R_S = Source Resistance
 $R_1 \approx R_S$

Logic	Device	VCC (V)	RL kΩ
CMOS	1/4 MC14001	+15	100
TTL	1/4 MC7400	+5.0	10

These quad comparators feature high gain, wide bandwidth characteristics. This gives the device oscillation tendencies if the outputs are capacitively coupled to the inputs via stray capacitance. This oscillation manifests itself during output transitions (V_{OL} to V_{OH}). To alleviate this situation input resistors $< 10\text{ k}\Omega$ should be used. The addition

$T_1 = T_2 = 0.69 RC$

$f \approx \frac{7.2}{C(\mu F)}$

$R_2 = R_3 = R_4$

$R_1 \approx R_2 // R_3 // R_4$

应用信息

of positive feedback ($< 10\text{ mV}$) is also recommended. It is good design practice to ground all unused input pins.

Differential input voltages may be larger than supply voltages without damaging the comparator's inputs. Voltages more negative than -300 mV should not be used.

图 9 : 过零检测器 (Single Supply)

D1 prevents input from going negative by more than 0.6 V.

$R_1 + R_2 = R_3$

$R_3 \leq \frac{R_5}{10}$ for small error in zero crossing

图 10 : 过零检测器 (Split Supplies)

$V_{in(min)} \approx 0.4\text{ V peak for } 1\% \text{ phase distortion } (\Delta\Theta).$
