MAX16976

# 28V, 600mA Automotive Step-Down Converter with Low Operating Current 

## General Description

The MAX16976 is a 600mA current-mode step-down converter with an integrated high-side switch. The device operates with input voltages from 3.5 V to 28 V while using only $45 \mu \mathrm{~A}$ quiescent current at no load. The switching frequency is adjustable from 220 kHz to 1.0 MHz by using an external resistor, and can be synchronized to an external clock. The device's output voltage is pin-selectable to a fixed 5 V or adjustable from 1 V to 10 V using external resistors. The wide input voltage range makes the device ideal for automotive and industrial applications.
The device operates in skip mode for reduced current consumption in light-load conditions. An adjustable reset threshold helps keep microcontrollers alive down to the lowest specified input voltage. Protection features include cycle-by-cycle current limit, soft-start, overvoltage, and thermal shutdown with automatic recovery. The device also features a power-good monitor to ease power-supply sequencing.
The device operates over the $-40^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$ automotive temperature range, and is available in a 16-pin QSOP package.

## Ordering Information appears at end of data sheet.

## ABSOLUTE MAXIMUM RATINGS

| SUP, SUPSW, LX, EN to GND | -0.3V to +45 V |
| :---: | :---: |
| BST to GND | -0.3V to +47V |
| BST to LX | -0.3V to +6V |
| OUT to GND | -0.3V to +12V |
| SUP to SUPSW | -0.3V to +0.3V |
| RESETI, FOSC, COMP, BIAS, FSYNC, CRES, RES, FB to GND | -0.3V to +6V |
| Output Short-Circuit Duration. | Continuous |

Continuous Power Dissipation $\left(\mathrm{T}_{\mathrm{A}}=+70^{\circ} \mathrm{C}\right)$
QSOP (derate $9.6 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ above $+70^{\circ} \mathrm{C}$ )................. 771.5 mW
Operating Temperature Range ........................ $40^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$
Junction Temperature ..................................................... $+150^{\circ} \mathrm{C}$
Storage Temperature Range............................ $-65^{\circ} \mathrm{C}$ to $+150^{\circ} \mathrm{C}$
Lead Temperature (soldering, 10s) ................................ $+300^{\circ} \mathrm{C}$
Soldering Temperature (reflow) ...................................... $+260^{\circ} \mathrm{C}$

Stresses beyond those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

## PACKAGE THERMAL CHARACTERISTICS (Note 1)

QSOP
Junction-to-Ambient Thermal Resistance ( $\theta_{\mathrm{JA}}$ ) ..... $103.7^{\circ} \mathrm{C} / \mathrm{W}$
Note 1: Package thermal resistances were obtained using the method described in JEDEC specification JESD51-7, using a fourlayer board. For detailed information on package thermal considerations, refer to www.maximintegrated.com/thermal-tutorial.

Pin Configuration

Pin Description

| PIN | NAME | FUNCTION |
| :---: | :---: | :---: |
| 1 | CRES | Analog Reset Timer. CRES sources $10 \mu \mathrm{~A}$ (typ) of current into an external capacitor to set the reset timeout period. Reset timeout period is defined as the time between the start of output regulation and $\overline{\mathrm{RES}}$ switching to high impedance. Leave CRES unconnected for minimum delay time. |
| 2 | FOSC | Resistor-Programmable Switching Frequency Control Input. Connect a resistor from FOSC to GND to set the switching frequency (see the Internal Oscillator section). |
| 3 | FSYNC | Synchronization Input. The device synchronizes to an external signal applied to FSYNC. The external signal period must be $10 \%$ shorter than the internal clock period for proper operation. |
| 4 | I.C. | Internally Connected. Connect to GND. |
| 5 | COMP | Error-Amplifier Output. Connect a compensation network from COMP to GND for stable operation. See the Compensation Network section. |
| 6 | FB | Feedback Input. Connect an external resistive divider from FB to OUT and GND to set the output voltage between 1 V and 10 V . Connect FB directly to BIAS to set the output voltage to 5V. See the Applications Information section. |
| 7 | OUT | Connect OUT to the output of the converter. OUT provides power to the internal circuitry when the output voltage of the converter is set between 3 V and 5.6 V . During shutdown, OUT is pulled to GND with a $50 \Omega$ resistor. |
| 8 | GND | Ground |
| 9 | BIAS | Linear Regulator Output. BIAS powers the internal circuitry. Bypass BIAS with a $1 \mu \mathrm{~F}$ capacitor to ground as close as possible to the device. During shutdown, BIAS is actively discharged through a $32 \mathrm{k} \Omega$ resistor. |
| 10 | BST | High-Side Driver Supply. Connect a $0.1 \mu \mathrm{~F}$ capacitor between LX and BST for proper operation. |
| 11 | SUP | Voltage Supply Input. SUP powers the internal linear regulator. Connect a $4.7 \mu \mathrm{~F}$ capacitor from SUP to ground. Connect SUP to SUPSW. |
| 12 | LX | Inductor Connection. Connect a rectifying Schottky diode between LX and GND. Connect an inductor from LX to the output. |

# 28V, 600mA Automotive Step-Down Converter with Low Operating Current 

Pin Description (continued)

| PIN | NAME | FUNCTION |
| :---: | :---: | :--- |
| 13 | SUPSW | Internal High-Side Switch Supply Input. SUPSW provides power to the internal switch. Connect a 4.7 <br> capacitor from SUPSW to ground. Connect SUP to SUPSW. See the Input Capacitor section. |
| 14 | EN | Battery-Compatible Enable Input. Drive EN low to disable the device. Drive EN high to enable the device. |
| 15 | $\overline{R E S}$ | Open-Drain Active-Low Reset Output. $\overline{\text { RES }}$ asserts when Vout is below the reset threshold set by RESETI. |
| 16 | RESETI | Reset Threshold Level Input. Connect to a resistive divider to set the reset threshold for $\overline{\text { RES. Connect }}$ <br> RESETI to GND to enable the internal reset threshold. |

Functional Diagram

# 28V, 600mA Automotive Step-Down Converter with Low Operating Current 

## Detailed Description

The MAX16976 is a constant-frequency, current-mode automotive buck converter with an integrated high-side switch. The device operates with input voltages from 3.5 V to 28 V and tolerates input transients up to 42 V . During undervoltage events, such as cold-crank conditions, the internal pass device maintains 93.5\% duty cycle for a short time.
An open-drain, active-low reset output helps to monitor the output voltage. The device offers an adjustable reset threshold that helps to keep microcontrollers alive down to the lowest specified input voltage and a capacitorprogrammable reset timeout to ensure proper startup.
The switching frequency is resistor-programmable from 220 kHz to 1.0 MHz to allow optimization for efficiency, noise, and board space. A clock input, FSYNC, allows the device to synchronize to an external clock.
During light-load conditions, the device enters skip mode that reduces the quiescent current down to $45 \mu \mathrm{~A}$ and increases light-load efficiency. The 5V fixed output voltage eliminates the need for external resistors and reduces the supply current by up to $50 \mu \mathrm{~A}$.

Linear Regulator Output (BIAS) The device includes a 5 V linear regulator, $\mathrm{V}_{\mathrm{BI}} \mathrm{AS}$, that provides power to the internal circuitry. Connect a $1 \mu \mathrm{~F}$ ceramic capacitor from BIAS to GND. When the output voltage is set between 3 V and 5.5 V , the internal linear regulator only provides power until the output is in regulation. The internal linear regulator turns off once the output is in regulation and allows OUT to provide power to the device. The internal regulator turns back on once the external load on the output of the device is higher than 100 mA . In addition, the linear regulator turns on anytime the output voltage is outside the 3 V to 5.5 V range.

External Clock Input (FSYNC) The device synchronizes to an external clock signal applied at FSYNC. The signal at FSYNC must have a frequency of $10 \%$ higher than the internal clock frequency for proper synchronization.

Adjustable Reset Level
The device features a programmable reset threshold using a resistive divider between OUT, RESETI, and GND. Connect RESETI to GND for the internal threshold. $\overline{R E S}$ asserts low when the output voltage falls to $93 \%$ of the programmed level. $\overline{\mathrm{RES}}$ deasserts when the output voltage goes above 95\% of the set voltage.

Some microprocessors accept a wide input voltage range (3.3V to 5 V , for example) and can operate during dropout of the device. Use a resistive divider at RESETI to adjust the reset activation level ( $\overline{\mathrm{RES}}$ goes low) to lower levels. The reference voltage at RESETI is 1.25 V (typ).
The device also offers a capacitor-programmable reset timeout period. Connect a capacitor from CRES to GND to adjust the reset timeout period. When the output voltage goes out of regulation, $\overline{\text { RES }}$ asserts low and the reset timing capacitor discharges with a 1 mA pulldown current. Once the output is back in regulation the reset timing capacitor recharges with $10 \mu \mathrm{~A}$ (typ) current. $\overline{\mathrm{RES}}$ stays low until the voltage at CRES reaches 1.13 V (typ).

## Dropout Operation

The device features an effective maximum duty cycle to help refresh the BST capacitor when continuously operated in dropout. When the high-side switch is on for three consecutive clock cycles, the device forces the high-side switch off during the final $35 \%$ of the fourth clock cycle. When the high-side switch is off, the LX node is pulled low by the current flowing through the inductor. This increases the voltage across the BST capacitor. To ensure that the inductor has enough current to pull LX to ground, an internal load sinks current from VOUT when the device is close to dropout and external load is small. Once the input voltage is increased above the dropout region, the device continues to regulate at the set output voltage.
The device operates with no load and no external clock at an effective maximum duty cycle of $93.5 \%$ in deep dropout. This effective maximum duty cycle is influenced by the external load and by the optional external synchronized clock.

System Enable (EN) An enable-control input (EN) activates the device from the low-power shutdown mode. EN is compatible with inputs from the automotive battery level down to 3.3V. The high-voltage compatibility allows EN to be connected to SUP, KEY/KL30, or the INH inputs of a CAN transceiver.
EN turns on the internal regulator. Once $\mathrm{V}_{\text {BIAS }}$ is above the internal lockout level, VUVL $=3.15 \mathrm{~V}$ (typ), the controller activates and the output voltage ramps up within 2048 cycles of the switching frequency.
A logic-low at EN shuts down the device. During shutdown, the internal linear regulator and gate drivers turn off. Shutdown mode reduces the quiescent current to $9 \mu \mathrm{~A}$ (typ). Drive EN high to turn on the device.

# 28V, 600mA Automotive Step-Down Converter with Low Operating Current 

Figure 1. Output Voltage/Reset Threshold Resistive Divider Network

## Overvoltage Protection

The device includes overvoltage protection circuitry that protects the device when there is an overvoltage condition at the output. If the output voltage increases by more than $12 \%$ of its set voltage, the device stops switching. The device resumes regulation once the overvoltage condition is removed.

## Overload Protection

The overload protection circuitry is activated when the device is in current limit and VOUT is below the reset threshold. Under these conditions, the device enters a soft-start mode. When the overcurrent condition is removed before the soft-start mode is over, the device regulates the output voltage to the set value. Otherwise, the soft-start cycle repeats until the overcurrent condition is removed.

## Skip Mode

During light-load operation, $I_{\text {INDUCTOR }} \leq 100 \mathrm{~mA}$, the device enters skip-mode operation. Skip mode turns off the internal switch and allows the output to drop below regulation voltage before the switch is turned on again. The lower the load current, the longer it takes for the regulator to initiate a new cycle effectively increasing light-load efficiency. During skip mode, the device quiescent current drops to as low as $45 \mu \mathrm{~A}$.

## Overtemperature Protection

Thermal-overload protection limits the total power dissipation in the device. When the junction temperature exceeds $+175^{\circ} \mathrm{C}$ (typ), an internal thermal sensor shuts down the step-down controller, allowing the device to cool. The thermal sensor turns on the device again after the junction temperature cools by $+15^{\circ} \mathrm{C}$.

## Applications Information

## Output Voltage/Reset Threshold Resistive Divider Network

Although the device's output voltage and reset threshold can be set individually, Figure 1 shows a combined resistive divider network to set the desired output voltage and the reset threshold using three resistors. Use the following formula to determine the $\mathrm{R}_{\text {FB3 }}$ of the resistive divider network:

$$
\mathrm{R}_{\mathrm{FB} 3}=\frac{\mathrm{R}_{\text {TOTAL }} \times \mathrm{V}_{\mathrm{REF}}}{\mathrm{~V}_{\text {OUT }}}
$$

where $\mathrm{V}_{\text {REF }}=1 \mathrm{~V}$, RTOTAL $=$ selected total resistance of $R_{F B 1}, R_{F B 2}$, and $R_{F B 3}$ in ohms, and $V_{\text {OUT }}$ is the desired output voltage in volts.

Use the following formula to calculate the value of $R_{\text {FB2 }}$ of the resistive divider network:

$$
R_{\mathrm{FB} 2}=\frac{\mathrm{R}_{\text {TOTAL }} \times \mathrm{V}_{\text {REF_RES }}}{V_{\text {RES }}}-R_{\text {FB3 }}
$$

where $V_{\text {REF_RES }}$ is 1.25 V (see the Electrical Characteristics table) and $\bar{V}_{\text {RES }}$ is the desired reset threshold in volts.
The precision of the reset threshold function is dependent on the tolerance of the resistors used for the divider.

## BST Capacitor Selection for Dropout Operation

The device includes an internal boost capacitor refresh algorithm for dropout operation. This is required to ensure proper boost capacitor voltage that delivers power to the gate-drive circuitry. When the HSFET is on consecutively for 3.65 clock cycles, the internal counter detects this and turns off the HSFET for 0.35 clock cycles. This is of particular concern when $\mathrm{V}_{\mathbb{N}}$ is falling and approaching $V_{\text {OUT }}$ at the minimum switching frequency ( 220 kHz ).
The worst-case condition for boost capacitor refresh time is with no load on the output. For the boost capacitor to recharge completely, the LX node must be pulled to ground. If there is no current through the inductor then the LX node does not go to ground. To solve this issue, an internal load of about 100 mA turns on at the sixth clock cycle, which is determined by a separate counter.
In the worst-case condition with no load, the LX node does not go below ground during the first detect of the

# 28V, 600mA Automotive Step-Down Converter with Low Operating Current 

3.65 clock cycles. The device waits for the next 3.65 clock cycles to finish. As a result, the soonest the LX node can go below ground is $4+3.65=7.65$ clock cycles. This time does not factor in the size of the inductor and the time it takes for the inductor current to build up to 100 mA (internal load).
No load minimum time before refresh is:

$$
\begin{aligned}
\Delta \mathrm{T}(\text { no load })= & 7.65 \text { clock cycles }=7.65 \times 4.54 \mu \mathrm{~s}(\text { at } \\
& 220 \mathrm{kHz})=34.73 \mu \mathrm{~s}
\end{aligned}
$$

Assuming a full 100 mA is needed to refresh the BST capacitor and depending on the size of the inductor, the time it takes to build up full 100 mA in the inductor is given by:
$\Delta \mathrm{T}$ (inductor) $=\mathrm{L} \times \Delta \mathrm{I} / \Delta \mathrm{V}$ (current build-up starts from the sixth clock cycle)
$L=$ inductor value chosen in the design guide.
$\Delta l$ is the required current $=100 \mathrm{~mA}$.
$\Delta \mathrm{V}=$ voltage across the inductor (assume this to be 0.5 V ), which means $\mathrm{V}_{\mathrm{IN}}$ is greater than $\mathrm{V}_{\mathrm{OUT}}$ by 0.5 V .

If $\Delta T$ (inductor) $<7.65-6$ (clock cycles) then the BST capacitor is sized as follows:
$B S T \_C A P \geq I \_B S T($ dropout $) \times \Delta T$ (no load) $/ \Delta V$ (BST capacitor)
$\Delta \mathrm{T}($ no load $)=7.65$ clock cycles $=34.73 \mu \mathrm{~s}$.
$\Delta \mathrm{V}$ (BST capacitor), for ( 3.3 V to 5 V ) output $=\mathrm{V}_{\text {OUT }}-2.7 \mathrm{~V}$ (2.7V is the minimum voltage allowed on the BST capacitor).
If $\Delta \mathrm{T}$ (inductor) $>7.65-6$ clock cycles then we need to wait for the next count of 3.65 clock cycles making $\Delta T$ (no load) $=11.65$ clock cycles.
Assume $\Delta T$ (no load) to be 16 clock cycles when designing the BST capacitor with a typical inductor value for 220 kHz operation.
The final BST_CAP equation is:

$$
\text { BST_CAP }=\underset{\text { capacitor })}{\text { I_BST }} \begin{gathered}
(\text { dropout }) \times \Delta T(\text { no load }) / \Delta V(B S T
\end{gathered}
$$

where:
I_BST (dropout) $=2.5 \mathrm{~mA}$ (worst case)
$\Delta \mathrm{T}($ no load $)=16$ clock cycles
$\Delta \mathrm{V}($ BST capacitor $)=\mathrm{V}_{\text {OUT }}-2.7 \mathrm{~V}$

## Reset Timeout Period

The device offers a capacitor-adjustable reset timeout period. CRES can source $10 \mu \mathrm{~A}$ of current. Use the following formula to set the timeout period.

$$
\text { RESET_TIMEOUT }=\frac{1.13 \mathrm{~V} \times \mathrm{C}}{10 \mu \mathrm{~A}}(\mathrm{~s})
$$

where C is the capacitor from CRES to GND in Farads.
Internal Oscillator
The device's internal oscillator is programmable from 220 kHz to 1.0 MHz using a single resistor at FOSC. Use the following formula to calculate the switching frequency:

$$
\mathrm{f} \operatorname{OSC}(\mathrm{~Hz}) \approx \frac{26.4 \times 10^{9}(\Omega \times \mathrm{Hz})}{\mathrm{R}}
$$

where $R$ is the resistor from FOSC to GND in ohms.
For example, a 220 kHz switching frequency is set with $R_{\text {FOSC }}=120 \mathrm{k} \Omega$. Higher frequencies allow designs with lower inductor values and less output capacitance. Consequently, peak currents and 12 R losses are lower at higher switching frequencies, but core losses, gatecharge currents, and switching losses increase.

## Inductor Selection

Three key inductor parameters must be specified for operation with the device: inductance value (L), inductor saturation current (ISAT), and DC resistance (RDCR). To select inductance value, the ratio of inductor peak-topeak AC current to DC average current (LIR) must be selected first. A good compromise between size and loss is a 30\% peak-to-peak ripple current to average-current ratio ( $\mathrm{LIR}=0.3$ ). The switching frequency, input voltage, output voltage, and selected LIR then determine the inductor value as follows:

$$
L=\frac{V_{\text {OUT }}\left(V_{\text {SUPSW }}-V_{\text {OUTT }}\right)}{V_{\text {SUPSW }} \text { SWlout }}
$$

where $V_{\text {SUPSW, }}$, VOUT, and IOUT are typical values (so that efficiency is optimum for typical conditions). The switching frequency is set by $\mathrm{R}_{\text {FOSC }}$. The exact inductor value is not critical and can be adjusted to make tradeoffs among size, cost, efficiency, and transient response requirements. Table 1 shows a comparison between small and large inductor sizes.
Table 1. Inductor Size Comparison

| INDUCTOR SIZE |  |
| :---: | :---: |
| SMALLER | LARGER |
| Lower price | Smaller ripple |
| Smaller form-factor | Higher efficiency |
| Faster load response | Larger fixed-frequency <br> range in skip mode |

## 28V, 600mA Automotive Step-Down Converter with Low Operating Current

The inductor value must be chosen so that the maximum inductor current does not reach the minimum current limit of the device. The optimum operating point is usually found between $15 \%$ and $35 \%$ ripple current. When pulse skipping (light loads), the inductor value also determines the load-current value at which PFM/PWM switchover occurs.
Find a low-loss inductor having the lowest possible DC resistance that fits in the allotted dimensions. Most inductor manufacturers provide inductors in standard values, such as $1.0 \mu \mathrm{H}, 1.5 \mu \mathrm{H}, 2.2 \mu \mathrm{H}, 3.3 \mu \mathrm{H}$, etc. Also look for nonstandard values, which can provide a better compromise in LIR across the input voltage range. If using a swinging inductor (where the no-load inductance decreases linearly with increasing current), evaluate the LIR with properly scaled inductance values. For the selected inductance value, the actual peak-to-peak inductor ripple current ( $\Delta I_{\text {INDUCTOR }}$ ) is defined by:

$$
\Delta_{\text {INDUCTOR }}=\frac{V_{\text {OUT }}\left(V_{\text {SUPSW }}-V_{\text {OUT }}\right)}{V_{\text {SUPSW }} \times f_{S W} \times L}
$$

where $\Delta^{\prime}{ }_{\text {INDUCTOR }}$ is in $A, L$ is in $H$, and $f$ sw is in $H z$.
Ferrite cores are often the best choices, although powdered iron is inexpensive and can work well at 220 kHz . The core must be large enough not to saturate at the peak inductor current (IPEAK):

$$
I_{\text {PEAK }}=I_{\mathrm{LOAD}(\mathrm{MAX})}+\frac{\left.\Delta\right|_{\text {INDUCTOR }}}{2}
$$

## Input Capacitor

The input filter capacitor reduces peak currents drawn from the power source and reduces noise and voltage ripple on the input caused by the circuit's switching.
The input capacitor RMS current requirement (IRMS) is defined by the following equation:

$$
I_{\text {RMS }}=I_{\text {LOAD }(M A X)} \frac{\sqrt{V_{\text {OUT }}\left(V_{\text {SUPSW }}-V_{\text {OUT }}\right)}}{V_{\text {SUPSW }}}
$$

$I_{\text {RMS }}$ is at a maximum value when the input voltage equals twice the output voltage $\left(\mathrm{V}_{\text {SUPSW }}=2 \mathrm{~V}_{\text {OUT }}\right)$, so $I_{\text {RMS }}($ MAX $)=l_{\text {LOAD }}($ MAX $) / 2$.
Choose an input capacitor that exhibits less than $+10^{\circ} \mathrm{C}$ self-heating temperature rise at the RMS input current for optimal long-term reliability.

The input-voltage ripple comprises $\Delta \mathrm{V}_{\mathrm{Q}}$ (caused by the capacitor discharge) and $\Delta \mathrm{V}_{\mathrm{ESR}}$ (caused by the ESR of the capacitor). Use low-ESR ceramic capacitors with high ripple-current capability at the input. Assume the contribution from $\Delta \mathrm{V}_{\mathrm{Q}}$ and $\Delta \mathrm{V}_{E S R}$ to be $50 \%$. Calculate the input capacitance and ESR required for a specified input-voltage ripple using the following equations:

$$
\mathrm{ESR}_{\mathrm{IN}}=\frac{\Delta \mathrm{V}_{\mathrm{ESR}}}{\mathrm{I}_{\mathrm{OUT}}+\frac{\Delta \mathrm{l}_{\mathrm{L}}}{2}}
$$

where:

$$
\Delta L_{\mathrm{L}}=\frac{\left(\mathrm{V}_{\text {SUPSW }}-V_{\text {OUT }}\right) \times \mathrm{V}_{\text {OUT }}}{V_{\text {SUPSW }} \times f_{S W} \times \mathrm{L}}
$$

and

$$
\mathrm{C}_{\mathrm{IN}}=\frac{\mathrm{I} \text { OUT } \times \mathrm{D}(1-\mathrm{D})}{\Delta \mathrm{V}_{\mathrm{Q}} \times \mathrm{f}_{\mathrm{SW}}}
$$

and

$$
\mathrm{D}=\frac{\mathrm{V}_{\text {OUT }}}{\mathrm{V}_{\text {SUPSW }}}
$$

IOUT is the maximum output current and $D$ is the duty cycle.

Output Capacitor
The output filter capacitor must have low enough equivalent series resistance (ESR) to meet output ripple and load transient requirements, yet have high enough ESR to satisfy stability requirements. The output capacitance must be high enough to absorb the inductor energy while transitioning from full-load to no-load conditions without tripping the overvoltage fault protection. When using high-capacitance, low-ESR capacitors, the filter capacitor's ESR dominates the output voltage ripple. So the size of the output capacitor depends on the maximum ESR required to meet the output voltage ripple ( $\mathrm{V}_{\mathrm{RI} \operatorname{IPPLE}}(\mathrm{P}-\mathrm{P})$ ) specifications:

$$
V_{R I P P L E}(P-P)=E S R \times I_{L O A D(M A X)} \times \operatorname{LIR}
$$

The actual capacitance value required relates to the physical size needed to achieve low ESR, as well as to the chemistry of the capacitor technology. Thus, the capacitor is usually selected by ESR and voltage rating rather than by capacitance value.

## 28V, 600mA Automotive Step-Down Converter with Low Operating Current

When using low-capacity filter capacitors, such as ceramic capacitors, size is usually determined by the capacity needed to prevent $V_{S A G}$ and $V_{S O A R}$ from causing problems during load transients. Generally, once enough capacitance is added to meet the overshoot requirement, undershoot at the rising load edge is no longer a problem. However, low-capacity filter capacitors typically have high-ESR zeros that can affect the overall stability.

## Rectifier Selection

The device requires an external Schottky diode rectifier as a freewheeling diode. Connect this rectifier close to the device using short leads and short PCB traces. Choose a rectifier with a continuous current rating higher than the highest output current-limit threshold (1.25A) and with a voltage rating higher than the maximum expected input voltage, $V_{\text {SUPSW. }}$. Use a low forward-voltage-drop Schottky rectifier to limit the negative voltage at LX. Avoid higher than necessary reverse-voltage Schottky rectifiers that have higher forward-voltage drops.

## Compensation Network

The device uses an internal transconductance error amplifier with its inverting input and its output available for external frequency compensation. The output capacitor and compensation network determine the loop stability. The inductor and the output capacitor are chosen based on performance, size, and cost. Additionally, the compensation network optimizes the control-loop stability.
The controller uses a current-mode control scheme that regulates the output voltage by forcing the required current through the external inductor, so the device uses the voltage drop across the high-side MOSFET. Currentmode control eliminates the double pole in the feedback loop caused by the inductor and output capacitor resulting in a smaller phase shift and requiring less elaborate error-amplifier compensation than voltage-mode control. A simple single series resistor $\left(\mathrm{R}_{\mathrm{C}}\right)$ and capacitor $\left(\mathrm{C}_{\mathrm{C}}\right)$ are all that is required to have a stable, high-bandwidth loop in applications where ceramic capacitors are used for output filtering (Figure 2). For other types of capacitors, due to the higher capacitance and ESR, the frequency of the zero created by the capacitance and ESR is lower than the desired closed-loop crossover frequency. To stabilize a nonceramic output capacitor loop, add another compensation capacitor ( $\mathrm{C}_{F}$ ) from COMP to GND to cancel this ESR zero.

The basic regulator loop is modeled as a power modulator, output feedback divider, and an error amplifier. The power modulator has a DC gain set by $g_{m c} \times R_{\text {LOAD }}$, with a pole and zero pair set by RLOAD, the output capacitor (COUT), and its ESR. The following equations allow to approximate the value for the gain of the power modulator (GAINMOD(dc)), neglecting the effect of the ramp stabilization. Ramp stabilization is necessary when the duty cycle is above $50 \%$ and is internally done for the device.

$$
\operatorname{GAIN}_{\mathrm{MOD}(\mathrm{dc})}=g_{\mathrm{mc}} \times \frac{R_{\mathrm{LOAD}} \times f_{S W} \times \mathrm{L}}{\mathrm{R}_{\mathrm{LOAD}}+\left(\mathrm{f}_{\mathrm{SW}} \times \mathrm{L}\right)}
$$

where RLOAD $=\mathrm{V}_{\text {OUT }} / \operatorname{LOUT}(\mathrm{MAX})$ in $\Omega$, fSW is the switching frequency in $\mathrm{MHz}, \mathrm{L}$ is the output inductance in $\mu \mathrm{H}$, and $\mathrm{gmc}_{\mathrm{mc}}=3 \mathrm{~S}$.
In a current-mode step-down converter, the output capacitor, its ESR, and the load resistance introduce a pole at the following frequency:

$$
f_{p M O D}=\frac{1}{2 \pi \times C_{O U T} \times\left(\frac{R_{L O A D} \times f_{S W} \times L}{R_{L O A D}+\left(f_{S W} \times L\right)}+E S R\right)}
$$

The output capacitor and its ESR also introduce a zero at:

$$
\mathrm{f}_{\mathrm{ZMOD}}=\frac{1}{2 \pi \times \mathrm{ESR} \times \mathrm{C}_{\mathrm{OUT}}}
$$

When COUT is composed of " $n$ " identical capacitors in parallel, the resulting COUT $=n \times \operatorname{COUT}(E A C H)$ and ESR $=\mathrm{ESR}_{(\mathrm{EACH})} / \mathrm{n}$. Note that the capacitor zero for a parallel combination of alike capacitors is the same as for an individual capacitor.

Figure 2. Compensation Network

# 28V, 600mA Automotive Step-Down Converter with Low Operating Current 

The feedback voltage-divider has a gain of GAINFB $=$ $\mathrm{V}_{\text {FB }} / V_{\text {OUT }}$, where $\mathrm{V}_{\text {FB }}$ is 1 V (typ). The transconductance error amplifier has a DC gain of GAINEA(DC) $=g_{m, E A} \times$ ROUT,EA, where $g_{m, E A}$ is the error-amplifier transconductance, which is $1000 \mu \mathrm{~S}$ (typ), and Rout, EA is the output resistance of the $50 \mathrm{M} \Omega$ error amplifier.
A dominant pole ( $f_{d p E A}$ ) is set by the compensation capacitor $\left(\mathrm{C}_{\mathrm{C}}\right)$ and the amplifier output resistance (ROUT,EA). A zero ( $f_{\text {ZEA }}$ ) is set by the compensation resistor ( $\mathrm{R}_{\mathrm{C}}$ ) and the compensation capacitor ( $\mathrm{C}_{\mathrm{C}}$ ). There is an optional pole ( $f_{p E A}$ ) set by $C_{F}$ and $R_{C}$ to cancel the output capacitor ESR zero if it occurs near the crossover frequency ( ${ }^{\mathrm{f}} \mathrm{C}$, where the loop gain equals $1(\mathrm{OdB})$ ).
Thus:

$$
\begin{gathered}
f_{d p E A}=\frac{1}{2 \pi \times C_{C} \times\left(R_{O U T, E A}+R_{C}\right)} \\
f_{z E A}=\frac{1}{2 \pi \times C_{C} \times R_{C}} \\
f_{p E A}=\frac{1}{2 \pi \times C_{F} \times R_{C}}
\end{gathered}
$$

The loop-gain crossover frequency ( $\mathrm{f}_{\mathrm{C}}$ ) is set below $1 / 5$ th the switching frequency and much higher than the power-modulator pole ( $f_{\mathrm{pMOD}}$ ):

$$
f_{\mathrm{pMOD}} \ll \mathrm{f}_{\mathrm{C}} \leq \frac{\mathrm{f}_{\mathrm{SW}}}{5}
$$

The total loop gain as the product of the modulator gain, the feedback voltage-divider gain, and the error-amplifier gain at ${ }_{\mathrm{f}} \mathrm{C}$ is equal to 1 . So:

$$
\operatorname{GAIN}_{\mathrm{MOD}(\mathrm{fC})} \times \frac{\mathrm{V}_{\mathrm{FB}}}{\mathrm{~V}_{\mathrm{OUT}}} \times \mathrm{GAIN}_{\mathrm{EA}\left(\mathrm{f}_{\mathrm{C}}\right)}=1
$$

For the case where $\mathrm{f}_{\mathrm{ZMOD}}$ is greater than $\mathrm{f}_{\mathrm{C}}$ :

$$
\begin{gathered}
\mathrm{GAIN}_{\mathrm{EA}(\mathrm{fC})}=g_{\mathrm{m}, \mathrm{EA}} \times \mathrm{R}_{\mathrm{C}} \\
\mathrm{GAIN}_{\mathrm{MOD}(\mathrm{fC})}=\mathrm{GAIN}_{\mathrm{MOD}(\mathrm{dc})} \times \frac{\mathrm{f}_{\mathrm{pMOD}}}{f_{\mathrm{C}}}
\end{gathered}
$$

Therefore:

$$
\operatorname{GAIN}_{\mathrm{MOD}(\mathrm{fC})} \times \frac{V_{\mathrm{FB}}}{V_{\mathrm{OUT}}} \times g_{\mathrm{m}, \mathrm{EA}} \times R_{\mathrm{C}}=1
$$

Solving for $\mathrm{R}_{\mathrm{C}}$ :

$$
R_{\mathrm{C}}=\frac{V_{\text {OUT }}}{g_{\mathrm{m}, \mathrm{EA}} \times \mathrm{V}_{\mathrm{FB}} \times \mathrm{GAIN}_{\mathrm{MOD}(\mathrm{fC})}}
$$

Set the error-amplifier compensation zero formed by $\mathrm{R}_{\mathrm{C}}$ and $C_{C}\left(f_{z E A}\right)$ at the $f_{p M O D}$. Calculate the value of $C_{C}$ as follows:

$$
\mathrm{C}_{\mathrm{C}}=\frac{1}{2 \pi \times \mathrm{f}_{\mathrm{pMOD}} \times \mathrm{R}_{\mathrm{C}}}
$$

If $\mathrm{f}_{\mathrm{ZMOD}}$ is lower than $5 \times \mathrm{f}_{\mathrm{C}}$, add a second capacitor, $C_{F}$, from COMP to GND and set the compensation pole formed by $R_{C}$ and $C_{F}\left(f_{p E A}\right)$ at the $f_{Z M O D}$. Calculate the value of $C_{F}$ as follows:

$$
C_{F}=\frac{1}{2 \pi \times f_{Z M O D} \times R_{C}}
$$

As the load current decreases, the modulator pole also decreases; however, the modulator gain increases accordingly and the crossover frequency remains the same. For the case where $f_{Z M O D}$ is less than $f_{C}$ :
The power-modulator gain at ${ }_{\mathrm{f}} \mathrm{C}$ is:

$$
\operatorname{GAIN}_{\mathrm{MOD}\left(\mathrm{f}_{\mathrm{C}}\right)}=\mathrm{GAIN}_{\mathrm{MOD}(\mathrm{dc})} \times \frac{\mathrm{f}_{\mathrm{pMOD}}}{\mathrm{f}_{\mathrm{zMOD}}}
$$

The error-amplifier gain at ${ }_{\mathrm{f}}^{\mathrm{C}}$ is:

$$
\operatorname{GAIN}_{E A\left(f_{C}\right)}=g_{m, E A} \times R_{C} \times \frac{f_{\mathrm{zMOD}}}{f_{C}}
$$

Therefore:

$$
\operatorname{GAIN}_{\mathrm{MOD}\left(\mathrm{f}_{\mathrm{C}}\right)} \times \frac{\mathrm{V}_{\mathrm{FB}}}{V_{\mathrm{OUT}}} \times g_{\mathrm{m}, \mathrm{EA}} \times R_{\mathrm{C}} \times \frac{f_{\mathrm{ZMOD}}}{f_{C}}=1
$$

Solving for $\mathrm{R}_{\mathrm{C}}$ :

$$
\mathrm{R}_{\mathrm{C}}=\frac{\mathrm{V}_{\mathrm{OUT}} \times \mathrm{f}_{\mathrm{C}}}{g_{\mathrm{m}, \mathrm{EA}} \times \mathrm{V}_{\mathrm{FB}} \times \mathrm{GAIN}_{\mathrm{MOD}\left(\mathrm{f}_{\mathrm{C}}\right)} \times \mathrm{f}_{\mathrm{zMOD}}}
$$

## 28V, 600mA Automotive Step-Down Converter with Low Operating Current

Set the error-amplifier compensation zero formed by $R_{C}$ and $C_{C}$ at the $f_{\text {pMOD }}\left(f_{Z E A}=f_{p M O D}\right)$ :

$$
\mathrm{C}_{\mathrm{C}}=\frac{1}{2 \pi \times \mathrm{f}_{\mathrm{pMOD}} \times \mathrm{R}_{\mathrm{C}}}
$$

If $\mathrm{f}_{\mathrm{ZMOD}}$ is less than $5 \times \mathrm{f}_{\mathrm{C}}$, add a second capacitor, $\mathrm{C}_{\mathrm{F}}$, from COMP to GND. Set $f_{p E A}=f_{\text {zMOD }}$ and calculate $\mathrm{C}_{\mathrm{F}}$ as follows:

$$
C_{F}=\frac{1}{2 \pi \times f_{Z M O D} \times R_{C}}
$$

PCB Layout Guidelines
Careful PCB layout is critical to achieve low switching losses and clean, stable operation. Use a multilayer board whenever possible for better noise immunity and power dissipation. Follow these guidelines for good PCB layout:

1) Use a large contiguous copper plane under the device package. Ensure that all heat-dissipating components have adequate cooling.
2) Isolate the power components and high-current path from the sensitive analog circuitry. This is essential to prevent any noise coupling into the analog signals.
3) Keep the high-current paths short, especially at the ground terminals. This practice is essential for stable, jitter-free operation. Make the high-current path comprising of an input capacitor, high-side FET, inductor, and the output capacitor as short as possible.
4) Keep the power traces and load connections short. This practice is essential for high efficiency. Use thick copper PCBs (2oz vs. 1oz) to enhance full-load efficiency.
5) Route the analog signal lines away from the highfrequency planes. This ensures integrity of sensitive signals feeding back into the device.
6) Make the ground connection for the analog and power section close to the device. This keeps the ground current loops to a minimum. In cases where only one ground is used, enough isolation between analog return signals and high power signals must be maintained.
