1. Immediate—Three bits in the command word.
2. Data Register—The three least significant bits of the data register specified in the instruction.
3. Source Function Code (SFC) Register
4. Destination Function Code (DFC) Register

The effective address is the address to test. The < level > operand specifies the level of the search. Level 0 specifies searching the address translation cache only, and levels 1–7 specify searching the translation tables only. The search ends at the specified level. A level 0 test does not return the same MMU status register values as a test with a nonzero level number.

Execution of the instruction continues to the requested level or until detected by one of the following conditions:

- Invalid Descriptor
- Limit Violation
- Bus Error Assertion (Physical Bus Error)

If there is a parameter specification for a translation table search, the physical address of the last descriptor successfully fetched loads into the address register. A successfully fetched descriptor occurs only if all portions of the descriptor can be read on the MC68030 without abnormal termination of the bus cycle. If the root pointer's bit 0 indicates page descriptor, the returned address is \$0. For a long descriptor, the physical address of the first long word is returned. The size of the descriptor (short or long) is not returned and must be determined from a knowledge of the translation table.

Condition Codes:

Not affected.

MMUSR:

B	L	S	0	W	I	M	0	0	T	0	0	0	0	*
*	*	*	0	*	*	*	0	0	0	0	0	0	0	*

MMUSR Bit	PTEST, Level 0	PTEST, Levels 1–7
Bus Error (B)	This bit is set if the bus error bit is set in the ATC entry for the specified logical address.	This bit is set if a bus error is encountered during the table search for the PTEST instruction.
Limit (L)	This bit is cleared.	This bit is set if an index exceeds a limit during the table search.
Supervisor or Violation (S)	This bit is cleared.	This bit is set if the S-bit of a long (S) format table descriptor or long format page descriptor encountered during the search is set and if the FC2-bit of the function code specified by the PTEST instruction is not equal to one. The S-bit is undefined if the bit is set.
Write Protected (W)	The bit is set if the WP-bit of the ATC entry is set. It is undefined if the I-bit is set.	This bit is set if a descriptor or page descriptor is encountered with the WP-bit set during the table search. The W-bit is undefined if the I-bit is set.
Invalid (I)	This bit indicates an invalid translation. The I-bit is set if the translation for the specified logical address is not resident in the ATC or if the B-bit of the corresponding ATC entry is set.	This bit indicates an invalid translation. The I-bit is set if the DT field of a table or a page descriptor encountered during the search is set to invalid or if either the B or L bit of the MMUSR are set during the table search.
Modified (M)	This bit is set if the ATC entry corresponding to the specified address has the modified bit set. It is undefined if the I-bit is set.	This bit is set if the page descriptor for the specified address has the modified bit set. It is undefined if I-bit is set.
Transparent (T)	This bit is set if a match occurred in either (or both) of the transparent translation registers (TT0 or TT1).	This bit is set to zero.
Number of Levels (N)	This 3-bit field is set to zero.	This 3-bit field contains the actual number of tables accessed during the search.

1	1	1	1	0	0	0	0	0	0	EFFECTIVE ADDRESS	
										MODE	REGIS
1	0	0	LEVEL			R/W	A	REGISTER			FC

Instruction Fields:

Effective Address field—Specifies the logical address to be tested. Only alterable addressing modes can be used as listed in the following table:

Addressing Mode	Mode	Register	Addressing Mode	Mode
Dn	—	—	(xxx).W	111
An	—	—	(xxx).L	111
(An)	010	reg. number:An	# < data >	—
(An) +	—	—		
—(An)	—	—		
(d ₁₆ ,An)	101	reg. number:An	(d ₁₆ ,PC)	—
(d ₈ ,An,Xn)	110	reg. number:An	(d ₈ ,PC,Xn)	—
(bd,An,Xn)	110	reg. number:An	(bd,PC,Xn)	—
([bd,An,Xn] ,od)	110	reg. number:An	([bd,PC,Xn] ,od)	—
([bd,An],Xn ,od)	110	reg. number:An	([bd,PC],Xn ,od)	—

Level field—Specifies the highest numbered level to be searched in the table. If this field contains 0, the A field and the register field must also be 0. An instruction takes an F-line exception when the level field is 0 and the A field is not 0.

R/W field—Specifies simulating a read or write bus cycle (no difference for MMU).
 0—Write
 1—Read

A field—Specifies the address register option.
 0—No address register.
 1—Return the address of the last descriptor searched in the address register field specified in the register field.

FC field—Function code of address to be tested.

10XXX — Function code is specified as bits XXX.

01DDD — Function code is specified as bits 2–0 of data register DDD.

00000 — Function code is specified as source function code register.

00001 — Function code is specified as destination function code register.

Assembler PTESTR FC, < ea >
Syntax: PTESTW FC, < ea >

Attributes: Unsized

Description: This instruction searches the access control registers for the descriptor corresponding to the < ea > field and sets the bit of the access control status register (ACUSR) according to the status of the descriptor.

The < function code > operand is specified in one of the following ways:

1. Immediate—Three bits in the command word.
2. Data Register—The three least significant bits of the data register specified in the instruction.
3. Source Function Code (SFC) Register
4. Destination Function Code (DFC) Register

The effective address is the address to test.

Condition Codes:

Not affected.

ACUSR:

x	x	x	0	x	x	x	0	0	AC	0	0	0	x	x
---	---	---	---	---	---	---	---	---	----	---	---	---	---	---

x = May be 0 or 1.

The AC-bit is set if a match occurs in either (or both) of the access control registers.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	
1	1	1	1	0	0	0	0	0	0	EFFECTIVE ADDRESS					
										MODE		REGISTER			FC
1	0	0	0	0	0	R/W	0	REGISTER			FC				

alterable addressing modes can be used as listed in the following table:

Addressing Mode	Mode	Register
Dn	—	—
An	—	—
(An)	010	reg. number:An
(An) +	—	—
—(An)	—	—
(d ₁₆ ,An)	101	reg. number:An
(d ₈ ,An,Xn)	110	reg. number:An
(bd,An,Xn)	110	reg. number:An
([bd,An,Xn] ,od)	110	reg. number:An
([bd,An],Xn ,od)	110	reg. number:An

Addressing Mode	Mode
(xxx).W	111
(xxx).L	111
# < data >	—
(d ₁₆ ,PC)	—
(d ₈ ,PC,Xn)	—
(bd,PC,Xn)	—
([bd,PC,Xn] ,od)	—
([bd,PC],Xn ,od)	—

R/W field—Specifies simulating a read or write bus cycle.

0—Write

1—Read

Register field—Specifies an address register for the instruction. When the register field contains 0, this field must contain 0.

FC field—Function code of address to be tested.

10XXX — Function code is specified as bits XXX.

01DDD — Function code is specified as bits 2–0 of data register DDD.

00000 — Function code is specified as source function code register.

00001 — Function code is specified as destination function code register.

NOTE

Assembler syntax for the MC68030 is PTESTR FC, < ea > ,#0 and PTESTW FC, < ea > ,#0.

Assembler PTESTR (An)
Syntax: PTESTW (An)

Attributes: Unsized

Description: This instruction searches the translation tables for the page descriptor corresponding to the test address in An and sets the bits of the MMU status register according to the status of the descriptors. The upper address bits of the test address and the physical address are also stored in the MMU status register. The PTESTR instruction simulates a read access and sets the U-bit in each descriptor during table search. PTESTW simulates a write access and also sets the M-bit in the descriptor. The MMU status register address translation cache entry, and the MMU status register.

A matching entry in the address translation cache (data or instruction) specific to the function code will be flushed by PTEST. Completion of PTEST results in the creation of a new address translation cache entry. The specification of the function code for the test address is in the destination function code (DFC) register. A PTEST instruction with a DFC value of 0, 3, 4, or 7 is undefined and will return an unknown value in the MMUSR.

Execution of the instruction continues until one of the following conditions occur:

- Match with one of the two transparent translation registers.
- Transfer Error Assertion (physical transfer error)
- Invalid Descriptor
- Valid Page Descriptor

Condition Codes:

Not affected.

MMU Status Register:

PHYSICAL ADDRESS	B	G	U1	U0	S	CM	M	0	W	T
*	*	*	*	*	*	*	*	0	*	*

Physical Address—This 20-bit field contains the upper bits of the translated address. Merging these bits with the lower bits of the logical address forms the actual physical address.

Bus Error (B)—Set if a transfer error is encountered during the table search of the PTEST instruction. If this bit is set, all other bits are zero.

Globally Shared (G)—Set if the G-bit is set in the page descriptor.

User Page Attributes (U1, U0)—Set if corresponding bits in the page descriptor are set.

Supervisor Protection (S)—Set if the S-bit in the page descriptor is set. This bit does not indicate that a violation has occurred.

Cache Mode (CM)—This 2-bit field is copied from the CM-bit in the page descriptor.

Modified (M)—Set if the M-bit is set in the page descriptor associated with the instruction.

Write Protect (W)—Set if the W-bit is set in any of the descriptors encountered during the table search. Setting of this bit does not indicate that a violation occurred.

Transparent Translation Register Hit (T)—Set if the PTEST address matches a transparent translation register hit for the instruction or data transparent translation register and the R-bit is set; all other bits are zero.

Resident (R)—Set if the PTEST address matches a transparent translation register hit if the table search completes by obtaining a valid page descriptor.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1
1	1	1	1	0	1	0	1	0	1	R/W	0	1	REG	

Instruction Fields:

R/W field—Specifies simulating a read or write bus transfer.

0—Write

1—Read

Register field—Specifies the address register containing the effective address of the instruction.

Assembler PTESTR (An)
Syntax: PTESTW (An)

Attributes: Unsized

Description: This instruction must not be executed on an MC68EC040. This instruction may cause extraneous bus cycles to occur and may result in unexpected error types.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1
1	1	1	1	0	1	0	1	0	1	R/W	0	1	REGIS	

Instruction Fields:

R/W field—Specifies simulating a read or write bus transfer.

0—Write

1—Read

Register field—Specifies the address register containing the effective address of the instruction.

Assembler PTESTR FC, < ea > ,# < level > ,(An)
Syntax: PTESTW FC, < ea > ,# < level > ,(An)

Attributes: Unsized

Description: If the E-bit of the translation control register is set, information about the address specified by FC and < ea > is placed in the PMMU status register. If the E-bit of the translation control register is clear, this instruction will cause a paged management unit illegal operation exception (vector \$39).

The function code for this operation may be specified as follows:

1. Immediate—The function code is four bits in the command word.
2. Data Register—The function code is in the lower four bits in the MC68020 register specified in the instruction.
3. Source Function Code (SFC) Register—The function code is in the SFC register in the CPU. Since the SFC of the MC68020 has only three implemented function codes, only function codes \$0D\$7 can be specified in this manner.
4. Destination Function Code (DFC) Register—The function code is in the DFC register in the CPU. Since the DFC of the MC68020 has only three implemented function codes, only function codes \$0D\$7 can be specified in this manner.

The effective address field specifies the logical address to be tested.

The # < level > parameter specifies the depth to which the translation table is searched. A value of zero specifies a search of the address translation cache. Values 1–7 cause the address translation cache to be ignored and specify the number of descriptors to fetch.

NOTE

Finding an address translation cache entry with < level > set to zero may result in a different value in the PMMU status register than forcing a table search. Only the I, W, G, M, and C bits of the PMMU status register are always the same in both cases.

are not modified by this instruction.

If there is a specified address register parameter, the physical address of the successfully fetched descriptor is loaded into the address register. A descriptor is successfully fetched if all portions of the descriptor can be read by the MC68851 before an abnormal termination of the bus cycle. If the DT field of the root pointer used in the page descriptor, the returned address is \$0.

The PTEST instruction continues searching the translation tables until reaching the requested level or until a condition occurs that makes further searching impossible (a DT field set to invalid, a limit violation, or a bus error from memory). The information in the PMMU status register reflects the accumulated values.

PMMU Status Register:

Bus Error (B)—Set if a bus error was received during a descriptor fetch, or if $BERF = 0$ and an entry was found in the address translation cache with its BERF cleared otherwise.

Limit (L)—Set if the limit field of a long descriptor was exceeded; cleared otherwise.

Supervisor Violation (S)—Set if a long descriptor indicated supervisor-only access and the $\langle fc \rangle$ parameter did not have bit 2 set; cleared otherwise.

Access Level Violation (A)—If PTESTR was specified, set if the RAL field of a descriptor would deny access. If PTESTW was specified, set if a WAL or FAL of a long descriptor would deny access; cleared otherwise.

Write Protection (W)—Set if the WP-bit of a descriptor was set or if a WAL or FAL of a long descriptor would deny access; cleared otherwise.

Invalid (I)—Set if a valid translation was not available; cleared otherwise.

Modified (M)—If the tested address is found in the address translation cache, set if the value of the M-bit in the address translation cache is set. If the tested address is not in the translation table, set if the M-bit of the page descriptor is set; cleared otherwise.

Globally Shared (C)—Set if the address is globally shared; cleared otherwise.

Level Number (N)—Set to the number of levels searched. A value of zero indicates early termination of the table search in the root pointer (DT = page descriptor) if the level specification was not zero. If the level specification was zero, N is set to zero.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2
1	1	1	1	0	0	0	0	0	0	EFFECTIVE ADDRESS MODE REG			
1	0	0	LEVEL			R/W	A-REGISTER			FC			

requested. Only control alterable addressing modes can be used as listed in the following table:

Addressing Mode	Mode	Register
Dn	—	—
An	—	—
(An)	010	reg. number:An
(An) +	—	—
—(An)	—	—
(d ₁₆ ,An)	101	reg. number:An
(d ₈ ,An,Xn)	110	reg. number:An
(bd,An,Xn)	110	reg. number:An
([bd,An,Xn] ,od)	110	reg. number:An
([bd,An],Xn ,od)	110	reg. number:An

Addressing Mode	Mode
(xxx).W	111
(xxx).L	111
# < data >	—
(d ₁₆ ,PC)	—
(d ₈ ,PC,Xn)	—
(bd,PC,Xn)	—
([bd,PC,Xn] ,od)	—
([bd,PC],Xn ,od)	—

NOTE

The effective address field must provide the MC68851 with the effective address of the logical address to be tested, not the effective address describing where the PTEST operand is located. For example, to test a logical address that is temporarily stored on the system stack, the instruction PTEST [(SP)] must be used since PTEST (SP) would test the mapping of the system stack (i.e., the effective address passed to the MC68851 is the effective address of the system stack, not the effective address formed by the operand located on the top of the stack).

1—Read
0—Write

A-Register field—Specifies the address register in which to load the last descriptor address.

0xxx — Do not return the last descriptor address to an address register.
1RRR — Return the last descriptor address to address register RRR.

NOTE

When the PTEST instruction specifies a level of zero, the A-register field must be 0000. Otherwise, an F-line exception is generated.

FC field—Function code of address to test.

1DDDD — Function code is specified as four bits DDDD.

01RRR — Function code is contained in CPU data register RRR.

00000 — Function code is contained in CPU source function code register.

00001 — Function code is contained in CPU destination function code register.

Else TRAP

Assembler

PTRAPcc

Syntax:

PTRAPcc.W # < data > PTRAPcc.L # < data >

Attributes:

Unsize or Size = (Word, Long)

Description: If the selected MC68851 condition is true, the processor initiates exception processing. The vector number is generated referencing the cpTRAPcc exception vector; the stacked program counter is the address of the next instruction if the selected condition is not true, no operation is performed, and execution continues with the next instruction. The immediate data operand is placed in the next word(s) following the MC68851 condition and is available for user definition to be used within the trap handler. Following the condition word, there may be a user-defined data operand specified as immediate data, to be used by the trap handler.

The condition specifier cc may specify the following conditions:

Specifier	Description	Condition Field
BS	B set	000000
LS	L set	000010
SS	S set	000100
AS	A set	000110
WS	W set	001000
IS	I set	001010
GS	G set	001100
CS	C set	001110

Specifier	Description	Condition Field
BC	B clear	000001
LC	L clear	000011
SC	S clear	000101
AC	A clear	000111
WC	W clear	001001
IC	I clear	001011
GC	G clear	001101
CC	C clear	001111

PMMU Status Register: Not affected

1	1	1	1	0	0	0	0	0	1	1	1	1	OP
0	0	0	0	0	0	0	0	0	0	MC68851 CONDITION			
16-BIT OPERAND OR MOST SIGNIFICANT WORD OF 32-BIT OPERAND (IF NEEDED)													
LEAST SIGNIFICANT WORD OF 32-BIT OPERAND (IF NEEDED)													

Instruction Fields:

Opmode field—Selects the instruction form.

- 010 — Instruction is followed by one operand word.
- 011 — Instruction is followed by two operand words.
- 100 — Instruction has no following operand words.

MC68851 Condition field—Specifies the coprocessor condition to be tested. is passed to the MC68851, which provides directives to the main processing this instruction.

Assembler PVALID VAL, < ea >
Syntax: PVALID An, < ea >

Attributes: Size = (Long)

Description: The upper bits of the source, VAL or An, compare with the upper bits of the destination, < ea >. The ALC field of the access control register defines the number of bits compared. If the upper bits of the source are numerically greater than (more privileged than) the destination, they cause a memory management access level exception. Otherwise, execution continues with the next instruction. If the MCR = 0, the access control register = 0, then this instruction always causes a paged memory management unit access level exception.

PMMU Status Register: Not affected.

Instruction Format 1:

VAL Contains Access Level to Test Against

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1
1	1	1	1	0	0	0	0	0	0	EFFECTIVE ADDRESS				
										MODE			REGIS	
0	0	1	0	1	0	0	0	0	0	0	0	0	0	0

against the valid access level register. Only control addressing modes can be used as listed in the following table:

Addressing Mode	Mode	Register
Dn	—	—
An	—	—
(An)	010	reg. number:An
(An) +	—	—
—(An)	—	—

([bd,An],Xn ,od)	110	reg. number:An	([bd,PC],Xn ,od)	—	

NOTE

The effective address field must provide the MC68851 with the effective address of the logical address to be validated, not the effective address describing where the PVALID operand is located. For example, to validate a logical address that is temporarily stored on the system stack, the instruction PVALID VAL,[(SP)] must be used since PVALID VAL,(SP) would validate the mapping on the system stack (i.e., the effective address passed to the MC68851 is the effective address of the system stack, not the effective address formed by the operand located on the top of the stack).

Register field—Specifies the main processor address register to be used for compare.

Assembler**Syntax:** RESET**Attributes:** Unsized

Description: Asserts the \overline{RSTO} signal for 512 (124 for MC68000, MC68001, MC68008, MC68010, and MC68302) clock cycles, resetting all external devices. The processor state, other than the program counter, is unaffected, and execution continues with the next instruction.

Condition Codes:

Not affected.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2
0	1	0	0	1	1	1	0	0	1	1	1	0	0

Else TRAP

Assembler

Syntax: RTE

Attributes: Unsized

Description: Loads the processor state information stored in the exception stack located at the top of the stack into the processor. The instruction examines the format field in the format/offset word to determine how much information is restored.

Condition Codes:

Set according to the condition code bits in the status register value restored from the stack.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1
0	1	0	0	1	1	1	0	0	1	1	1	0	0	1

Format/Offset Word (in Stack Frame):

MC68010, MC68020, MC68030, MC68040, CPU32

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1
FORMAT				0	0	VECTOR OFFSET								

Format Field of Format/Offset Word:

Contains the format code, which implies the stack frame size (including the format/offset word). For further information, refer to **Appendix B Exception Processing Reference**.

Assembler**Syntax:** STOP # < data >**Attributes:** Unsized

Description: Moves the immediate operand into the status register (both supervisor portions), advances the program counter to point to the next instruction, stops the fetching and executing of instructions. A trace, interrupt, or reset causes the processor to resume instruction execution. A trace exception occurs if instruction tracing is enabled (T0 = 1, T1 = 0) when the STOP instruction begins execution. If an interrupt request is asserted with a priority higher than the priority set by the new status register value, an interrupt exception occurs; otherwise, the interrupt request is ignored. External reset always initiates reset exception processing.

Condition Codes:

Set according to the immediate operand.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	
0	1	0	0	1	1	1	0	0	1	1	1	0	0	
IMMEDIATE DATA														

Instruction Fields:

Immediate field—Specifies the data to be loaded into the status register.

SECTION 7 CPU32 INSTRUCTIONS

This section describes the instructions provided for the CPU32. The CPU32 can execute object code from an MC68000 and MC68010 and many of the instructions of the M

There are three new instructions provided for the CPU32: enter background mode (LBGM), low-power stop (LPSTOP), and table lookup and interpolate (TBLS, TBLSN, TBLUN, TBLUN). Table 7-1 lists the MC68020 instructions not supported by the CPU32.

Table 7-1. MC68020 Instructions Not Supported

Mnemonic	Description
BFCHG	Test Bit Field and Change
BFCLR	Test Bit Field and Clear
BFEXTS	Signed Bit Field Extract
BFEXTU	Unsigned Bit Field Extract
BFFFO	Bit Field Find First One
BFINS	Bit Field Insert
BFSET	Test Bit Field and Set
BFTST	Test Bit Field
CALLM	CALL Module
CAS	Compare and Swap Operands
CAS2	Compare and Swap Dual Operands
cpBcc	Branch on Coprocessor Condition
cpDBcc	Test Coprocessor Condition Decrement and Branch
cpGEN	Coprocessor General Function
cpRESTORE	Coprocessor Restore Function
cpSAVE	Coprocessor Save Function
cpScc	Set on Coprocessor Condition
cpTRAPcc	Trap on Coprocessor Condition
RTM	Return from Module
PACK	Pack BCD
UNPK	Unpack BCD

Table 7-2. M68000 Family Addressing Modes

Addressing Mode	Syntax	MC68000 MC68010	CPU32	M

Assembler

Syntax: BGND

Attributes: Size = (Unsize)

Description: The processor suspends instruction execution and enters background mode if background mode is enabled. The freeze output is asserted to acknowledge entry into background mode. Upon exiting background mode, instruction execution continues with the instruction pointed to by the current program counter. If background mode is not enabled, the processor initiates illegal instruction exception processing. The vector number is generated to reference the illegal instruction exception processing. Refer to the appropriate user’s manual for detailed information on background mode.

Condition Codes:

X	N	Z	V	C

0	1	0	0	1	0	1	0	1	1	1	1	1	0	1

STOP
Else TRAP

Assembler

Syntax: LPSTOP # < data >

Attributes: Size = (Word) Privileged

Description: The immediate operand moves into the entire status register, the counter advances to point to the next instruction, and the processor stops fetching instructions. A CPU LPSTOP broadcast cycle is executed to CPU to copy the updated interrupt mask to the external bus interface (EBI). The clocks are stopped.

Instruction execution resumes when a trace, interrupt, or reset exception occurs. A trace exception will occur if the trace state is on when the LPSTOP instruction is executed. If an interrupt request is asserted with a higher priority than the priority level set by the new status register value, an interrupt exception occurs. Otherwise, the interrupt request is ignored. If the bit of the immediate operand corresponding to the S-bit is off, execution of the instruction will cause a bus violation. An external reset always initiates reset exception processing.

Condition Codes:

Set according to the immediate operand.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2
1	1	1	1	1	0	0	0	0	0	0	0	0	0
0	0	0	0	0	0	0	1	1	1	0	0	0	0
IMMEDIATE DATA													

Instruction Fields:

Immediate field—Specifies the data to be loaded into the status register.

$$\text{ENTRY}(n) + \{(\text{ENTRY}(n + 1) - \text{ENTRY}(n)) \times \text{Dx } 7 - 0\} \div 256$$

Unrounded:

$$\text{ENTRY}(n) \times 256 + \{(\text{ENTRY}(n + 1) - \text{ENTRY}(n)) \times \text{Dx } 7 - 0\}$$

Where ENTRY(n) and ENTRY(n + 1) are either:

1. Consecutive entries in the table pointed to by the < ea > indexed by Dx 15 – 8 π SIZE or;
2. The registers Dym, Dyn respectively.

Assembler	TBLS. < size > < ea > ,Dx	Result rounded
Syntax:	TBLSN. < size > < ea > ,Dx	Result not rounded
	TBLS. < size > Dym:Dyn, Dx	Result rounded
	TBLSN. < size > Dym:Dyn, Dx	Result not rounded

Attributes: Size = (Byte, Word, Long)

Description: The TBLS and TBLSN instructions allow the efficient use of piecewise compressed data tables to model complex functions. The TBLS instruction has two modes of operation: table lookup and interpolate mode and data register interpolate mode.

For table lookup and interpolate mode, data register Dx 15 – 0 contains the independent variable X. The effective address points to the start of a signed byte or long-word table containing a linearized representation of the dependent variable as a function of X. In general, the independent variable, located in the low-order bits of Dx, consists of an 8-bit integer part and an 8-bit fractional part. An assumed origin point is located between bits 7 and 8. The integer part, Dx 15 – 8, is scaled by the operand size and is used as an offset into the table. The selected entry in the table is subtracted from the next consecutive entry. A fractional portion of this difference is taken by multiplying by the interpolation fraction, Dx 7 – 0. The adjusted difference is then added to the selected table entry. The result is returned in the destination register, Dx.

in place of the two table entries. For this mode, only the fractional portion, $Dx \div 15 - 8$, is used in the interpolation, and the integer portion, $Dx \div 15 - 8$, is ignored. The interpolation mode may be used with several table lookup and interpolations of multidimensional functions.

Signed table entries range from -2^{n-1} to $2^{n-1} - 1$; whereas, unsigned table entries range from 0 to $2^n - 1$ where n is 8, 16, or 32 for byte, word, and long-word respectively.

Rounding of the result is optionally selected via the "R" instruction field. (TABLE), the fractional portion is rounded according to the round-to-nearest mode. The following table summarizes the rounding procedure:

Adjusted Difference Fraction	Rounding Adjustment
$\leq -1/2$	- 1
$> -1/2$ and $< 1/2$	+ 0
$\geq 1/2$	+ 1

The adjusted difference is then added to the selected table entry. The rounded result is returned in the destination data register, Dx . Only the portion of the register corresponding to the selected size is affected.

	31	24	23	16	15	8	7
BYTE	UNAFFECTED		UNAFFECTED		UNAFFECTED		RESULT
WORD	UNAFFECTED		UNAFFECTED		RESULT		RESULT
LONG	RESULT		RESULT		RESULT		RESULT

byte, the integer portion of the result is returned in Dx 15 – 8; the integer portion of a word result is stored in Dx 23 – 8; the least significant 24 bits of a long result are stored in Dx 31 – 8. Byte and word results are sign-extended to fill the entire 32-bit register.

	31	24	23	16	15	8	7
BYTE	SIGN-EXTENDED		SIGN-EXTENDED		RESULT		FRACTION
WORD	SIGN-EXTENDED		RESULT		RESULT		FRACTION
LONG	RESULT		RESULT		RESULT		FRACTION

NOTE

The long-word result contains only the least significant 24 bits of integer precision.

For all sizes, the 8-bit fractional portion of the result is returned to the low byte of the data register, Dx 7 – 0. User software can make use of the fractional data to correct cumulative errors in lengthy calculations or implement rounding algorithms different from that provided by other forms of TBLS. The previously described assumption of a radix point places two restrictions on the programmer:

1. Tables are limited to 257 entries in length.
2. Interpolation resolution is limited to 1/256, the distance between consecutive entries. The assumed radix point should not, however, be construed by the programmer as a requirement that the independent variable be calculated as a fractional number in the range $0 < \pi < 255$. On the contrary, X should be considered an integer in the range $0 < \pi < 65535$, realizing that the table is actually a compressed representation of a linearized function in which only every 256th value is actually stored in memory.

X	N	Z	V	C
—	*	*	*	0

X — Not affected.

N — Set if the most significant bit of the result is set; cleared otherwise.

Z — Set if the result is zero; cleared otherwise.

V — Set if the integer portion of an unrounded long result is not in the range
 $\leq \text{Result} \leq (2^{23}) - 1$; cleared otherwise.

C — Always cleared.

Instruction Format:

TABLE LOOKUP AND INTERPOLATE

15	14	13	12	11	10	9	8	7	6	5	4	3	2
1	1	1	1	1	0	0	0	0	0	EFFECTIVE ADDRESS

													REGIS
0	REGISTER Dx			1	R	0	1	SIZE		0	0	0	REGIS

Effective address field (table lookup and interpolate mode only)—Specifies destination location. Only control alterable addressing modes are allowed in the following table:

Addressing Mode	Mode	Register
Dn	—	—
An	—	—
(An)	—	—
(An) +	—	—
– (An)	100	reg. number:An
(d ₁₆ ,An)	101	reg. number:An
(d ₈ ,An,Xn)	110	reg. number:An
(bd,An,Xn)	110	reg. number:An

Addressing Mode	Mode
(xxx).W	111
(xxx).L	111
# < data >	—
(d ₁₆ ,PC)	111
(d ₈ ,PC,Xn)	111
(bd,PC,Xn)	111

Size Field—Specifies the size of operation.

- 00 — Byte Operation
- 01 — Word Operation
- 10 — Long Operation

Register field—Specifies the destination data register, Dx. On entry, the register contains the interpolation fraction and entry number.

Dym, Dyn field—If the effective address mode field is nonzero, this operand register is unused and should be zero. If the effective address mode field is zero, the interpolation variant of this instruction is implied, and Dyn specifies one of two source operands.

Rounding mode field—The R-bit controls the rounding of the final result. When R=1, the result is rounded according to the round-to-nearest algorithm. When R=0, the result is returned unrounded.

$ENTRY(n) + \{(ENTRY(n + 1) - ENTRY(n)) \times Dx \div 256\}$
 Unrounded:

$ENTRY(n) \times 256 + \{(ENTRY(n + 1) - ENTRY(n)) \times Dx \div 256\}$

Where ENTRY(n) and ENTRY(n + 1) are either:

1. Consecutive entries in the table pointed to by the <ea> indexed by Dx 15 – 8 π SIZE or;
2. The registers Dym, Dyn respectively

Assembler Syntax:	TBLU. < size > < ea > ,Dx	Result rounded
	TBLUN. < size > < ea > ,Dx	Result not rounded
	TBLU. < size > Dym:Dyn, Dx	Result rounded
	TBLUN. < size > Dym:Dyn, Dx	Result not rounded

Attributes: Size = (Byte, Word, Long)

Description: The TBLU and TBLUN instructions allow the efficient use of piecewise compressed data tables to model complex functions. The TBLU instruction has two modes of operation: table lookup and interpolate mode and data register in mode.

For table lookup and interpolate mode, data register Dx 15 – 0 contains the independent variable X. The effective address points to the start of a unsigned word, or long-word table containing a linearized representation of the dependent variable, Y, as a function of X. In general, the independent variable, located in the order word of Dx, consists of an 8-bit integer part and an 8-bit fractional part. The assumed radix point is located between bits 7 and 8. The integer part, Dx 15 – 8, is scaled by the operand size and is used as an offset into the table. The selected entry in the table is subtracted from the next consecutive entry. A fractional portion of the difference is taken by multiplying by the interpolation fraction, Dx 7 – 0. The result difference is then added to the selected table entry. The result is returned to the destination data register, Dx.

in place of the two table entries. For this mode, only the fractional portion, Dx 15 – 8, is ignored. The interpolation mode may be used with several table lookup and interpolations for multidimensional functions.

Signed table entries range from -2^{n-1} to $2^{n-1} - 1$; whereas, unsigned table entries range from 0 to $2^n - 1$ where n is 8, 16, or 32 for byte, word, and long-word respectively. The unsigned and unrounded table results will be zero-extended or sign-extended.

Rounding of the result is optionally selected via the "R" instruction field. In (TABLE), the fractional portion is rounded according to the round-to-nearest algorithm. The rounding procedure can be summarized by the following table:

Adjusted Difference Fraction	Rounding Adjustment
$\geq 1/2$	+ 1
$< 1/2$	+ 0

The adjusted difference is then added to the selected table entry. The rounded result is returned in the destination data register, Dx. Only the portion of the register corresponding to the selected size is affected.

	31	24	23	16	15	8	7
BYTE	UNAFFECTED		UNAFFECTED		UNAFFECTED		RESULT
WORD	UNAFFECTED		UNAFFECTED		RESULT		RESULT
LONG	RESULT		RESULT		RESULT		RESULT

If R = 1 (TBLUN), the result is returned in register Dx without rounding. If the result is a byte, the integer portion of the result is returned in Dx 15 – 8; the integer portion of a word result is stored in Dx 23 – 8; the least significant 24 bits of a long result are stored in Dx 31 – 8. Byte and word results are sign-extended to fill the entire 32-bit register.

	31	24	23	16	15	8	7
BYTE	SIGN-EXTENDED	SIGN-EXTENDED	SIGN-EXTENDED	RESULT	RESULT	RESULT	FRACTION
WORD	SIGN-EXTENDED	SIGN-EXTENDED	RESULT	RESULT	RESULT	RESULT	FRACTION
LONG	SIGN-EXTENDED	SIGN-EXTENDED	RESULT	RESULT	RESULT	RESULT	FRACTION

NOTE

The long-word result contains only the least significant 24 bits of integer precision.

For all sizes, the 8-bit fractional portion of the result is returned in the low byte of the data register, Dx 7 – 0. User software can make use of the fractional data to correct cumulative errors in lengthy calculations or implement rounding algorithms different from that provided by other forms of TBLU. The previously described assumption of a floating-point places two restrictions on the programmer:

1. Tables are limited to 257 entries in length.
2. Interpolation resolution is limited to 1/256, the distance between consecutive table entries. The assumed radix point should not, however, be construed by the programmer as a requirement that the independent variable be calculated as a fractional number in the range $0 \leq X \leq 255$. On the contrary, X should be considered to be an integer in the range $0 \leq X \leq 65535$, realizing that the table actually a compressed representation of a linearized function in which only the 256th value is actually stored in memory.

Condition Codes:

X	N	Z	V	C
—	*	*	*	0

X — Not affected.

N — Set if the most significant bit of the result is set; cleared otherwise.

Z — Set if the result is zero; cleared otherwise.

V — Set if the integer portion of an unrounded long result is not in the range $-(2^{23}) \leq \text{Result} \leq (2^{23}) - 1$; cleared otherwise.

C — Always cleared.

TABLE LOOKUP AND INTERPOLATE

- 01 — Word Operation
- 10 — Long Operation

contains the interpolation fraction and entry number.

Dym, Dyn field—If the effective address mode field is nonzero, this operand is unused and should be zero. If the effective address mode field is zero, the interpolation variant of this instruction is implied, and Dyn specifies one or two source operands.

Rounding mode field—The R-bit controls the rounding of the final result. When the result is rounded according to the round-to-nearest algorithm. When the result is returned unrounded.

SECTION 8 INSTRUCTION FORMAT SUMMARY

This section contains a listing of the M68000 family instructions in binary format. in opcode order for the M68000 family instruction set.

8.1 INSTRUCTION FORMAT

The following paragraphs present a summary of the binary encoding fields.

8.1.1 Coprocessor ID Field

This field specifies which coprocessor in a system is to perform the operation. With directly supported floating-point instructions for the MC68040, this field must be set to 0.

8.1.2 Effective Address Field

This field specifies which addressing mode is to be used. For some operations, hardware-enforced restrictions on the available addressing modes allowed.

8.1.3 Register/Memory Field

This field is common to all arithmetic instructions. A zero in this field indicates a register operation, and a one indicates an <ea>-to-register operation.

8.1.4 Source Specifier Field

This field is common to all arithmetic instructions. The value of the register/memory field affects this field's definition. If R/M = 0, specifies the source floating-point data format (FPDR). If R/M = 1, specifies the source operand data format.

- 000 — Long-Word Integer (L)
- 001 — Single-Precision Real (S)
- 010 — Extended-Precision Real (X)
- 011 — Packed-Decimal Real (P)
- 100 — Word Integer (W)
- 101 — Double-Precision Real (D)
- 110 — Byte Integer (B)

This field is common to all conditional instructions and specifies the conditional test to be evaluated. Table 8-1 shows the binary encodings for the conditional tests.

8.1.7 Shift and Rotate Instructions

The following paragraphs define the fields used with the shift and rotate instructions.

8.1.7.1 Count Register Field. If $i/r = 0$, this field contains the rotate (shift) count of zero specifies 8). If $i/r = 1$, this field specifies a data register that contains the rotate count. The following shift and rotate fields are encoded as follows:

dr field

0 — Rotate (shift) Right

1 — Rotate (shift) Left

i/r field

0 — Immediate Rotate (shift) Count

1 — Register Rotate (shift) Count

8.1.7.2 Register Field. This field specifies a data register to be rotated (shifted).

000010	OGT	Ordered Greater Than
000011	OGE	Ordered Greater Than or Equal
000100	OLT	Ordered Less Than
000101	OLE	Ordered Less Than or Equal
000110	OGL	Ordered Greater Than or Less Than
000111	OR	Ordered
001000	UN	Unordered
001001	UEQ	Unordered or Equal
001010	UGT	Unordered or Greater Than
001011	UGE	Unordered or Greater Than or Equal
001100	ULT	Unordered or Less Than

8.1.9 Opmode Field

Refer to the applicable instruction descriptions for the encoding of this field in **Section 5 Integer Instructions**, **Section 5 Floating Point Instructions**, **Section 6 Supervisor (Privileged) Instructions**, and **Section 7 CPU32 Instructions**.

8.1.10 Address/Data Field

This field specifies the type of general register. The encoding is:

- 0 — Data Register
- 1 — Address Register

8.2 OPERATION CODE MAP

Table 8-2 lists the encoding for bits 15 – 12 and the operation performed.

Table 8-2. Operation Code Map

Bits 15 – 12	Operation
0000	Bit Manipulation/MOVEP/Immediate
0001	Move Byte
0010	Move Long
0011	Move Word
0100	Miscellaneous
0101	ADDQ/SUBQ/ScC/DBcc/TRAPcc
0110	Bcc/BSR/BRA
0111	MOVEQ
1000	OR/DIV/SBCD
1001	SUB/SUBX
1010	(Unassigned, Reserved)
1011	CMP/EOR
1100	AND/MUL/ABCD/EXG
1101	ADD/ADDX
1110	Shift/Rotate/Bit Field
1111	Coprocessor Interface/MC68040 and CPU32 Extensions

APPENDIX A PROCESSOR INSTRUCTION SUMMARY

This appendix provides a quick reference of the M68000 family instructions. The organization of this section is by processors and their addressing modes. All references to MC68000, MC68020, and MC68030 include references to the corresponding embedded controllers, MC68EC000, MC68EC020, and MC68EC030. All references to the MC68040 include the MC68LC040 and MC68EC040. This referencing applies throughout this appendix unless otherwise specified. Table A-1 lists the M68000 family instructions by mnemonic and indicates which processors they apply to.

Table A-1. M68000 Family Instruction Set And Processor Cross-Reference

Mnemonic	68000	68008	68010	68020	68030	68040	68881/ 68882	68851

NOTES:

1. Privileged (Supervisor) Instruction.
2. Not applicable to MC68EC040 and MC68LC040
3. These instructions are software supported on the MC68040.
4. This instruction is not privileged for the MC68000 and MC68008.
5. Not applicable to MC68EC030.

Data Addressing Modes

Mode	Generation
Register Direct Addressing Data Register Direct Address Register Direct	<ea> = Dn <ea> = An
Absolute Data Addressing Absolute Short Absolute Long	<ea> = (Next Word) <ea> = (Next Two Words)
Program Counter Relative Addressing Relative with Offset Relative with Index and Offset	<ea> = (PC) + d ₁₆ <ea> = (PC) + d ₈
Register Indirect Addressing Register Indirect Postincrement Register Indirect Predecrement Register Indirect Register Indirect with Offset Indexed Register Indirect with Offset	<ea> = (An) <ea> = (An), An - An + N An - An - N, <ea> = (An) <ea> = (An) + d ₁₆ <ea> = (An) + (Xn) + d ₈
Immediate Data Addressing Immediate Quick Immediate	DATA = Next Word(s) Inherent Data
Implied Addressing Implied Register	<ea> = SR, USP, SSP, PC, VBR, SFC, DFC

N = 1 for byte, 2 for word, and 4 for long word. If An is the stack pointer and the operand size is byte, N = 2 to keep the stack pointer on a word boundary.

A.5.2 MC68881/MC68882 Addressing Modes

The MC68881/MC68882 does not perform address calculations. When the floating-point coprocessor instructs the processor to transfer an operand via the coprocessor, the processor performs the addressing mode calculation requested in the instruction.

A.6 MC68851 COPROCESSORS

The following paragraphs provide information on the MC68851 instruction set and addressing modes.

A.6.1 MC68851 Instruction Set

Table A-13 lists the instructions used with the MC68851 coprocessor.

Table A-13. MC68851 Instruction Set

Mnemonic	Description
PBcc	Branch on PMMU Condition
PDBcc	Test, Decrement, and Branch on PMMU Condition
PFLUSH	Flush Entry(ies) in the ATCs
PFLUSHA	Flush Entry(ies) in the ATCs

PScC	Set on PMMU Condition
PTEST	Test a Logical Address
PTRAPcc	Trap on PMMU Condition
PVALID	Validate a Pointer

A.6.2 MC68851 Addressing Modes

The MC68851 supports the same addressing modes as the MC68020 (see Table A-1).

APPENDIX B EXCEPTION PROCESSING REFERENCE

This appendix provides a quick reference for system programmers who are already familiar with the stack frames. For more detail, please refer to the appropriate user's manual.

B.1 EXCEPTION VECTOR ASSIGNMENTS FOR THE M68000 FAMILY

Table B-1 lists all vector assignments up to and including the MC68040 and its derivatives. Many of these vector assignments are processor specific. For instance, the coprocessor protocol violation vector, only applies to the MC68020, MC68030, and MC68EC030. Refer to the appropriate user's manual to determine which exception type is applicable to a specific processor.

APPENDIX C S-RECORD OUTPUT FORMAT

The S-record format for output modules is for encoding programs or data files in a format for transportation between computer systems. The transportation process is visually monitored, and the S-records can be easily edited.

C.1 S-RECORD CONTENT

Visually, S-records are essentially character strings made of several fields that identify record type, record length, memory address, code/data, and checksum. Each byte of data encodes as a two-character hexadecimal number: the first character represents the high-order four bits, and the second character represents the low-order four bits of the byte. Figure C-1 illustrates the five fields that comprise an S-record. Table C-1 lists the composition of each S-record field.

TYPE	RECORD LENGTH	ADDRESS	CODE/DATA	CHECKSUM
------	---------------	---------	-----------	----------

Figure C-1. Five Fields of an S-Record

Table C-1. Field Composition of an S-Record

Field	Printable Characters	Contents
Type	2	S-record type—S0, S1, etc.
Record Length	2	The count of the character pairs in the record, excluding the type and record length.
Address	4, 6, or 8	The 2-, 3-, or 4-byte address at which the data field is to be loaded into memory.
Code/Data	0–2n	From 0 to n bytes of executable code, memory loadable data, or descriptive information. For compatibility with teletypewriters, some programs may limit the number of bytes to as few as 28 printable characters in the S-record).
Checksum	2	The least significant byte of the one's complement of the sum of the values represented by the pairs of characters making up the record length, address, and the code/data fields.

There are eight types of S-records to accommodate the encoding, transportation, and decoding functions. The various Motorola record transportation control programs (upload, download, etc.), cross assemblers, linkers, and other file creating or debugging programs, only utilize S-records serving the programOs purpose. For more information on the port of specific S-records, refer to the userOs manual for that program.

An S-record format module may contain S-records of the following types:

- S0 — The header record for each block of S-records. The code/data field may contain any descriptive information identifying the following block of S-records. Under VERSAdos, the resident linkerOs IDENT command can be used to designate module name, version number, revision number, and descriptive information that will make up the header record. The address field is normally blank.
- S1 — A record containing code/data and the 2-byte address at which the code/data is to reside.
- S2 — A record containing code/data and the 3-byte address at which the code/data is to reside.
- S3 — A record containing code/data and the 4-byte address at which the code/data is to reside.
- S5 — A record containing the number of S1, S2, and S3 records transmitted in a particular block. This count appears in the address field. There is no code/data field.
- S7 — A termination record for a block of S3 records. The address field may contain the 4-byte address of the instruction to which control is to be passed. There is no code/data field.
- S8 — A termination record for a block of S2 records. The address field may contain the 3-byte address of the instruction to which control is to be passed. There is no code/data field.
- S9 — A termination record for a block of S1 records. The address field may contain the 2-byte address of the instruction to which control is to be passed. Under VERSAdos, the resident linkerOs ENTRY command can be used to specify this address. If this address is not specified, the first entry point specification encountered in the object module input will be used. There is no code/data field.

Each block of S-records uses only one termination record. S7 and S8 records are used when control is to be passed to a 3- or 4- byte address; otherwise, an S9 is used for termination. Normally, there is only one header record, although it is possible for multiple header records to occur.

Programs are available for downloading or uploading a file in S- record format from a host system to an 8- or 16-bit microprocessor- based system. A typical S-record-format module is printed or displayed as follows:

```
S00600004844521B
S1130000285F245F2212226A000424290008237C2A
S11300100002000800082629001853812341001813
S113002041E900084E42234300182342000824A952
S107003000144ED492
S9030000FC
```

The module has an S0 record, four S1 records, and an S9 record. The following pairs comprise the S-record-format module.

S0 Record:

- S0 — S-record type S0, indicating that it is a header record.
- 06 — Hexadecimal 06 (decimal 6), indicating that six character pairs (or ASCII characters) follow.
- 0000—A 4-character, 2-byte address field; zeros in this example.
- 48 — ASCII H
- 44 — ASCII D
- 52 — ASCII R
- 1B — The checksum.

First S1 Record:

- S1 — S-record type S1, indicating that it is a code/data record to be loaded/erased at a 2-byte address.
- 13 — Hexadecimal 13 (decimal 19), indicating that 19 character pairs, representing 19 bytes of binary data, follow.
- 0000—A 4-character, 2-byte address field (hexadecimal address 0000) where the data that follows is to be loaded.

285F	MOVE.L	(A7) +, A4
245F	MOVE.L	(A7) +, A2
2212	MOVE.L	(A2), D1
226A0004	MOVE.L	4(A2), A1
24290008	MOVE.L	FUNCTION(A1), D2
237C	MOVE.L	#FORCEFUNC, FUNCTION(A1)

The rest of this code continues in the remaining S1 record's code/data fields and memory location 0010, etc.

2A — The checksum of the first S1 record.

The second and third S1 records also contain hexadecimal 13 (decimal 19) characters and end with checksums 13 and 52, respectively. The fourth S1 record contains 07 character pairs and has a checksum of 92.

S9 Record:

S9 — S-record type S9, indicating that it is a termination record.

03 — Hexadecimal 03, indicating that three character pairs (3 bytes) follow.

0000—The address field, zeros.

FC — The checksum of the S9 record.

Each printable character in an S-record encodes in hexadecimal (ASCII in this case) a representation of the binary bits that transmit. Figure C-2 illustrates the sending of an S1 record. Table C-2 lists the ASCII code for S-records.

TYPE		RECORD LENGTH			ADDRESS				CODE/DATA													
S	1	1	3		0	0	0	0	2	8	5	F	****									
5	3	3	1	3	1	3	3	3	0	3	0	3	0	3	2	3	8	3	5	4	6	****
