### Description

The CPC1560 is a 1-Form-A (Single Pole, Normally Open) optically isolated MOSFET switch that provides fast turn-on of loads up to 600mA<sub>DC</sub> in a DC-Only configuration, 300mA<sub>rms</sub> in an AC/DC configuration; active current-limit circuitry; and 3750V<sub>rms</sub> of I/O isolation.

Fast turn-on is accomplished with the use of an external charge storage capacitor that provides the necessary charge required by the internal switching MOSFETs. The device charges this capacitor, through bootstrap diodes, from the load voltage, thereby alleviating the need for an additional power supply.

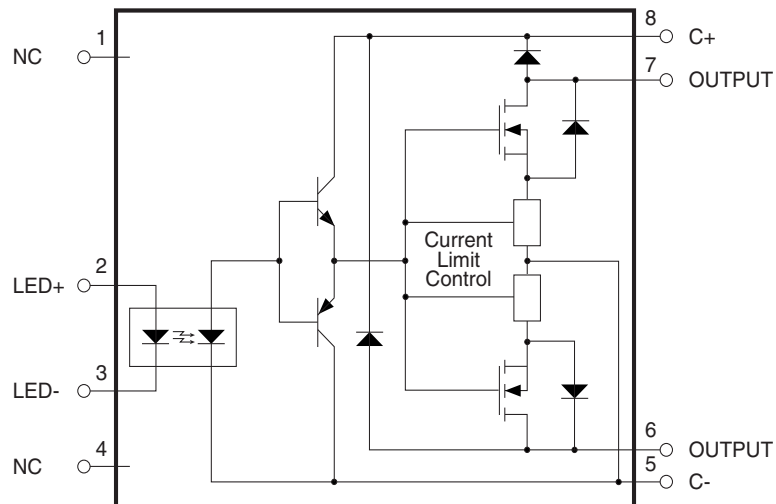

The CPC1560 incorporates thermal shutdown circuitry for improved survivability in harsh environments, and is designed to pass regulatory voltage surge requirements when provided with appropriate over-voltage protection circuitry.

Designed specifically for environmentally demanding AC or DC applications, where printed circuit board space is at a premium and additional power supplies are not available, the CPC1560 is an ideal solution.

## 2. Introduction

The CPC1560 is an optically coupled Solid State Relay (SSR) that is self-biased from the load supply. An external charge storage capacitor is used to greatly speed up SSR turn-on. The CPC1560 also incorporates current limiting and a thermal shutdown feature in the output circuitry, which make the device ideal for use in harsh conditions.

## 3. Functional Description

Internally, the device is composed of an LED, a photovoltaic array with control circuitry, and two MOSFET output switches.

Input current to the LED is the turn-on signal to the SSR's output MOSFET switches. The LED illuminates the photovoltaics, which provide current to the gates of the output MOSFETs, causing them to conduct. The charge provided to the MOSFET gates initially includes the charge stored in the external capacitor, which causes the SSR to conduct much more quickly than if only the photovoltaic current were used.

When the Load Voltage ( $V_L$ ) is first applied to the inactive outputs, the external storage capacitor begins to charge. To ensure proper operation, the storage capacitor should be equal to or greater than the total gate capacitance of the two output MOSFET switches. The charge is passed through bootstrap diodes, which prevent the charge from escaping and discharging the capacitor through the MOSFET output switch when the SSR is turned on. The input control current is applied, then the charge is transferred from the storage capacitor through the internal NPN bipolar transistor along with the charge from the photovoltaic, to the MOSFET gates to accomplish a rapid turn-on. After the capacitor has discharged and the MOSFETs have turned on, the photocurrent from the photovoltaic continues to flow into the gates, keeping the MOSFETs turned on.

When the input control current is removed, the gate current stops flowing and the PNP bipolar transistor is on, discharging the MOSFET gates. The MOSFETs are now off. At this point the capacitor begins to recharge for the next turn on cycle.

The non-conducting, optical coupling space between the LED and the photovoltaics provides  $3750V_{rms}$  of isolation between the control input and the switched output of the CPC1560.

Important things to note about the operation of the CPC1560:

- The device is designed to maintain its guaranteed operating characteristics with DC input control current ( $I_F$ ) in the range of 2.5mA to 10mA (see

“Recommended Operating Conditions” on page 4). The device will operate at input currents above and below this range, but device operating characteristics are not guaranteed.

- There is a minimum LED input current required for the device to shut off: typically about 0.43mA at 25°C (see “Electrical Specifications” on page 5).
- The output switch will only withstand a maximum of 60 volts across its terminals before breaking down (see “Absolute Maximum Ratings” on page 3). The maximum voltage generally occurs when the load is off.

The CPC1560 has two different operating configurations: unidirectional DC-only configuration, and bidirectional AC/DC configuration.

In the unidirectional DC-only configuration, the device switches load voltages with a fixed polarity, while in the AC/DC configuration it can switch voltages with either positive or negative polarities.

The advantage of operating the device in the DC-only configuration is the ability to switch larger load currents. The advantage of operating it in the AC/DC configuration is the flexibility of switching load voltages of either polarity.

## 4. Device Configuration

### 4.1 LED Resistor

To assure proper operation of the CPC1560, the LED resistor selection should comply with the recommended operating conditions. Although the LED is capable of being operated up to the absolute maximum ratings, this is not recommended. Operating the LED beyond the recommended operating conditions may prevent the current limit and thermal shutdown functions from performing properly. The equation used to calculate the max resistor value:

$$R_{LED\_MAX} = \frac{V_{IN\_MIN} - V_{LOW\_MAX} - V_{F\_MAX}}{I_{F\_MIN}}$$

- $I_{F\_MIN}$  = Minimum Input Control Current
- $V_{IN\_MIN}$  = Minimum Input Power Source
- $V_{LOW\_MAX}$  = Maximum Logic Level Low Voltage
- $V_{F\_MAX}$  = Maximum Forward Voltage Drop of LED
- $R_{LED\_MAX}$  = Maximum Input Resistor to LED

## 4.2 Storage Capacitor

The CPC1560 requires the use of an external capacitor ( $C_{EXT}$ ) to meet the device's specifications. This external storage capacitor enables the relay to turn on quickly by holding a reservoir of charge to be transferred to the gates of the MOSFET pair. The capacitor must have a minimum working voltage greater than the load voltage, and must be connected from pin 8 (C+), the capacitor's positive voltage terminal, to pin 5 (C-), the capacitor's negative voltage terminal.

Proper selection of the external capacitor begins with the recommended range provided in the "Recommended Operating Conditions" on page 4, and the maximum voltage at the CPC1560 outputs, including transients and faults. The nominal value of the capacitor needs to be chosen so that when the effects of tolerance, temperature coefficient, and (for some types of capacitor) derating due to bias voltage are accounted for, the capacitor's value remains within the recommended range over the operational conditions of the end product.

## 5. Operational Behavior

### 5.1 Operating Frequency

#### 5.1.1 Duty Cycle/Power Dissipation

Equation 1 shows the relationship between power dissipation, operating frequency, and duty cycle for the CPC1560 device. From this equation, it can be seen that both switching frequency ( $f_{switch}$ ) and duty cycle (D) contribute to power dissipation. The first one by generating switching losses, and the second one by generating ON losses. Switching losses are those caused by changes in the energy state of the load components when the device is switching on and off (i.e.  $E_{RISE}$  and  $E_{FALL}$ ), and ON losses are those caused by the flow of current ( $I_L$ ) through the part's on-resistance ( $R_{ON}$ ) when it is switched on.

$$(1) P_{avg} = I_L^2 \cdot R_{ON} \cdot D + f_{switch} \cdot (E_{RISE} + E_{FALL})$$

Because a higher operating frequency translates into higher power consumed by the part, care must be taken to limit its value in order to protect the device from exceeding its maximum power rating. When doing this, both the maximum allowed power dissipation in the part and the ON duty cycle,  $D = t_{ON} / (t_{ON} + t_{OFF})$ , must be taken into consideration.

#### 5.1.2 Temperature Effects

When setting the operating frequency of the CPC1560, the user must also take into account power dissipation over temperature.

#### 5.1.3 Elements of Operating Frequency

In addition to ambient temperature, the maximum frequency of the CPC1560 is also determined by the MOSFET's turn-on and turn-off times and the load voltage rise and fall times as follows:

$$(2) f_{MAX} = \frac{1}{3} (t_{ON} + t_{OFF})^{-1}$$

Where 1/3 is a multiplication factor for temperature and process variations.

## 5.2 Switching Losses

During the transition intervals of the switching process, the load components change energy states, which results in switching losses as the energy passes through the MOSFETs. This energy transfer is manifested in the form of heat dissipation and must be taken into consideration.

Energy is transferred during the turn-off intervals. This energy, called  $E_{rise}$ , will be absorbed by the MOSFET output switches, and if present parasitic load capacitance and the protection device.

Energy is also transferred during the turn-on intervals and is called  $E_{fall}$ . This energy will be absorbed by the MOSFET output switches, which is why this energy should be limited to the "peak turn-on energy" values specified in the Absolute Maximum Ratings Table of this datasheet.

The user of the CPC1560 device must understand the details of the load behavior and keep in mind the device's recommended operating conditions in order to adequately size the load components and protect the application circuit.

The average power of the CPC1560 output MOSFET for any specific application and for any load type given by Equation 1 and repeated here is:

$$(3) P_{avg} = I_L^2 \cdot R_{ON} \cdot D + f_{switch} \cdot (E_{RISE} + E_{FALL})$$

From this equation we can see how the switching losses ( $E_{RISE}$  and  $E_{FALL}$ ), together with the "on losses," contribute to the CPC1560's output power dissipation.

The user must also know that the recommended operating conditions for  $I_L$ ,  $f_{SWITCH}$ , load capacitance

( $C_{LOAD}$ ) and load inductance ( $L_{LOAD}$ ), along with other recommended operating conditions given in this datasheet, are constrained by the 85°C operation of most industrial applications. For lower operating temperature ranges, these values can be de-rated using the information provided in the temperature graphs in this datasheet.

#### 5.2.1 Effects of Ambient Temperature

One of the most important factors is the temperature variation of the environment. From the **Maximum Allowed Energy Dissipation During  $t_{RISE}$**  graphs (AC and DC) in this datasheet, the user can see how the energy dissipated in the part during  $t_{RISE}$  increases with increasing ambient temperature.

The operating frequency of the device is directly related to the amount of energy dissipated in it during the transition times,  $t_{RISE}$  and  $t_{FALL}$ , which increases rapidly with temperature, as seen in the previously mentioned graphs. Depending on the operating temperature range of the application, the user must derate the maximum allowed energy in the part during  $t_{RISE}$  and  $t_{FALL}$  (according to the temperature graphs provided) in order to limit the operating switching frequency.

### 5.3 Current Limit and Thermal Shutdown

#### 5.3.1 Current Limit

The CPC1560 has a current limit feature in which current through the output switches is limited to a value larger than the recommended operating current.

In the AC/DC configuration, the CPC1560 has bidirectional current limiting, which consists of current limit circuits in both positive and negative polarities. In the DC-only configuration, the DC current limit consists of the parallel of the two AC current limit circuits in the positive DC polarity.

The current limit function has a negative temperature coefficient in which increasing temperature lowers the current limit threshold of the device. Prolonged periods of current limiting will cause the temperature of the device to increase, and, if allowed to continue, will activate the device's thermal shutdown circuitry, forcing the output switches to turn off.

#### 5.3.2 Thermal Shutdown

The purpose of the thermal shutdown feature is to completely shut down the operation of the device when its junction temperature has gone above 130°C, whether this is due to high power dissipation in the

device in the form of heat or an increase in the ambient temperature.

The thermal shutdown feature and the current limit feature provide great power cross immunity to the device for improved survivability in harsh environments.

### 5.4 dV/dt Fault Tolerance

The CPC1560 device has a finite dV/dt fault tolerance for both the AC/DC and DC-only configurations, which must not be exceeded.

The dV/dt tolerance for the device in the AC/DC configuration is double that of the DC-only configuration (see **“Absolute Maximum Ratings” on page 3**). This is because the dV/dt value of the CPC1560 is inversely proportional to the size of the output switch's  $C_{RSS}$ , or “reverse transfer capacitance,” and this capacitance in the DC-only configuration is double that in the AC/DC configuration.

### 5.5 Power Derating

Bear in mind the power rating of the CPC1560 when operating the device at elevated temperatures. The Absolute Maximum Ratings table shows that the maximum allowed power dissipation at 25°C is 800mW, which is the maximum power that can be dissipated before the junction temperature of the device reaches 125°C.

In order to keep the CPC1560 operating within its power rating, use the Maximum Allowed Load Current graphs provided earlier in this document.

### 5.6 Rise and Fall Times

The CPC1560 has rise and fall times that are primarily limited by internal parasitic elements of the device; the load components only play a secondary role. This can be appreciated in the turn-off graph of an application circuit operating at 45V, where the slope of the load voltage starts scooping down into a more capacitive shape after approximately 15 volts.

**DC-Only Application Circuit  
Resistive Load Turn-Off Characteristics  
(Supply=45V<sub>DC</sub>, R<sub>LOAD</sub>=75Ω)**

### 5.7 Over-Voltage Protection

#### 5.7.1 Stored Energy in the Load

During the CPC1560's switching periods, energy is transferred between the load components, the CPC1560 device, and, if used, the over-voltage protection circuitry.

When the output switch turns off, inductive loads (L<sub>LOAD</sub>) transfer their stored energy into the MOSFET switches, the load capacitance, and the over-voltage protector. (See the turn-off graph for a 45V inductive load application circuit.)

When the output switch turns on, the energy in the load inductor is zero, and the load capacitor (C<sub>LOAD</sub>) must transfer its stored energy into the MOSFET.

**DC-Only Application Circuit  
Inductive Load Turn-Off Characteristics  
(Supply=45V, R<sub>LOAD</sub>=75Ω, L<sub>LOAD</sub>=630μH)**

5.7.2 Protection Methods

One way to protect the CPC1560 and application circuit components from damage when excessive stored energy is suddenly released into the output MOSFETs of the CPC1560, is to add a Transient Voltage Suppressor (TVS) across the output switches. Use a unidirectional TVS from the outputs to C- for the DC-only configuration, and use a bidirectional TVS across the output pins for the AC/DC configuration as shown in the diagrams below.

In order to calculate the required TVS value, the user has to compare working voltage of the application circuit to the breakdown voltage of the CPC1560 with the TVS maximum clamping voltage ratings. The TVS maximum clamping voltage capability must be, at a minimum, equal to the specific peak pulse current of the load. This must be done to ensure the TVS can

easily absorb any excess energy coming from the inductive load ( $L_{LOAD}$ ).

In addition to the TVS, other protection techniques are also available depending on the type of load the user is trying to switch. For purely resistive loads the user may rely on the output transistor to handle any parasitic energy. For very low to moderately inductive loads (e.g. remote switching of a load through a long cable), a voltage suppressor or TVS can be used as explained before. For heavily inductive loads, a fly-back diode connected across the load element is recommended

For much higher inductive loads, other circuit techniques, device ratings and/or protector types must be considered<sup>1</sup>. Of paramount importance is that the designer know the characteristics of the load being switched.

## 6 Manufacturing Information

### 6.1 Moisture Sensitivity

All plastic encapsulated semiconductor packages are susceptible to moisture ingress. IXYS Integrated Circuits Division classified all of its plastic encapsulated devices for moisture sensitivity according to the latest version of the joint industry standard, **IPC/JEDEC J-STD-020**, in force at the time of product evaluation. We test all of our products to the maximum conditions set forth in the standard, and guarantee proper operation of our devices when handled according to the limitations and information in that standard as well as to any limitations set forth in the information or standards referenced below.

Failure to adhere to the warnings or limitations as established by the listed specifications could result in reduced product performance, reduction of operable life, and/or reduction of overall reliability.

This product carries a **Moisture Sensitivity Level (MSL) rating** as shown below, and should be handled according to the requirements of the latest version of the joint industry standard **IPC/JEDEC J-STD-033**.

Device	Moisture Sensitivity Level (MSL) Rating
CPC1560G / CPC1560GS	MSL 1

### 6.2 ESD Sensitivity

This product is **ESD Sensitive**, and should be handled according to the industry standard **JESD-625**.

### 6.3 Reflow Profile

This product has a maximum body temperature and time rating as shown below. All other guidelines of **J-STD-020** must be observed.

Device	Maximum Temperature x Time
CPC1560G / CPC1560GS	250°C for 30 seconds

### 6.4 Board Wash

IXYS Integrated Circuits Division recommends the use of no-clean flux formulations. However, board washing to remove flux residue is acceptable. Since IXYS Integrated Circuits Division employs the use of silicone coating as an optical waveguide in many of its optically isolated products, the use of a short drying bake may be necessary if a wash is used after solder reflow processes. Chlorine-based or Fluorine-based solvents or fluxes should not be used. Cleaning methods that employ ultrasonic energy should not be used.
