## Dynamic Differential Hall Effect Sensor

## Data Sheet Version 1.1

## Features

- High sensitivity
- Single chip solution
- Symmetrical thresholds
- High resistance to Piezo effects
- South and north pole pre-induction possible
- Low cut-off frequency
- Digital output signal
- Advanced performance by dynamic self calibration principle
- Two-wire and three-wire configuration possible
- Wide operating temperature range
- Fast start-up time
- Large operating air-gaps
- Reverse voltage protection at Vs- PIN
- Short- circuit and over temperature protection of output
- Digital output signal (voltage interface)
- Module style package with two integrated capacitors:
- 4.7nF between Q and GND
- $47 \mathrm{nF}^{1}$ between $\mathrm{V}_{\mathrm{S}}$ and GND: Needed for micro cuts in power supply

| Type | Marking | Ordering Code | Package |
| :---: | :---: | :---: | :---: |
| TLE4926C-HT E6547 | $26 D 8$ | SP000718258 | PG-SSO-3-92 |

[^0]
## General Information

The TLE4926C-HT E6547 is an active Hall sensor suited to detect the motion and position of ferromagnetic and permanent magnet structures. An additional self-calibration module has been implemented to achieve optimum accuracy during normal running operation. It comes in a three-pin package for the supply voltage and an open drain output.

Figure 1: Pin configuration PG-SSO-3-92

Pin definition and Function

| Pin No. | Symbol | Function |
| :--- | :--- | :--- |
| 1 | $V_{\mathrm{S}}$ | Supply Voltage |
| 2 | GND | Ground |
| 3 | Q | Open Drain Output |

## Functional Description

The differential Hall sensor IC detects the motion and position of ferromagnetic and permanent magnet structures by measuring the differential flux density of the magnetic field. To detect ferromagnetic objects the magnetic field must be provided by a back biasing permanent magnet (south or north pole of the magnet attached to the rear unmarked side of the IC package).

Offset cancellation is achieved by advanced digital signal processing. Immediately after power-on motion is detected (start-up mode). After a few transitions the sensor has finished self-calibration and switches to a highaccuracy mode (running mode). In running mode switching occurs at signal zerocrossing of the arithmetic mean of max and min value of magnetic differential signal. $\Delta \mathrm{B}$ is defined as difference between hall plate 1 and hall plate 2.

Figure 2: Block diagram of TLE4926C-HT E6547

## Circuit Description

The TLE4926C-HT E6547 is comprised of a supply voltage regulator, a pair of hall probes, spaced at 2.5 mm , differential amplifier, noise-shaping filter, comparator, advanced digital signal processor (DSP), A/D and D/A converter and an open drain output.

Startup mode:
The differential signal is digitized in the A/D converter and fed into the dsp part of the circuit. There a rising or falling transition is detected and the output stage is triggered accordingly. As the signal is not offset compensated at this time, the output does not necessarily switch at zero-crossing of the magnetic signal. Signal peaks are also detected in the digital circuit and their arithmetic mean value can be calculated. The offset of this mean value is determined and fed into the offset
cancellation DAC. This procedure can be repeated with increasing accuracy. After few increments the IC is switched into the high accuracy running mode.

## Running mode:

In running mode the output is triggered by the comparator. An offset cancellation feedback loop is formed by the A/D converter, dsp and offset cancellation D/A converter. In running mode switching always occurs at zero-crossing. It is only affected by the (small) remaining offset of the comparator and by the remaining propagation delay time of the signal path, mainly determined by the noiseshaping filter. Nevertheless signals below a defined threshold are not detected to avoid unwanted parasitic switching.

Figure 3: Startup of the device
At transition from startup-mode to running mode switching timing is moving from low-accuracy to high accuracy zero-crossing.

### 1.1 Absolute Maximum Ratings

| No. | Parameter | Symbol | min | Typ | max | Unit | Remarks |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 1.1.1 | Supply voltage | $\mathrm{V}_{\mathrm{s}}$ | $\begin{aligned} & -18 \\ & -24 \\ & -26 \\ & -28 \end{aligned}$ |  | $\begin{aligned} & 18 \\ & 24 \\ & 26 \\ & 28 \end{aligned}$ | $\begin{aligned} & \mathrm{V} \\ & \mathrm{~V} \\ & \mathrm{~V} \\ & \mathrm{~V} \end{aligned}$ | 1 h with $\mathrm{R}_{\text {series }} \geq 200 \Omega^{2}$ <br> 5 min with $\mathrm{R}_{\text {series }} \geq 200 \Omega^{2}$ <br> 1 min with $R_{\text {Series }} \geq 200 \Omega^{2}$ |
| 1.1.2 | Supply current | Is | -10 |  | 25 | mA |  |
| 1.1.3 | Output OFF voltage | $V_{Q}$ | $\begin{aligned} & -0.3 \\ & -18 \\ & -18 \\ & -1.0 \end{aligned}$ |  | $\begin{aligned} & 18 \\ & 24 \\ & 26 \end{aligned}$ | $\begin{aligned} & \mathrm{V} \\ & \mathrm{~V} \\ & \mathrm{~V} \\ & \mathrm{~V} \end{aligned}$ | 1h with $R_{\text {Load }} \geq 500 \Omega$ 5 min with $\mathrm{R}_{\text {Load }} \geq 500 \Omega$ 1 h (protected by internal series resistor) |
| 1.1.4 | Output ON voltage | $V_{Q}$ |  |  | 16 <br> 18 <br> 24 | V <br> V <br> V | Current internal limited by short circuit protection ( $72 \mathrm{~h} @ \mathrm{~T}_{\mathrm{A}}<40^{\circ} \mathrm{C}$ ). Current internal limited by short circuit protection (1h @ $\mathrm{T}_{\mathrm{A}}<40^{\circ} \mathrm{C}$ ). <br> Current internal limited by short circuit protection $\left(1 \min @ T_{A}<40^{\circ} \mathrm{C}\right)$. |
| 1.1.5 | Continuous output current | $\mathrm{I}_{0}$ | -50 |  | 50 | mA | - |
| 1.1.6 | Junction temperature | $\mathrm{T}_{\mathrm{j}}$ | -40 |  | $\begin{aligned} & 155 \\ & 165 \\ & 175 \\ & 195 \end{aligned}$ | $\begin{aligned} & { }^{\circ} \mathrm{C} \\ & { }^{\circ} \mathrm{C} \\ & { }^{\circ} \mathrm{C} \\ & { }^{\circ} \mathrm{C} \\ & { }^{\circ} \mathrm{C} \end{aligned}$ | 5000h (not additive) 2500h (not additive) 500 h (not additive) $10 \times 1 \mathrm{~h}$ (additive to the other life times). |
| 1.1.7 | Storage temperature | Ts | -40 |  | 150 | ${ }^{\circ} \mathrm{C}$ | - |
| 1.1.8 | Thermal resistance junction-air for PG-SSO-3-92 | $\mathrm{R}_{\text {th JA }}$ |  |  | 190 | K/W | Lower values are possible with overmoulded devices. |

Note: Stresses above those listed here may cause permanent damage to the device. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

[^1]1.2 ESD Protection

| No. | Parameter | Symbol |  | $\max$ | Unit | Remarks |
| :---: | :---: | :---: | :---: | :---: | :---: | :--- |
| 1.2.1 | ESD - protection <br> PG-SSO-3-92 | $\mathrm{V}_{\text {ESD }}$ |  | $\pm 6$ | kV | According to standard <br> EIA/JESD22-A114-B <br> Human Body Model <br> (HBM 1500 Ohm/100pF) |

### 2.1 Operating Range

| No. | Parameter | Symbol | min | typ | max | Unit | Remarks |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :--- |
| 2.1.1 | Supply voltage | $\mathrm{V}_{\mathrm{S}}$ | 3.2 |  | 18 | V | Continuous |
|  |  |  |  |  |  |  |  |

[^2]| 2.1.6 | Operating junction <br> temperature | $\mathrm{T}_{\mathrm{j}}$ | -40 |  |  | ${ }^{\circ} \mathrm{C}$ | - |
| :--- | :---: | :---: | :--- | :--- | :--- | :--- | :--- |
|  |  |  |  |  | 155 | ${ }^{\circ} \mathrm{C}$ | 5000 h (not additive) |
|  |  |  |  | 165 | ${ }^{\circ} \mathrm{C}$ | 2500 h (not additive) |  |
|  |  |  |  | 175 | ${ }^{\circ} \mathrm{C}$ | 500 h (not additive) <br> reduced signal <br> quality permittable <br> (e.g. jitter) |  |

Note: Unless otherwise noted, all temperatures refer to junction temperature. For the supply voltage lower than $28 \mathrm{~V}\left(\mathrm{R}_{\text {Series }} \geq 200 \Omega\right)$ and junction temperature lower than $195^{\circ} \mathrm{C}$ the magnetic and $A C / D C$ characteristics can exceed the specification limits.

### 2.2 AC/DC Characteristics

Over operating range, unless otherwise specified. Typical values correspond to $\mathrm{V}_{\mathrm{s}}=12 \mathrm{~V}$ and $\mathrm{T}_{\mathrm{A}}=25^{\circ} \mathrm{C}$

| No. | Parameter | Symbol | min | typ | max | Unit | Remarks |

measurement condition: $\mathrm{n} \geq 1000$
Figure 5 Definition of signal jitter

## Application Configurations

Two possible applications are shown in Figure 8 and Figure 9 (Toothed and Magnet Wheel).
The difference between two-wire and three-wire application is shown in Figure 10.

## Gear Tooth Sensing

In the case of ferromagnetic toothed wheel application the IC has to be biased by the south or north pole of a permanent magnet (e.g. $\mathrm{SmCO}_{5}$ (Vacuumschmelze VX145)) with the dimensions $8 \mathrm{~mm} \times 5 \mathrm{~mm} \times 3 \mathrm{~mm}$ ) which should cover both Hall probes.
The maximum air gap depends on

- the magnetic field strength (magnet used; pre-induction) and
- the toothed wheel that is used (dimensions, material, etc.; resulting differential field).
a centered distance of Hall probes
b Hall probes to IC surface
L IC surface to tooth wheel
$\mathrm{a}=2.5 \mathrm{~mm}$
$\mathrm{b}=0.3 \mathrm{~mm}$

Figure 6 Sensor spacing

Figure 7 Toothed wheel dimensions

Figure 8 TLE4926C-HT E6547, with ferromagnetic toothed wheel

Figure 9 TLE4926C-HT E6547, with magnet wheel

Figure 10 Application circuits TLE4926C-HT E6547 (capacitors included in package)

Enabling point for releasing output: $\mathrm{B} 1-\mathrm{B} 2<\Delta \mathrm{B}_{\mathrm{ENRP}}$. Next zero crossing switches the output OFF ( $\mathrm{V}_{\mathrm{Q}}=\mathrm{HIGH}$ ).
Enabling point for operate point: B1-B2> B $_{\text {ENOP }}$. Next zero crossing switches the output $\mathrm{ON}\left(\mathrm{V}_{\mathrm{Q}}=\mathrm{LOW}\right)$.
$\Delta \mathrm{B}_{\mathrm{HYS}}=\left|\Delta \mathrm{B}_{\text {ENOP }}-\Delta \mathrm{B}_{\text {ENRP }}\right|$
Outside of a permanent magnet the magnetic induction (=flux density) points from north to the south pole. It is common to define positive flux if the south pole of a magnet is on the branded side of the IC. This is equivalent to the north pole of the magnet on the rear side of the IC.

Figure 11 System operation with hidden hysteresis

Appendix: Calculation of mechanical errors:

## Systematic Phase Error $\varphi$

The systematic error comes in because of the delay-time between the threshold point and the time when the output is switching. It can be calculated as follows:

$$
\varphi=\frac{360^{\circ} \bullet n}{60} \bullet t_{d}
$$

... systematic phase error in ${ }^{\circ}$
n $\quad$... speed of the camshaft-wheel in $\mathrm{min}^{-1}$
$t_{d} \quad .$. delay time (see specification) in sec

## Systematic Phase Error $\Delta \varphi$

The systematic phase error includes the error due to the variation of the delay time with temperature and the error caused by the resolution of the threshold. It can be calculated in the following way:

$$
\Delta \varphi_{d}=\frac{360^{\circ} \bullet n}{60} \bullet \Delta t_{d}
$$

$\Delta \varphi_{\mathrm{d}} \quad \ldots$ systematic phase error due to the variation of the delay time over temperature in ${ }^{\circ}$
n $\quad$... speed of the camshaft wheel in $\mathrm{min}^{-1}$
$\Delta t_{d} \quad$... variation of delay time over temperature in sec

## Jitter (Repeatability)

The phase jitter is normally caused by the analogue system noise. If there is an update of the offset-DAC due to the algorithm, what could happen after each tooth, then an additional step in the phase occurs (see description of the algorithm). This is not included in the following calculations. The noise is transformed through the slope of the magnetic edge into a phase error. The phase jitter is determined by the two formulas:

Figure 13: Phase-Jitter

$$
\varphi_{\text {Jitter_typ }}=\frac{\partial \varphi}{\partial B} \bullet\left(B_{\text {neff_typ }}\right)
$$

|  |  | $\varphi_{\text {Jitter_max }}=\frac{\partial \varphi}{\partial B} \bullet\left(B_{\text {neff_max }}\right)$ |
| :--- | :--- | :--- |

## Example:

```
Assumption:
\(\mathrm{n}=4500 \mathrm{~min}^{-1}\)
\(\mathrm{t}_{\mathrm{d}}=14 \mu \mathrm{~s}\)
\(\Delta \mathrm{t}_{\mathrm{d}}= \pm 3 \mu \mathrm{~s}\)
\(\frac{\partial B}{\partial \varphi}=3 \mathrm{mT} /{ }^{\circ}\)
\(\mathrm{B}_{\text {neff_typ }}= \pm 40 \mu \mathrm{~T} \quad\left(1 \sigma\right.\)-value at \(\left.\mathrm{Tj}=25^{\circ} \mathrm{C}\right)\)
\(\mathrm{B}_{\text {neff_max }}= \pm 210 \mu \mathrm{~T}\left(3 \sigma\right.\)-value at \(\left.\mathrm{Tj}=175^{\circ} \mathrm{C}\right)\)
```

| Calculation: | $\varphi=0.378^{\circ}$ | $\ldots$ | systematic phase error |
| :--- | :--- | :--- | :--- |
| variation | $\Delta \varphi_{\mathrm{d}}= \pm 0.081^{\circ}$ | $\ldots$ | systematic phase error due to delay time |
|  |  |  |  |
|  | $\varphi_{\text {Jiter_typ }}= \pm 0.013^{\circ}$ | $\ldots$ | typical phase jitter $\left(1 \sigma\right.$-value at $\left.\mathrm{Tj}=25^{\circ} \mathrm{C}\right)$ |
|  | $\varphi_{\text {Jitter_max }}= \pm 0.07^{\circ}$ | $\ldots$ | maximum phase jitter $\left(3 \sigma\right.$-value at $\left.\mathrm{Tj}=175^{\circ} \mathrm{C}\right)$ |

$\Delta B_{P P}=4 \mathrm{mT}$ (ideal sinusoidal signal); $\mathrm{V}_{\mathrm{S}}=13.5 \mathrm{~V} \pm 0,5 \mathrm{~V}, \mathrm{f}_{\mathrm{B}}=200 \mathrm{~Hz} ; \mathrm{T}=25^{\circ} \mathrm{C} ; \mathrm{R}_{\text {Series }} \geq 200 \Omega$;

| No. | Parameter | Symbol | Level $/ \mathrm{max}$ | Remarks |
| :---: | :---: | :---: | :---: | :---: |
| 4.1 .3 | EMC field strength | ЕТЕм-Cell $^{\text {IV } / 200 \mathrm{~V} / \mathrm{m}}$ | AM $=80 \%, \mathrm{f}=1 \mathrm{kHz} ;$ |  |

Note: Stresses above those listed here may cause permanent damage to the device. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.
Test condition for the trigger window: $f_{B-\text {-field }}=200 \mathrm{~Hz}, B_{p p}=4 m T$, vertical limits are $\pm 10 \%$ of $V_{Q}$ and horizontal limits are $\pm 200 \mu \mathrm{~s}$.

## Appendix A: Package information:

Pure tin covering (green lead plating) is used. Product is RoHS (Restriction of Hazardous Substances) compliant and marked with letter G in front of the data code marking and may contain a data matrix code on the rear side of the package (see also information note 136/03). Please refer to your key account team or regional sales if your need further information.

[^0]:    ${ }^{1}$ value of capacitor: $47 n F \pm 10 \%$; (excluded drift due to temperature and over lifetime); ceramic: X8R; maximum voltage: 50V.

[^1]:    ${ }^{2}$ Accumulated life time.

[^2]:    ${ }^{3}$ Output of the IC is locked in present state (high-state or low-state) after an internal reset is launched. This reset happens typically every 780 ms when there is no output switching in either case. See also 2.2.14. A voltage reset causes a release of the output and output is in high state after power on again.

[^3]:    ${ }^{4}$ value of capacitor: $4.7 \mathrm{nF} \pm 10 \%$; (excluded drift due to temperature); ceramic: X 8 R ; maximum voltage: 50 V . The rise time is defined as the time between the 10 and $90 \%$ value.

[^4]:    ${ }^{5}$ see footnote 4.
    ${ }_{7}^{6}$ only valid for the falling edge.
    ${ }^{7}$ Not subject to production test-verified by design/characterisation
    ${ }^{8}$ measured with a sinusoidal-field with 10 mTpp and a frequency of 1 kHz .
    ${ }^{9}$ related to $\mathrm{Tj}=175^{\circ} \mathrm{C}$.
    ${ }^{10}$ output will switch if magnetic signal is changing more that $2 \mathrm{x}\left|\Delta \mathrm{B}_{\text {min }}\right|$ within offset recalibration time even below 1 Hz once per magnetic edge, increased phase error is possible

[^5]:    ${ }^{11}|\Delta \mathrm{Bmin}|$ refers to $50 \%$ criteria: $50 \%$ of output pulses are lost, sinusoidal input signal
    ${ }^{12}$ exceeding this limit might result in decreased duty cycle performance. With higher values the internal measured signal will be clipped. This will decrease the phase accuracy.
    ${ }^{13}$ this corresponds to a $\Delta \mathrm{B}_{0}=0 \mathrm{mT}$ (magnetic offset).

[^6]:    ${ }^{16}$ Output signal overlayed by burst pulse
    ${ }^{17}$ Suppressed $\mathrm{U}_{\mathrm{s}}{ }^{*}=35 \mathrm{~V}$
