## 2.2.1 Package Pin Summary

The following general scheme is used to describe each pin:

**Table 8 Package Pin Mapping Description**

Function	Package A	Package B	...	Pad Type	Notes
Name	N	Ax	...	A2	

The table is sorted by the “Function” column, starting with the regular Port pins (Px.y), followed by the dedicated pins (i.e. PORST) and supply pins.

The following columns, titled with the supported package variants, lists the package pin number to which the respective function is mapped in that package.

The “Pad Type” indicates the employed pad type (A1, A1+, A2, special=special pad, In=input pad, AN/DIG\_IN=analog and digital input, Power=power supply). Details about the pad properties are defined in the Electrical Parameters.

In the “Notes”, special information to the respective pin/function is given, i.e. deviations from the default configuration after reset. Per default the regular Port pins are configured as direct input with no internal pull device active.

### 2.2.2 Port I/O Functions

The following general scheme is used to describe each Port pin:

**Table 10 Port I/O Function Description**

Function	Outputs			Inputs		
	ALT1	ALn	HWO0	HWIO	Input	Input
P0.0		MODA.OUT	MODB.OUT	MODB.INA	MODC.INA	
Pn.y	MODA.OUT				MODA.INA	MODC.INB

**Figure 8 Simplified Port Structure**

Pn.y is the port pin name, defining the control and data bits/registers associated with it. As GPIO, the port is under software control. Its input value is read via Pn\_IN.y, Pn\_OUT defines the output value.

Up to four alternate output functions (ALT1/2/3/4) can be mapped to a single port pin, selected by Pn\_IOCR.PC. The output value is directly driven by the respective module, with the pin characteristics controlled by the port registers (within the limits of the connected pad).

The port pin input can be connected to multiple peripherals. Most peripherals have an input multiplexer to select between different possible input sources.

The input path is also active while the pin is configured as output. This allows to feedback an output to on-chip resources without wasting an additional external pin.

By Pn\_HWSEL it is possible to select between different hardware “masters” (HWO0/HWIO, HWO1/HWI1). The selected peripheral can take control of the pin(s). Hardware control overrules settings in the respective port pin registers.

### 2.3 Power Connection Scheme

Figure 9. shows a reference power connection scheme for the XMC4500.

**Figure 9 Power Connection Scheme**

Every power supply pin needs to be connected. Different pins of the same supply need also to be externally connected. As example, all  $V_{DDP}$  pins must be connected externally to one  $V_{DDP}$  net. In this reference scheme one 100 nF capacitor is connected at each supply pin against  $V_{SS}$ . An additional 10  $\mu$ F capacitor is connected to the  $V_{DDP}$  nets and an additional 10  $\mu$ F capacitor to the  $V_{DDC}$  nets.

The XMC4500 has a common ground concept, all  $V_{SS}$ ,  $V_{SSA}$  and  $V_{SSO}$  pins share the same ground potential. In packages with an exposed die pad it must be connected to the common ground as well.

$V_{AGND}$  is the low potential to the analog reference  $V_{AREF}$ . Depending on the application it can share the common ground or have a different potential.

When  $V_{DDP}$  is supplied,  $V_{BAT}$  must be supplied as well. If no other supply source (e.g. battery) is connected to  $V_{BAT}$ , the  $V_{BAT}$  pin can also be connected directly to  $V_{DDP}$ .

## **3 Electrical Parameters**

### **3.1 General Parameters**

#### **3.1.1 Parameter Interpretation**

The parameters listed in this section partly represent the characteristics of the XMC4500 and partly its requirements on the system. To aid interpreting the parameters easily when evaluating them for a design, they are marked with a two-letter abbreviation in column "Symbol":

- **CC**  
Such parameters indicate **C**ontroller **C**haracteristics, which are a distinctive feature of the XMC4500 and must be regarded for system design.
- **SR**  
Such parameters indicate **S**ystem **R**equirements, which must be provided by the application system in which the XMC4500 is designed in.

### 3.1.2 Absolute Maximum Ratings

Stresses above the values listed under “Absolute Maximum Ratings” may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions may affect device reliability.

**Table 12 Absolute Maximum Rating Parameters**

Parameter	Symbol		Values			Unit	Note / Test Condition
			Min.	Typ.	Max.		
Storage temperature	$T_{ST}$	SR	-65	–	150	°C	–
Junction temperature	$T_J$	SR	-40	–	150	°C	–
Voltage at 3.3 V power supply pins with respect to $V_{SS}$	$V_{DDP}$	SR	–	–	4.3	V	–
Voltage on any Class A and dedicated input pin with respect to $V_{SS}$	$V_{IN}$	SR	-1.0	–	$V_{DDP} + 1.0$ or max. 4.3	V	whichever is lower
Voltage on any analog input pin with respect to $V_{AGND}$	$V_{AIN}$ $V_{AREF}$	SR	-1.0	–	$V_{DDP} + 1.0$ or max. 4.3	V	whichever is lower
Input current on any pin during overload condition	$I_{IN}$	SR	-10	–	+10	mA	
Absolute maximum sum of all input circuit currents for one port group during overload condition <sup>1)</sup>	$\Sigma I_{IN}$	SR	-25	–	+25	mA	
Absolute maximum sum of all input circuit currents during overload condition	$\Sigma I_{IN}$	SR	-100	–	+100	mA	

1) The port groups are defined in [Table 16](#).

**Figure 10** explains the input voltage ranges of  $V_{IN}$  and  $V_{AIN}$  and its dependency to the supply level of  $V_{DDP}$ . The input voltage must not exceed 4.3 V, and it must not be more than 1.0 V above  $V_{DDP}$ . For the range up to  $V_{DDP} + 1.0$  V also see the definition of the overload conditions in [Section 3.1.3](#).

Figure 10 Absolute Maximum Input Voltage Ranges

### 3.1.3 Pin Reliability in Overload

When receiving signals from higher voltage devices, low-voltage devices experience overload currents and voltages that go beyond their own IO power supplies specification.

**Table 13** defines overload conditions that will not cause any negative reliability impact if all the following conditions are met:

- full operation life-time is not exceeded
- **Operating Conditions** are met for
  - pad supply levels ( $V_{DDP}$  or  $V_{DDA}$ )
  - temperature

If a pin current is outside of the **Operating Conditions** but within the overload conditions, then the parameters of this pin as stated in the Operating Conditions can no longer be guaranteed. Operation is still possible in most cases but with relaxed parameters.

*Note: An overload condition on one or more pins does not require a reset.*

*Note: A series resistor at the pin to limit the current to the maximum permitted overload current is sufficient to handle failure situations like short to battery.*

**Table 13**      **Overload Parameters**

Parameter	Symbol		Values			Unit	Note / Test Condition
			Min.	Typ.	Max.		
Input current on any port pin during overload condition	$I_{OV}$	SR	-5	–	5	mA	
Absolute sum of all input circuit currents for one port group during overload condition <sup>1)</sup>	$I_{OVG}$	SR	–	–	20	mA	$\Sigma I_{OVx} $ , for all $I_{OVx} < 0$ mA
			–	–	20	mA	$\Sigma I_{OVx} $ , for all $I_{OVx} > 0$ mA
Absolute sum of all input circuit currents during overload condition	$I_{OVs}$	SR	–	–	80	mA	$\Sigma I_{OVG}$

1) The port groups are defined in [Table 16](#).

**Figure 11** shows the path of the input currents during overload via the ESD protection structures. The diodes against  $V_{DDP}$  and ground are a simplified representation of these ESD protection structures.

**Figure 11**      **Input Overload Current via ESD structures**

[Table 14](#) and [Table 15](#) list input voltages that can be reached under overload conditions. Note that the absolute maximum input voltages as defined in the [Absolute Maximum Ratings](#) must not be exceeded during overload.

1) See also the Supply Monitoring thresholds, [Section 3.3.2](#).

2) Voltage overshoot to 4.0 V is permissible at Power-Up and  $\overline{PORST}$  low, provided the pulse duration is less than 100  $\mu$ s and the cumulated sum of the pulses does not exceed 1 h over lifetime.

3) To start the hibernate domain it is required that  $V_{BAT} \geq 2.1$  V, for a reliable start of the oscillation of RTC\_XTAL in crystal mode it is required that  $V_{BAT} \geq 3.0$  V.

4) The port groups are defined in [Table 16](#).

## 3.2 DC Parameters

### 3.2.1 Input/Output Pins

The digital input stage of the shared analog/digital input pins is identical to the input stage of the standard digital input/output pins.

The Pull-up on the PORST pin is identical to the Pull-up on the standard digital input/output pins.

*Note: These parameters are not subject to production test, but verified by design and/or characterization.*

PORST pull-down current	$ I_{PPD} $ CC	13	–	mA	$V_{IN} = 1.0 \text{ V}$

1) Current required to override the pull device with the opposite logic level (“force current”).

With active pull device, at load currents between force and keep current the input state is undefined.

2) Load current at which the pull device still maintains the valid logic level (“keep current”).

With active pull device, at load currents between force and keep current the input state is undefined.

3) Hysteresis is implemented to avoid metastable states and switching due to internal ground bounce. It can not be guaranteed that it suppresses switching due to external system noise.

**Figure 13 Pull Device Input Characteristics**

**Figure 13** visualizes the input characteristics with an active internal pull device:

- in the cases “A” the internal pull device is overridden by a strong external driver;
- in the cases “B” the internal pull device defines the input logical state against a weak external load.

- 1) A running conversion may become imprecise in case the normal conditions are violated (voltage overshoot).
- 2) If the analog reference voltage is below  $V_{DDA}$ , then the ADC converter errors increase. If the reference voltage is reduced by the factor  $k$  ( $k < 1$ ), TUE, DNL, INL, Gain, and Offset errors increase also by the factor  $1/k$ .
- 3) The leakage current definition is a continuous function, as shown in figure ADCx Analog Inputs Leakage. The numerical values defined determine the characteristic points of the given continuous linear approximation - they do not define step function (see [Figure 16](#)).
- 4) The sampling capacity of the conversion C-network is pre-charged to  $V_{AREF}/2$  before the sampling moment. Because of the parasitic elements, the voltage measured at AINx can deviate from  $V_{AREF}/2$ .
- 5) Applies to AINx, when used as alternate reference input.
- 6) This represents an equivalent switched capacitance. This capacitance is not switched to the reference voltage at once. Instead, smaller capacitances are successively switched to the reference voltage.
- 7) For 10-bit conversions, the errors are reduced to 1/4; for 8-bit conversions, the errors are reduced to 1/16. Never less than  $\pm 1$  LSB.
- 8) The sum of DNL/INL/GAIN/OFF errors does not exceed the related total unadjusted error TUE.

**Electrical Parameters**

- 9) This parameter is valid for soldered devices and requires careful analog board design.
- 10) Resulting worst case combined error is arithmetic combination of TUE and  $EN_{RMS}$ .
- 11) Value is defined for one sigma Gauss distribution.
- 12) The resulting current for a conversion can be calculated with  $I_{AREF} = Q_{CONV} / t_c$ .  
The fastest 12-bit post-calibrated conversion of  $t_c = 550$  ns results in a typical average current of  $I_{AREF} = 54.5 \mu A$ .

**Figure 14 VADC Reference Voltage Range**

The power-up calibration of the VADC requires a maximum number of  $4 \cdot 352 \cdot f_{ADCI}$  cycles.

**Figure 15 VADC Input Circuits**

**Figure 16 VADC Analog Input Leakage Current**

**Conversion Time**

**Table 24 Conversion Time (Operating Conditions apply)**

Parameter	Symbol	Values	Unit	Note
Conversion time	$t_C$ CC	$2 \times T_{ADC} + (2 + N + STC + PC + DM) \times T_{ADCI}$	$\mu\text{s}$	N = 8, 10, 12 for N-bit conversion $T_{ADC} = 1 / f_{PERIPH}$ $T_{ADCI} = 1 / f_{ADCI}$

- STC defines additional clock cycles to extend the sample time
- PC adds two cycles if post-calibration is enabled
- DM adds one cycle for an extended conversion time of the MSB

**Conversion Time Examples**

System assumptions:

$f_{ADC} = 120 \text{ MHz}$  i.e.  $t_{ADC} = 8.33 \text{ ns}$ ,  $DIVA = 3$ ,  $f_{ADCI} = 30 \text{ MHz}$  i.e.  $t_{ADCI} = 33.3 \text{ ns}$

According to the given formulas the following minimum conversion times can be achieved (STC = 0, DM = 0):

12-bit post-calibrated conversion (PC = 2):

$t_{CN12C} = (2 + 12 + 2) \times t_{ADCI} + 2 \times t_{ADC} = 16 \times 33.3 \text{ ns} + 2 \times 8.33 \text{ ns} = 550 \text{ ns}$

12-bit uncalibrated conversion:

$t_{CN12} = (2 + 12) \times t_{ADCI} + 2 \times t_{ADC} = 14 \times 33.3 \text{ ns} + 2 \times 8.33 \text{ ns} = 483 \text{ ns}$

10-bit uncalibrated conversion:

$t_{CN10} = (2 + 10) \times t_{ADCI} + 2 \times t_{ADC} = 12 \times 33.3 \text{ ns} + 2 \times 8.33 \text{ ns} = 417 \text{ ns}$

8-bit uncalibrated:

$t_{CN8} = (2 + 8) \times t_{ADCI} + 2 \times t_{ADC} = 10 \times 33.3 \text{ ns} + 2 \times 8.33 \text{ ns} = 350 \text{ ns}$

2) The external oscillator circuitry must be optimized by the customer and checked for negative resistance and amplitude as recommended and specified by crystal suppliers.

- 4) If the shaper unit is enabled and not bypassed.
- 5) If the shaper unit is bypassed, dedicated DC-thresholds have to be met.
- 6) Hysteresis is implemented to avoid metastable states and switching due to internal ground bounce. It can not be guaranteed that it suppresses switching due to external system noise.

$$t_{ODLY\_F} + t_{DATA\_DELAY} + t_{TAP\_DELAY} + t_{ISU} < t_{WL}$$

With clock delay:

$$t_{ODLY\_F} + t_{DATA\_DELAY} + t_{TAP\_DELAY} + t_{ISU} < t_{WL} + t_{CLK\_DELAY} \quad (2)$$

$$t_{DATA\_DELAY} + t_{TAP\_DELAY} + t_{WL} < t_{PP} + t_{CLK\_DELAY} - t_{ISU} - t_{ODLY\_F} \quad (3)$$

$$t_{DATA\_DELAY} + t_{TAP\_DELAY} + 20 < 40 + t_{CLK\_DELAY} - 5 - 10$$

$$t_{DATA\_DELAY} < 5 + t_{CLK\_DELAY} - t_{TAP\_DELAY}$$

The data can be delayed versus clock up to 5 ns in ideal case of  $t_{WL} = 20$  ns.

### Full-Speed Write Meeting Hold (Minimum Delay)

The following equations show how to calculate the allowed skew range between the SD\_CLK and SD\_DAT/CMD signals on the PCB.

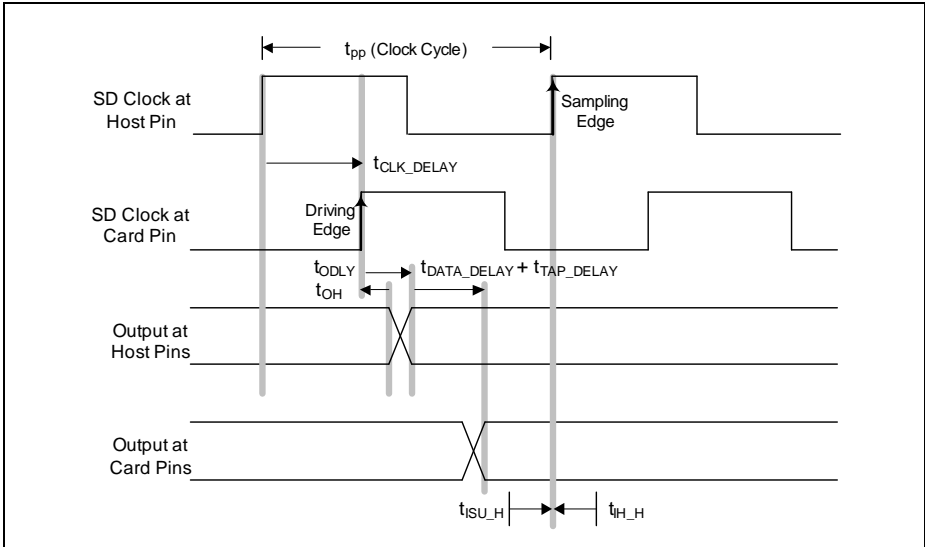

$$t_{CLK\_DELAY} < t_{WL} + t_{OH\_F} + t_{DATA\_DELAY} + t_{TAP\_DELAY} - t_{IH} \quad (4)$$

$$t_{CLK\_DELAY} < 20 + t_{DATA\_DELAY} + t_{TAP\_DELAY} - 5$$

$$t_{DATA\_DELAY} < 15 + t_{CLK\_DELAY} + t_{TAP\_DELAY}$$

The clock can be delayed versus data up to 18.2 ns (external delay line) in ideal case of  $t_{WL} = 20$  ns, with maximum  $t_{TAP\_DELAY} = 3.2$  ns programmed.

**Full-Speed Input Path (Read)**

**Figure 38 Full-Speed Input Path**

**Full-Speed Read Meeting Setup (Maximum Delay)**

The following equations show how to calculate the allowed combined propagation delay range of the SD\_CLK and SD\_DAT/CMD signals on the PCB.

(5)

$$t_{CLK\_DELAY} + t_{DATA\_DELAY} + t_{TAP\_DELAY} + t_{ODLY} + t_{ISU\_F} < 0,5 \times t_{pp}$$

$$t_{CLK\_DELAY} + t_{DATA\_DELAY} < 0,5 \times t_{pp} - t_{ODLY} - t_{ISU\_F} - t_{TAP\_DELAY}$$

$$t_{CLK\_DELAY} + t_{DATA\_DELAY} < 20 - 14 - 2 - t_{TAP\_DELAY}$$

$$t_{CLK\_DELAY} + t_{DATA\_DELAY} < 4 - t_{TAP\_DELAY}$$

The data + clock delay can be up to 4 ns for a 40 ns clock cycle.

**Electrical Parameters**

**Full-Speed Read Meeting Hold (Minimum Delay)**

The following equations show how to calculate the allowed combined propagation delay range of the SD\_CLK and SD\_DAT/CMD signals on the PCB.

(6)

$$t_{\text{CLK\_DELAY}} + t_{\text{OH}} + t_{\text{DATA\_DELAY}} + t_{\text{TAP\_DELAY}} > t_{\text{IH\_F}}$$

$$t_{\text{CLK\_DELAY}} + t_{\text{DATA\_DELAY}} > t_{\text{IH\_F}} - t_{\text{OH}} - t_{\text{TAP\_DELAY}}$$

$$t_{\text{CLK\_DELAY}} + t_{\text{DATA\_DELAY}} > 2 - t_{\text{TAP\_DELAY}}$$

The data + clock delay must be greater than 2 ns if  $t_{\text{TAP\_DELAY}}$  is not used.

If the  $t_{\text{TAP\_DELAY}}$  is programmed to at least 2 ns, the data + clock delay must be greater than 0 ns (or less). This is always fulfilled.

No clock delay:

(7)

$$t_{ODLY\_H} + t_{DATA\_DELAY} + t_{TAP\_DELAY} + t_{ISU} < t_{WL}$$

With clock delay:

(8)

$$t_{ODLY\_H} + t_{DATA\_DELAY} + t_{TAP\_DELAY} + t_{ISU} < t_{WL} + t_{CLK\_DELAY}$$

The data delay is less than the clock delay by at least 10 ns in the ideal case where  $t_{WL} = 10$  ns.

**High-Speed Write Meeting Hold (Minimum Delay)**

The following equations show how to calculate the allowed skew range between the SD\_CLK and SD\_DAT/CMD signals on the PCB.

(10)

$$t_{CLK\_DELAY} < t_{WL} + t_{OH\_H} + t_{DATA\_DELAY} + t_{TAP\_DELAY} - t_{IH}$$

$$t_{CLK\_DELAY} - t_{DATA\_DELAY} < t_{WL} + t_{OH\_H} + t_{TAP\_DELAY} - t_{IH}$$

$$t_{CLK\_DELAY} - t_{DATA\_DELAY} < 10 + 2 + t_{TAP\_DELAY} - 2$$

$$t_{CLK\_DELAY} - t_{DATA\_DELAY} < 10 + t_{TAP\_DELAY}$$

The clock can be delayed versus data up to 13.2 ns (external delay line) in ideal case of  $t_{WL} = 10$  ns, with maximum  $t_{TAP\_DELAY} = 3.2$  ns programmed.

$$t_{CLK\_DELAY} + t_{DATA\_DELAY} < t_{pp} - t_{ODLY} - t_{ISU\_H} - t_{TAP\_DELAY}$$

$$t_{CLK\_DELAY} + t_{DATA\_DELAY} < 20 - 14 - 2 - t_{TAP\_DELAY}$$

$$t_{CLK\_DELAY} + t_{DATA\_DELAY} < 4 - t_{TAP\_DELAY}$$

The data + clock delay can be up to 4 ns for a 20 ns clock cycle.

### High-Speed Read Meeting Hold (Minimum Delay)

The following equations show how to calculate the allowed combined propagation delay range of the SD\_CLK and SD\_DAT/CMD signals on the PCB.

(12)

$$t_{\text{CLK\_DELAY}} + t_{\text{OH}} + t_{\text{DATA\_DELAY}} + t_{\text{TAP\_DELAY}} > t_{\text{IH\_H}}$$

$$t_{\text{CLK\_DELAY}} + t_{\text{DATA\_DELAY}} > t_{\text{IH\_H}} - t_{\text{OH}} - t_{\text{TAP\_DELAY}}$$

$$t_{\text{CLK\_DELAY}} + t_{\text{DATA\_DELAY}} > 2 - 2,5 - t_{\text{TAP\_DELAY}}$$

$$t_{\text{CLK\_DELAY}} + t_{\text{DATA\_DELAY}} > -0,5 - t_{\text{TAP\_DELAY}}$$

The data + clock delay must be greater than -0.5 ns for a 20 ns clock cycle. This is always fulfilled.

1) An active edge can be a rising or falling edge, depending on the settings of bits BFCON.EBSE / ECSE and the clock divider ratio.

Negative minimum values for these parameters mean that the last data read during a burst may be corrupted. However, with clock feedback enabled, this value is an oversampling not required for the internal bus transaction, and will be discarded.

2) This parameter is valid for BUSCONx.EBSE = 1 and BUSAPx.EXTCLK = 0<sub>B</sub>.

For BUSCONx.EBSE = 1 and other values of BUSAPx.EXTCLK, ADV and BAA will be delayed by 1/2 of the internal bus clock period  $T_{CPU} = 1 / f_{CPU}$ .

For BUSCONx. EBSE = 0 and BUSAPx.EXTCLK = 11<sub>B</sub>, add 2 internal bus clock periods.

For BUSCONx. EBSE = 0 and other values of BUSAPx.EXTCLK, add 1 internal bus clock period.

**Electrical Parameters**

3) If the clock feedback is not enabled, the input signals are latched using the internal clock in the same way as for asynchronous access. Thus,  $t_5$ ,  $t_6$ ,  $t_7$  and  $t_8$  from the asynchronous timing apply.

## 4 Package and Reliability

The XMC4500 is a member of the XMC4000 Family of microcontrollers. It is also compatible to a certain extent with members of similar families or subfamilies.

Each package is optimized for the device it houses. Therefore, there may be slight differences between packages of the same pin-count but for different device types. In particular, the size of the Exposed Die Pad may vary.

If different device types are considered or planned for an application, it must be ensured that the board layout fits all packages under consideration.

### 4.1 Package Parameters

**Table 64** provides the thermal characteristics of the packages used in XMC4500.

**Table 64 Thermal Characteristics of the Packages**

		-	23.0	K/W	PG-LQFP-100-11 <sup>1)</sup>
		-	21.0	K/W	PG-LQFP-100-25 <sup>1)</sup>

1) Device mounted on a 4-layer JEDEC board (JESD 51-7) with thermal vias; exposed pad soldered.

*Note: For electrical reasons, it is required to connect the exposed pad to the board ground  $V_{SS}$ , independent of EMC and thermal requirements.*

#### 4.1.1 Thermal Considerations

When operating the XMC4500 in a system, the total heat generated in the chip must be dissipated to the ambient environment to prevent overheating and the resulting thermal damage.

The maximum heat that can be dissipated depends on the package and its integration into the target board. The “Thermal resistance  $R_{\Theta JA}$ ” quantifies these parameters. The

**Package and Reliability**

power dissipation must be limited so that the average junction temperature does not exceed 150 °C.

The difference between junction temperature and ambient temperature is determined by

$$\Delta T = (P_{\text{INT}} + P_{\text{IOSTAT}} + P_{\text{IODYN}}) \times R_{\Theta\text{JA}}$$

The internal power consumption is defined as

$$P_{\text{INT}} = V_{\text{DDP}} \times I_{\text{DDP}} \text{ (switching current and leakage current).}$$

The static external power consumption caused by the output drivers is defined as

$$P_{\text{IOSTAT}} = \Sigma((V_{\text{DDP}} - V_{\text{OH}}) \times I_{\text{OH}}) + \Sigma(V_{\text{OL}} \times I_{\text{OL}})$$

The dynamic external power consumption caused by the output drivers ( $P_{\text{IODYN}}$ ) depends on the capacitive load connected to the respective pins and their switching frequencies.

If the total power dissipation for a given system configuration exceeds the defined limit, countermeasures must be taken to ensure proper system operation:

- Reduce  $V_{\text{DDP}}$ , if possible in the system
- Reduce the system frequency
- Reduce the number of output pins
- Reduce the load on active output drivers
