# IR3859MPbF 

## SupIRBuck ${ }^{\text {™ }}$

## HIGHLY EFFICIENT

## INTEGRATED 9A, SYNCHRONOUS BUCK REGULATOR

## Features

- Greater than 95\% Maximum Efficiency
- Wide Input Voltage Range 1.5 V to 21 V
- Wide Output Voltage Range 0.7 V to $0.9 *$ Vin
- Continuous 9A Load Capability
- Integrated Bootstrap-diode
- High Bandwidth E/A for excellent transient performance
- Programmable Switching Frequency up to 1.5 MHz
- Programmable Over Current Protection
- Over Voltage Protection
- Dedicated input for output voltage monitoring
- Programmable PGood output
- Hiccup Current Limit
- Precision Reference Voltage (0.7V, +/-1\%)
- Programmable Soft-Start
- Enable Input with Voltage Monitoring Capability
- Enhanced Pre-Bias Start-up
- Seq input for Tracking applications
- External Synchronization
- $-40^{\circ} \mathrm{C}$ to $125^{\circ} \mathrm{C}$ operating junction temperature
- Thermal Protection
- $4 \mathrm{~mm} \times 5 \mathrm{~mm}$ Power QFN Package
- Halogen Free, Lead Free and RoHS compliant

## Description

The IR3859 SupIRBuck ${ }^{\text {TM }}$ is an easy-to-use, fully integrated and highly efficient DC/DC synchronous Buck regulator. The MOSFETs copackaged with the on-chip PWM controller make IR3859 a space-efficient solution, providing accurate power delivery for low output voltage applications.

IR3859 is a versatile regulator which offers programmability of start up time, switching frequency and current limit while operating in wide input and output voltage range.

The switching frequency is programmable from 250 kHz to 1.5 MHz for an optimum solution.

It also features important protection functions, such as Pre-Bias startup, hiccup current limit and thermal shutdown to give required system level security in the event of fault conditions.

## Applications

- Server Applications
- Storage Applications
- Embedded Telecom Systems
- Distributed Point of Load Power Architectures
- Netcom Applications
- Computing Peripheral Voltage Regulators
- General DC-DC Converters

Fig. 1. Typical application diagram

```
ABSOLUTE MAXIMUM RATINGS
(Voltages referenced to GND unless otherwise specified)
- Vin -0.3 V to 25 V
- Vcc -0.3 V to 8 V (Note2)
- Boot -0.3 V to 33 V
- SW -0.3 V to \(25 \mathrm{~V}(\mathrm{DC}),-4 \mathrm{~V}\) to \(25 \mathrm{~V}(\mathrm{AC}, 100 \mathrm{~ns})\)
- Boot to SW -0.3 V to \(\mathrm{Vcc}+0.3 \mathrm{~V}\) (Note1)
- OCSet -0.3 V to 30 V (Max 30mA)
- Input / output Pins -0.3 V to \(\mathrm{Vcc}+0.3 \mathrm{~V}\) (Note1)
- PGND to GND -0.3 V to +0.3 V
- Storage Temperature Range \(-55^{\circ} \mathrm{C}\) То \(150^{\circ} \mathrm{C}\)
- Junction Temperature Range \(-40^{\circ} \mathrm{C}\) To \(150^{\circ} \mathrm{C}\) (Note2)
- ESD Classification JEDEC Class 1C
- Moisture sensitivity level JEDEC Level 3@260ํ.C (Note5)
```

## Note1: Must not exceed 8 V

Note2: Vcc must not exceed 7.5V for Junction Temperature between $-10^{\circ} \mathrm{C}$ and $-40^{\circ} \mathrm{C}$
Stresses beyond those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications are not implied.

## PACKAGE INFORMATION

$4 \mathrm{~mm} \times 5 \mathrm{~mm}$ POWER QFN

## ORDERING INFORMATION

| PACKAGE <br> DESIGNATOR | PACKAGE <br> DESCRIPTION | PIN COUNT | PARTS PER <br> REEL |
| :---: | :---: | :---: | :---: |
| $M$ | IR3859MTRPbF | 17 | 4000 |
| $M$ | IR3859MTR1PbF | 17 | 750 |

## Block Diagram

Fig. 2. Simplified block diagram of the IR3859

## Pin Description

| Pin | Name | Description |
| :---: | :---: | :---: |
| 1 | Fb | Inverting input to the error amplifier. This pin is connected directly to the output of the regulator via resistor divider to set the output voltage and provide feedback to the error amplifier. |
| 2 | Vsns | Sense pin for PGood |
| 3 | Comp | Output of error amplifier. An extemal resistor and capacitor network is typically connected from this pin to Fb pin to provide loop compensation. |
| 4;17 | Gnd | Signal ground for internal reference and control circuitry. |
| 5 | Rt | Set the switching frequency. Connect an external resistor from this pin to Gnd to set the switching frequency. See Table 1 for Fs vs. Rt. |
| 6 | SS/SD | Soft start / shutdown. This pin provides user programmable soft-start function. Connect an extemal capacitor from this pin to Gnd to set the start up time of the output voltage. The converter can be shutdown by pulling this pin below 0.3 V . |
| 7 | OCSet | Current limit set point. A resistor from this pin to SW pin will set the current limit threshold. |
| 8 | PGood | Power Good status pin. Output is open drain. Connect a pull up resistor from this pin to Vcc. |
| 9 | Sync | Sync pin, connect external system clock to synchronize multiple POLs with the same frequency |
| 10 | $\mathrm{V}_{\text {cc }}$ | This pin powers the internal IC and the drivers. A minimum of 1uF high frequency capacitor must be connected from this pin to the power ground (PGnd). |
| 11 | PGnd | Power Ground. This pin serves as a separated ground for the MOSFET drivers and should be connected to the system's power ground plane. |
| 12 | SW | Switch node. This pin is connected to the output inductor. |
| 13 | $\mathrm{V}_{\text {IN }}$ | Input voltage connection pin. |
| 14 | Boot | Supply voltage for high side driver. A 0.1 uF capacitor must be connected from this pin to SW. |
| 15 | Enable | Enable pin to turn on and off the device. Use two external resistors to set the tum on threshold (see Enable section). Connect this pin to Vcc if it is not used. |
| 16 | Seq | Sequence pin. Use two external resistors to set Simultaneous Power up sequencing. If this pin is not used connect to Vcc. |

## Circuit Description

## THEORY OF OPERATION

## Introduction

The IR3859 uses a PWM voltage mode control scheme with external compensation to provide good noise immunity and maximum flexibility in selecting inductor values and capacitor types.

The switching frequency is programmable from 250 kHz to 1.5 MHz and provides the capability of optimizing the design in terms of size and performance.

IR3859 provides precisely regulated output voltage programmed via two external resistors from 0.7 V to $0.9^{*} \mathrm{Vin}$.
The IR3859 operates with an external bias supply from 4.5 V to 5.5 V , allowing an extended operating input voltage range from 1.5 V to 21 V .

The device utilizes the on-resistance of the low side MOSFET as current sense element, this method enhances the converter's efficiency and reduces cost by eliminating the need for external current sense resistor.

IR3859 includes two low $R_{\text {ds(on) }}$ MOSFETs using IR's HEXFET technology. These are specifically designed for high efficiency applications.

## Under-Voltage Lockout and POR

The under-voltage lockout circuit monitors the input supply Vcc and the Enable input. It assures that the MOSFET driver outputs remain in the off state whenever either of these two signals drop below the set thresholds. Normal operation resumes once Vcc and Enable rise above their thresholds.
The POR (Power On Ready) signal is generated when all these signals reach the valid logic level (see system block diagram). When the POR is asserted the soft start sequence starts (see soft start section).

## Enable

The Enable features another level of flexibility for start up. The Enable has precise threshold which is internally monitored by Under-Voltage Lockout (UVLO) circuit. Therefore, the IR3859 will turn on only when the voltage at the Enable pin exceeds this threshold, typically, 1.2 V .

If the input to the Enable pin is derived from the bus voltage by a suitably programmed resistive divider, it can be ensured that the IR3859 does not turn on until the bus voltage reaches the desired level. Only after the bus voltage reaches or exceeds this level will the voltage at Enable pin exceed its threshold, thus enabling the IR3859. Therefore, in addition to being a logic input pin to enable the IR3859, the Enable feature, with its precise threshold, also allows the user to implement an Under-Voltage Lockout for the bus voltage $V_{i n}$. This is desirable particularly for high output voltage applications, where we might want the IR3859 to be disabled at least until $V_{\text {in }}$ exceeds the desired output voltage level.

Fig. 3a. Normal Start up, Device turns on when the Bus voltage reaches 10.2 V

Figure 3b. shows the recommended start-up sequence for the non-sequenced operation of IR3859, when Enable is used as a logic input.

Fig. 3b. Recommended startup sequence, Non-Sequenced operation

Figure 3c. shows the recommended startup sequence for sequenced operation of IR3859 with Enable used as logic input.

Fig. 3c. Recommended startup sequence, Sequenced operation

## Pre-Bias Startup

IR3859 is able to start up into pre-charged output, which prevents oscillation and disturbances of the output voltage.
The output starts in asynchronous fashion and keeps the synchronous MOSFET off until the first gate signal for control MOSFET is generated. Figure 4 shows a typical Pre-Bias condition at start up.
The synchronous MOSFET always starts with a narrow pulse width and gradually increases its duty cycle with a step of $25 \%, 50 \%, 75 \%$ and $100 \%$ until it reaches the steady state value. The number of these startup pulses for the synchronous MOSFET is internally programmed. Figure 5 shows a series of $32,16,8$ startup pulses.

Fig. 4. Pre-Bias startup

Fig. 5. Pre-Bias startup pulses

## Soft-Start

The IR3859 has a programmable soft-start to control the output voltage rise and to limit the current surge at the start-up. To ensure correct start-up, the soft-start sequence initiates when the Enable and Vcc rise above their UVLO thresholds and generate the Power On Ready (POR) signal. The internal current source (typically 20uA) charges the external capacitor $\mathrm{C}_{\mathrm{ss}}$ linearly from VV to 3 V . Figure 6 shows the waveforms during the soft start.
The start up time can be estimated by:

$$
\begin{equation*}
T_{\text {start }}=\frac{(1.4-0.7) * C_{\mathrm{Ss}}}{20 \mu \mathrm{~A}} \tag{1}
\end{equation*}
$$

During the soft start the OCP is enabled to protect the device for any short circuit and over current condition.

Fig. 6. Theoretical operation waveforms during soft-start

## Operating Frequency

The switching frequency can be programmed between $250 \mathrm{kHz}-1500 \mathrm{kHz}$ by connecting an external resistor from $R_{t}$ pin to Gnd. Table 1 tabulates the oscillator frequency versus $\mathrm{R}_{\mathrm{t}}$.

Table 1. Switching Frequency and $\mathrm{I}_{\text {ocset }}$ vs. External Resistor $\left(R_{t}\right)$

| $\boldsymbol{R}_{\boldsymbol{t}}(\mathbf{k} \boldsymbol{\Omega})$ | $\boldsymbol{F}_{\boldsymbol{s}}(\mathbf{k H z})$ | $I_{\text {ocset }}(\boldsymbol{\mu \mathrm { A } )}$ |
| :--- | :--- | :--- |
| 47.5 | 300 | 29.4 |
| 35.7 | 400 | 39.2 |
| 28.7 | 500 | 48.7 |
| 23.7 | 600 | 59.07 |
| 20.5 | 700 | 68.2 |
| 17.8 | 800 | 78.6 |
| 15.8 | 900 | 88.6 |
| 14.3 | 1000 | 97.9 |
| 12.7 | 1100 | 110.2 |
| 11.5 | 1200 | 121.7 |
| 10.7 | 1300 | 130.8 |
| 9.76 | 1400 | 143.4 |
| 9.31 | 1500 | 150.3 |

## Shutdown

The IR3859 can be shutdown by pulling the Enable pin below its 1 V threshold. This will tristate both, the high side driver as well as the low side driver. Alternatively, the output can be shutdown by pulling the soft-start pin below 0.3 V . Normal operation is resumed by cycling the voltage at the Soft Start pin.

## Over-Current Protection

The over current protection is performed by sensing current through the $\mathrm{R}_{\mathrm{DS}(\text { on })}$ of low side MOSFET. This method enhances the converter's efficiency and reduces cost by eliminating a current sense resistor. As shown in figure 7, an external resistor ( $\mathrm{R}_{\mathrm{Ocset}}$ ) is connected between OCSet pin and the switch node (SW) which sets the current limit set point.

An internal current source sources current (locset ) out of the OCSet pin. This current is a function of Rt and hence, of the free-running switching frequency.

$$
\begin{equation*}
I_{\text {OCSet }}(\mu \mathrm{A})=\frac{1400}{R_{t}(\mathrm{k} \Omega)} \tag{2}
\end{equation*}
$$

Table 1. shows $l_{\text {Ocset }}$ at different switching frequencies. The internal current source develops a voltage across $R_{\text {Ocset }}$. When the low side MOSFET is turned on, the inductor current flows through the Q2 and results in a voltage at OCSet which is given by:

$$
\begin{equation*}
V_{\mathrm{OCSet}}=\left(I_{\mathrm{OCSet}} * R_{\mathrm{OCSet}}\right)-\left(R_{D S(o n)} * I_{L}\right) . \tag{3}
\end{equation*}
$$

Fig. 7. Connection of over current sensing resistor
An over current is detected if the OCSet pin goes below ground. Hence, at the current limit threshold, $V_{\text {OCset }}=0$. Then, for a current limit setting $I_{\text {Limit }}, R_{\text {Ocset }}$ is calculated as follows:

$$
\begin{equation*}
R_{\mathrm{OCSet}}=\frac{R_{D S(\text { on })} * I_{\text {Limit }}}{I_{\text {OCSet }}} \tag{4}
\end{equation*}
$$

An overcurrent detection trips the OCP comparator, latches OCP signal and cycles the soft start function in hiccup mode.
The hiccup is performed by shorting the soft-start capacitor to ground and counting the number of switching cycles. The Soft Start pin is held low until 4096 cycles have been completed. The OCP signal resets and the converter recovers. After every soft start cycle, the converter stays in this mode until the overload or short circuit is removed.
The OCP circuit starts sampling current typically 160 ns after the low gate drive rises to about 3 V . This delay functions to filter out switching noise.

## Thermal Shutdown

Temperature sensing is provided inside IR3859. The trip threshold is typically set to $140^{\circ} \mathrm{C}$. When trip threshold is exceeded, thermal shutdown turns off both MOSFETs and discharges the soft start capacitor.

Automatic restart is initiated when the sensed temperature drops within the operating range. There is a $20^{\circ} \mathrm{C}$ hysteresis in the thermal shutdown threshold.

## Output Voltage Sequencing

The IR3859 can accommodate user programmable sequencing options using Seq, Enable and Power Good pins.

Fig. 8a. Simultaneous Power-up of the slave with respect to the master.

Through these pins, voltage sequencing such as simultaneous and sequential can be implemented. Figure 8. shows simultaneous sequencing configurations. In simultaneous power-up, the voltage at the Seq pin of the slave reaches 0.7 V before the Fb pin of the master. For $\mathbf{R}_{\mathrm{E}} / \mathbf{R}_{\mathbf{F}}=\mathbf{R}_{\mathrm{C}} / \mathbf{R}_{\mathrm{D}}$, therefore, the output voltage of the slave follows that of the master until the voltage at the Seq pin of the slave reaches 0.7 V . After the voltage at the Seq pin of the slave exceeds 0.85 V , the internal 0.7 V reference of the slave dictates its output voltage.

Fig. 8b. Application Circuit for Simultaneous Sequencing

## Power-Good and Over-voltage Protection

The $V_{\text {sns }}$ pin forms an input to a window comparator whose upper and lower thresholds are 0.805 V and 0.595 V , respectively. Hence, the Power Good signal is flagged when the $\mathrm{V}_{\text {sns }}$ pin voltage is within the PGood window, i.e. between 0.595 V to 0.805 V , as shown in figure 9 . The PGood pin is open drain and it needs to be externally pulled high. High state indicates that output is in regulation. Figure 9a shows the PGood timing diagram for non-tracking operation. In this case, during startup, PGood goes high after the SS voltage reaches 2.1 V if the Vsns voltage is within the PGood comparator window. Figure 9.a and Figure 9.b also show a 256 cycle delay between the Vsns voltage entering within the thresholds defined by the PGood window and PGood going high.

If the output voltage exceeds the over voltage threshold, an over voltage trip signal asserts, this will result to turn off the high side driver and turn on the low side driver until the Vsns voltage drops below 1.15*Vref threshold. Both drivers are latched off until a reset performed by cycling either Vcc or Enable.
The OVP threshold can be externally programmed to user defined value. Figure 10 shows the response in over-voltage condition.

TIMING DIAGRAM OF PGOOD FUNCTION

Fig.9a IR3859 Non-Tracking Operation (Seq=Vcc)

Fig.9b IR3859 Tracking Operation

## TIMING DIAGRAM OF Over Voltage Protection

After Vsns gets above the Over Voltage threshold, upper Switch stays off and lower switch stays ON as long as the Vsns voltage is above the over voltage threshold. (i.e. from point $A$ to point $B$ ). After point $B$, both switched stays off till /POR recycles.

Fig. 10 IR3859 Over Voltage Timing Diagram

## External Synchronization

The IR3859 incorporates an internal circuit which enables synchronization of the internal oscillator (using rising edge) to an external clock. An external resistor from Rt pin to Gnd is still required to set the free-running frequency close to the Sync input frequency. This function is important to avoid sub-harmonic oscillations due to beat frequency for embedded systems when multiple POL (point of load) regulators are used. The synchronization clock can be applied during IR3859 normal operation or before IR3859 startup. In any case, IR3859 will perform with the external after the end of the PreBias cycle.
Applying the external signal to the Sync input changes the effective value of the ramp signal (Vramp/Vosc).
$V_{\text {OSC }(\text { eff })}=1.8 \times f_{\text {Free_Run }} / f_{\text {Sync }}$
Equation (5) shows that the effective amplitude of the ramp $\left(\mathrm{V}_{\text {osc(eff) }}\right)$ is reduced after the external Sync signal is applied. More difference between
the frequency of the Sync ( $\mathrm{f}_{\text {Sync }}$ ) and the freerunning frequency ( $\mathrm{f}_{\text {Free Run }}$ ) results in more change in the effective amplitude of the ramp signal.
Therefore, since the ramp amplitude takes part in calculating the loop-gain and bandwidth of the regulator, it is recommended not to use a Sync frequency which is much higher than the freerunning frequency. In addition, the effective value of the ramp signal, given by equation (5), should be used when the compensator is designed for the regulator.
The pulse width of the external clock, which is applied to the sync, should be greater than 100ns and its high level should be greater than 2 V , while its lower level is less than 0.6 V . If this pin is left floating, the IC will run with the free running frequency set by the resistor Rt.

## Minimum on time Considerations

The minimum ON time is the shortest amount of time for which the Control FET may be reliably turned on, and this depends on the internal timing delays. For the IR3859, the typical minimum on-time is specified as 50 ns .
Any design or application using the IR3859 must ensure operation with a pulse width that is higher than this minimum on-time and preferably higher than 100 ns. This is necessary for the circuit to operate without jitter and pulse-skipping, which can cause high inductor current ripple and high output voltage ripple.

$$
\begin{aligned}
t_{\text {on }} & =\frac{D}{F_{s}} \\
& =\frac{V_{\text {out }}}{V_{\text {in }} \times F_{s}}
\end{aligned}
$$

In any application that uses the IR3859, the following condition must be satisfied:

$$
\begin{aligned}
& t_{\text {on }(\text { min })} \leq t_{\text {on }} \\
& \therefore t_{\text {on }(\text { min })} \leq \frac{V_{\text {out }}}{V_{\text {in }} \times F_{s}} \\
& \therefore V_{\text {in }} \times F_{s} \leq \frac{V_{\text {out }}}{t_{\text {on (min })}}
\end{aligned}
$$

The minimum output voltage is limited by the reference voltage and hence $\mathrm{V}_{\text {out(min) }}=0.7 \mathrm{~V}$. Therefore, for $\mathrm{V}_{\text {out(min) }}=0.7 \mathrm{~V}$,

$$
\begin{aligned}
& \therefore \mathrm{V}_{\text {in }} \times F_{\text {s }} \leq \frac{V_{\text {out (min) }}}{t_{\text {on (min) }}} \\
& \therefore \mathrm{V}_{\text {in }} \times F_{s} \leq \frac{0.7 \mathrm{~V}}{100 \mathrm{~ns}}=7 \times 10^{6} \mathrm{~V} / \mathrm{s}
\end{aligned}
$$

Therefore, at the maximum recommended input voltage 21 V and minimum output voltage, the converter should be designed at a switching frequency that does not exceed 333 kHz . Conversely, for operation at the maximum recommended operating frequency 1.65 MHz and minimum output voltage, any voltage above 4.2 V may not be stepped down without pulseskipping.

## Maximum Duty Ratio Considerations

A fixed off-time of 200 ns maximum is specified for the IR3859. This provides an upper limit on the operating duty ratio at any given switching frequency. It is clear, that higher the switching frequency, the lower is the maximum duty ratio at which the IR3859 can operate. To allow a margin of 50 ns , the maximum operating duty ratio in any application using the IR3859 should still accommodate about 250 ns off-time. Fig 10. shows a plot of the maximum duty ratio $\mathrm{v} / \mathrm{s}$ the switching frequency, with 250 ns off-time.

Fig. 11. Maximum duty cycle v/s switching frequency.

## Application Information

## Design Example:

The following example is a typical application for IR3859. The application circuit is shown on page 25.

$$
\begin{aligned}
& V_{\text {in }}=12 \mathrm{~V}(13.2 \mathrm{~V} \text { max }) \\
& V_{o}=1.8 \mathrm{~V} \\
& I_{o}=9 \mathrm{~A} \\
& \Delta V_{o} \leqslant \pm 5 \% \text { of } \mathrm{V}_{o} \\
& F_{s}=600 \mathrm{kHz}
\end{aligned}
$$

## Enabling the IR3859

As explained earlier, the precise threshold of the Enable lends itself well to implementation of a UVLO for the Bus Voltage.

For a maximum Enable threshold of $\mathrm{V}_{\mathrm{EN}}=1.36 \mathrm{~V}$

$$
\begin{gather*}
V_{i n(\min )} * \frac{R_{2}}{R_{1}+R_{2}}=V_{E N}=1.36 \mathrm{~V} \ldots  \tag{6}\\
R_{2}=R_{1} \frac{V_{E N}}{V_{i n(\text { min })}-V_{E N}} \ldots \ldots \ldots(7
\end{gather*}
$$

For a $V_{\text {in }(\mathrm{min})}=10.2 \mathrm{~V}, \mathrm{R}_{1}=49.9 \mathrm{~K}$ and $\mathrm{R}_{2}=7.5 \mathrm{~K}$ is a good choice.

## Programming the frequency

For $F_{s}=600 \mathrm{kHz}$, select $R_{t}=23.7 \mathrm{k} \Omega$, using Table. 1.

## Output Voltage Programming

Output voltage is programmed by reference voltage and external voltage divider. The Fb pin is the inverting input of the error amplifier, which is internally referenced to 0.7 V . The divider is ratioed to provide 0.7 V at the Fb pin when the output is at its desired value. The output voltage is defined by using the following equation:

$$
\begin{equation*}
V_{o}=V_{r e f} *\left(1+\frac{R_{8}}{R_{9}}\right) \tag{8}
\end{equation*}
$$

When an external resistor divider is connected to the output as shown in figure 12.
Equation (6) can be rewritten as:

$$
\begin{equation*}
R_{9}=R_{8} *\left(\frac{V_{r e f}}{V_{o}-V_{r e f}}\right) \tag{9}
\end{equation*}
$$

For the calculated values of R8 and R9 see feedback compensation section.

Fig. 12. Typical application of the IR3859 for programming the output voltage

## Soft-Start Programming

The soft-start timing can be programmed by selecting the soft-start capacitance value. From (1), for a desired start-up time of the converter, the soft start capacitor can be calculated by using:

$$
\begin{equation*}
C_{S S}(\mu \mathrm{~F})=T_{\text {start }}(\mathrm{ms}) \times 0.02857 \tag{10}
\end{equation*}
$$

Where $T_{\text {start }}$ is the desired start-up time (ms).
For a start-up time of 3.5 ms , the soft-start capacitor will be $0.099 \mu \mathrm{~F}$. Choose a $0.1 \mu \mathrm{~F}$ ceramic capacitor.

## Bootstrap Capacitor Selection

To drive the Control FET, it is necessary to supply a gate voltage at least 4 V greater than the voltage at the SW pin, which is connected the source of the Control FET. This is achieved by using a bootstrap configuration, which comprises the internal bootstrap diode and an external bootstrap capacitor (C6), as shown in Fig. 13. The operation of the circuit is as follows: When the lower MOSFET is turned on, the capacitor node connected to SW is pulled down to ground. The capacitor charges towards $V_{c c}$ through the internal bootstrap diode, which has a forward voltage drop $V_{D}$. The voltage $V_{c}$ across the bootstrap capacitor C6 is approximately given as

$$
\begin{equation*}
V_{c} \cong V_{c c}-V_{D} \tag{11}
\end{equation*}
$$

When the upper MOSFET turns on in the next cycle, the capacitor node connected to SW rises to the bus voltage $V_{i n}$. However, if the value of C6 is appropriately chosen, the voltage Vc
across C6 remains approximately unchanged and the voltage at the Boot pin becomes:

$$
\begin{equation*}
V_{\text {Boot }} \cong V_{i n}+V_{c C}-V_{D} \tag{12}
\end{equation*}
$$

Fig. 13. Bootstrap circuit to generate Vc voltage

A bootstrap capacitor of value 0.1 uF is suitable for most applications.

## Input Capacitor Selection

The ripple current generated during the on time of the upper MOSFET should be provided by the input capacitor. The RMS value of this ripple is expressed by:

$$
\begin{equation*}
I_{R M S}=I_{O} * \sqrt{D *(1-D)} \tag{13}
\end{equation*}
$$

$$
\begin{equation*}
D=\frac{V_{0}}{V_{i n}} \tag{14}
\end{equation*}
$$

Where:
$D$ is the Duty Cycle
$I_{R M S}$ is the RMS value of the input capacitor current.
lo is the output current.
For $I_{0}=9 \mathrm{~A}$ and $D=0.15$, the $I_{R M S}=3.21 \mathrm{~A}$.
Ceramic capacitors are recommended due to their peak current capabilities. They also feature low ESR and ESL at higher frequency which enables better efficiency. For this application, it is advisable to have $4 \times 10 \mathrm{uF} 25 \mathrm{~V}$ ceramic capacitors C3216X5R1E106M from TDK. In addition to these, although not mandatory, a $1 \mathrm{X} 330 \mathrm{uF}, 25 \mathrm{~V}$ SMD capacitor EEV-FK1E331P may also be used as a bulk capacitor and is recommended if the input power supply is not located close to the converter.

## Inductor Selection

The inductor is selected based on output power, operating frequency and efficiency requirements. A low inductor value causes large ripple current, resulting in the smaller size, faster response to a load transient but poor efficiency and high output noise. Generally, the selection of the inductor value can be reduced to the desired maximum ripple current in the inductor ( $\Delta i$ ) . The optimum point is usually found between $20 \%$ and $50 \%$ ripple of the output current.
For the buck converter, the inductor value for the desired operating ripple current can be determined using the following relation:

$$
\begin{gather*}
V_{i n}-V_{o}=L * \frac{\Delta i}{\Delta t} ; \quad \Delta t=D * \frac{1}{F_{s}}  \tag{15}\\
L=\left(V_{i n}-V_{o}\right) * \frac{V_{o}}{V_{i n} * \Delta i^{*} F_{s}}
\end{gather*}
$$

Where:

$$
\begin{aligned}
& V_{i n}=\text { Maximum input voltage } \\
& V_{o}=\text { Output Voltage } \\
& \Delta i=\text { Inductor ripple current } \\
& F_{s}=\text { Switching frequency } \\
& \Delta t=\text { Turn on time } \\
& D=\text { Duty cycle }
\end{aligned}
$$

If $\Delta i \approx 42 \%\left(I_{o}\right)$, then the output inductor is calculated to be $0.69 \mu \mathrm{H}$. Select $L=0.68 \mu \mathrm{H}$.
The ETQP4LR68XFC from Panasonic provides a compact inductor suitable for this application.

## Output Capacitor Selection

The voltage ripple and transient requirements determine the output capacitors type and values. The criteria is normally based on the value of the Effective Series Resistance (ESR). However the actual capacitance value and the Equivalent Series Inductance (ESL) are other contributing components. These components can be described as

$$
\begin{gather*}
\Delta V_{o}=\Delta V_{o(E S R)}+\Delta V_{o(E S L)}+\Delta V_{o(C)} \\
\Delta V_{o(E S R)}=\Delta I_{L}{ }^{*} E S R \\
\Delta V_{o(E S L)}=\left(\frac{V_{\text {in }}-V_{o}}{L}\right) * E S L \\
\Delta V_{o(C)}=\frac{\Delta I_{L}}{8{ }^{*} C_{o}^{*} F_{S}}  \tag{16}\\
\Delta V_{o}=\text { Output voltage ripple } \\
\Delta I_{L}=\text { Inductor ripple current }
\end{gather*}
$$

Since the output capacitor has a major role in the overall performance of the converter and determines the result of transient response, selection of the capacitor is critical. The IR3859 can perform well with all types of capacitors.
As a rule, the capacitor must have low enough ESR to meet output ripple and load transient requirements.
The goal for this design is to meet the voltage ripple requirement in the smallest possible capacitor size. Therefore it is advisable to select ceramic capacitors due to their low ESR and ESL and small size. Six of the TDK C2102X5R0J226M (22uF, 6.3V, 3mOhm) capacitors is a good choice.

## Feedback Compensation

The IR3859 is a voltage mode controller. The control loop is a single voltage feedback path including error amplifier and error comparator. To achieve fast transient response and accurate output regulation, a compensation circuit is necessary. The goal of the compensation network is to provide a closed-loop transfer function with the highest 0 dB crossing frequency and adequate phase margin (greater than $45^{\circ}$ ).

The output LC filter introduces a double pole, $-40 \mathrm{~dB} /$ decade gain slope above its corner resonant frequency, and a total phase lag of $180^{\circ}$ (see figure 13). The resonant frequency of the LC filter is expressed as follows:

$$
\begin{equation*}
F_{L C}=\frac{1}{2 * \pi \sqrt{L_{0} * C_{0}}} \tag{17}
\end{equation*}
$$

Figure 14 shows gain and phase of the LC filter. Since we already have $180^{\circ}$ phase shift from the output filter alone, the system runs the risk of being unstable.

Fig. 14. Gain and Phase of LC filter

The IR3859 uses a voltage-type error amplifier with high-gain ( 110 dB ) and wide-bandwidth. The output of the amplifier is available for DC gain control and AC phase compensation.
The error amplifier can be compensated either in Type-II or Type-III compensation.
Local feedback with Type-II compensation is shown in figure 14.
This method requires that the output capacitor should have enough ESR to satisfy stability requirements. In general, for Type-II compensation the output capacitor's ESR generates a zero typically at 5 kHz to 50 kHz which is essential for an acceptable phase margin.
The ESR zero of the output capacitor is expressed as follows:

$$
\begin{equation*}
F_{E S R}=\frac{1}{2 * \pi^{*} E S R^{*} C_{0}} \tag{18}
\end{equation*}
$$

Fig. 15. Type II compensation network and its asymptotic gain plot

The transfer function $\left(V_{e} / V_{o}\right)$ is given by:

$$
\begin{equation*}
\frac{V_{e}}{V_{o}}=H(s)=-\frac{Z_{f}}{Z_{I N}}=-\frac{1+s R_{3} C_{4}}{s R_{8} C_{4}} \tag{19}
\end{equation*}
$$

The (s) indicates that the transfer function varies as a function of frequency. This configuration introduces a gain and zero, expressed by:

$$
\begin{align*}
& |H(s)|=\frac{R_{3}}{R_{8}} \ldots \ldots  \tag{20}\\
& F_{z}=\frac{1}{2 \pi^{*} R_{3}{ }^{*} C_{4}} \tag{21}
\end{align*}
$$

First select the desired zero-crossover frequency $\left(F_{o}\right)$ :

$$
F_{o}>F_{E S R} \text { and } F_{o} \leq(1 / 5 \sim 1 / 10)^{*} F_{s}
$$

Use the following equation to calculate R3:

$$
\begin{equation*}
R_{3}=\frac{V_{o S C}{ }^{*} F_{o}{ }^{*} F_{E S R}{ }^{*} R_{8}}{V_{i n}{ }^{*} F_{L C}^{2}} \tag{22}
\end{equation*}
$$

Where:
$V_{\text {in }}=$ Maximum Input Voltage
$V_{\text {osc }}=$ Oscillator Ramp Voltage
$F_{o}=$ Crossover Frequency
$F_{E S R}=$ Zero Frequency of the Output Capacitor
$F_{L C}=$ Resonant Frequency of the Output Filter
$R_{8}=$ Feedback Resistor
To cancel one of the LC filter poles, place the zero before the LC filter resonant frequency pole:

$$
\begin{align*}
& F_{z}=75 \% F_{L C} \\
& F_{z}=0.75^{*} \frac{1}{2 \pi \sqrt{L_{o}{ }^{*} C_{o}}} . \tag{23}
\end{align*}
$$

Use equations (21), (22) and (23) to calculate C4.
One more capacitor is sometimes added in parallel with C4 and R3. This introduces one more pole which is mainly used to suppress the switching noise.
The additional pole is given by:

$$
\begin{equation*}
F_{P}=\frac{1}{2 \pi * R_{3} * \frac{C_{4} * C_{P O L E}}{C_{4}+C_{P O L E}}} \tag{24}
\end{equation*}
$$

The pole sets to one half of the switching frequency which results in the capacitor $\mathrm{C}_{\text {POLE }}$ :

$$
\begin{equation*}
C_{P O L E}=\frac{1}{\pi^{*} R_{3}{ }^{*} F_{s}-\frac{1}{C_{4}}} \cong \frac{1}{\pi^{*} R_{3}{ }^{*} F_{s}} \ldots \tag{25}
\end{equation*}
$$

For a general solution for unconditional stability for any type of output capacitors, and a wide range of ESR values, we should implement local feedback with a Type-III compensation network. The typically used compensation network for voltage-mode controller is shown in figure 16.
Again, the transfer function is given by:

$$
\frac{V_{e}}{V_{o}}=H(s)=-\frac{Z_{f}}{Z_{I N}}
$$

By replacing $Z_{i n}$ and $Z_{f}$ according to figure 16 , the transfer function can be expressed as:
$H(s)=\frac{-\left(1+s R_{3} C_{4}\right)\left[1+s C_{7}\left(R_{8}+R_{10}\right)\right]}{s R_{8}\left(C_{4}+C_{3}\right)\left[1+s R_{3}\left(\frac{C_{4}{ }^{*} C_{3}}{C_{4}+C_{3}}\right)\right]\left(1+s R_{10} C_{7}\right)}$

Fig.16. Type III Compensation network and its asymptotic gain plot

The compensation network has three poles and two zeros and they are expressed as follows:

$$
\begin{align*}
& F_{P_{1}}=0  \tag{27}\\
& F_{P 2}=\frac{1}{2 \pi^{*} R_{10}{ }^{*} C_{7}} .  \tag{28}\\
& F_{P 3}=\frac{1}{2 \pi * R_{3}\left(\frac{C_{4}{ }^{*} C_{3}}{C_{4}+C_{3}}\right)} \cong \frac{1}{2 \pi * R_{3}{ }^{*} C_{3}} .  \tag{29}\\
& F_{Z 1}=\frac{1}{2 \pi^{*} R_{3}{ }^{*} C_{1}} \text {.. }  \tag{30}\\
& F_{Z 2}=\frac{1}{2 \pi^{*} C_{7}{ }^{*}\left(R_{8}+R_{10}\right)} \cong \frac{1}{2 \pi^{*} C_{7}{ }^{*} R_{8}} . \tag{31}
\end{align*}
$$

Cross over frequency is expressed as:
$F_{o}=R_{3}{ }^{*} C_{7} * \frac{V_{\text {in }}}{V_{\text {osc }}} * \frac{1}{2 \pi * L_{o}{ }^{*} C_{o}}$.
Based on the frequency of the zero generated by the output capacitor and its ESR, relative to crossover frequency, the compensation type can be different. The table below shows the compensation types for relative locations of the crossover frequency.

| Compensator <br> Type | $F_{\text {ESR }}$ vs $F_{o}$ | Output <br> Capacitor |
| :---: | :---: | :---: |
| Type II | $F_{\mathrm{LC}}<\mathrm{F}_{\mathrm{ESR}}<\mathrm{F}_{\mathrm{o}}<\mathrm{F}_{\mathrm{s}} / 2$ | Electrolytic <br> Tantalum |
| Type III | $\mathrm{F}_{\mathrm{LC}}<\mathrm{F}_{\mathrm{o}}<\mathrm{F}_{\mathrm{ESR}}$ | Tantalum <br> Ceramic |

The higher the crossover frequency, the potentially faster the load transient response. However, the crossover frequency should be low enough to allow attenuation of switching noise. Typically, the control loop bandwidth or crossover frequency is selected such that

$$
F_{o} \leq(1 / 5 \sim 1 / 10)^{*} F_{s}
$$

The DC gain should be large enough to provide high DC-regulation accuracy. The phase margin should be greater than $45^{\circ}$ for overall stability.

For this design we have:
$V_{\text {in }}=12 \mathrm{~V}$
$\mathrm{V}_{0}=1.8 \mathrm{~V}$
$\mathrm{V}_{\text {osc }}=1.8 \mathrm{~V}$
$V_{\text {ref }}=0.7 \mathrm{~V}$
$\mathrm{L}_{\mathrm{o}}=0.68 \mathrm{uH}$
$\mathrm{C}_{\mathrm{o}}=6 \times 22 \mathrm{uF}, \mathrm{ESR}=3 \mathrm{mOhm}$ each
It must be noted here that the value of the capacitance used in the compensator design must be the small signal value. For instance, the small signal capacitance of the 22uF capacitor used in this design (i.e. C3216X5R1E106M from TDK) is 9.5 uF at 1.8 VDC bias and 600 kHz frequency. It is this value that must be used for all computations related to the compensation. The small signal value may be obtained from the manufacturer's datasheets, design tools or SPICE models. Alternatively, they may also be inferred from measuring the power stage transfer function of the converter and measuring the double pole frequency $F_{L C}$ and using equation (16) to compute the small signal $C_{o}$.

These result to:
$F_{L C}=25.5 \mathrm{kHz}$
$F_{E S R}=5.5 \mathrm{MHz}$
$F_{s} / 2=300 \mathrm{kHz}$

## Select crossover frequency $\boldsymbol{F}_{\mathbf{o}} \mathbf{= 1 0 0} \mathbf{~ k H z}$

Since $F_{L C}<F_{o}<F_{s} / 2<F_{E S R}$, Type-III is selected to place the pole and zeros.

Detailed calculation of compensation Type-III
Desired Phase Margin $\Theta=70^{\circ}$
$F_{Z 2}=F_{o} \sqrt{\frac{1-\sin \Theta}{1+\sin \Theta}}=17.63 \mathrm{kHz}$
$F_{P 2}=F_{o} \sqrt{\frac{1+\sin \Theta}{1-\sin \Theta}}=567.1 \mathrm{kHz}$
Select $F_{Z 1}=0.5^{*} F_{Z 2}=8.82 \mathrm{kHz}$ and
$F_{P 3}=0.5^{*} F_{s}=300 \mathrm{kHz}$
Select $\mathrm{C}_{7}=2.2 \mathrm{nF}$
Calculate $R_{3}, C_{3}$ and $C_{4}$ :
$R_{3}=\frac{2 \pi{ }^{*} F_{o}{ }^{*} L_{o}{ }^{*} C_{o}{ }^{*} V_{\text {osc }}}{C_{7}{ }^{*} V_{\text {in }}} ; R_{3}=1.66 \mathrm{k} \Omega$
Select: $R_{3}=1.65 \mathrm{k} \Omega$
$C_{4}=\frac{1}{2 \pi^{*} F_{Z 1}{ }^{*} R_{3}} ; C_{4}=10.94 \mathrm{nF}$, Select $C_{4}=10 \mathrm{nF}$
$C_{3}=\frac{1}{2 \pi^{*} F_{P 3}{ }^{*} R_{3}} ; C_{3}=321 \mathrm{pF}$, Select $C_{3}=270 \mathrm{pF}$
Calculate $R_{10}, R_{8}$ and $R_{9}$ :
$R_{10}=\frac{1}{2 \pi^{*} C_{7}{ }^{*} F_{P 2}} ; \quad R_{10}=128 \Omega$, Select $R_{10}=130 \Omega$
$R_{8}=\frac{1}{2 \pi{ }^{*} C_{7}{ }^{*} F_{Z 2}}-R_{10} ; R_{8}=3.97 \mathrm{k} \Omega$,
Select $R_{8}=4.02 \mathrm{k} \Omega$
$R_{9}=\frac{V_{\text {ref }}}{V_{o}-V_{\text {ref }}} * R_{8} ; R_{9}=2.56 \mathrm{k} \Omega$ Select $R_{9}=2.55 \mathrm{k} \Omega$

## Programming the Current-Limit

The Current-Limit threshold can be set by connecting a resistor ( $\mathrm{R}_{\mathrm{OCSET}}$ ) from the SW pin to the OCSet pin. The resistor can be calculated by using equation (4). This resistor $\mathrm{R}_{\text {OCSET }}$ must be placed close to the IC.
The $R_{D S(o n)}$ has a positive temperature coefficient and it should be considered for the worst case operation.

$$
\begin{equation*}
I_{S E T}=I_{L(\text { critical })}=\frac{R_{\text {OCSet }} * I_{\text {OCSet }}}{R_{D S(\text { on })}} \tag{32}
\end{equation*}
$$

$$
\begin{aligned}
& R_{D S(\text { on })}=11 \mathrm{~m} \Omega * 1.25=13.75 \mathrm{~m} \Omega \\
& I_{S E T} \cong I_{o(L I M)}=9 \mathrm{~A} * 1.5=13.5 \mathrm{~A} \\
& (50 \% \text { over nominal output current ) } \\
& \left.I_{\text {OCSet }}=59.07 \mu \mathrm{~A} \quad \text { (at } F_{s}=600 \mathrm{kHz}\right) \\
& R_{\text {OCSet }}=3.14 \mathrm{k} \Omega \text { Select } R_{7}=3.16 \mathrm{k} \Omega
\end{aligned}
$$

## Setting the Power Good Threshold

Power Good threshold can be programmed by using two external resistors (R5, R7 on Page 24).

The following formula can be used to set the threshold:

$$
\begin{equation*}
R_{6}=\left(\frac{V_{o\left(P G o o d \_T H\right)}}{0.85^{*} V_{\text {ref }}}-1\right) * R_{7} \tag{33}
\end{equation*}
$$

Where: $0.85^{*} V$ ref is reference of the internal comparator, for IR3859.
$\mathrm{V}_{\mathrm{o} \text { (PGood_TH) }}$ is the selectable output voltage threshold for power good, for this design it is 1.53 V (i.e. $0.85^{* 1.8 V}$ ).

Select $R_{7}=2.55 \mathrm{KOhm}$
Using (24): $R_{5}=3.97 \mathrm{KOhm}$
Select $R_{6}=4.02 \mathrm{KOhm}$
The PGood is an open drain output. Hence, it is necessary to use a pull up resistor $R_{P G}$ from PGood pin to Vcc. The value of the pull-up resistor must be chosen such as to limit the current flowing into the PGood pin, when the output voltage is not in regulation, to less than 5 mA . A typical value used is $10 \mathrm{k} \Omega$.

## Application Diagram:

Fig. 17. Application circuit diagram for a 12 V to $1.8 \mathrm{~V}, 9 \mathrm{~A}$ Point Of Load Converter

Suggested Bill of Materials for the application circuit:

| Part Reference | Quantity | Value | Description | Manufacturer | Part Number |

## Layout Considerations

The layout is very important when designing high frequency switching converters. Layout will affect noise pickup and can cause a good design to perform with less than expected results.
Make all the connections for the power components in the top layer with wide, copper filled areas or polygons. In general, it is desirable to make proper use of power planes and polygons for power distribution and heat dissipation.
The inductor, output capacitors and the IR3859 should be as close to each other as possible. This helps to reduce the EMI radiated by the power traces due to the high switching currents through them. Place the input capacitor directly at the Vin pin of IR3859.
The feedback part of the system should be kept away from the inductor and other noise sources.
The critical bypass components such as capacitors for Vcc should be close to their respective pins. It is important to place the feedback components including feedback resistors and compensation components close to Fb and Comp pins.

The connection between the OCSet resistor and the SW pin should not share any trace with the connection between the bootstrap capacitor and the SW pin. Instead, it is recommended to use a Kelvin connection of the trace from the OCSet resistor and the trace from the bootstrap capacitor at the SW pin.
In a multilayer PCB use one layer as a power ground plane and have a control circuit ground (analog ground), to which all signals are referenced. The goal is to localize the high current path to a separate loop that does not interfere with the more sensitive analog control function. These two grounds must be connected together on the PC board layout at a single point. The Power QFN is a thermally enhanced package. Based on thermal performance it is recommended to use at least a 4-layers PCB. To effectively remove heat from the device the exposed pad should be connected to the ground plane using vias. Figure 28 illustrates the implementation of the layout guidelines outlined above, on the IRDC3859 4 layer demoboard.

Fig. 28a. IRDC3859 demoboard layout considerations - Top Layer

Single point connection between AGND \& PGND; It should be close to the SupIRBuck, kept away from noise sources.

Fig. 28b. IRDC3859 demoboard layout considerations - Bottom Layer

Fig. 28c. IRDC3859 demoboard layout considerations - Mid Layer 1

Use separate trace for connecting Boost cap and Rocset to the switch node and with the minimum length traces. Avoid big loops.

Feedback trace should be kept away form noise sources

Fig. 28d. IRDC3859 demoboard layout considerations - Mid Layer 2

## PCB Metal and Components Placement

Evaluations have shown that the best overall performance is achieved using the substrate/PCB layout as shown in following figures. PQFN devices should be placed to an accuracy of 0.050 mm on both $X$ and Y axes. Self-centering behavior is highly dependent on solders and processes, and experiments should be run to confirm the limits of self-centering on specific processes. For further information, please refer to "SupIRBuck ${ }^{\text {TM }}$ Multi-Chip Module (MCM) Power Quad Flat No-Lead (PQFN) Board Mounting Application Note." (AN-1132)

PCB metal pad spacing (all dimensions in mm)

## Solder Resist

IR recommends that the larger Power or Land Area pads are Solder Mask Defined (SMD.) This allows the underlying Copper traces to be as large as possible, which helps in terms of current carrying capability and device cooling capability.

When using SMD pads, the underlying copper traces should be at least 0.05 mm larger (on each edge) than the Solder Mask window, in order to accommodate any layer to layer misalignment. (i.e. 0.1 mm in X \& Y.)

However, for the smaller Signal type leads around the edge of the device, IR recommends that these are Non Solder Mask Defined or Copper Defined.

When using NSMD pads, the Solder Resist Window should be larger than the Copper Pad by at least 0.025 mm on each edge, (i.e. 0.05 mm in $\mathrm{X} \mathrm{\& Y}$,) in order to accommodate any layer to layer misalignment.

Ensure that the solder resist in-between the smaller signal lead areas are at least 0.15 mm wide, due to the high $\mathrm{x} / \mathrm{y}$ aspect ratio of the solder mask strip.

All Dimensions in mm

## Stencil Design

Stencils for PQFN can be used with thicknesses of 0.100-0.250mm (0.004-0.010"). Stencils thinner than 0.100 mm are unsuitable because they deposit insufficient solder paste to make good solder joints with the ground pad; high reductions sometimes create similar problems. Stencils in the range of $0.125 \mathrm{~mm}-0.200 \mathrm{~mm}(0.005-0.008$ "), with suitable reductions, give the best results.

Evaluations have shown that the best overall performance is achieved using the stencil design shown in following figure. This design is for a stencil thickness of $0.127 \mathrm{~mm}\left(0.005{ }^{\prime \prime}\right)$. The reduction should be adjusted for stencils of other thicknesses.
