## 1 FEATURES

- ◆ Power supply : VDD = VDDQ = 1.2V (1.14V to 1.26V); VPP = 2.5V (2.375V to 2.75V)
- ◆ JEDEC standard package: x16 96-ball FBGA
- ◆ Array Configuration : 8 banks (x16) 2 groups of 4 banks
- ◆ 8n-bit prefetch architecture
- ◆ Burst Length (BL): 8 and 4 with Burst Chop (BC)
- ◆ Programmable CAS Latency (CL)
- ◆ Programmable CAS Write Latency (CWL)
- ◆ Internal generated Vref for data inputs
- ◆ On-Die Termination (ODT) : Support Nominal, Park and Dynamic ODT
- ◆ Differential clock and data strobe inputs (CK\_t, CK\_c; DQS\_t, DQS\_c)
- ◆ Interface: 1.2V Pseudo Open Drain (POD) IO
- ◆ Per DRAM Addressability (PDA)
- ◆ Data Bus Inversion (DBI)
- ◆ Data Mask (DM) for write data
- ◆ Maximum Power Saving Mode (MPSM)
- ◆ Asynchronous reset for power up
- ◆ Precharge: Auto precharge option for each burst access
- ◆ Operating case temperature :  $-40^{\circ}\text{C} \leq \text{TCase} \leq 95^{\circ}\text{C}$
- ◆ Support auto-refresh and self-refresh mode
- ◆ Average Refresh Period:
  - $7.8\mu\text{s}$  at  $-40^{\circ}\text{C} \leq \text{TCase} \leq 85^{\circ}\text{C}$
  - $3.9\mu\text{s}$  at  $85^{\circ}\text{C} < \text{TCase} \leq 95^{\circ}\text{C}$
- ◆ Fine granularity refresh 2x, 4x mode for smaller tRFC
- ◆ Programmable data strobe preambles
- ◆ Command Address (CA) Parity is supported
- ◆ Write Cyclic Redundancy Code (CRC) is supported
- ◆ Connectivity test mode (TEN) is supported
- ◆ Gear Down Mode
- ◆ Output driver calibration through ZQ pin (RZQ:  $240\text{ohm} \pm 1\%$ )
- ◆ JEDEC JESD-79-4 compliant
- ◆ RoHS compliant

### Note:

The functionality described and the timing specifications included in this datasheet are for the DLL Enabled mode of operation (normal operation), unless specifically stated otherwise.

### 4 BALL ASSIGNMENTS

#### 4.1 96-Ball FBGA (x16) ball assignments

## 4.2 Ball Description

Symbol	Type	Function
CK_t, CK_c	Input	<b>Clock:</b> CK_t and CK_c are differential clock inputs. All address and control input signals are sampled on the crossing of the positive edge of CK_t and negative edge of CK_c.
CKE	Input	<b>Clock Enable:</b> CKE High activates, and CKE Low deactivates, internal clock signals and device input buffers and output drivers. Taking CKE Low provides Precharge Power-Down and Self-Refresh operation (all banks idle), or Active Power-Down (row Active in any bank). CKE is synchronous for Self-Refresh exit. After VREFCA and Internal DQ Vref have become stable during the power on and initialization sequence, they must be maintained during all operations (including Self-Refresh). CKE must be maintained high throughout Read and Write accesses. Input buffers, excluding CK_t, CK_c, ODT and CKE are disabled during power-down. Input buffers, excluding CKE, are disabled during Self-Refresh.
CS_n	Input	<b>Chip Select:</b> All commands are masked when CS_n is registered HIGH. CS_n provides for external Rank selection on systems with multiple Ranks. CS_n is considered part of the command code.
ODT	Input	<b>On Die Termination:</b> ODT (registered High) enables RTT_NOM termination resistance internal to the DDR4 SDRAM. When enabled, ODT is only applied to each DQ, DQS_t, DQS_c and DM_n/DBI_n/TDQS_t, NU/TDQS_c (When TDQS is enabled via Mode Register A11=1 in MR1) signal for x8 configurations. For x16 configuration ODT is applied to each DQ, DQSU_t, DQSU_c, DQSL_t, DQSL_c, DMU_n, and DML_n signal. The ODT pin will be ignored if MR1 is programmed to disable RTT_NOM.
ACT_n	Input	<b>Activation Command Input:</b> ACT_n defines the Activation command being entered along with CS_n. The input into RAS_n/A16, CAS_n/A15 and WE_n/A14 will be considered as Row Address A16, A15 and A14.
RAS_n/A16, CAS_n/A15, WE_n/A14	Input	<b>Command Inputs:</b> RAS_n/A16, CAS_n/A15 and WE_n/A14 (along with CS_n) define the command being entered. These balls have multi function. For example, for activation with ACT_n Low, those are Addressing like A16,A15 and A14 but for non-activation command with ACT_n High, those are Command pins for Read, Write and other command defined in command truth table.
DM_n, DBI_n (DMU_n, DBIU_n DML_n, DBIL_n)	I/O	<b>Input Data Mask and Data Bus Inversion:</b> DM_n is an input mask signal for write data. Input data is masked when DM_n is sampled LOW coincident with that input data during a Write access. DM_n is sampled on both edges of DQS. DM is muxed with DBI function by Mode Register A10, A11, A12 setting in MR5. For x8 device, the function of DM or TDQS is enabled by Mode Register A11 setting in MR1. DBI_n is an input/output identifying whether to store/output the true or inverted data. If DBI_n is LOW, the data will be stored/output after inversion inside the DDR4 SDRAM and not inverted if DBI_n is HIGH. TDQS is only supported in X8.
BG0-BG1	Input	<b>Bank Group Inputs:</b> BG0-BG1 define to which bank group an Active, Read, Write or Precharge command is being applied. BG0 also determines which mode register is to be accessed during a MRS cycle. x4/x8 have BG0 and BG1, but x16 has only BG0.

Symbol	Type	Function
BA0-BA1	Input	<b>Bank Address Inputs:</b> BA0-BA1 define to which bank an Active, Read, Write or Precharge command is being applied. Bank address also determines which mode register is to be accessed during a MRS cycle.
A0-A16	Input	<b>Address Inputs:</b> Provide the row address for ACTIVATE commands and the column address for Read/Write commands to select one location out of the memory array in the respective bank. (A10/AP, A12/BC_n, RAS_n/A16, CAS_n/A15 and WE_n/A14 have additional functions, see other rows. The address inputs also provide the op-code during Mode Register Set commands. A17 is only defined for the x4 configuration.
A10/AP	Input	<b>Auto-precharge:</b> A10 is sampled during Read/Write commands to determine whether Auto-precharge should be performed to the accessed bank after the Read/Write operation. (HIGH: Auto-precharge; LOW: no Auto-precharge). A10 is sampled during a Precharge command to determine whether the Precharge applies to one bank (A10 LOW) or all banks (A10 HIGH). If only one bank is to be precharged, the bank is selected by bank addresses.
A12/BC_n	Input	<b>Burst Chop:</b> A12/BC_n is sampled during Read and Write commands to determine if burst chop (on-the-fly) will be performed. (HIGH, no burst chop; LOW: burst chopped). See “Command Truth Table” of Operation Guide for details.
RESET_n	Input	<b>Active Low Asynchronous Reset:</b> Reset is active when RESET_n is LOW, and inactive when RESET_n is HIGH. RESET_n must be HIGH during normal operation. RESET_n is a CMOS rail to rail signal with DC high and low at 80% and 20% of VDD.
DQ	I/O	<b>Data Input/Output:</b> Bi-directional data bus. If CRC is enabled via mode register, then CRC code is added at the end of Data Burst. Any DQ from DQ3~DQ0 may indicate the internal Vref level during test via Mode Register Setting MR4 A4=High. During this mode, RTT value should be set to Hi-Z. Refer to vendor specific data sheets to determine which DQ is used.
DQS_t, DQS_c, DQSU_t, DQSU_c, DQSL_t, DQSL_c	I/O	<b>Data Strobe:</b> Output with Read data, input with Write data. Edge-aligned with Read data, centered-aligned with Write data. For x16, DQSL corresponds to the data on DQL0-DQL7; DQSU corresponds to the data on DQU0-DQU7. The data strobe DQS_t, DQSL_t and DQSU_t are paired with differential signals DQS_c, DQSL_c, and DQSU_c, respectively, to provide differential pair signaling to the system during Reads and Writes. DDR4 SDRAM supports differential data strobe only and does not support single-ended.
TDQS_t, TDQS_c	Output	<b>Termination Data Strobe:</b> TDQS_t/TDQS_c is applicable for x8 DRAMs only. When enabled via Mode Register A11 = 1 in MR1, the DRAM will enable the same termination resistance function on TDQS_t/TDQS_c that is applied to DQS_t/DQS_c. When disabled via mode register A11 = 0 in MR1, DM/DBI/TDQS will provide the data mask function or Data Bus Inversion depending on MR5; A11, A12, A10 and TDQS_c is not used. x4/ x16 DRAMs must disable the TDQS function via mode register A11 = 0 in MR1.
PAR	Input	<b>Command and Address Parity Input:</b> DDR4 Supports Even Parity Check in DRAMs with MR setting. Once it is enabled via Register in MR5, then DRAM calculates Parity with ACT_n, RAS_n/A16, CAS_n/A15, WE_n/A14, BG0-BG1, BA0-BA1, A0-A16. Command and address inputs shall have parity check performed when commands are latched via the rising edge of CK_t and when CS_n is low

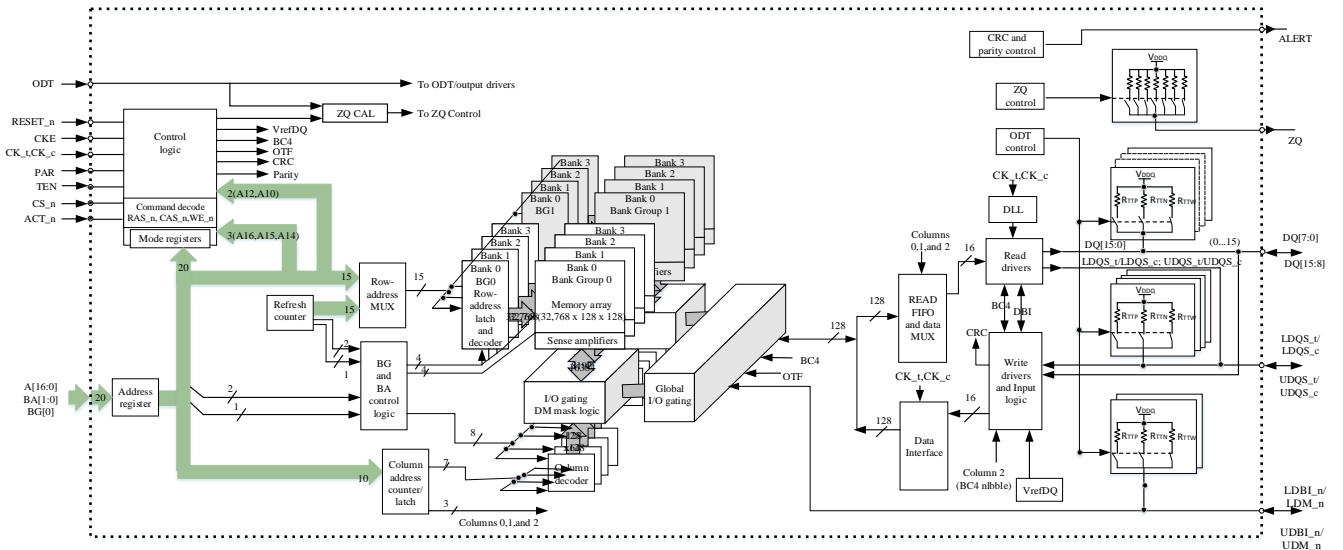

Symbol	Type	Function
ALERT_n	I/O	<b>ALERT:</b> It has multi functions such as CRC error flag, Command and Address Parity error flag as output signal. If there is error in CRC, then Alert_n goes LOW for the period time interval and goes back HIGH. If there is error in Command Address Parity Check, then ALERT_n goes LOW for relatively long period until on going DRAM internal recovery transaction to complete. During Connectivity Test mode, this pin works as an input. Using this signal or not is dependent on system. In case of not connected as Signal, ALERT_n pin must be bounded to VDD on board.
TEN	Input	<b>Connectivity Test Mode Enable:</b> Required on X16 devices and optional input on x4/x8 with densities equal to or greater than 8Gb. High in this pin will enable Connectivity Test Mode operation along with other pins. It is a CMOS rail to rail signal with AC high and low at 80% and 20% of VDD. Using this signal or not is dependent on system. This pin may be DRAM internally pulled low through a weak pull-down resistor to VSS.
NC		<b>No Connect:</b> No internal electrical connection is present.
VDDQ	Supply	<b>DQ Power Supply:</b> 1.2 V +/- 0.06 V
VSSQ	Supply	<b>DQ Ground</b>
VDD	Supply	<b>Power Supply:</b> 1.2 V +/- 0.06 V
VSS	Supply	<b>Ground</b>
VPP	Supply	<b>DRAM Activating Power Supply:</b> 2.5V (2.375V min, 2.75V max)
VREFCA	Supply	<b>Reference voltage for CA</b>
ZQ	Supply	<b>Reference Pin for ZQ calibration</b>

### 5 Functional Block Diagram

DDR4 SDRAM is a high-speed, CMOS dynamic random access memory. It is internally configured as an 16-bank (4-banks per Bank Group) DRAM.

## 6 ABSOLUTE MAXIMUM RATINGS

### 6.1 Absolute Maximum DC Ratings

Table 6-1. Absolute Maximum DC Ratings

Symbol	Parameter	Min	Max	Unit	Note
VDD	Voltage on VDD pin relative to Vss	-0.3	1.5	V	1,3
VDDQ	Voltage on VDDQ pin relative to Vss	-0.3	1.5	V	1,3
VPP	Voltage on VPP pin relative to Vss	-0.3	3.0	V	4
V <sub>IN</sub> , V <sub>OUT</sub>	Voltage on any pin except VrefCA relative to Vss	-0.3	1.5	V	1,3,5
T <sub>STG</sub>	Storage Temperature	-55	100	°C	1,2

Note:

1. Stresses greater than those listed under “Absolute Maximum Ratings” may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect reliability.
2. Storage Temperature is the case surface temperature on the center/top side of the DRAM. For the measurement conditions, please refer to JESD51-2 standard.
3. VDD and VDDQ must be within 300 mV of each other at all times; and VREFCA must be not greater than 0.6 x VDDQ, When VDD and VDDQ are less than 500 mV; VREF may be equal to or less than 300 mV.
4. VPP must be equal or greater than VDD/VDDQ at all times.
5. Overshoot area above 1.5V is specified in [Section 7.3.5](#) and [Section 7.3.6](#).

### 6.2 Recommended DC Operating Conditions

Table 6-2. Recommended DC Operating Conditions

Symbol	Parameter	Ratings			Unit	Note
		Min	Typ.	Max		
VDD	Supply voltage	1.14	1.2	1.26	V	1,2,3
VDDQ	Supply voltage for output	1.14	1.2	1.26	V	1,2,3
VPP	Wordline supply voltage	2.375	2.5	2.75	V	3

Note:

1. Under all conditions VDDQ must be less than or equal to VDD.
2. VDDQ tracks with VDD. AC parameters are measured with VDD and VDDQ tied together.
3. DC bandwidth is limited to 20MHz.

### 6.3 DRAM Component Operating Temperature Range

Table 6-3. Operating Temperature Range

Symbol	Parameter	Rating	Unit	Note
T <sub>OPER</sub>	Normal Temperature Range	-40~85	°C	1,2
	Extended Temperature Range	85~95	°C	1,3

Note:

1. Operating Temperature T<sub>OPER</sub> is the case surface temperature on the center/top side of the DRAM. For measurement

conditions, please refer to the JEDEC document JESD51-2.

2. The Normal Temperature Range specifies the temperatures where all DRAM specifications will be supported. During operation, the DRAM case temperature must be maintained between 0 - 85°C under all operating conditions for the commercial offering; The industrial and automotive temperature offerings allow the case temperature to go below 0°C to -40°C.
3. Some applications require operation of the DRAM in the Extended Temperature Range between 85 °C and 95 °C case temperature. Full specifications are guaranteed in this range, but the following additional conditions apply:
  - Refresh commands must be doubled in frequency, therefore reducing the Refresh interval tREFI to 3.9 μs. It is also possible to specify a component with 1X refresh (tREFI to 7.8μs) in the Extended Temperature Range. Please refer to the DIMM SPD for option availability.
  - If Self-Refresh operation is required in the Extended Temperature Range, then it is mandatory to either use the Manual Self-Refresh mode with Extended Temperature Range capability (MR2 A6 = 0 and MR2 A7 = 1) or enable the optional Auto Self-Refresh mode (MR2 A6 = 1 and MR2 A7 = 1).

## 7 AC AND DC INPUT MEASUREMENT LEVELS

### 7.1 AC and DC Logic Input Levels for Single-ended Signals

Table 7-1. Single-ended AC and DC Input Levels for Command and Address

Symbol	Parameter	1600/1866/2133/2400		2666/3200		Unit	Note
		Min	Max	Min	Max		
VIH.CA(DC75)	DC input logic high	VREFCA + 0.075	VDD	-	-	V	
VIL.CA(DC75)	DC input logic low	VSS	VREFCA - 0.075	-	-	V	
VIH.CA(DC65)	DC input logic high	-	-	VREFCA + 0.065	VDD	V	
VIL.CA(DC65)	DC input logic low	-	-	VSS	VREFCA - 0.065	V	
VIH.CA(AC100)	AC input logic high	VREF + 0.1	Note 2	-	-	V	1
VIL.CA(AC100)	AC input logic low	Note 2	VREF - 0.1	-	-	V	1
VIH.CA(AC90)	AC input logic high	-	-	VREF + 0.09	Note 2	V	1
VIL.CA(AC90)	AC input logic low	-	-	Note 2	VREF - 0.09	V	1
VREFCA(DC)	Reference voltage for ADD, CMD inputs	0.49*VDD	0.51*VDD	0.49*VDD	0.51*VDD	V	2,3

Note:

1. See "Overshoot and Undershoot Specifications"
2. The AC peak noise on VREFCA may not allow VREFCA to deviate from VREFCA(DC) by more than  $\pm 1\%VDD$  (for reference: approx.  $\pm 12mV$ )
3. For reference: approx.  $VDD/2 \pm 12 mV$

### 7.2 AC and DC Logic Input Measurement Levels: Vref Tolerances

The DC-tolerance limits and AC-noise limits for the reference voltages VrefCA is illustrated in the Figure 7-1 below. It shows a valid reference voltage Vref(t) as a function of time. (Vref stands for VrefCA).

Vref(DC) is the linear average of Vref(t) over a very long period of time (for example, 1 second). This average has to meet the min/max requirement in Figure 7-1. Furthermore Vref(t) may temporarily deviate from Vref(DC) by no more than ± 1% VDD

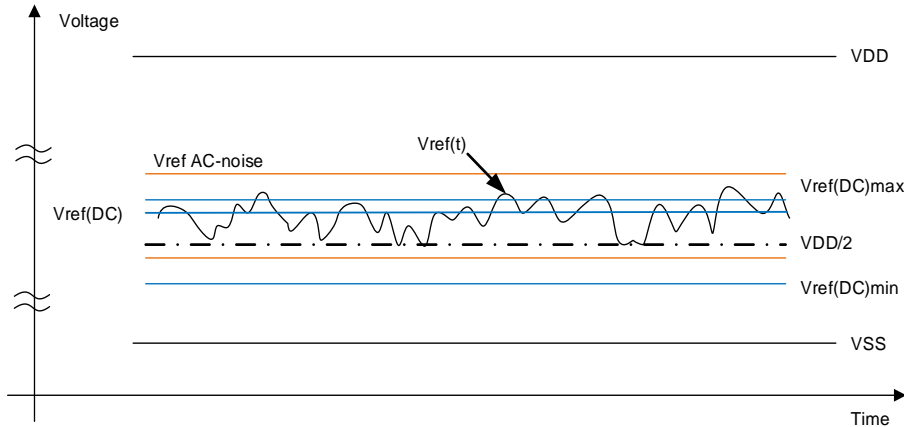

Figure 7-1. Illustration of Vref(DC) Tolerance and Vref AC-noise Limits

The voltage levels for setup and hold time measurements VIH(AC), VIH(DC), VIL(AC) and VIL(DC) are dependent on Vref.

“Vref” should be understood as Vref(DC)

This clarifies that DC-variations of Vref affect the absolute voltage a signal has to reach to achieve a valid high or low level, and therefore the time to which setup and hold is measured. System timing and voltage budgets need to account for Vref(DC) deviations from the optimum position within the data-eye of the input signals.

This also clarifies that the DRAM setup/hold specification and derating values need to include time and voltage associated with Vref AC-noise. Timing and voltage effects due to AC-noise on Vref up to the specified limit (± 1% of VDD) are included in DRAM timings and their associated deratings.

### 7.3 AC and DC Logic Input Levels for Differential Signals

#### 7.3.1 AC and DC Logic Input Levels for Differential Signals

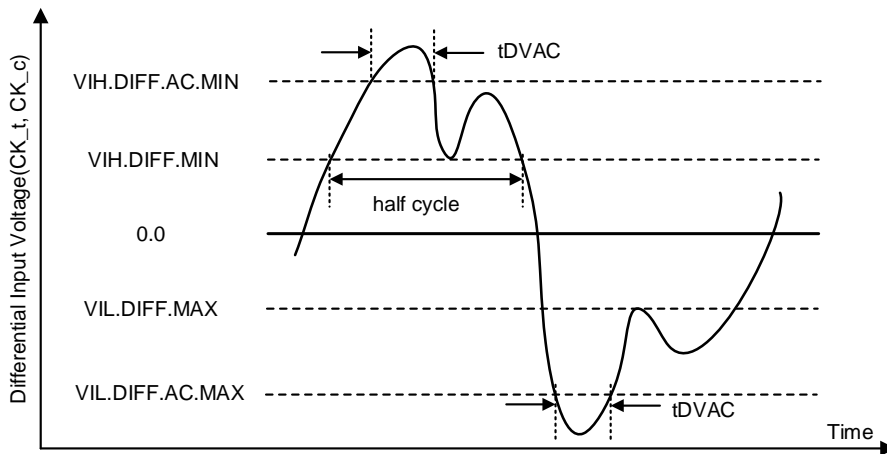

Figure 7-2. Definition of Differential AC-Swing and “Time above AC-Level” tDVAC

Note:

1. Differential signal rising edge from VIL.DIFF.MAX to VIH.DIFF.MIN must be monotonic slope.
2. Differential signal falling edge from VIH.DIFF.MIN to VIL.DIFF.MAX must be monotonic slope.

### 7.3.2 Differential Swing Requirements for Clock (CK<sub>t</sub> - CK<sub>c</sub>)

Table 7-2. Differential Input Levels Requirements for CK<sub>t</sub> - CK<sub>c</sub>

Symbol	Parameter	1600/1866/2133		2400/2666		3200		Unit	Note
		Min	Max	Min	Max	Min	Max		
VIHdiff	differential input high	+ 0.150	Note 3	+ 0.135	Note 3	+ 0.110	Note 3	V	1
VILdiff	differential input low	Note 3	- 0.150	Note 3	- 0.135	Note 3	- 0.110	V	1
VIHdiff(AC)	differential input high ad	2 x (VIH(AC) - VREF)	Note 3	2 x (VIH(AC) - VREF)	Note 3	2 x (VIH(AC) - VREF)	Note 3	V	2
VILdiff(AC)	differential input low ac	Note 3	2 x (VIL(AC) - VREF)	Note 3	2 x (VIL(AC) - VREF)	Note 3	2 x (VIL(AC) - VREF)	V	2

Note:

1. Used to define a differential signal slew-rate.
2. for CK<sub>t</sub> - CK<sub>c</sub> use VIH.CA/VIL.CA(AC) of ADD/CMD and VREFCA;
3. These values are not defined; however, the differential signals CK<sub>t</sub> - CK<sub>c</sub>, need to be within the respective limits (VIH.CA(DC) max, VIL.CA(DC)min) for single-ended signals as well as the limitations for overshoot and undershoot.

7.3.3 Differential Swing Requirements for Clock (CK<sub>t</sub> - CK<sub>c</sub>)

Each individual component of a differential signal (CK<sub>t</sub>, CK<sub>c</sub>) has also to comply with certain requirements for single-ended signals.

CK<sub>t</sub> and CK<sub>c</sub> have to approximately reach VSEHmin/VSELmax (approximately equal to the ac-levels (VIH.CA(ac)/VIL.CA(ac)) for ADD/CMD signals) in every half-cycle.

Note that the applicable ac-levels for ADD/CMD might be different per speed-bin etc. E.g., if different value than VIH.CA(AC100)/VIL.CA(AC100) is used for ADD/CMD signals, then these ac-levels apply also for the single-ended signals CK<sub>t</sub> and CK<sub>c</sub>.

Figure 7-3. Single-ended Requirement for CK

Note that, while ADD/CMD signal requirements are with respect to VrefCA, the single-ended components of differential signals have a requirement with respect to VDD/2; this is nominally the same. The transition of single-ended signals through the ac-levels is used to measure setup time. For single-ended components of differential signals the requirement to reach VSELmax, VSEHmin has no bearing on timing, but adds a restriction on the common mode characteristics of these signals.

Table 7-4. Single-ended Levels Requirements for CK<sub>t</sub>, CK<sub>c</sub>

Note

- For CK<sub>t</sub>-CK<sub>c</sub> use VIH.CA/VIL.CA(AC) of ADD/CMD.
- VIH(AC)/VIL(AC) for ADD/CMD is based on VREFCA.
- These values are not defined, however the single-ended signals CK<sub>t</sub>, CK<sub>c</sub> need to be within the respective limits (VIH.CA(DC) max, VIL.CA(DC)min) for single-ended signals as well as the limitations for overshoot and undershoot.

## 7.4 Slew Rate Definitions for Differential Input Signals

### 7.4.1 Slew Rate Definitions for Differential Input Signals

Input slew rate for differential signals (CK\_t, CK\_c) are defined and measured as shown in Table 7-8 and Figure 7-7.

Table 7-8. CK Differential Input Slew Rate Definition

Description	From	To	Defined by
Differential input slew rate for rising edge (CK_t-CK_c)	VILdiffmax	VIHdiffmin	$[VIHdiffmin - VILdiffmax] / \Delta TRdiff$
Differential input slew rate for falling edge (CK_t-CK_c)	VIHdiffmin	VILdiffmax	$[VIHdiffmin - VILdiffmax] / \Delta TFdiff$

Note:

- The differential signal (i. e., CK\_t-CK\_c) must be linear between these thresholds.

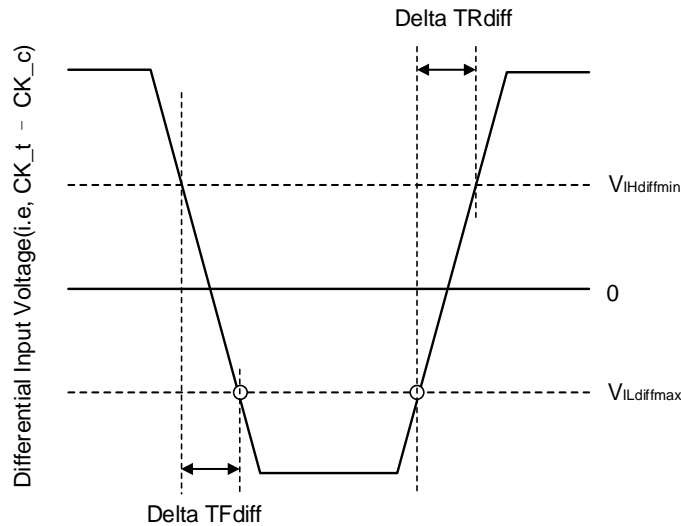

Figure 7-7. Differential Input Slew Rate Definition for CK\_t, CK\_c

### 7.4.2 Slew Rate Definitions for Differential Input Signals (CMD/ADD)

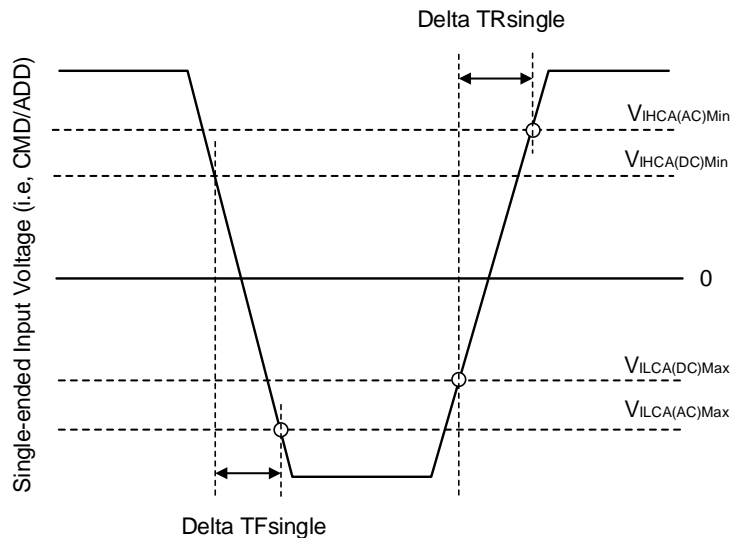

Figure 7-8. Single-ended Input Slew Rate Definition for CMD and ADD

Note:

1. Single-ended input slew rate for rising edge =  $\{VIHCA(AC)Min - VILCA(DC)Max\} / \Delta TR$  single.
2. Single-ended input slew rate for falling edge =  $\{VIHCA(DC)Min - VILCA(AC)Max\} / \Delta TF$  single.
3. Single-ended signal rising edge from  $VILCA(DC)Max$  to  $VIHCA(DC)Min$  must be monotonic slope.
4. Single-ended signal falling edge from  $VIHCA(DC)Min$  to  $VILCA(DC)Max$  must be monotonic slope.

### 7.5 CK Differential Input Point Voltage

To guarantee tight setup and hold times as well as output skew parameters with respect to clock, each cross point voltage of differential input signals (CK\_t, CK\_c) must meet the requirements in. The differential input cross point voltage  $V_{ix}$  is measured from the actual cross point of true and complement signals to the midlevel between of VDD and VSS.

DC Input Low Voltage	VIL(DC)_RESET	VSS	0.3VDD	V	1
Rising Time	TR_RESET	-	1.0	μs	4
RESET Pulse Width	tPW_RESET	1.0	-	μs	3,5

Note:

1. After RESET\_n is registered Low, RESET\_n level shall be maintained below VIL(DC)\_RESET during tPW\_RESET, otherwise, SDRAM may not be reset.
2. Once RESET\_n is registered High, RESET\_n level must be maintained above VIH(DC)\_RESET, otherwise, SDRAM operation will not be guaranteed until it is reset asserting RESET\_n signal Low.
3. RESET is destructive to data contents.
4. No slope reversal (ringback) requirement during its level transition from Low to High.
5. This definition is applied only “Reset Procedure at Power Stable”.
6. Overshoot might occur. It should be limited by the Absolute Maximum DC Ratings.
7. Undershoot might occur. It should be limited by Absolute Maximum DC Ratings.

V <sub>ILDiffPeak</sub>	VIL.DIFF.Peak Voltage	Note2	-186	Note2	-160	Note2	-150	Note2	-140	mV	1

Note:

- Used to define a differential signal slew-rate.
- These values are not defined; however, the differential signals DQS<sub>t</sub> - DQS<sub>c</sub>, need to be within the respective limits of Overshoot, Undershoot Specification for single-ended signals.

### 7.7.3 Peak Voltage Calculation Method

The peak voltage of Differential DQS signals are calculated in a following equation.

$$VIH.DIFF.Peak\ Voltage = \text{Max}(f(t))$$

$$VIL.DIFF.Peak\ Voltage = \text{Min}(f(t))$$

$$f(t) = VDQS\_t - VDQS\_c$$

The  $\text{Max}(f(t))$  or  $\text{Min}(f(t))$  used to determine the midpoint which to reference the +/-35% window of the exempt non-monotonic signaling shall be the smallest peak voltage observed in all UI's.

Figure 7-12. Definition of Differential DQS Peak Voltage and Range of Exempt Nonmonotonic Signaling

### 7.7.4 Differential Input Cross Point Voltage

To achieve tight RxMask input requirements as well as output skew parameters with respect to strobe, the cross point voltage of differential input signals (DQS\_t, DQS\_c) must meet the requirements in Table 7-13. The differential input cross point voltage VIX\_DQS (VIX\_DQS\_FR and VIX\_DQS\_RF) is measured from the actual cross point of DQS\_t, DQS\_c relative to the VDQSmid of the DQS\_t and DQS\_c signals.

VDQSmid is the midpoint of the minimum levels achieved by the transitioning DQS\_t and DQS\_c signals, and noted by VDQS\_trans. VDQS\_trans is the difference between the lowest horizontal tangent above VDQSmid of the transitioning DQS signals and the highest horizontal tangent below VDQSmid of the transitioning DQS signals.

A nonmonotonic transitioning signal's ledge is exempt or not used in determination of a horizontal tangent provided the said ledge occurs within +/- 35% of the midpoint of either VIH.DIFF. Peak Voltage (DQS\_t rising) or VIL.DIFF.Peak Voltage (DQS\_c rising), refer to Figure 7-12. A secondary horizontal tangent resulting from a ring-back transition is also exempt in determination of a horizontal tangent. That is, a falling transition's horizontal tangent is derived from its negative slope to zero slope transition (point A in Figure 7-13) and a ring-back's horizontal tangent derived from its positive slope to zero slope transition (point B in Figure 7-13) is not a valid horizontal tangent; and a rising transition's horizontal tangent is derived from its positive slope to zero slope transition (point C in Figure 7-13) and a ring-back's horizontal tangent derived from its negative slope to zero slope transition (point D in Figure 7-13) is not a valid horizontal tangent.

Figure 7-13. Vix Definition (DQS)

Table 7-13. Cross Point Voltage for DQS Differential Input Signals

VDQSmid_to_Vcent	VDQSmid offset relative to Vcent_DQ(midpoint)	-	min(VIHdiff,50)	mV	3,4,5

Note:

1. Vix\_DQS\_Ratio is DQS Vix crossing (Vix\_DQS\_FR or Vix\_DQS\_RF) divided by VDQS\_trans. VDQS\_trans is the difference between the lowest horizontal tangent above VDQSmid of the transitioning DQS signals and the highest horizontal tangent below VDQSmid of the transitioning DQS signals.
2. VDQSmid will be similar to the VREFDQ internal setting value obtained during Vref Training if the DQS and DQs drivers and paths are matched.
3. The maximum limit shall not exceed the smaller of VIHdiff minimum limit or 50mV.
4. Vix measurements are only applicable for transitioning DQS\_t and DQS\_c signals when toggling data, preamble and high-z states are not applicable conditions.
5. The parameter VDQSmid is defined for simulation and ATE testing purposes, it is not expected to be tested in a system.

### 7.7.5 Differential Input Slew Rate Definition

Input slew rate for differential signals (DQS<sub>t</sub>, DQS<sub>c</sub>) are defined and measured as shown in Figure 7-14 and Table 7-14.

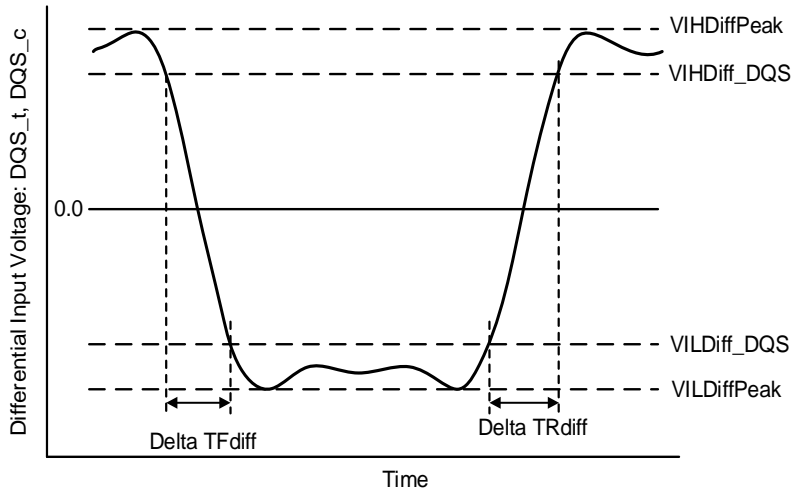

Figure 7-14. Differential Input Slew Rate Definition for DQS<sub>t</sub>, DQS<sub>c</sub>

Note:

1. Differential signal rising edge from VILdiff\_DQS to VIHdiff\_DQS must be monotonic slope.
2. Differential signal falling edge from VIHdiff\_DQS to VILdiff\_DQS must be monotonic slope.

## 8 AC&DC OUTPUT MEASUREMENT LEVELS

### 8.1 Output Driver DC Electronic Characteristics

The DDR4 driver supports two different RON values. These RON values are referred as strong (low RON) and weak mode (high RON). A functional representation of the output buffer is shown in Figure 8-1 below. Output driver impedance RON is defined as the individual pull-up and pull-down resistors ( $R_{ON_{Pu}}$  and  $R_{ON_{Pd}}$ ).

$$R_{ON_{Pu}} = \frac{V_{DDQ} - V_{out}}{|I_{out}|} \text{ under the condition that } R_{ON_{Pd}} \text{ is off}$$

$$R_{ON_{Pd}} = \frac{V_{out}}{|I_{out}|} \text{ under the condition that } R_{ON_{Pu}} \text{ is off.}$$

Mismatch DQ-DQ within byte variation pull-up, MMPdPdd		VOMdc=0.8*VDDQ			10	%	1,2,4

Note:

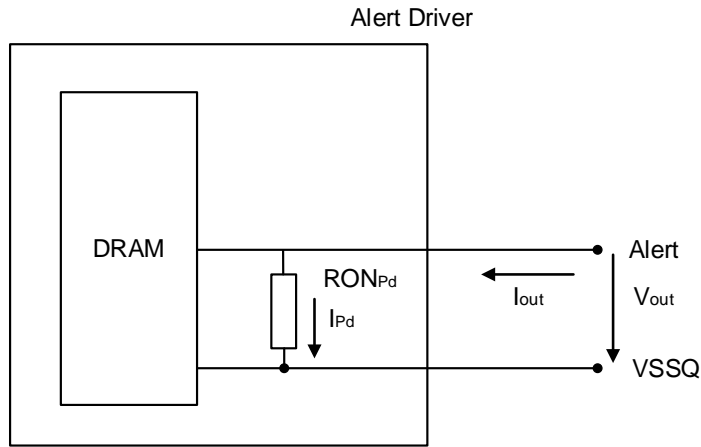

1. The tolerance limits are specified after calibration with stable voltage and temperature. For the behavior of the tolerance limits if temperature or voltage changes after calibration, see following section on voltage and temperature sensitivity (TBD).
2. Pull-up and pull-dn output driver impedances are recommended to be calibrated at 0.8\*VDDQ. Other calibration schemes may be used to achieve the linearity spec shown above, e.g. calibration at 0.5\*VDDQ and 1.1\*VDDQ.
3. Measurement definition for mismatch between pull-up and pull-down, MMPuPd: Measure RONPu and RONPD both at 0.8\*VDD separately; RONnom is the nominal RON value.
4.  $MMPuPdd = [(RONPu - RONPd / RONNOM)] * 100$
5. RON variance range ratio to RON Nominal value in a given component, including DQS\_t and DQS\_c.
6.  $MMPuPdd = [(RONPuMax - RONPuMin / RONNOM)] * 100$
7.  $MMPdPdd = [(RONPdMax - RONPdMin / RONNOM)] * 100$
8. This parameter of x16 device is specified for Upper byte and Lower byte.

### 8.1.1 Alert\_n Output Driver Characteristic

A functional representation of the output buffer is shown in the figure below. Output driver impedance RON is defined as follows:

$$RON_{Pd} = \frac{V_{out}}{|I_{out}|} \text{ under the condition that } RON_{Pu} \text{ is off.}$$

Resister	Vout	Min	Max	Unit	Note
RON <sub>Pd</sub>	VOL <sub>dc</sub> =0.1*VDDQ	0.3	1.2	34Ω	1
	VOM <sub>dc</sub> =0.8*VDDQ	0.4	1.2	34Ω	1
	VOH <sub>dc</sub> =1.1*VDDQ	0.4	1.4	34Ω	1

Note:

VDDQ voltage is at VDDQ DC. VDDQ DC definition is TBD.

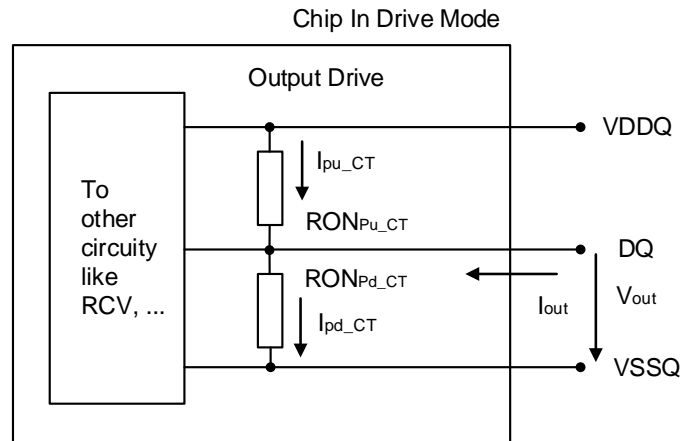

### 8.1.2 Output Driver Characteristic of Connectivity Test (CT) Mode

Following output driver impedance RON will be applied Test Output Pin during Connectivity Test (CT) Mode. The individual pull-up and pull-down resistors (RONPu\_CT and RONPd\_CT) are defined as follows:

$$RON_{Pu\_CT} = \frac{V_{DDQ} - V_{out}}{|I_{out}|}$$

$$RON_{Pd\_CT} = \frac{V_{out}}{|I_{out}|}$$

RON <sub>NOM_CT</sub>	Resister	Vout	Max	Unit
34Ω	RON <sub>Pd_CT</sub>	VOB <sub>dc</sub> =0.2*V <sub>DDQ</sub>	1.9	34Ω
		VOL <sub>dc</sub> =0.5*V <sub>DDQ</sub>	2.0	34Ω
		VOM <sub>dc</sub> =0.8*V <sub>DDQ</sub>	2.2	34Ω
		VOH <sub>dc</sub> =1.1*V <sub>DDQ</sub>	2.5	34Ω
	RON <sub>Pu_CT</sub>	VOB <sub>dc</sub> =0.2*V <sub>DDQ</sub>	2.5	34Ω
		VOL <sub>dc</sub> =0.5*V <sub>DDQ</sub>	2.2	34Ω
		VOM <sub>dc</sub> =0.8*V <sub>DDQ</sub>	2.0	34Ω
		VOH <sub>dc</sub> =1.1*V <sub>DDQ</sub>	1.9	34Ω

Note:

Connectivity test mode uses un-calibrated drivers, showing the full range over PVT. No mismatch between pull up and pull down is defined.

## 8.2 Single-ended AC& DC Output Levels

Table 8-2. Single-ended AC&DC Output Levels

Symbol	Parameter	DDR4-1600 to DDR4-3200	Unit
$V_{OH}(DC)$	DC output high measurement level (for IV curve linearity)	$1.1 \times V_{DDQ}$	V
$V_{OM}(DC)$	DC output mid measurement level (for IV curve linearity)	$0.8 \times V_{DDQ}$	V
$V_{OL}(DC)$	DC output low measurement level (for IV curve linearity)	$0.5 \times V_{DDQ}$	V
$V_{OH}(AC)$	AC output high measurement level (for output SR)	$(0.7+0.15) \times V_{DDQ}$	V
$V_{OL}(AC)$	AC output low measurement level (for output SR)	$(0.7-0.15) \times V_{DDQ}$	V

Note:

The swing of  $\pm 0.15 \times V_{DDQ}$  is based on approximately 50% of the static single-ended output peak-to-peak swing with a driver impedance of  $RZQ/7\Omega$  and an effective test load of  $50\Omega$  to  $V_{TT} = V_{DDQ}$ .

Symbol	Parameter	DDR4-1600 to DDR4-3200	Unit
$V_{OH,diff}(AC)$	AC differential output high measurement level (for output SR)	$+ 0.3 \times V_{DDQ}$	V
$V_{OL,diff}(AC)$	AC differential output low measurement level (for output SR)	$-0.3 \times V_{DDQ}$	V

Note:

The swing of  $\pm 0.3 \times V_{DDQ}$  is based on approximately 50% of the static differential output peak-to-peak swing with a driver impedance of  $RZQ/7\Omega$  and an effective test load of  $50\Omega$  to  $V_{TT} = V_{DDQ}$  at each of the differential outputs.

### 8.4 Single-ended Output Slew Rate

With the reference load for timing measurements, output slew rate for falling and rising edges is defined and measured between  $V_{OL(AC)}$  and  $V_{OH(AC)}$  for single ended signals as shown in Table 8-4 and Figure 8-2.

**Table 8-4. Single-ended Output Slew Rate Definition**

Description	Measured		Defined by
	From	To	
Single ended output slew rate for rising edge	$V_{OL(AC)}$	$V_{OH(AC)}$	$[V_{OH(AC)} - V_{OL(AC)}] / \Delta TR_{se}$
Single ended output slew rate for falling edge	$V_{OH(AC)}$	$V_{OL(AC)}$	$[V_{OH(AC)} - V_{OL(AC)}] / \Delta TF_{se}$

Note:

Output slew rate is verified by designed and characterization, and may not be subject to production test.

**Figure 8-2. Single-ended Output Slew Rate Definition**

**Table 8-5. Single-ended Output Slew Rate**

Parameter	Symbol	DDR4-1600 to DDR4-3200		Unit
		Min	Max	
Single ended output slew rate	SRQse	4	9	V/ns

Description:

SR: Slew Rate; Q: Query Output (like in DQ, which stands for Data-in, Query-Output) se: Single-ended Signals; For RON = RZQ/7 setting

Note:

In two cases, a maximum slew rate of 12 V/ns applies for a single DQ signal within a byte lane.

- Case 1 is defined for a single DQ signal within a byte lane which is switching into a certain direction (either from high to low or low to high) while all remaining DQ signals in the same byte lane are static (i.e. they stay at either high or low).
- Case 2 is defined for a single DQ signal within a byte lane which is switching into a certain direction (either from high to low or low to high) while all remaining DQ signals in the same byte lane are switching into the opposite direction (i.e. from low to high or high to low respectively). For the remaining DQ signal switching into the opposite direction, the regular maximum limit of 9 V/ns applies).

### 8.5 Differential Output Slew Rate

With the reference load for timing measurements, output slew rate for falling and rising edges is defined and measured between VOLdiff(AC) and VOHdiff(AC) for differential signals as shown in Table 8-6 and Figure 8-3.

Table 8-6. Differential Output Slew Rate Definition

Description	Measured		Defined by
	From	To	
Differential output slew rate for rising edge	VOLdiff(AC)	VOHdiff(AC)	$[V_{OHdiff}(AC) - V_{OLdiff}(AC)] / \Delta TR_{diff}$
Differential output slew rate for falling edge	VOHdiff(AC)	VOLdiff(AC)	$[V_{OHdiff}(AC) - V_{OLdiff}(AC)] / \Delta TF_{diff}$

Note:

Output slew rate is verified by design and characterization, and may not be subject to production test.

Figure 8-3. Differential Output Slew Rate Definition

Table 8-7. Differential Output Slew Rate

Parameter	Symbol	DDR4-1600 to DDR4-3200		Unit
		Min	Max	
Differential output slew rate	SRQdiff	8	18	V/ns

Description:

SR: Slew Rate; Q: Query Output (like in DQ, which stands for Data-in, Query-Output);

Diff: Differential Signals; For RON = RZQ/7 setting

### 8.6 Single-ended AC& DC Output Levels of Connectivity Test Mode

Following output parameters will be applied for DDR4 SDRAM Output Signal during Connectivity Test Mode.

Table 8-8. Single-ended AC&DC Output Level of Connectivity Test Mode

Symbol	Parameter	DDR4-1600 to DDR4-3200	Unit	Note
$V_{OH(DC)}$	DC output high measurement level (for IV curve linearity)	$1.1 \times V_{DDQ}$	V	
$V_{OM(DC)}$	DC output mid measurement level (for IV curve linearity)	$0.8 \times V_{DDQ}$	V	
$V_{OL(DC)}$	DC output low measurement level (for IV curve linearity)	$0.5 \times V_{DDQ}$	V	
$V_{OB(DC)}$	DC output below measurement level (for IV curve linearity)	$0.2 \times V_{DDQ}$	V	
$V_{OH(AC)}$	AC output high measurement level (for output SR )	$V_{TT} + (0.1 \times V_{DDQ})$	V	1
$V_{OL(AC)}$	AC output below measurement level (for output SR)	$V_{TT} - (0.1 \times V_{DDQ})$	V	1

Note:

The effective test load is 50Ω terminated by  $V_{TT} = 0.5 \times V_{DDQ}$ .

## Speed Bin Table Note

### Absolute Specifications

- VDDQ = VDD = 1.20V ± 0.06 V
  - VPP = 2.5V (2.375V min, 2.75V max)
  - The values defined with above-mentioned table are DLL ON case.
  - DDR4-1600, 1866, 2133, 2400, 2666 and 3200 Speed Bin Tables are valid only when Gear Down Mode is disabled.
1. The CL setting and CWL setting result in tCK(avg).MIN and tCK(avg).MAX requirements. When making a selection of tCK(avg), both need to be fulfilled: Requirements from CL setting as well as requirements from CWL setting.
  2. tCK(avg).MIN limits: Since CAS Latency is not purely analog - data and strobe output are synchronized by the DLL-all possible intermediate frequencies may not be guaranteed. CL in clock cycle is calculated from tAA following rounding algorithm defined in JEDEC-79C Section 13.5.
  3. tCK(avg).MAX limits: Calculate tCK(avg) = tAA.MAX / CL SELECTED and round the resulting tCK(avg) down to the next valid speed bin (i.e. 1.5ns or 1.25ns or 1.071 ns or 0.937 ns or 0.833 ns). This result is tCK(avg).MAX corresponding to CL SELECTED.
  4. 'Reserved' settings are not allowed. User must program a different value.
  5. 'Optional' settings allow certain devices in the industry to support this setting, however, it is not a mandatory feature. Refer to supplier's data sheet and/or the DIMM SPD information if and how this setting is supported.
  6. Any DDR4-1866 speed bin also supports functional operation at lower frequencies as shown in the corresponding table which are not subject to Production Tests but verified by Design/ Characterization.
  7. Any DDR4-2133 speed bin also supports functional operation at lower frequencies as shown in the corresponding table which are not subject to Production Tests but verified by Design/ Characterization.
  8. Any DDR4-2400 speed bin also supports functional operation at lower frequencies as shown in the corresponding table which are not subject to Production Tests but verified by Design/ Characterization.
  9. Any DDR4-2666 speed bin also supports functional operation at lower frequencies as shown in the corresponding table which are not subject to Production Tests but verified by Design/ Characterization.
  10. Any DDR4-3200 speed bin also supports functional operation at lower frequencies as shown in the corresponding table which are not subject to Production Tests but verified by Design/ Characterization.
  11. DDR4-1600 AC timing apply if DRAM operates at lower than 1600 MT/s data rate.
  12. Parameters apply from tCK(avg)min to tCK(avg)max at all standard JEDEC clock period values as stated in the Speed Bin Tables.
  13. CL number in parentheses, it means that these numbers are optional.
  14. DDR4 SDRAM supports CL=9 as long as a system meets tAA(min).
  15. Each speed bin lists the timing requirements that need to be supported in order for a given DRAM to be JEDEC compliant. JEDEC compliance does not require support for all speed bins within a given speed. JEDEC compliance requires meeting the parameters for a least one of the listed speed bins.

## 10 IDD AND IDDQ SPECIFICATION PARAMETERS AND TEST CONDITIONS

### 10.1 IDD, IPP and IDDQ Measurement Conditions

Figure 10-1 shows the setup and test load for IDD, IPP and IDDQ measurements.

- IDD currents (such as IDD0, IDD0A, IDD1, IDD1A, IDD2N, IDD2NA, IDD2NL, IDD2NT, IDD2P, IDD2Q, IDD3N, IDD3NA, IDD3P, IDD4R, IDD4RA, IDD4W, IDD4WA, IDD5B, IDD5F2, IDD5F4, IDD6N, IDD6E, IDD6R, IDD6A, IDD7 and IDD8) are measured as time-averaged currents with all VDD balls of the DDR4 SDRAM under test tied together. Any IPP or IDDQ current is not included in IDD currents.
- IPP currents have the same definition as IDD except that the current on the VPP supply is measured.
- IDDQ currents (such as IDDQ2NT and IDDQ4R) are measured as time-averaged currents with all VDDQ balls of the DDR4 SDRAM under test tied together. Any IDD current is not included in IDDQ currents.

Attention: IDDQ values cannot be directly used to calculate IO power of the DDR4 SDRAM. They can be used to support correlation of simulated IO power to actual IO power as outlined in Figure 10-2. In DRAM module application, IDDQ cannot be measured separately since VDD and VDDQ are using one merged-power layer in Module PCB.

For IDD, IPP and IDDQ measurements, the following definitions apply:

- “0” and “Low” is defined as  $V_{IN} \leq V_{ILAC}(\max)$ .
- “1” and “High” is defined as  $V_{IN} \geq V_{IHAC}(\min)$ .
- “MID-LEVEL” is defined as inputs are  $V_{REF} = V_{DD} / 2$ .
- Basic IDD, IPP and IDDQ Measurement Conditions are described in Table 10-2.
- Detailed IDD, IPP and IDDQ Measurement-Loop Patterns are described in Table 10-3.
- IDD Measurements are done after properly initializing the DDR4 SDRAM. This includes but is not limited to setting  
RON = RZQ/7 (34 Ohm in MR1);  
RTT\_NOM = RZQ/6 (40 Ohm in MR1);  
RTT\_WR = RZQ/2 (120 Ohm in MR2);  
RTT\_PARK = Disable;  
Qoff = 0B (Output Buffer enabled) in MR1;  
TDQS\_t disabled in MR1;  
CRC disabled in MR2;  
CA parity feature disabled in MR5;  
Gear down mode disabled in MR3;  
Read/Write DBI disabled in MR5;  
DM disabled in MR5
- Attention: The IDD, IPP and IDDQ Measurement-Loop Patterns need to be executed at least one time before actual IDD or IDDQ measurement is started.
- Define D = {CS\_n, ACT\_n, RAS\_n, CAS\_n, WE\_n}: = {High, Low, Low, Low, Low}
- Define D# = {CS\_n, ACT\_n, RAS\_n, CAS\_n, WE\_n}: = {High, High, High, High, High}; apply invert of BG/BA changes when directed above.

## Note:

1. This parameter is not subject to production test. It is verified by design and characterization. The silicon only capacitance is validated by deembedding the package L & C parasitic. The capacitance is measured with VDD, VDDQ, VSS, VSSQ applied with all other signal pins floating. Measurement procedure TBD.
2. DQ, DM<sub>n</sub>, DQS<sub>T</sub>, DQS<sub>C</sub>, TDQS<sub>T</sub>, TDQS<sub>C</sub>. Although the DM, TDQS<sub>T</sub> and TDQS<sub>C</sub> pins have different functions, the loading matches DQ and DQS.
3. This parameter applies to monolithic devices only; stacked/dual-die devices are not covered here.
4. Absolute value CK<sub>T</sub> - CK<sub>C</sub>.
5. Absolute value of C<sub>IO</sub>(DQS<sub>T</sub>) - C<sub>IO</sub>(DQS<sub>C</sub>).
6. C<sub>I</sub> applies to ODT, CS<sub>n</sub>, CKE, A0 - A17, BA0 - BA1, BG0 - BG1, RAS<sub>n</sub> / A16, CAS<sub>n</sub> / A15, WE<sub>n</sub> / A14, ACT<sub>n</sub> and PAR.
7. C<sub>DI\_CTRL</sub> applies to ODT, CS<sub>n</sub> and CKE.
8. C<sub>DI\_CTRL</sub> = C<sub>I</sub>(CTRL) - 0.5\*(C<sub>I</sub>(CLK<sub>T</sub>) + C<sub>I</sub>(CLK<sub>C</sub>)).
9. C<sub>DI\_ADD\_CMD</sub> applies to, A0 - A17, BA0 - BA1, BG0 - BG1, RAS<sub>n</sub> / A16, CAS<sub>n</sub> / A15, WE<sub>n</sub> / A14, ACT<sub>n</sub> and PAR.
10. C<sub>DI\_ADD\_CMD</sub> = C<sub>I</sub>(ADD\_CMD) - 0.5\*(C<sub>I</sub>(CLK<sub>T</sub>) + C<sub>I</sub>(CLK<sub>C</sub>)).
11. C<sub>DIO</sub> = C<sub>IO</sub>(DQ, DM) - 0.5\*(C<sub>IO</sub>(DQS<sub>T</sub>) + C<sub>IO</sub>(DQS<sub>C</sub>)).
12. Maximum external load capacitance on ZQ pin: tbd pF.
13. TEN pin may be DRAM internally pulled low through a weak pull-down resistor to VSS. In this case CTEN might not be valid and system shall verify TEN signal with Vendor specific information.

Note:

1. Package implementations shall meet spec if the Zpkg and Pkg Delay fall within the ranges shown, and the maximum Lpkg and Cpkg do not exceed the maximum value shown.
2. It is assumed that Lpkg can be approximated as  $Lpkg = Z_o * T_d$ .
3. It is assumed that Cpkg can be approximated as  $Cpkg = T_d / Z_o$ .

## 12 ELECTRICAL CHARACTERISTICS & AC TIMING

### 12.1 Reference Load for AC Timing and Output Slew Rate

Figure 12-1 represents the effective reference load of 50 ohms used in defining the relevant AC timing parameters of the device as well as output slew rate measurements.

RON nominal of DQ, DQS\_t and DQS\_c drivers uses 34 ohms to specify the relevant AC timing parameter values of the device.

- The maximum DC High level of Output signal = 1.0\*VDDQ
- The minimum DC Low level of Output signal =  $\{34 / (34 + 50)\} * VDDQ = 0.4 * VDDQ$
- The nominal reference level of an Output signal can be approximated by the following:
- The center of maximum DC High and minimum DC Low =  $\{(1 + 0.4) / 2\} * VDDQ = 0.7 * VDDQ$

The actual reference level of Output signal might vary with driver RON and reference load tolerances. Thus, the actual reference level or midpoint of an output signal is at the widest part of the output signal's eye. Prior to measuring AC parameters, the reference level of the verification tool should be set to an appropriate level.

It is not intended as a precise representation of any particular system environment or a depiction of the actual load presented by a production tester. System designers should use IBIS or other simulation tools to correlate the timing reference load to a system environment. Manufacturers correlate to their production test conditions, generally one or more coaxial transmission lines terminated at the tester electronics.

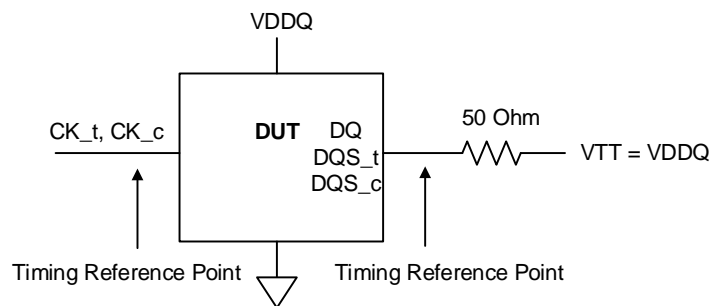

Figure 12-1. Reference Load for AC Timing and Output Slew Rate

### 12.2 tREFI

Average periodic Refresh interval (tREFI) of DDR4 SDRAM is defined as shown in Table 12-1 below.

Table 12-1. tREFI by Device Density

Parameter	Symbol	4Gb	Unit	
Average periodic refresh interval	tREFI	0 °C ≤ TCASE ≤ 85 °C	7.8	μs
		85 °C ≤ TCASE ≤ 95 °C	3.9	μs

### 12.3 Clock Specification

The jitter specified is a random jitter meeting a Gaussian distribution. Input clocks violating the min/max values may result in malfunction of the DDR4 SDRAM device.

#### 12.3.1 Definition for tCK(abs)

tCK(abs) is defined as the absolute clock period, as measured from one rising edge to the next consecutive rising edge. tCK(abs) is not subject to production test.

### 12.3.2 Definition for tCK(avg)

tCK(avg) is calculated as the average clock period across any consecutive 200 cycle window, where each clock period is calculated from rising edge to rising edge.

$$tCK(avg) = \left( \sum_{j=1}^N tCK(abs)_j \right) / N \quad N=200$$

### 12.3.3 Definition for tCH(avg) and Tcl(avg)

tCH(avg) is defined as the average high pulse width, as calculated across any consecutive 200 high pulses.

$$tCH(avg) = \left( \sum_{j=1}^N tCH_j \right) / (N \times tCK(avg)) \quad N=200$$

tCL(avg) is defined as the average low pulse width, as calculated across any consecutive 200 low pulses.

$$tCL(avg) = \left( \sum_{j=1}^N tCL_j \right) / (N \times tCK(avg)) \quad N=200$$

### 12.3.4 Definition for tERR(nper)

tERR is defined as the cumulative error across n consecutive cycles of n x tCK(avg). tERR is not subject to production test.

## Note:

- Start of internal Write transaction is defined as follows:
  - For BL8 (Fixed by MRS and on-the-fly): Rising clock edge 4 clock cycles after WL.
  - For BC4 (on-the-fly): Rising clock edge 4 clock cycles after WL.
  - For BC4 (Fixed by MRS): Rising clock edge 2 clock cycles after WL.
- A separate timing parameter will cover the delay from Write to Read when CRC and DM are simultaneously enabled.
- Commands requiring a locked DLL are Read (and Read Auto Precharge) and synchronous ODT commands.
- tWR is defined in ns, for calculation of tWRPDEN it is necessary to round up tWR/tCK following rounding algorithm defined in [Section 12.5](#).
- WR in clock cycles as programmed in MR0.
- tREFI depends on T<sub>OPER</sub>.
- CKE is allowed to be registered low while operations such as row activation, precharge, autoprecharge or refresh are in progress, but power-down IDD spec will not be applied until finishing those operations.
- For these parameters, the DDR4 SDRAM device supports  $tnPARAM[nCK]=RU\{tPARAM[ns]/tCK(avg)[ns]\}$ , which is in clock cycles assuming all input clock jitter specifications are satisfied.

9. When CRC and DM are both enabled,  $tWR\_CRC\_DM$  is used in place of  $tWR$ .
10. When CRC and DM are both enabled,  $tWTR\_S\_CRC\_DM$  is used in place of  $tWTR\_S$ .
11. When CRC and DM are both enabled,  $tWTR\_L\_CRC\_DM$  is used in place of  $tWTR\_L$ .
12. The max value are system dependent.
13. DQ to DQS total timing per group where the total includes the sum of deterministic and random timing terms for a specified BER. BER spec and measurement.
14. The deterministic component of the total timing. Measurement method TBD.
15. DQ to DQ static offset relative to strobe per group. Measurement method TBD.
16. This parameter will be characterized and guaranteed by design.
17. When the device is operated with the input clock jitter, this parameter needs to be derated by the actual  $tjit(per)\_total$  of the input clock. (output deratings are relative to the SDRAM input clock). Example TBD.
18. DRAM DBI mode is off.
19. DRAM DBI mode is enabled. Applicable to x8 and x16 DRAM only.
20.  $tQSL$  describes the instantaneous differential output low pulse width on  $DQS\_t - DQS\_c$ , as measured from on falling edge to the next consecutive rising edge.
21.  $tQSL$  describes the instantaneous differential output high pulse width on  $DQS\_t - DQS\_c$ , as measured from on falling edge to the next consecutive rising edge.
22. There is no maximum cycle time limit besides the need to satisfy the refresh interval  $tREFI$ .
23.  $tCH(abs)$  is the absolute instantaneous clock high pulse width, as measured from one rising edge to the following falling edge.
24.  $tCL(abs)$  is the absolute instantaneous clock low pulse width, as measured from one falling edge to the following rising edge.
25. Total jitter includes the sum of deterministic and random jitter terms for a specified BER. BER target and measurement method are TBD.
26. The deterministic jitter component out of the total jitter. This parameter is characterized and guaranteed by design.
27. This parameter has to be even number of clocks.
28. When CRC and DM are both enabled,  $tWR\_CRC\_DM$  is used in place of  $tWR$ .
29. When CRC and DM are both enabled  $tWTR\_S\_CRC\_DM$  is used in place of  $tWTR\_S$ .
30. When CRC and DM are both enabled  $tWTR\_L\_CRC\_DM$  is used in place of  $tWTR\_L$ .
31. After CKE is registered Low, CKE signal level shall be maintained below  $VILDC$  for  $tCKE$  specification (Low pulse width).
32. After CKE is registered High, CKE signal level shall be maintained above  $VIHDC$  for  $tCKE$  specification (High pulse width).
33. Defined between end of MPR Read burst and MRS which reloads MPR or disables MPR function.
34. Parameters apply from  $tCK(avg)min$  to  $tCK(avg)max$  at all standard JEDEC clock period values as stated in the "Speed Bin".
35. This parameter must keep consistency with "Speed Bin".

36. DDR4-1600 AC timing apply if DRAM operates at lower than 1600 MT/s data rate.  $UI=tCK(avg)min/2$ .
37. Applied when DRAM is in DLL ON mode.
38. Assume no jitter on input clock signals to the DRAM.
39. Value is only valid for RONNOM =  $34\Omega$ .
40. 1tCK toggle mode with setting MR4:A11 to 0.
41. 2tCK toggle mode with setting MR4:A11 to 1, which is valid for DDR4-2400/2666/3200 speed grade.
42. 1tCK mode with setting MR4:A12 to 0.
43. 2tCK mode with setting MR4:A12 to 1, which is valid for DDR4-2400/2666/3200 speed grade.
44. The maximum read preamble is bounded by tLZ(DQS)min on the left side and tDQSCK(max) on the right side. See "Clock to Data Strobe Relationship" of DDR4 Operation Guide Boundary of DQS Low-Z occur one cycle earlier in 2tCK toggle mode which is illustrated in "Read Preamble".
45. DQ falling signal middle-point of transferring from High to Low to first rising edge of DQS diff-signalcross-point.
46. Last falling edge of DQS diff-signal cross-point to DQ rising signal middle-point of transferring from Low to High
47. VerfDQ value must be set to either its midpoint or Vcent\_DQ(midpoint) in order to capture DQ0 or DQL0 low level for entering PDA mode.
48. The maximum read postamble is bound by tDQSCK(min) plus tQSH(min) on the left side and tHZ(DQS)max on the right side. See "Clock to Data Strobe Relationship" of DDR4 Operation Guide.
49. Reference level of DQ output signal is specified with a midpoint as a widest part of Output signal eye which should be approximately  $0.7 * VDDQ$  as a center level of the static single-ended output peak-to-peak swing with a driver impedance of 34 ohms and an effective test load of 50 ohms to  $VTT = VDDQ$ .
50. For MR7 commands, the minimum delay to a subsequent non-MRS command is 5nCK.

### 12.5 Rounding Algorithms

Software algorithms for calculation of timing parameters are subject to rounding errors from many sources. For example, a system may use a memory clock with a nominal frequency of 933.33 MHz, or a clock period of 1.0714 ns. Similarly, a system with a memory clock frequency of 1066.66 MHz yields mathematically a clock period of 0.9375 ns. In most cases, it is impossible to express all digits after the decimal point exactly, and rounding must be done because the DDR4 SDRAM specification establishes a minimum granularity for timing parameters of 1 ps.

Rules for rounding must be defined to allow optimization of device performance without violating device parameters. These algorithms rely on results that are within correction factors on device testing and specification to avoid losing performance due to rounding errors.

These rules are:

- Clock periods such as tCKAVGmin are defined to 1 ps of accuracy; for example, 0.9375... ns is defined as 937 ps and 1.0714 ns is defined as 1071 ps.
- Using real math, parameters like tAAmin, tRCDmin, etc. which are programmed in systems in numbers of clocks (nCK) but expressed in units of time (in ns) are divided by the clock period (in ns) yielding a unitless ratio, a correction factor of 2.5% is subtracted, then the result is set to the next higher integer number of clocks:  
 $nCK = \text{ceiling} [ (\text{parameter\_in\_ns} / \text{application\_tCK\_in\_ns}) - 0.025 ]$
- Alternatively, programmers may prefer to use integer math instead of real math by expressing timing in ps, scaling the desired parameter value by 1000, dividing by the application clock period, adding an inverse correction factor of 97.4%, dividing the result by 1000, then truncating down to the next lower integer value:  
 $nCK = \text{truncate} [ \{ (\text{parameter\_in\_ps} \times 1000) / (\text{application\_tCK\_in\_ps}) + 974 \} / 1000 ]$
- Either algorithm yields identical results. In case of conflict between results, the preferred algorithm is the integer math algorithm.
- This algorithm applies to all timing parameters documented in a Serial Presence Detect (SPD) when converting from ns to nCK. Other timing parameters may use a simpler algorithm:  
 $nCK = \text{ceiling} (\text{parameter\_in\_ns} \div \text{application\_tCK\_in\_ns})$ .

### 12.6 The DQ Input Receiver Compliance Mask for Voltage and Timing

The DQ input receiver compliance mask for voltage and timing is shown in Figure 12-2 below. The receiver mask (Rx Mask) defines area the input signal must not encroach in order for the DRAM input receiver to be able to successfully capture a valid input signal with BER of 1e-16; Any input signal encroaching within the Rx Mask is subject to being invalid data. The Rx Mask is the receiver property for each DQ input pin and it is not the valid data-eye.

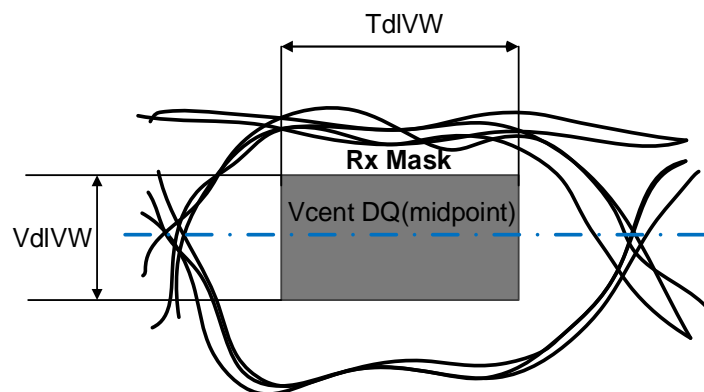

Figure 12-2. DQ Receiver(Rx) Compliance mask

Figure 12-3. Across Pin Vref DQ Voltage Variation

The Vref\_DQ voltage is an internal reference voltage level that shall be set to the properly trained setting, which is generally Vcent\_DQ(midpoint), in order to have valid Rx Mask values.

Vcent\_DQ(pin avg) is defined as the midpoint between the largest Vref\_DQ voltage level and the smallest Vref\_DQ voltage level across all DQ pins for a given DRAM component. Each DQ pin Vref level is defined by the center, i.e. widest opening, of the cumulative data input eye as depicted in Figure 12-3. This clarifies that any DRAM component level variation must be accounted for within the DRAM Rx mask. The component level Vref will be set by the system to account for RON and ODT settings.

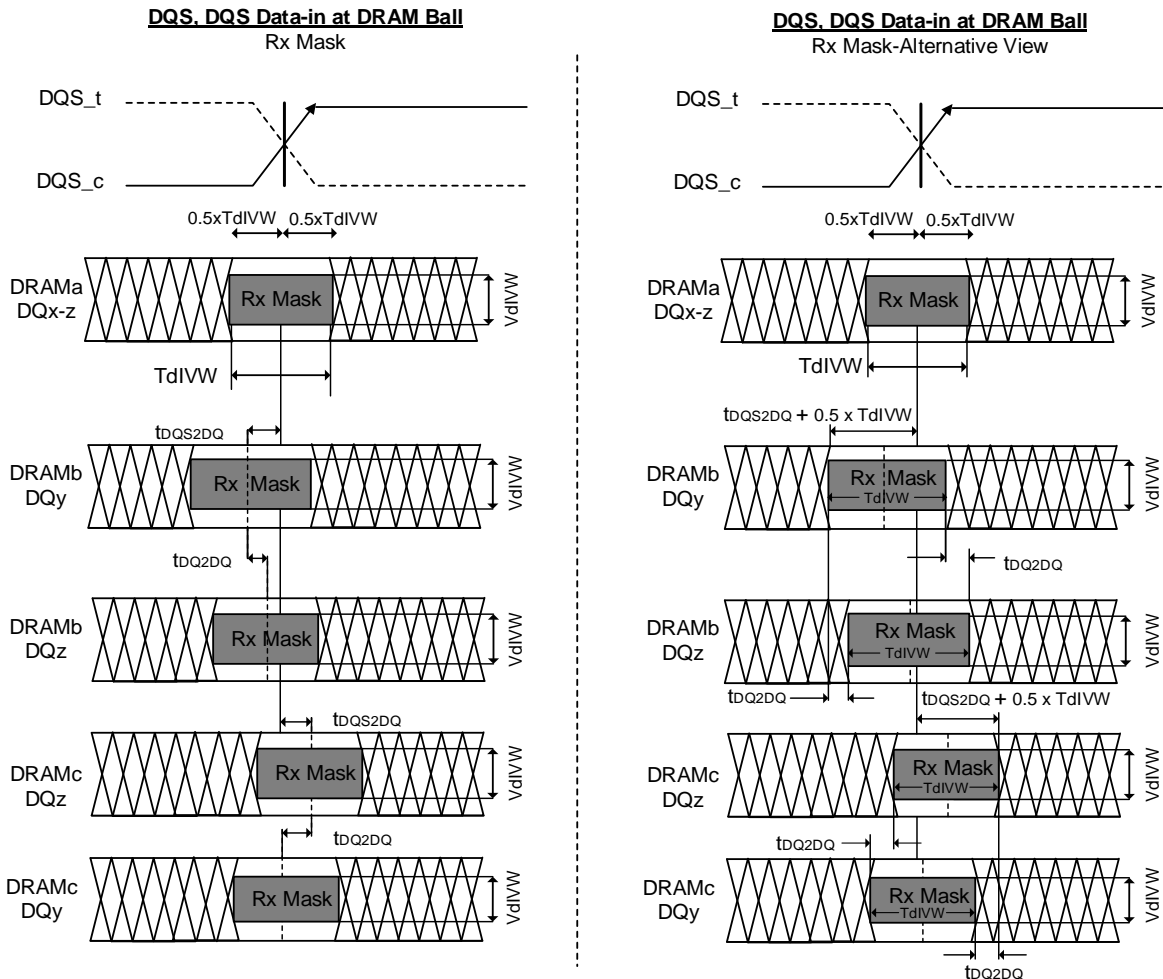

Figure 12-4. DQS to DQ and DQ to DQ Timings at DRAM Balls

Note:

- DQx represents an optimally centered mask.
- DQy represents earliest valid mask.
- DQz represents lasted valid mask.

Note:

- DRAMa represents a DRAM without any DQS/DQ skews.
- DRAMb represents a DRAM with early skews (negative  $t_{DQS2DQ}$ ).
- DRAMc represents a DRAM with delayed skews (positive  $t_{DQS2DQ}$ ).

Note:

1. Figures show skew allowed between DRAM to DRAM and DQ to DQ for a DRAM. Signals assume data centered aligned at DRAM Latch.
2. TdiPW is not shown; composite data-eyes shown would violate TdiPW.
3. VCENT DQ(midpoint) is not shown but is assumed to be midpoint of VdiVW.

All of the timing term in

are measured at the VdiVW voltage levels centered around

Vcent\_DQ(midpoint) and are referenced to the DQS\_t/DQS\_c center aligned to the DQ per pin.

The rising edge slew rates are defined by srr1 and srr2. The slew rate measurement points for a rising edge are shown in Figure 12- below: A low to high transition tr1 is measured from 0.5\*VdiVW(max) below Vcent\_DQ(midpoint) to the last transition through 0.5\*VdiVW(max) above Vcent\_DQ(midpoint) to the first transition through the 0.5\*VIHL\_AC(min) above Vcent\_DQ(midpoint).

Rising edge slew rate equations:

- $srr1 = VdiVW(max) / tr1$
- $srr2 = (VIHL\_AC(min) - VdiVW(max)) / (2*tr2)$

Figure 12-5. Slew Rate Conditions for Rising Transition

The falling edge slew rates are defined by srf1 and srf2. The slew rate measurement points for a falling edge are shown in Figure 12- below: A high to low transition tf1 is measured from 0.5\*VdiVW(max) above Vcent\_DQ(midpoint) to the last transition through 0.5\*VdiVW(max) below Vcent\_DQ(midpoint) while tf2 is measured from the last transition through 0.5\*VdiVW(max) below Vcent\_DQ(midpoint) to the first transition through the 0.5\*VIHL\_AC(min) below Vcent\_DQ(pin mid).

Falling edge slew rate equations:

- $srf1 = VdiVW(max) / tf1$
- $srf2 = (VIHL\_AC(min) - VdiVW(max)) / (2*tf2)$

Note:

1. Data Rx mask voltage and timing total input valid window where VdIVW is centered around Vcent\_DQ (midpoint) after VrefDQ training is completed. The data Rx mask is applied per bit and should include voltage and temperature drift terms. The input buffer design specification is to achieve at least a BER = e-16 when the Rx mask is not violated. The BER will be characterized and extrapolated if necessary using a dual dirac method from a higher BER(tbd)
2. Defined over the DQ internal Vref range 1.

3. Overshoot and Undershoot Specifications see “AC Overshoot Specification for Data, Strobe and Mask”
4. DQ input pulse signal swing into the receiver must meet or exceed VIH<sub>L</sub> AC(min). VIH<sub>L</sub> AC(min) is to be achieved on an UI basis when a rising and falling edge occur in the same UI, i.e. a valid TdiPW.
5. DQ minimum input pulse width defined at the Vcent<sub>DQ</sub>(midpoint).
6. DQS to DQ offset is skew between DQS and DQs within a nibble (x4) or word (x8, x16) at the DDR4 SDRAM balls over process, voltage, and temperature.
7. DQ to DQ offset is skew between DQs within a nibble (x4) or word (x8, x16) at the DDR4 SDRAM balls for a given component over process, voltage, and temperature.
8. Input slew rate over VdiVW Mask centered at Vcent<sub>DQ</sub>(midpoint). Slowest DQ slew rate to fastest DQ slew rate per transition edge must be within 1.7 V/ns of each other.
9. Input slew rate between VdiVW Mask edge and VIH<sub>L</sub> AC(min) points.
10. All Rx Mask specifications must be satisfied for each UI. For example, if the minimum input pulse width is violated when satisfying TdiVW(min), VdiVW(max), and minimum slew rate limits, then either TdiVW(min) or minimum slew rates would have to be increased to the point where the minimum input pulse width would no longer be violated.

## 12.7 Command, Control, and Address Setup, Hold, and Derating

The total tIS (setup time) and tIH (hold time) required is calculated to account for slew rate variation by adding the data sheet tIS (base) values, the VIL(AC)/VIH(AC) points, and tIH (base) values, the VIL(DC)/VIH(DC) points; to the  $\Delta tIS$  and  $\Delta tIH$  derating values, respectively. The base values are derived with single-end signals at 1V/ns and differential clock at 2V/ns. Example: tIS (total setup time) = tIS (base) +  $\Delta tIS$ . For a valid transition, the input signal has to remain above/ below VIH(AC)/VIL(AC) for the time defined by tVAC.

Although the total setup time for slow slew rates might be negative (for example, a valid input signal will not have reached VIH(AC)/VIL(AC) at the time of the rising clock transition), a valid input signal is still required to complete the transition and to reach VIH(AC)/VIL(AC). For slew rates that fall between the values listed in derating tables, the derating values may be obtained by linear interpolation.

Setup (tIS) nominal slew rate for a rising signal is defined as the slew rate between the last crossing of VIL(DC)max and the first crossing of VIH(AC)min that does not ring back below VIH(DC)min. Setup (tIS) nominal slew rate for a falling signal is defined as the slew rate between the last crossing of VIH(DC)min and the first crossing of VIL(AC)max that does not ring back above VIL(DC)max. Hold (tIH) nominal slew rate for a rising signal is defined as the slew rate between the last crossing of VIL(DC)max and the first crossing of VIH(AC)min that does not ring back below VIH(DC)min.

Hold (tIH) nominal slew rate for a falling signal is defined as the slew rate between the last crossing of VIH(DC)min and the first crossing of VIL(AC)min that does not ring back above VIL(DC)max.

### 13 REVISION HISTORY

Version No	Description	Page	Date
1.0	Initial release	All	2021-4-28
1.1	Update Pad name description and extend the operating temperature from -40 to 95 °C	5/14/46	2021-7-21
1.2	Update the IDD, IDDQ and IPP Specifications of DDR4-2400/2666/3200 speed grade	72/73	2021-9-13
1.3	Update functional block diagram	14	2021-11-2
1.4	Update some details about speed bins and operations; Update some details about Measurement-Loop Pattern Update some details about input/output capacitance; Update some details about timing parameters by speed bin.	P41/P42/P43/P44 P59/P65 P75/P76 P80/P81/P86	2022-3-9
