

FEATURES

- Operational V_{IN} up to +40V
- +70V/-50V Voltage Transients
- Available with 3.3V or 5.0V Output Voltage
- Ultra Low Ground Pin Current, 25 μ A Typical for 100 μ A Load
- V_{OUT} Initial Accuracy of $\pm 1.5\%$
- V_{OUT} Accurate to $\pm 3\%$ Over Load and Temperature Conditions
- Low Dropout Voltage, 200mV Typical with 150mA Load
- Low Off State Ground Pin Current for LM9076D in 8-pin SOP Package
- Delayed \overline{RESET} Output Pin for Low V_{OUT} Detection

DESCRIPTION

The LM9076 is a $\pm 3\%$, 150mA logic controlled voltage regulator. The regulator features an active low delayed reset output flag which can be used to reset a microprocessor system at turn-on and in the event that the regulator output voltage falls below a minimum value. An external capacitor programs a delay times interval before the reset output pin can return high.

Designed for automotive and industrial applications, the LM9076 contains a variety of protection features such as thermal shutdown, input transient protection and a wide operating temperature range. The LM9076 uses a PNP pass transistor which allows low drop-out voltage operation.

ORDERING INFORMATION

| Device | Package |
|-------------|-----------|
| LM9076D-x.x | SOP-8 |

xx: Output Voltage

ABSOLUTE MAXIMUM RATINGS ^(Note 1)

| CHARACTERISTIC | SYMBOL | MIN | MAX | UNIT |
|--|-------------------------------|------|------------------------|--------------------|
| Input Voltage (DC) | V_{IN} | -15 | 50 | V |
| Input Voltage (+Transient) $t < 10\text{ms}$, Duty Cycle $< 1\%$ | V_{IN} | - | 60 | V |
| Input Voltage (-Transient) $t < 1.0\text{ms}$, Duty Cycle $< 1\%$ | V_{IN} | -50 | - | V |
| SHUTDOWN Pin | $V_{SHUTDOWN}$ | -15 | 52 | V |
| $\overline{\text{RESET}}$ Pin | $V_{\overline{\text{RESET}}}$ | -0.3 | 20 | V |
| DELAY Pin | V_{DELAY} | -0.3 | $V_{\text{OUT}} + 0.3$ | V |
| ESD Immunity (HBM) | V_{ESD} | - | ± 2 | kV |
| Maximum Junction Temperature | T_J | - | 175 | $^{\circ}\text{C}$ |
| Storage Temperature | T_{STG} | -65 | 150 | $^{\circ}\text{C}$ |

Note 1. Stresses beyond those listed under *Absolute Maximum Ratings* may cause permanent damage to the device. These are stress ratings only and functional operation of the device at these or any other conditions beyond those indicated under *Recommended Operating Conditions* is not implied. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.

RECOMMENDED OPERATING RATINGS ^(Note 2)

| CHARACTERISTIC | SYMBOL | MIN | MAX | UNIT |
|--------------------------------------|----------------|------|-----|--------------------|
| IN Pin | V_{IN} | 5.35 | 40 | V |
| SHUTDOWN Pin | $V_{SHUTDOWN}$ | 0 | 40 | V |
| Operating Junction Temperature Range | T_J | -40 | 125 | $^{\circ}\text{C}$ |

Note 2. The device is not guaranteed to function outside its operating ratings.

ORDERING INFORMATION

| VOUT | Package | Order No. | Description | Supplied As | Status |
|------|-----------|-------------|------------------------|-------------|------------|
| 3.3V | TO-263-5L | LM9076R-3.3 | | Tape & Reel | Contact us |

TYPICAL OPERATING CHARACTERISTICS

T.B.D.

APPLICATION INFORMATION

REGULATOR BASICS

The LM9076 regulator is suitable for Automotive and Industrial applications where continuous connection to a battery supply is required (refer to *Typical Application Circuits*).

The pass element of the regulator is a PNP device which requires an output bypass capacitor for stability. The minimum bypass capacitance for the output is 10 μ F (refer to ESR limitations). A 22 μ F or larger, output bypass capacitor is recommended for typical applications.

INPUT CAPACITOR

The LM9076 requires a low source impedance to maintain regulator stability because critical portions of the internal bias circuitry are connected directly to IN pin. In general, a 10 μ F electrolytic capacitor, located within two inches of the LM9076, is adequate for a majority of applications. Additionally, and at a minimum, a 0.1 μ F ceramic capacitor should be located between the LM9076 IN pin and GND pin, and as close as is physically possible to the LM9076 itself.

OUTPUT CAPACITOR

An output bypass capacitor is required for stability. This capacitance must be placed between the LM9076 OUT pin and GND pin, as close as is physically possible, using traces that are not part of the load current path.

The output capacitor must meet the requirements for minimum capacitance and also maintain the appropriate ESR value across the entire operating ambient temperature range. There is no limit to the maximum output capacitance as long as ESR is maintained.

The minimum bypass capacitance for the output is 10 μ F (refer to ESR limitations). A 22 μ F, or larger, output bypass capacitor is recommended for typical applications.

Solid tantalums capacitors are recommended as they generally maintain capacitance and ESR ratings over a wide temperature range. Ceramic capacitor types XR7 and XR5 may be used if a series resistor is added to simulate the minimum ESR requirement.

Aluminum electrolytic capacitors are not recommended as they are subject to wide changes in capacitance and ESR across temperature.

DELAY CAPACITOR

The capacitor on the DELAY pin must be a low leakage type since the charge current is minimal (420nA typical) and the pin must fully charge to V_{OUT} . Ceramic, Mylar, and polystyrene capacitor types are generally recommended, although changes in capacitance values across temperature changes will have some effect on the delay timing.

Any leakage of the I_{DELAY} current, be it through the delay capacitor or any other path, will extend the delay time, possibly to the point that the $\overline{\text{RESET}}$ pin output does not go high.

SHUTDOWN PIN (LM9076D ONLY)

The basic On/Off control of the regulator is accomplished with the SHUTDOWN pin. By pulling the SHUTDOWN pin high the regulator output is switched off. When the regulator is switched off the load on the battery will be primarily due to the SHUTDOWN pin current.

When the SHUTDOWN pin is low, or left open, the regulator is switched on. When an unregulated supply, such as V BATTERY, is used to pull the SHUTDOWN pin high a series resistor in the range of 10k Ω to 50k Ω is recommended to provide reverse voltage transient protection of the SHUTDOWN pin. Adding a small capacitor (0.001 μF typical) from the SHUTDOWN pin to GND will add noise immunity to prevent accidental turn on due to noise on the supply line.

$\overline{\text{RESET}}$ FLAG

The $\overline{\text{RESET}}$ pin is an open collector output which requires an external pull-up resistor to develop the reset signal. The external pull-up resistor should be in the range of 10k Ω to 200k Ω .

At V_{IN} values of less than typically 2V the $\overline{\text{RESET}}$ pin voltage will be high. For V_{IN} values between typically 2V and approximately $V_{\text{OUT}} + V_{\text{BE}}$ the $\overline{\text{RESET}}$ pin voltage will be low. For V_{IN} values greater than approximately $V_{\text{OUT}} + V_{\text{BE}}$ the $\overline{\text{RESET}}$ pin voltage will be dependent on the status of the OUT pin voltage and the Delayed Reset circuitry. The value of V_{BE} is typically 600mV at 25 $^{\circ}\text{C}$ and will decrease approximately 2mV for every 1 $^{\circ}\text{C}$ increase in the junction temperature. During normal operation the $\overline{\text{RESET}}$ pin voltage will be high.

Any load condition that causes the OUT pin voltage to drop below typically 89% of normal will activate the Delayed Reset circuit and the $\overline{\text{RESET}}$ pin will go low for the duration of the delay time.

Any line condition that causes IN pin voltage to drop below typically $V_{\text{OUT}} + V_{\text{BE}}$ will cause the $\overline{\text{RESET}}$ pin to go low without activating the Delayed Reset circuitry.

Excessive thermal dissipation will raise the junction temperature and could activate the Thermal Shutdown circuitry which, in turn, will cause the $\overline{\text{RESET}}$ pin to go low.

For the LM9076D, pulling the SHUTDOWN pin high will turn off the output which, in turn, will cause the $\overline{\text{RESET}}$ pin to go low once the V_{OUT} voltage has decayed to a value that is less than typically 89% of normal.

RESET DELAY TIME

When the regulator output is switched on, or after recovery from brief V_{OUT} fault condition, the \overline{RESET} flag can be programmed to remain low for an additional delay time. This will give time for any system reference voltages, clock signals, etc., to stabilize before the micro-controller resumes normal operation.

This delay time is controlled by the capacitor value on the DELAY pin. During normal operation the DELAY capacitor is charged to near V_{OUT} . When a V_{OUT} fault is removed, the V_{OUT} returns to the normal operating value, the DELAY capacitor begins charging at a typical constant $0.420\mu A$ rate. When the voltage on the DELAY capacitor reaches the same potential as the OUT pin the \overline{RESET} pin will be allowed to return high.

The typical \overline{RESET} delay time can be calculated with following formula:

$$t_{DELAY} = V_{OUT} \times (C_{DELAY} / I_{DELAY}) \quad (1)$$

For the LM9076-3.3 with a C_{DELAY} value of $0.001\mu F$ and a I_{DELAY} of $0.420\mu A$ the typical \overline{RESET} delay time is:

$$t_{DELAY} = 3.3V \times (0.001\mu F / 0.420\mu A) = 7.8ms \quad (2)$$

For the LM9076-5.0 with a C_{DELAY} value of $0.001\mu F$ and a I_{DELAY} value of $0.420\mu A$ the typical \overline{RESET} delay time is:

$$t_{DELAY} = 5.0V \times (0.001\mu F / 0.420\mu A) = 11.9ms \quad (3)$$

THERMAL PROTECTION

Device operational range is limited by the maximum junction temperature (T_J). The junction temperature is influenced by the ambient temperature (T_A), package selection, input voltage (V_{IN}), and the output load current. When operating with maximum load currents the input voltage and/or ambient temperature will be limited.

Even though the LM9076 is equipped with circuitry to protect itself from excessive thermal dissipation, it is not recommended that the LM9076 be operated at, or near, the maximum recommended die junction temperature (T_J) as this may impair long term device reliability.

The thermal protection circuitry monitors the temperature at the die level. When the die temperature exceeds typically $160^\circ C$ the voltage regulator output will be switched off.

REVISION NOTICE

The description in this datasheet is subject to change without any notice to describe its electrical characteristics properly.
